Generic Attribute Profile (GATT) The GATT layer manages the service database providing APIs for service registration and attribute declaration.

The GATT Client initiates commands and requests towards the GATT Server, and can receive responses, indications and notifications sent by the server. It is enabled through the configuration option: `CONFIG_BT_GATT_CLIENT`

The GATT Server accepts incoming commands and requests from the GATT Client, and sends responses, indications and notifications to the client.

Services can be registered using the `bt_gatt_service_register()` API which takes the `bt_gatt_service` struct that provides the list of attributes the service contains. The helper macro `BT_GATT_SERVICE()` can be used to declare a service.

Attributes can be declared using the `bt_gatt_attr` struct or using one of the helper macros:

`BT_GATT_PRIMARY_SERVICE`
: Declares a Primary Service.

`BT_GATT_SECONDARY_SERVICE`
: Declares a Secondary Service.

`BT_GATT_INCLUDE_SERVICE`
: Declares a Include Service.

`BT_GATT_CHARACTERISTIC`
: Declares a Characteristic.

`BT_GATT_DESCRIPTOR`
: Declares a Descriptor.

`BT_GATT_ATTRIBUTE`
: Declares an Attribute.

`BT_GATT_CCC`
: Declares a Client Characteristic Configuration.

`BT_GATT_CEP`
: Declares a Characteristic Extended Properties.

`BT_GATT_CUD`
: Declares a Characteristic User Format.

Each attribute contain a `uuid`, which describes their type, a `read` callback, a `write` callback and a set of permission. Both read and write callbacks can be set to NULL if the attribute permission don't allow their respective operations.

Note

32-bit UUIDs are not supported in GATT. All 32-bit UUIDs shall be converted to 128-bit UUIDs when the UUID is contained in an ATT PDU.

Note

Attribute `read` and `write` callbacks are called directly from RX Thread thus it is not recommended to block for long periods of time in them.

Attribute value changes can be notified using `bt_gatt_notify()` API, alternatively there is `bt_gatt_notify_cb()` where it is possible to pass a callback to be called when it is necessary to know the exact instant when the data has been transmitted over the air. Indications are supported by `bt_gatt_indicate()` API.

Discover procedures can be initiated with the use of `bt_gatt_discover()` API which takes the `bt_gatt_discover_params` struct which describes the type of discovery. The parameters also serves as a filter when setting the `uuid` field only attributes which matches will be discovered, in contrast setting it to NULL allows all attributes to be discovered.

Note

Caching discovered attributes is not supported.

Read procedures are supported by `bt_gatt_read()` API which takes the `bt_gatt_read_params` struct as parameters. In the parameters one or more attributes can be set, though setting multiple handles requires the option: `CONFIG_BT_GATT_READ_MULTIPLE`

Write procedures are supported by `bt_gatt_write()` API and takes `bt_gatt_write_params` struct as parameters. In case the write operation don't require a response

`bt_gatt_write_without_response()` or `bt_gatt_write_without_response_cb()` APIs can be used, with the later working similarly to `bt_gatt_notify_cb()`.

Subscriptions to notification and indication can be initiated with use of `bt_gatt_subscribe()` API which takes `bt_gatt_subscribe_params` as parameters. Multiple subscriptions to the same attribute are supported so there could be multiple `notify` callback being triggered for the same attribute. Subscriptions can be removed with use of `bt_gatt_unsubscribe()` API.

Note

When subscriptions are removed `notify` callback is called with the data set to NULL.

Bluetooth Mesh

Bluetooth Mesh Profile The Bluetooth Mesh profile adds secure wireless multi-hop communication for Bluetooth Low Energy. This module implements the Bluetooth Mesh Protocol Specification v1.1.1.

Read more about Bluetooth Mesh on the Bluetooth SIG Website.

Core The core provides functionality for managing the general Bluetooth Mesh state.

Low Power Node The Low Power Node (LPN) role allows battery powered devices to participate in a mesh network as a leaf node. An LPN interacts with the mesh network through a Friend node, which is responsible for relaying any messages directed to the LPN. The LPN saves power by keeping its radio turned off, and only wakes up to either send messages or poll the Friend node for any incoming messages.

The radio control and polling is managed automatically by the mesh stack, but the LPN API allows the application to trigger the polling at any time through `bt_mesh_lpn_poll()`. The LPN operation parameters, including poll interval, poll event timing and Friend requirements is controlled through the `CONFIG_BT_MESH_LOW_POWER` option and related configuration options.

When using the LPN feature with logging, it is strongly recommended to only use the `CONFIG_LOG_MODE_DEFERRED` option. Log modes other than the deferred may cause unintended delays during processing of log messages. This in turns will affect scheduling of the receive delay and receive window. The same limitation applies for the `CONFIG_BT_MESH_FRIEND` option.

Replay Protection List The Replay Protection List (RPL) is used to hold recently received sequence numbers from elements within the mesh network to perform protection against replay attacks.

To keep a node protected against replay attacks after reboot, it needs to store the entire RPL in the persistent storage before it is powered off. Depending on the amount of traffic in a mesh network, storing recently seen sequence numbers can make flash wear out sooner or later. To mitigate this, `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` can be used. This option postpones storing of RPL entries in the persistent storage.

This option, however, doesn't completely solve the issue as the node may get powered off before the timer to store the RPL is fired. To ensure that messages can not be replayed, the node can initiate storage of the pending RPL entry (or entries) at any time (or sufficiently before power loss) by calling `bt_mesh_rpl_pending_store()`. This is up to the node to decide, which RPL entries are to be stored in this case.

Setting `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` to -1 allows to completely switch off the timer, which can help to significantly reduce flash wear out. This moves the responsibility of storing RPL to the user application and requires that sufficient power backup is available from the time this API is called until all RPL entries are written to the flash.

Finding the right balance between `CONFIG_BT_MESH_RPL_STORE_TIMEOUT` and calling `bt_mesh_rpl_pending_store()` may reduce a risk of security vulnerability and flash wear out.

Persistent storage The mesh stack uses the *Settings Subsystem* for storing the device configuration persistently. When the stack configuration changes and the change needs to be stored persistently, the stack schedules a work item. The delay between scheduling the work item and submitting it to the workqueue is defined by the `CONFIG_BT_MESH_STORE_TIMEOUT` option. Once storing of data is scheduled, it can not be rescheduled until the work item is processed. Exceptions are made in certain cases as described below.

When IV index, Sequence Number or CDB configuration have to be stored, the work item is submitted to the workqueue without the delay. If the work item was previously scheduled, it will be rescheduled without the delay.

The Replay Protection List uses the same work item to store RPL entries. If storing of RPL entries is requested and no other configuration is pending to be stored, the delay is set to `CONFIG_BT_MESH_RPL_STORE_TIMEOUT`. If other stack configuration has to be stored, the delay defined by the `CONFIG_BT_MESH_STORE_TIMEOUT` option is less than `CONFIG_BT_MESH_RPL_STORE_TIMEOUT`, and the work item was scheduled by the Replay Protection List, the work item will be rescheduled.

When the work item is running, the stack will store all pending configuration, including the RPL entries.

Work item execution context The `CONFIG_BT_MESH_SETTINGS_WORKQ` option configures the context from which the work item is executed. This option is enabled by default, and results in stack using a dedicated cooperative thread to process the work item. This allows the stack to process other incoming and outgoing messages, as well as other work items submitted to the system workqueue, while the stack configuration is being stored.

When this option is disabled, the work item is submitted to the system workqueue. This means that the system workqueue is blocked for the time it takes to store the stack's configuration. It is not recommended to disable this option as this will make the device non-responsive for a noticeable amount of time.

Advertisement identity All mesh stack bearers advertise data with the `BT_ID_DEFAULT` local identity. The value is preset in the mesh stack implementation. When Bluetooth® Low Energy (LE) and Bluetooth Mesh coexist on the same device, the application should allocate and configure another local identity for Bluetooth LE purposes before starting the communication.

Access layer The access layer is the application's interface to the Bluetooth Mesh network. The access layer provides mechanisms for compartmentalizing the node behavior into elements and models, which are implemented by the application.

Mesh models The functionality of a mesh node is represented by models. A model implements a single behavior the node supports, like being a light, a sensor or a thermostat. The mesh models are grouped into *elements*. Each element is assigned its own unicast address, and may only contain one of each type of model. Conventionally, each element represents a single aspect of the mesh node behavior. For instance, a node that contains a sensor, two lights and a power outlet would spread this functionality across four elements, with each element instantiating all the models required for a single aspect of the supported behavior.

The node's element and model structure is specified in the node composition data, which is passed to `bt_mesh_init()` during initialization. The Bluetooth SIG have defined a set of foundation models (see *Mesh models*) and a set of models for implementing common behavior in the Bluetooth Mesh Model Specification. All models not specified by the Bluetooth SIG are vendor models, and must be tied to a Company ID.

Mesh models have several parameters that can be configured either through initialization of the mesh stack or with the *Configuration Server*:

Opcode list The opcode list contains all message opcodes the model can receive, as well as the minimum acceptable payload length and the callback to pass them to. Models can support any number of opcodes, but each opcode can only be listed by one model in each element.

The full opcode list must be passed to the model structure in the composition data, and cannot be changed at runtime. The end of the opcode list is determined by the special `BT_MESH_MODEL_OP_END` entry. This entry must always be present in the opcode list, unless the list is empty. In that case, `BT_MESH_MODEL_NO_OPS` should be used in place of a proper opcode list definition.

AppKey list The AppKey list contains all the application keys the model can receive messages on. Only messages encrypted with application keys in the AppKey list will be passed to the model.

The maximum number of supported application keys each model can hold is configured with the `CONFIG_BT_MESH_MODEL_KEY_COUNT` configuration option. The contents of the AppKey list is managed by the *Configuration Server*.

Subscription list A model will process all messages addressed to the unicast address of their element (given that the utilized application key is present in the AppKey list). Additionally, the model will process packets addressed to any group or virtual address in its subscription list. This allows nodes to address multiple nodes throughout the mesh network with a single message.

The maximum number of supported addresses in the Subscription list each model can hold is configured with the `CONFIG_BT_MESH_MODEL_GROUP_COUNT` configuration option. The contents of the subscription list is managed by the *Configuration Server*.

Model publication The models may send messages in two ways:

- By specifying a set of message parameters in a `bt_mesh_msg_ctx`, and calling `bt_mesh_model_send()`.
- By setting up a `bt_mesh_model_pub` structure and calling `bt_mesh_model_publish()`.

When publishing messages with `bt_mesh_model_publish()`, the model will use the publication parameters configured by the *Configuration Server*. This is the recommended way to send unprompted model messages, as it passes the responsibility of selecting message parameters to the network administrator, which likely knows more about the mesh network than the individual nodes will.

To support publishing with the publication parameters, the model must allocate a packet buffer for publishing, and pass it to `bt_mesh_model_pub.msg`. The Config Server may also set up period publication for the publication message. To support this, the model must populate the `bt_mesh_model_pub.update` callback. The `bt_mesh_model_pub.update` callback will be called right before the message is published, allowing the model to change the payload to reflect its current state.

By setting `bt_mesh_model_pub.retr_update` to 1, the model can configure the `bt_mesh_model_pub.update` callback to be triggered on every retransmission. This can, for example, be used by models that make use of a Delay parameter, which can be adjusted for every retransmission. The `bt_mesh_model_pub_is_retransmission()` function can be used to differentiate a first publication and a retransmission. The `BT_MESH_PUB_MSG_TOTAL` and

BT_MESH_PUB_MSG_NUM macros can be used to return total number of transmissions and the retransmission number within one publication interval.

Extended models The Bluetooth Mesh specification allows the mesh models to extend each other. When a model extends another, it inherits that model's functionality, and extension can be used to construct complex models out of simple ones, leveraging the existing model functionality to avoid defining new opcodes. Models may extend any number of models, from any element. When one model extends another in the same element, the two models will share subscription lists. The mesh stack implements this by merging the subscription lists of the two models into one, combining the number of subscriptions the models can have in total. Models may extend models that extend others, creating an "extension tree". All models in an extension tree share a single subscription list per element it spans.

Model extensions are done by calling bt_mesh_model_extend() during initialization. A model can only be extended by one other model, and extensions cannot be circular. Note that binding of node states and other relationships between the models must be defined by the model implementations.

The model extension concept adds some overhead in the access layer packet processing, and must be explicitly enabled with CONFIG_BT_MESH_MODEL_EXTENSIONS to have any effect.

Model data storage Mesh models may have data associated with each model instance that needs to be stored persistently. The access API provides a mechanism for storing this data, leveraging the internal model instance encoding scheme. Models can store one user defined data entry per instance by calling bt_mesh_model_data_store(). To be able to read out the data the next time the device reboots, the model's bt_mesh_model_cb.settings_set callback must be populated. This callback gets called when model specific data is found in the persistent storage. The model can retrieve the data by calling the read_cb passed as a parameter to the callback. See the *Settings* module documentation for details.

When model data changes frequently, storing it on every change may lead to increased wear of flash. To reduce the wear, the model can postpone storing of data by calling bt_mesh_model_data_store_schedule(). The stack will schedule a work item with delay defined by the CONFIG_BT_MESH_STORE_TIMEOUT option. When the work item is running, the stack will call the bt_mesh_model_cb.pending_store callback for every model that has requested storing of data. The model can then call bt_mesh_model_data_store() to store the data.

If CONFIG_BT_MESH_SETTINGS_WORKQ is enabled, the bt_mesh_model_cb.pending_store callback is called from a dedicated thread. This allows the stack to process other incoming and outgoing messages while model data is being stored. It is recommended to use this option and the bt_mesh_model_data_store_schedule() function when large amount of data needs to be stored.

Composition Data The Composition Data provides information about a mesh device. A device's Composition Data holds information about the elements on the device, the models that it supports, and other features. The Composition Data is split into different pages, where each page contains specific feature information about the device. In order to access this information, the user may use the *Configuration Server* model or, if supported, the *Large Composition Data Server* model.

Composition Data Page 0 Composition Data Page 0 provides the fundamental information about a device, and is mandatory for all mesh devices. It contains the element and model composition, the supported features, and manufacturer information.

Composition Data Page 1 Composition Data Page 1 provides information about the relationships between models, and is mandatory for all mesh devices. A model may extend and/or correspond to one or more models. A model can extend another model by calling bt_mesh_model_extend(), or correspond to another model by calling bt_mesh_model_correspond(). CONFIG_BT_MESH_MODEL_EXTENSION_LIST_SIZE specifies how

many model relations can be stored in the composition on a device, and this number should reflect the number of `bt_mesh_model_extend()` and `bt_mesh_model_correspond()` calls.

Composition Data Page 2 Composition Data Page 2 provides information for supported mesh profiles. Mesh profile specifications define product requirements for devices that want to support a specific Bluetooth SIG defined profile. Currently supported profiles can be found in section 3.12 in Bluetooth SIG Assigned Numbers. Composition Data Page 2 is only mandatory for devices that claim support for one or more mesh profile(s).

Composition Data Pages 128, 129 and 130 Composition Data Pages 128, 129 and 130 mirror Composition Data Pages 0, 1 and 2 respectively. They are used to represent the new content of the mirrored pages when the Composition Data will change after a firmware update. See *Composition Data and Models Metadata* for details.

Delayable messages The delayable message functionality is enabled with Kconfig option `CONFIG_BT_MESH_ACCESS_DELAYABLE_MSG`. This is an optional functionality that implements specification recommendations for messages that are transmitted by a model in a response to a received message, also called response messages.

Response messages should be sent with the following random delays:

- Between 20 and 50 milliseconds if the received message was sent to a unicast address
- Between 20 and 500 milliseconds if the received message was sent to a group or virtual address

The delayable message functionality is triggered if the `bt_mesh_msg_ctx.rnd_delay` flag is set. The delayable message functionality stores messages in the local memory while they are waiting for the random delay expiration.

If the transport layer doesn't have sufficient memory to send a message at the moment the random delay expires, the message is postponed for another 10 milliseconds. If the transport layer cannot send a message for any other reason, the delayable message functionality raises the `bt_mesh_send_cb.start` callback with a transport layer error code.

If the delayable message functionality cannot find enough free memory to store an incoming message, it will send messages with delay close to expiration to free memory.

When the mesh stack is suspended or reset, messages not yet sent are removed and the `bt_mesh_send_cb.start` callback is raised with an error code.

Note

When a model sends several messages in a row, it may happen that the messages are not sent in the order they were passed to the access layer. This is because some messages can be delayed for a longer time than the others.

Disable the randomization by setting the `bt_mesh_msg_ctx.rnd_delay` to `false`, when a set of messages originated by the same model needs to be sent in a certain order.

Delayable publications The delayable publication functionality implements the specification recommendations for message publication delays in the following cases:

- Between 20 to 500 milliseconds when the Bluetooth Mesh stack starts or when the publication is triggered by the `bt_mesh_model_publish()` function
- Between 20 to 50 milliseconds for periodically published messages

This feature is optional and enabled with the `CONFIG_BT_MESH_DELAYABLE_PUBLICATION` Kconfig option. When enabled, each model can enable or disable the delayable publication by setting the

`bt_mesh_model_pub.delayable` bit field to `1` or `0` correspondingly. This bit field can be changed at any time.

API reference
Access layer

Mesh models

Foundation models The Bluetooth Mesh specification defines foundation models that can be used by network administrators to configure and diagnose mesh nodes.

Bridge Configuration Client The Bridge Configuration Client is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_BRG_CFG_CLI` option.

The Bridge Configuration Client model provides functionality for configuring the subnet bridge functionality of another Mesh node containing the *Bridge Configuration Server*. The device key of the node containing the target Bridge Configuration Server is used for access layer security.

If present, the Bridge Configuration Client model must only be instantiated on the primary element.

API reference
Bridge Configuration Client Model

Bridge Configuration Server The Bridge Configuration Server model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_BRG_CFG_SRV` configuration option. This model extends the *Configuration Server* model.

The Bridge Configuration Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used for supporting and configuring the Subnet Bridge feature.

The Bridge Configuration Server model relies on a *Bridge Configuration Client* to configure it. The Bridge Configuration Server model only accepts messages encrypted with the node's device key.

If present, the Bridge Configuration Server model must be instantiated on the primary element.

The Bridge Configuration Server model provides access to the following three states:

- Subnet Bridge
- Bridging Table
- Bridging Table Size

For more information about the states, see *Subnet Bridge states*.

API reference
Bridge Configuration Server Model

Configuration Client The Configuration Client model is a foundation model defined by the Bluetooth Mesh specification. It provides functionality for configuring most parameters of a mesh node, including encryption keys, model configuration and feature enabling.

The Configuration Client model communicates with a *Configuration Server* model using the device key of the target node. The Configuration Client model may communicate with servers on other nodes or self-configure through the local Configuration Server model.

All configuration functions in the Configuration Client API have `net_idx` and `addr` as their first parameters. These should be set to the network index and primary unicast address that the target node was provisioned with.

The Configuration Client model is optional, and it must only be instantiated on the primary element if present in the Composition Data.

API reference
Configuration Client Model

Configuration Server The Configuration Server model is a foundation model defined by the Bluetooth Mesh specification. The Configuration Server model controls most parameters of the mesh node. It does not have an API of its own, but relies on a *Configuration Client* to control it.

The Configuration Server model is mandatory on all Bluetooth Mesh nodes, and must only be instantiated on the primary element.

API reference
Configuration Server Model

Health Client The Health Client model interacts with a Health Server model to read out diagnostics and control the node's attention state.

All message passing functions in the Health Client API have `cli` as their first parameter. This is a pointer to the client model instance to be used in this function call. The second parameter is the `ctx` or message context. Message context contains netkey index, appkey index and unicast address that the target node uses.

The Health Client model is optional, and may be instantiated on any element. However, if a Health Client model is instantiated on an element other than the primary, an instance must also be present on the primary element.

See *Health faults* for a list of specification defined fault values.

API reference
Health Client Model

Health Server The Health Server model provides attention callbacks and node diagnostics for *Health Client* models. It is primarily used to report faults in the mesh node and map the mesh nodes to their physical location.

If present, the Health Server model must be instantiated on the primary element.

Faults The Health Server model may report a list of faults that have occurred in the device's lifetime. Typically, the faults are events or conditions that may alter the behavior of the node, like power outages or faulty peripherals. Faults are split into warnings and errors. Warnings indicate conditions that are close to the limits of what the node is designed to withstand, but not necessarily damaging to the device. Errors indicate conditions that are outside of the node's design limits, and may have caused invalid behavior or permanent damage to the device.

Fault values `0x01` to `0x7f` are reserved for the Bluetooth Mesh specification, and the full list of specification defined faults are available in *Health faults*. Fault values `0x80` to `0xff` are vendor specific. The list of faults are always reported with a company ID to help interpreting the vendor specific faults.

Attention state The attention state is used to make the device call attention to itself through some physical behavior like blinking, playing a sound or vibrating. The attention state may be used during provisioning to let the user know which device they're provisioning, as well as through the Health models at runtime.

The attention state is always assigned a timeout in the range of one to 255 seconds when enabled. The Health Server API provides two callbacks for the application to run their attention calling behavior: `bt_mesh_health_srv_cb.attn_on` is called at the beginning of the attention period, `bt_mesh_health_srv_cb.attn_off` is called at the end.

The remaining time for the attention period may be queried through `bt_mesh_health_srv.attn_timer`.

API reference
Health Server Model

Health faults Fault values defined by the Bluetooth Mesh specification.

Health faults

Large Composition Data Client The Large Composition Data Client model is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_LARGE_COMP_DATA_CLI` option.

The Large Composition Data Client model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and supports the functionality of reading pages of Composition Data that do not fit in a Config Composition Data Status message and reading the metadata of the model instances on a node that supports the *Large Composition Data Server* model.

The Large Composition Data Client model communicates with a Large Composition Data Server model using the device key of the node containing the target Large Composition Data Server model instance.

If present, the Large Composition Data Client model must only be instantiated on the primary element.

API reference
Large Composition Data Client model

Large Composition Data Server The Large Composition Data Server model is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_LARGE_COMP_DATA_SRV` option.

The Large Composition Data Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of exposing pages of Composition Data that do not fit in a Config Composition Data Status message and to expose metadata of the model instances.

The Large Composition Data Server does not have an API of its own and relies on a *Large Composition Data Client* to control it. The model only accepts messages encrypted with the node's device key.

If present, the Large Composition Data Server model must only be instantiated on the primary element.

Models metadata The Large Composition Data Server model allows each model to have a list of model's specific metadata that can be read by the Large Composition Data Client model. The metadata list can be associated with the `bt_mesh_model` through the `bt_mesh_model.metadata` field. The metadata list consists of one or more entries defined

by the bt_mesh_models_metadata_entry structure. Each entry contains the length and ID of the metadata, and a pointer to the raw data. Entries can be created using the BT_MESH_MODELS_METADATA_ENTRY macro. The BT_MESH_MODELS_METADATA_END macro marks the end of the metadata list and must always be present. If the model has no metadata, the helper macro BT_MESH_MODELS_METADATA_NONE can be used instead.

API reference
Large Composition Data Server model

On-Demand Private Proxy Client The On-Demand Private Proxy Client model is a foundation model defined by the Bluetooth Mesh specification. The model is optional, and is enabled with the CONFIG_BT_MESH_OD_PRIV_PROXY_CLI option.

The On-Demand Private Proxy Client model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to set and retrieve the On-Demand Private GATT Proxy state. The state defines how long a node will advertise Mesh Proxy Service with Private Network Identity type after it receives a Solicitation PDU.

The On-Demand Private Proxy Client model communicates with an On-Demand Private Proxy Server model using the device key of the node containing the target On-Demand Private Proxy Server model instance.

If present, the On-Demand Private Proxy Client model must only be instantiated on the primary element.

Configurations The On-Demand Private Proxy Client model behavior can be configured with the transmission timeout option CONFIG_BT_MESH_OD_PRIV_PROXY_CLI_TIMEOUT. The CONFIG_BT_MESH_OD_PRIV_PROXY_CLI_TIMEOUT controls how long the Client waits for a state response message to arrive in milliseconds. This value can be changed at runtime using bt_mesh_od_priv_proxy_cli_timeout_set().

API reference
Bluetooth Mesh On-Demand Private GATT Proxy Client

On-Demand Private Proxy Server The On-Demand Private Proxy Server model is a foundation model defined by the Bluetooth Mesh specification. It is enabled with the CONFIG_BT_MESH_OD_PRIV_PROXY_SRV option.

The On-Demand Private Proxy Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and supports the configuration of advertising with Private Network Identity type of a node that is a recipient of Solicitation PDUs by managing its On-Demand Private GATT Proxy state.

When enabled, the *Solicitation PDU RPL Configuration Server* is also enabled. The On-Demand Private Proxy Server is dependent on the *Private Beacon Server* to be present on the node.

The On-Demand Private Proxy Server does not have an API of its own, and relies on a *On-Demand Private Proxy Client* to control it. The On-Demand Private Proxy Server model only accepts messages encrypted with the node's device key.

If present, the On-Demand Private Proxy Server model must only be instantiated on the primary element.

API reference
Bluetooth Mesh On-Demand Private GATT Proxy Server

Opcodes Aggregator Client The Opcodes Aggregator Client model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_OP_AGG_CLI` option.

The Opcodes Aggregator Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of dispatching a sequence of access layer messages to nodes supporting the *Opcodes Aggregator Server* model.

The Opcodes Aggregator Client model communicates with an Opcodes Aggregator Server model using the device key of the target node or the application keys configured by the Configuration Client.

If present, the Opcodes Aggregator Client model must only be instantiated on the primary element.

The Opcodes Aggregator Client model is implicitly bound to the device key on initialization. It should be bound to the same application keys as the client models that are used to produce the sequence of messages.

To be able to aggregate a message from a client model, it should support an asynchronous API, for example through callbacks.

API reference
Opcodes Aggregator Client model

Opcodes Aggregator Server The Opcodes Aggregator Server model is a foundation model defined by the Bluetooth mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_OP_AGG_SRV` option.

The Opcodes Aggregator Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of processing a sequence of access layer messages.

The Opcodes Aggregator Server model accepts messages encrypted with the node's device key or the application keys.

If present, the Opcodes Aggregator Server model must only be instantiated on the primary element.

The targeted server models should be bound to the same application key that is used to encrypt the sequence of access layer messages sent to the Opcodes Aggregator Server.

The Opcodes Aggregator Server handles aggregated messages and dispatches them to the respective models and their message handlers. Current implementation assumes that responses are sent from the same execution context as the received message and doesn't allow to send a postponed response, for example from a work queue.

API reference
Opcodes Aggregator Server model

Private Beacon Client The Private Beacon Client model is a foundation model defined by the Bluetooth mesh specification. It is enabled with the `CONFIG_BT_MESH_PRIV_BEACON_CLI` option.

The Private Beacon Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and provides functionality for configuring the *Private Beacon Server* models.

The Private Beacons feature adds privacy to the different Bluetooth Mesh beacons by periodically randomizing the beacon input data. This protects the mesh node from being tracked by devices outside the mesh network, and hides the network's IV index, IV update and the Key Refresh state.

The Private Beacon Client model communicates with a *Private Beacon Server* model using the device key of the target node. The Private Beacon Client model may communicate with servers on other nodes or self-configure through the local Private Beacon Server model.

All configuration functions in the Private Beacon Client API have `net_idx` and `addr` as their first parameters. These should be set to the network index and the primary unicast address the target node was provisioned with.

If present, the Private Beacon Client model must only be instantiated on the primary element.

API reference
Bluetooth Mesh Private Beacon Client

Private Beacon Server The Private Beacon Server model is a foundation model defined by the Bluetooth mesh specification. It is enabled with `CONFIG_BT_MESH_PRIV_BEACON_SRV` option.

The Private Beacon Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and controls the mesh node's Private Beacon state, Private GATT Proxy state and Private Node Identity state.

The Private Beacons feature adds privacy to the different Bluetooth Mesh beacons by periodically randomizing the beacon input data. This protects the mesh node from being tracked by devices outside the mesh network, and hides the network's IV index, IV update and the Key Refresh state. The Private Beacon Server must be instantiated for the device to support sending of the private beacons, but the node will process received private beacons without it.

The Private Beacon Server does not have an API of its own, but relies on a *Private Beacon Client* to control it. The Private Beacon Server model only accepts messages encrypted with the node's device key.

The application can configure the initial parameters of the Private Beacon Server model through the `bt_mesh_priv_beacon_srv` instance passed to `BT_MESH_MODEL_PRIV_BEACON_SRV`. Note that if the mesh node stored changes to this configuration in the settings subsystem, the initial values may be overwritten upon loading.

If present, the Private Beacon Server model must only be instantiated on the primary element.

API reference
Bluetooth Mesh Private Beacon Server

Remote Provisioning Client The Remote Provisioning Client model is a foundation model defined by the Bluetooth mesh specification. It is enabled with the `CONFIG_BT_MESH_RPR_CLI` option.

The Remote Provisioning Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1. This model provides functionality to remotely provision devices into a mesh network, and perform Node Provisioning Protocol Interface procedures by interacting with mesh nodes that support the *Remote Provisioning Server* model.

The Remote Provisioning Client model communicates with a Remote Provisioning Server model using the device key of the node containing the target Remote Provisioning Server model instance.

If present, the Remote Provisioning Client model must be instantiated on the primary element.

Scanning The scanning procedure is used to scan for unprovisioned devices located nearby the Remote Provisioning Server. The Remote Provisioning Client starts a scan procedure by using the `bt_mesh_rpr_scan_start()` call:

```
static void rpr_scan_report(struct bt_mesh_rpr_cli *cli,
            const struct bt_mesh_rpr_node *srv,
            struct bt_mesh_rpr_unprov *unprov,
            struct net_buf_simple *adv_data)
{
```

(continues on next page)

(continued from previous page)

```
}

struct bt_mesh_rpr_cli rpr_cli = {
   .scan_report = rpr_scan_report,
};

const struct bt_mesh_rpr_node srv = {
   .addr = 0x0004,
   .net_idx = 0,
   .ttl = BT_MESH_TTL_DEFAULT,
};

struct bt_mesh_rpr_scan_status status;
uint8_t *uuid = NULL;
uint8_t timeout = 10;
uint8_t max_devs = 3;

bt_mesh_rpr_scan_start(&rpr_cli, &srv, uuid, timeout, max_devs, &status);
```

The above example shows pseudo code for starting a scan procedure on the target Remote Provisioning Server node. This procedure will start a ten-second, multiple-device scanning where the generated scan report will contain a maximum of three unprovisioned devices. If the UUID argument was specified, the same procedure would only scan for the device with the corresponding UUID. After the procedure completes, the server sends the scan report that will be handled in the client's `bt_mesh_rpr_cli.scan_report` callback.

Additionally, the Remote Provisioning Client model also supports extended scanning with the `bt_mesh_rpr_scan_start_ext()` call. Extended scanning supplements regular scanning by allowing the Remote Provisioning Server to report additional data for a specific device. The Remote Provisioning Server will use active scanning to request a scan response from the unprovisioned device if it is supported by the unprovisioned device.

Provisioning The Remote Provisioning Client starts a provisioning procedure by using the `bt_mesh_provision_remote()` call:

```
struct bt_mesh_rpr_cli rpr_cli;

const struct bt_mesh_rpr_node srv = {
   .addr = 0x0004,
   .net_idx = 0,
   .ttl = BT_MESH_TTL_DEFAULT,
};

uint8_t uuid[16] = { 0xaa };
uint16_t addr = 0x0006;
uint16_t net_idx = 0;

bt_mesh_provision_remote(&rpr_cli, &srv, uuid, net_idx, addr);
```

The above example shows pseudo code for remotely provisioning a device through a Remote Provisioning Server node. This procedure will attempt to provision the device with the corresponding UUID, and assign the address 0x0006 to its primary element using the network key located at index zero.

Note

During the remote provisioning, the same `bt_mesh_prov` callbacks are triggered as for ordinary provisioning. See section *Provisioning* for further details.

Re-provisioning In addition to scanning and provisioning functionality, the Remote Provisioning Client also provides means to reconfigure node addresses, device keys and Composition Data on devices that support the *Remote Provisioning Server* model. This is provided through the Node Provisioning Protocol Interface (NPPI) which supports the following three procedures:

- Device Key Refresh procedure: Used to change the device key of the Target node without a need to reconfigure the node.
- Node Address Refresh procedure: Used to change the node's device key and unicast address.
- Node Composition Refresh procedure: Used to change the device key of the node, and to add or delete models or features of the node.

The three NPPI procedures can be initiated with the `bt_mesh_reprovision_remote()` call:

```
struct bt_mesh_rpr_cli rpr_cli;
struct bt_mesh_rpr_node srv = {
   .addr = 0x0006,
   .net_idx = 0,
   .ttl = BT_MESH_TTL_DEFAULT,
};

bool composition_changed = false;
uint16_t new_addr = 0x0009;

bt_mesh_reprovision_remote(&rpr_cli, &srv, new_addr, composition_changed);
```

The above example shows pseudo code for triggering a Node Address Refresh procedure on the Target node. The specific procedure is not chosen directly, but rather through the other parameters that are inputted. In the example we can see that the current unicast address of the Target is 0x0006, while the new address is set to 0x0009. If the two addresses were the same, and the `composition_changed` flag was set to true, this code would instead trigger a Node Composition Refresh procedure. If the two addresses were the same, and the `composition_changed` flag was set to false, this code would trigger a Device Key Refresh procedure.

API reference

Remote Provisioning Client model

Remote Provisioning Server The Remote Provisioning Server model is a foundation model defined by the Bluetooth mesh specification. It is enabled with the `CONFIG_BT_MESH_RPR_SRV` option.

The Remote Provisioning Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and is used to support the functionality of remotely provisioning devices into a mesh network.

The Remote Provisioning Server does not have an API of its own, but relies on a *Remote Provisioning Client* to control it. The Remote Provisioning Server model only accepts messages encrypted with the node's device key.

If present, the Remote Provisioning Server model must be instantiated on the primary element.

Note that after refreshing the device key, node address or Composition Data through a Node Provisioning Protocol Interface (NPPI) procedure, the `bt_mesh_prov.reprovisioned` callback is triggered. See section *Remote Provisioning Client* for further details.

How to integrate the model into an application To add the Remote Provisioning Server model in your application, do the following:

1. Enable Kconfig in your project configuration:

```
CONFIG_BT_MESH_RPR_SRV=y
```

2. Add the model instance into the model list `bt_mesh_elem.models` of the primary element using the `BT_MESH_MODEL_RPR_SRV` macro, for example:

```
static const struct bt_mesh_model models[] = {
        BT_MESH_MODEL_CFG_SRV,
        BT_MESH_MODEL_HEALTH_SRV(&health_srv, &health_pub),
        BT_MESH_MODEL_RPR_SRV,
        /* ... */
};

static const struct bt_mesh_elem elements[] = {
        BT_MESH_ELEM(0, models, BT_MESH_MODEL_NONE),
};
```

3. Enable PB-Remote by calling `bt_mesh_prov_enable()` with `BT_MESH_PROV_REMOTE`:

```
err = bt_mesh_prov_enable(BT_MESH_PROV_REMOTE);
if (err) {
        printk("PB-Remote enable failed (err %d)\n", err);
}
```

Limitations The following limitations apply to Remote Provisioning Server model:

- Provisioning of unprovisioned device using PB-GATT is not supported.
- All Node Provisioning Protocol Interface (NPPI) procedures are supported. However, if the composition data of a device gets changed after device firmware update (see *firmware effect*), it is not possible for the device to remain provisioned. The device should be unprovisioned if its composition data is expected to change.

API reference
Remote provisioning server

SAR Configuration Client The SAR Configuration Client model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_SAR_CFG_CLI` configuration option.

The SAR Configuration Client model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and it supports the configuration of the lower transport layer behavior of a node that supports the *SAR Configuration Server* model.

The model can send messages to query or change the states supported by the SAR Configuration Server (SAR Transmitter and SAR Receiver) using SAR Configuration messages.

The SAR Transmitter procedure is used to determine and configure the SAR Transmitter state of a SAR Configuration Server. Function calls `bt_mesh_sar_cfg_cli_transmitter_get()` and `bt_mesh_sar_cfg_cli_transmitter_set()` are used to get and set the SAR Transmitter state of the Target node respectively.

The SAR Receiver procedure is used to determine and configure the SAR Receiver state of a SAR Configuration Server. Function calls `bt_mesh_sar_cfg_cli_receiver_get()` and `bt_mesh_sar_cfg_cli_receiver_set()` are used to get and set the SAR Receiver state of the Target node respectively.

For more information about the two states, see *SAR states*.

An element can send any SAR Configuration Client message at any time to query or change the states supported by the SAR Configuration Server model of a peer node. The SAR Configuration Client model only accepts messages encrypted with the device key of the node supporting the SAR Configuration Server model.

If present, the SAR Configuration Client model must only be instantiated on the primary element.

API reference
Bluetooth Mesh SAR Configuration Client Model

SAR Configuration Server The SAR Configuration Server model is a foundation model defined by the Bluetooth Mesh specification. It is an optional model, enabled with the `CONFIG_BT_MESH_SAR_CFG_SRV` configuration option.

The SAR Configuration Server model is introduced in the Bluetooth Mesh Protocol Specification version 1.1, and it supports the configuration of the *segmentation and reassembly (SAR)* behavior of a Bluetooth Mesh node. The model defines a set of states and messages for the SAR configuration.

The SAR Configuration Server model defines two states, SAR Transmitter state and SAR Receiver state. For more information about the two states, see *SAR states*.

The model also supports the SAR Transmitter and SAR Receiver get and set messages.

The SAR Configuration Server model does not have an API of its own, but relies on a *SAR Configuration Client* to control it. The SAR Configuration Server model only accepts messages encrypted with the node's device key.

If present, the SAR Configuration Server model must only be instantiated on the primary element.

API reference
Bluetooth Mesh SAR Configuration Server Model

Solicitation PDU RPL Configuration Client The Solicitation PDU RPL Configuration Client model is a foundation model defined by the Bluetooth mesh specification. The model is optional, and is enabled through the `CONFIG_BT_MESH_SOL_PDU_RPL_CLI` option.

The Solicitation PDU RPL Configuration Client model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and supports the functionality of removing addresses from the solicitation replay protection list (SRPL) of a node that supports the *Solicitation PDU RPL Configuration Server* model.

The Solicitation PDU RPL Configuration Client model communicates with a Solicitation PDU RPL Configuration Server model using the application keys configured by the Configuration Client.

If present, the Solicitation PDU RPL Configuration Client model must only be instantiated on the primary element.

Configurations The Solicitation PDU RPL Configuration Client model behavior can be configured with the transmission timeout option `CONFIG_BT_MESH_SOL_PDU_RPL_CLI_TIMEOUT`. The `CONFIG_BT_MESH_SOL_PDU_RPL_CLI_TIMEOUT` controls how long the Solicitation PDU RPL Configuration Client waits for a response message to arrive in milliseconds. This value can be changed at runtime using `bt_mesh_sol_pdu_rpl_cli_timeout_set()`.

API reference
Bluetooth Mesh Solicitation PDU RPL Client

Solicitation PDU RPL Configuration Server The Solicitation PDU RPL Configuration Server model is a foundation model defined by the Bluetooth mesh specification. The model is enabled if the node has the *On-Demand Private Proxy Server* enabled.

The Solicitation PDU RPL Configuration Server model was introduced in the Bluetooth Mesh Protocol Specification version 1.1, and manages the Solicitation Replay Protection List (SRPL) saved on the device. The SRPL is used to reject Solicitation PDUs that are already processed by a node. When a valid Solicitation PDU message is successfully processed by a node, the SSRC field and SSEQ field of the message are stored in the node's SRPL.

The Solicitation PDU RPL Configuration Server does not have an API of its own, and relies on a *Solicitation PDU RPL Configuration Client* to control it. The model only accepts messages encrypted with an application key as configured by the Configuration Client.

If present, the Solicitation PDU RPL Configuration Server model must only be instantiated on the primary element.

Configurations For the Solicitation PDU RPL Configuration Server model, the `CONFIG_BT_MESH_PROXY_SRPL_SIZE` option can be configured to set the size of the SRPL.

API reference
Bluetooth Mesh Solicitation PDU RPL Server

Model specification models In addition to the foundation models defined in the Bluetooth Mesh specification, the Bluetooth Mesh Model Specification defines several models, some of which are implemented in Zephyr:

BLOB Transfer models The Binary Large Object (BLOB) Transfer models implement the Bluetooth Mesh Binary Large Object Transfer Model specification version 1.0 and provide functionality for sending large binary objects from a single source to many Target nodes over the Bluetooth Mesh network. It is the underlying transport method for the *Device Firmware Update (DFU)*, but may be used for other object transfer purposes. The implementation is in experimental state.

The BLOB Transfer models support transfers of continuous binary objects of up to 4 GB (2^{32} bytes). The BLOB transfer protocol has built-in recovery procedures for packet losses, and sets up checkpoints to ensure that all targets have received all the data before moving on. Data transfer order is not guaranteed.

BLOB transfers are constrained by the transfer speed and reliability of the underlying mesh network. Under ideal conditions, the BLOBs can be transferred at a rate of up to 1 kbps, allowing a 100 kB BLOB to be transferred in 10-15 minutes. However, network conditions, transfer capabilities and other limiting factors can easily degrade the data rate by several orders of magnitude. Tuning the parameters of the transfer according to the application and network configuration, as well as scheduling it to periods with low network traffic, will offer significant improvements on the speed and reliability of the protocol. However, achieving transfer rates close to the ideal rate is unlikely in actual deployments.

There are two BLOB Transfer models:

BLOB Transfer Server The Binary Large Object (BLOB) Transfer Server model implements reliable receiving of large binary objects. It serves as the backend of the *Firmware Update Server*, but can also be used for receiving other binary images.

BLOBs As described in *BLOB Transfer models*, the binary objects transferred by the BLOB Transfer models are divided into blocks, which are divided into chunks. As the transfer is controlled by the BLOB Transfer Client model, the BLOB Transfer Server must allow blocks to come in any order. The chunks within a block may also come in any order, but all chunks in a block must be received before the next block is started.

The BLOB Transfer Server keeps track of the received blocks and chunks, and will process each block and chunk only once. The BLOB Transfer Server also ensures that any missing chunks are resent by the BLOB Transfer Client.

Usage The BLOB Transfer Server is instantiated on an element with a set of event handler callbacks:

```
static const struct bt_mesh_blob_srv_cb blob_cb = {
    /* Callbacks */
};

static struct bt_mesh_blob_srv blob_srv = {
    .cb = &blob_cb,
};

static const struct bt_mesh_model models[] = {
    BT_MESH_MODEL_BLOB_SRV(&blob_srv),
};
```

A BLOB Transfer Server is capable of receiving a single BLOB transfer at a time. Before the BLOB Transfer Server can receive a transfer, it must be prepared by the user. The transfer ID must be passed to the BLOB Transfer Server through the `bt_mesh_blob_srv_recv()` function before the transfer is started by the BLOB Transfer Client. The ID must be shared between the BLOB Transfer Client and the BLOB Transfer Server through some higher level procedure, like a vendor specific transfer management model.

Once the transfer has been set up on the BLOB Transfer Server, it's ready for receiving the BLOB. The application is notified of the transfer progress through the event handler callbacks, and the BLOB data is sent to the BLOB stream.

The interaction between the BLOB Transfer Server, BLOB stream and application is shown below:

Transfer suspension The BLOB Transfer Server keeps a running timer during the transfer, that is reset on every received message. If the BLOB Transfer Client does not send a message before the transfer timer expires, the transfer is suspended by the BLOB Transfer Server.

The BLOB Transfer Server notifies the user of the suspension by calling the `suspended` callback. If the BLOB Transfer Server is in the middle of receiving a block, this block is discarded.

The BLOB Transfer Client may resume a suspended transfer by starting a new block transfer. The BLOB Transfer Server notifies the user by calling the `resume` callback.

Transfer recovery The state of the BLOB transfer is stored persistently. If a reboot occurs, the BLOB Transfer Server will attempt to recover the transfer. When the Bluetooth Mesh subsystem is started (for instance by calling `bt_mesh_init()`), the BLOB Transfer Server will check for aborted transfers, and call the `recover` callback if there is any. In the recover callback, the user must provide a BLOB stream to use for the rest of the transfer. If the recover callback doesn't return successfully or does not provide a BLOB stream, the transfer is abandoned. If no recover callback is implemented, transfers are always abandoned after a reboot.

After a transfer is successfully recovered, the BLOB Transfer Server enters the suspended state. It will stay suspended until the BLOB Transfer Client resumes the transfer, or the user cancels it.

Note

The BLOB Transfer Client sending the transfer must support transfer recovery for the transfer to complete. If the BLOB Transfer Client has already given up the transfer, the BLOB Transfer Server will stay suspended until the application calls `bt_mesh_blob_srv_cancel()`.

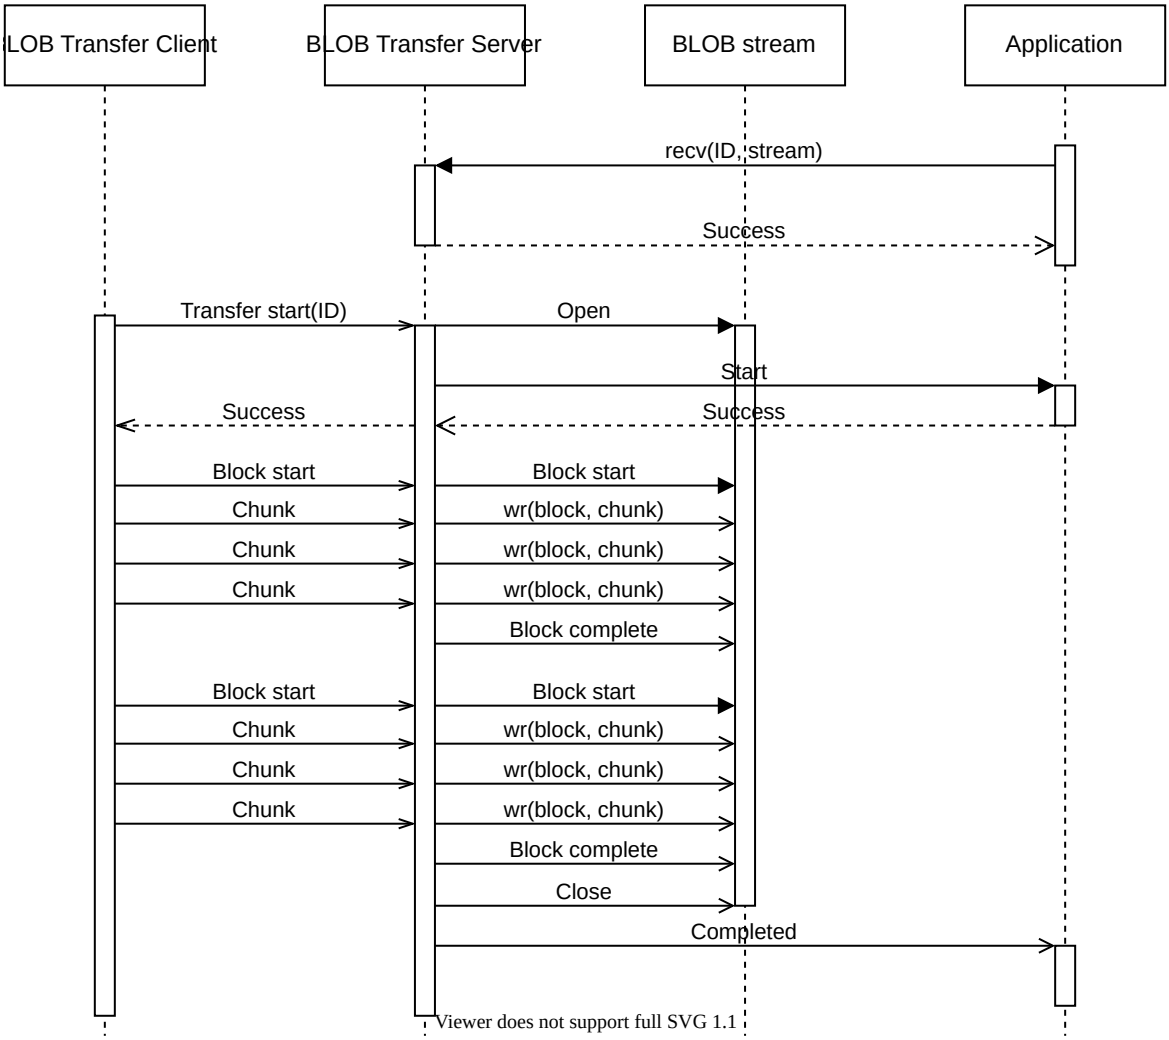

Fig. 19: BLOB Transfer Server model interaction

API reference

Bluetooth Mesh BLOB Transfer Server model API

BLOB Transfer Client The Binary Large Object (BLOB) Transfer Client is the sender of the BLOB transfer. It supports sending BLOBs of any size to any number of Target nodes, in both Push BLOB Transfer Mode and Pull BLOB Transfer Mode.

Usage

Initialization The BLOB Transfer Client is instantiated on an element with a set of event handler callbacks:

```
static const struct bt_mesh_blob_cli_cb blob_cb = {
      /* Callbacks */
};

static struct bt_mesh_blob_cli blob_cli = {
      .cb = &blob_cb,
};

static const struct bt_mesh_model models[] = {
      BT_MESH_MODEL_BLOB_CLI(&blob_cli),
};
```

Transfer context Both the transfer capabilities retrieval procedure and the BLOB transfer uses an instance of a `bt_mesh_blob_cli_inputs` to determine how to perform the transfer. The BLOB Transfer Client Inputs structure must at least be initialized with a list of targets, an application key and a time to live (TTL) value before it is used in a procedure:

```
static struct bt_mesh_blob_target targets[3] = {
        { .addr = 0x0001 },
        { .addr = 0x0002 },
        { .addr = 0x0003 },
};
static struct bt_mesh_blob_cli_inputs inputs = {
        .app_idx = MY_APP_IDX,
        .ttl = BT_MESH_TTL_DEFAULT,
};

sys_slist_init(&inputs.targets);
sys_slist_append(&inputs.targets, &targets[0].n);
sys_slist_append(&inputs.targets, &targets[1].n);
sys_slist_append(&inputs.targets, &targets[2].n);
```

Note that all BLOB Transfer Servers in the transfer must be bound to the chosen application key.

Group address The application may additionally specify a group address in the context structure. If the group is not `BT_MESH_ADDR_UNASSIGNED`, the messages in the transfer will be sent to the group address, instead of being sent individually to each Target node. Mesh Manager must ensure that all Target nodes having the BLOB Transfer Server model subscribe to this group address.

Using group addresses for transferring the BLOBs can generally increase the transfer speed, as the BLOB Transfer Client sends each message to all Target nodes at the same time. However, sending large, segmented messages to group addresses in Bluetooth Mesh is generally less reliable than sending them to unicast addresses, as there is no transport layer acknowledgment

mechanism for groups. This can lead to longer recovery periods at the end of each block, and increases the risk of losing Target nodes. Using group addresses for BLOB transfers will generally only pay off if the list of Target nodes is extensive, and the effectiveness of each addressing strategy will vary heavily between different deployments and the size of the chunks.

Transfer timeout If a Target node fails to respond to an acknowledged message within the BLOB Transfer Client's time limit, the Target node is dropped from the transfer. The application can reduce the chances of this by giving the BLOB Transfer Client extra time through the context structure. The extra time may be set in 10-second increments, up to 182 hours, in addition to the base time of 20 seconds. The wait time scales automatically with the transfer TTL.

Note that the BLOB Transfer Client only moves forward with the transfer in following cases:

- All Target nodes have responded.
- A node has been removed from the list of Target nodes.
- The BLOB Transfer Client times out.

Increasing the wait time will increase this delay.

BLOB transfer capabilities retrieval It is generally recommended to retrieve BLOB transfer capabilities before starting a transfer. The procedure populates the transfer capabilities from all Target nodes with the most liberal set of parameters that allows all Target nodes to participate in the transfer. Any Target nodes that fail to respond, or respond with incompatible transfer parameters, will be dropped.

Target nodes are prioritized according to their order in the list of Target nodes. If a Target node is found to be incompatible with any of the previous Target nodes, for instance by reporting a non-overlapping block size range, it will be dropped. Lost Target nodes will be reported through the `lost_target` callback.

The end of the procedure is signalled through the `caps` callback, and the resulting capabilities can be used to determine the block and chunk sizes required for the BLOB transfer.

BLOB transfer The BLOB transfer is started by calling `bt_mesh_blob_cli_send()` function, which (in addition to the aforementioned transfer inputs) requires a set of transfer parameters and a BLOB stream instance. The transfer parameters include the 64-bit BLOB ID, the BLOB size, the transfer mode, the block size in logarithmic representation and the chunk size. The BLOB ID is application defined, but must match the BLOB ID the BLOB Transfer Servers have been started with.

The transfer runs until it either completes successfully for at least one Target node, or it is cancelled. The end of the transfer is communicated to the application through the `end` callback. Lost Target nodes will be reported through the `lost_target` callback.

API reference

Bluetooth Mesh BLOB Transfer Client model API

The BLOB Transfer Client is instantiated on the sender node, and the BLOB Transfer Server is instantiated on the receiver nodes.

Concepts The BLOB transfer protocol introduces several new concepts to implement the BLOB transfer.

BLOBs BLOBs are binary objects up to 4 GB in size, that can contain any data the application would like to transfer through the mesh network. The BLOBs are continuous data objects, divided into blocks and chunks to make the transfers reliable and easy to process. No limitations are put on the contents or structure of the BLOB, and applications are free to define any encoding or compression they'd like on the data itself.

The BLOB transfer protocol does not provide any built-in integrity checks, encryption or authentication of the BLOB data. However, the underlying encryption of the Bluetooth Mesh protocol provides data integrity checks and protects the contents of the BLOB from third parties using network and application level encryption.

Blocks The binary objects are divided into blocks, typically from a few hundred to several thousand bytes in size. Each block is transmitted separately, and the BLOB Transfer Client ensures that all BLOB Transfer Servers have received the full block before moving on to the next. The block size is determined by the transfer's `block_size_log` parameter, and is the same for all blocks in the transfer except the last, which may be smaller. For a BLOB stored in flash memory, the block size is typically a multiple of the flash page size of the Target devices.

Chunks Each block is divided into chunks. A chunk is the smallest data unit in the BLOB transfer, and must fit inside a single Bluetooth Mesh access message excluding the opcode (379 bytes or less). The mechanism for transferring chunks depends on the transfer mode.

When operating in Push BLOB Transfer Mode, the chunks are sent as unacknowledged packets from the BLOB Transfer Client to all targeted BLOB Transfer Servers. Once all chunks in a block have been sent, the BLOB Transfer Client asks each BLOB Transfer Server if they're missing any chunks, and resends them. This is repeated until all BLOB Transfer Servers have received all chunks, or the BLOB Transfer Client gives up.

When operating in Pull BLOB Transfer Mode, the BLOB Transfer Server will request a small number of chunks from the BLOB Transfer Client at a time, and wait for the BLOB Transfer Client to send them before requesting more chunks. This repeats until all chunks have been transferred, or the BLOB Transfer Server gives up.

Read more about the transfer modes in *Transfer modes* section.

BLOB streams In the BLOB Transfer models' APIs, the BLOB data handling is separated from the high-level transfer handling. This split allows reuse of different BLOB storage and transfer strategies for different applications. While the high level transfer is controlled directly by the application, the BLOB data itself is accessed through a *BLOB stream*.

The BLOB stream is comparable to a standard library file stream. Through opening, closing, reading and writing, the BLOB Transfer model gets full access to the BLOB data, whether it's kept in flash, RAM, or on a peripheral. The BLOB stream is opened with an access mode (read or write) before it's used, and the BLOB Transfer models will move around inside the BLOB's data in blocks and chunks, using the BLOB stream as an interface.

Interaction Before the BLOB is read or written, the stream is opened by calling its `open` callback. When used with a BLOB Transfer Server, the BLOB stream is always opened in write mode, and when used with a BLOB Transfer Client, it's always opened in read mode.

For each block in the BLOB, the BLOB Transfer model starts by calling `block_start`. Then, depending on the access mode, the BLOB stream's `wr` or `rd` callback is called repeatedly to move data to or from the BLOB. When the model is done processing the block, it calls `block_end`. When the transfer is complete, the BLOB stream is closed by calling `close`.

Implementations The application may implement their own BLOB stream, or use the implementations provided by Zephyr:

BLOB Flash The BLOB Flash Readers and Writers implement BLOB reading to and writing from flash partitions defined in the *flash map*.

BLOB Flash Reader The BLOB Flash Reader interacts with the BLOB Transfer Client to read BLOB data directly from flash. It must be initialized by calling `bt_mesh_blob_flash_rd_init()` before being passed to the BLOB Transfer Client. Each BLOB Flash Reader only supports one transfer at the time.

BLOB Flash Writer The BLOB Flash Writer interacts with the BLOB Transfer Server to write BLOB data directly to flash. It must be initialized by calling `bt_mesh_blob_flash_rd_init()` before being passed to the BLOB Transfer Server. Each BLOB Flash Writer only supports one transfer at the time, and requires a block size that is a multiple of the flash page size. If a transfer is started with a block size lower than the flash page size, the transfer will be rejected.

The BLOB Flash Writer copies chunk data into a buffer to accommodate chunks that are unaligned with the flash write block size. The buffer data is padded with `0xff` if either the start or length of the chunk is unaligned.

API Reference
Bluetooth Mesh BLOB flash stream

Transfer capabilities Each BLOB Transfer Server may have different transfer capabilities. The transfer capabilities of each device are controlled through the following configuration options:

- `CONFIG_BT_MESH_BLOB_SIZE_MAX`
- `CONFIG_BT_MESH_BLOB_BLOCK_SIZE_MIN`
- `CONFIG_BT_MESH_BLOB_BLOCK_SIZE_MAX`
- `CONFIG_BT_MESH_BLOB_CHUNK_COUNT_MAX`

The `CONFIG_BT_MESH_BLOB_CHUNK_COUNT_MAX` option is also used by the BLOB Transfer Client and affects memory consumption by the BLOB Transfer Client model structure.

To ensure that the transfer can be received by as many servers as possible, the BLOB Transfer Client can retrieve the capabilities of each BLOB Transfer Server before starting the transfer. The client will transfer the BLOB with the highest possible block and chunk size.

Transfer modes BLOBs can be transferred using two transfer modes, Push BLOB Transfer Mode and Pull BLOB Transfer Mode. In most cases, the transfer should be conducted in Push BLOB Transfer Mode.

In Push BLOB Transfer Mode, the send rate is controlled by the BLOB Transfer Client, which will push all the chunks of each block without any high level flow control. Push BLOB Transfer Mode supports any number of Target nodes, and should be the default transfer mode.

In Pull BLOB Transfer Mode, the BLOB Transfer Server will "pull" the chunks from the BLOB Transfer Client at its own rate. Pull BLOB Transfer Mode can be conducted with multiple Target nodes, and is intended for transferring BLOBs to Target nodes acting as *Low Power Node*. When operating in Pull BLOB Transfer Mode, the BLOB Transfer Server will request chunks from the BLOB Transfer Client in small batches, and wait for them all to arrive before requesting more chunks. This process is repeated until the BLOB Transfer Server has received all chunks in a block. Then, the BLOB Transfer Client starts the next block, and the BLOB Transfer Server requests all chunks of that block.

Transfer timeout The timeout of the BLOB transfer is based on a Timeout Base value. Both client and server use the same Timeout Base value, but they calculate timeout differently.

The BLOB Transfer Server uses the following formula to calculate the BLOB transfer timeout:

```
10 * (Timeout Base + 1) seconds
```

For the BLOB Transfer Client, the following formula is used:

```
(10000 * (Timeout Base + 2)) + (100 * TTL) milliseconds
```

where TTL is time to live value set in the transfer.

API reference This section contains types and defines common to the BLOB Transfer models.

Bluetooth Mesh BLOB model API

Device Firmware Update (DFU) Bluetooth Mesh supports the distribution of firmware images across a mesh network. The Bluetooth mesh DFU subsystem implements the Bluetooth Mesh Device Firmware Update Model specification version 1.0.

Bluetooth Mesh DFU implements a distribution mechanism for firmware images, and does not put any restrictions on the size, format or usage of the images. The primary design goal of the subsystem is to provide the qualifiable parts of the Bluetooth Mesh DFU specification, and leave the usage, firmware validation and deployment to the application.

The DFU specification is implemented in the Zephyr Bluetooth Mesh DFU subsystem as three separate models:

Firmware Update Server The Firmware Update Server model implements the Target node functionality of the *Device Firmware Update (DFU)* subsystem. It extends the *BLOB Transfer Server*, which it uses to receive the firmware image binary from the Distributor node.

Together with the extended BLOB Transfer Server model, the Firmware Update Server model implements all the required functionality for receiving firmware updates over the mesh network, but does not provide any functionality for storing, applying or verifying the images.

Firmware images The Firmware Update Server holds a list of all the updatable firmware images on the device. The full list shall be passed to the server through the `_imgs` parameter in `BT_MESH_DFU_SRV_INIT`, and must be populated before the Bluetooth Mesh subsystem is started. Each firmware image in the image list must be independently updatable, and should have its own firmware ID.

For instance, a device with an upgradable bootloader, an application and a peripheral chip with firmware update capabilities could have three entries in the firmware image list, each with their own separate firmware ID.

Receiving transfers The Firmware Update Server model uses a BLOB Transfer Server model on the same element to transfer the binary image. The interaction between the Firmware Update Server, BLOB Transfer Server and application is described below:

Transfer check The transfer check is an optional pre-transfer check the application can perform on incoming firmware image metadata. The Firmware Update Server performs the transfer check by calling the `check` callback.

The result of the transfer check is a pass/fail status return and the expected `bt_mesh_dfu_effect`. The DFU effect return parameter will be communicated back to the Distributor, and should indicate what effect the firmware update will have on the mesh state of the device.

Composition Data and Models Metadata If the transfer will cause the device to change its Composition Data or become unprovisioned, this should be communicated through the effect parameter of the metadata check.

When the transfer will cause the Composition Data to change, and the *Remote Provisioning Server* is supported, the Composition Data of the new firmware image will be represented by Composition Data Pages 128, 129, and 130. The Models Metadata of the new firmware image will be

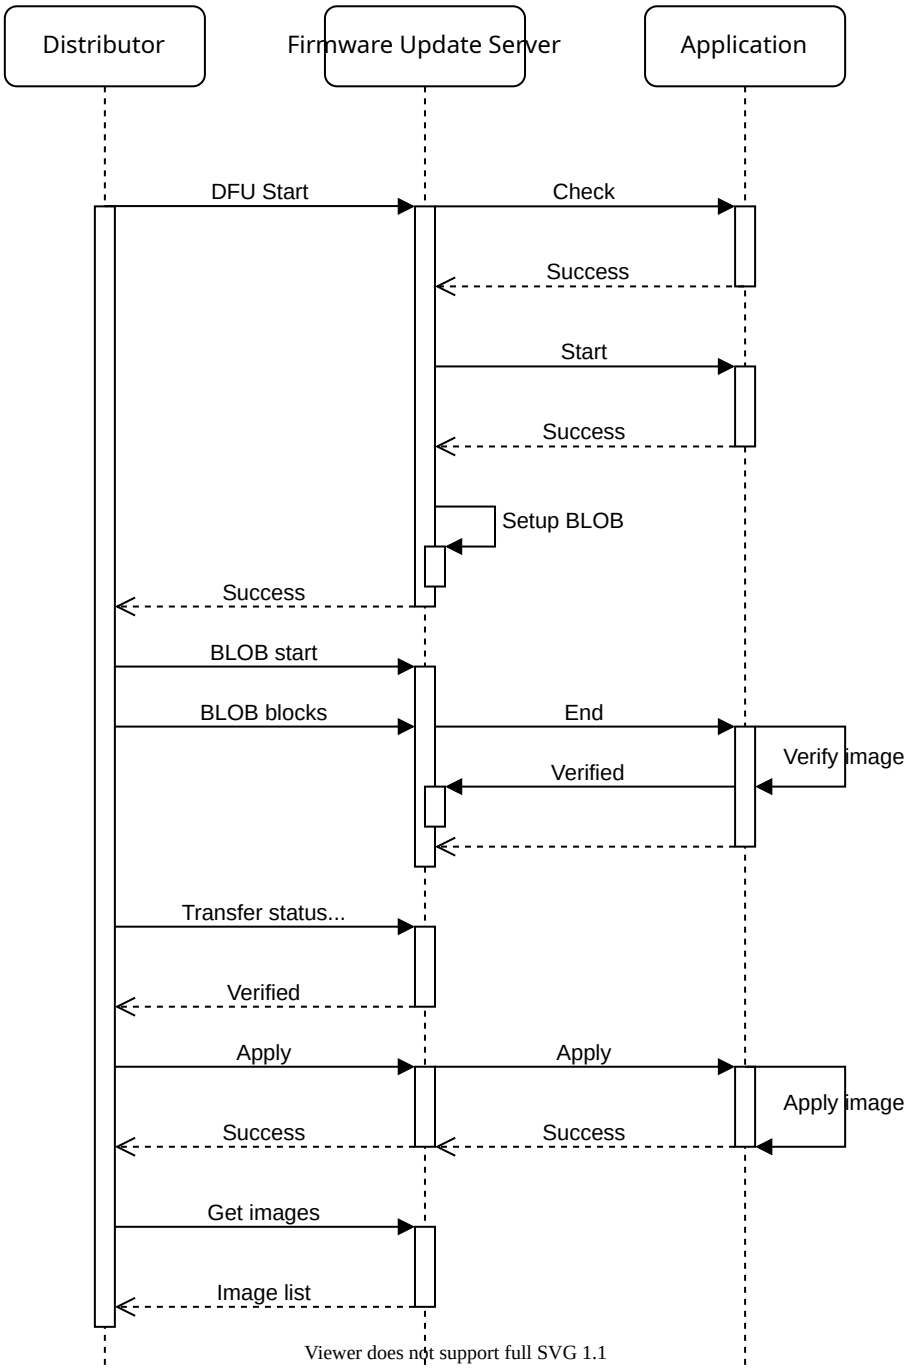

Fig. 20: Bluetooth Mesh Firmware Update Server transfer

represented by Models Metadata Page 128. Composition Data Pages 0, 1 and 2, and Models Metadata Page 0, will represent the Composition Data and the Models Metadata of the old firmware image until the device is reprovisioned with Node Provisioning Protocol Interface (NPPI) procedures using the *Remote Provisioning Client*.

The application must call functions `bt_mesh_comp_change_prepare()` and `bt_mesh_models_metadata_change_prepare()` to store the existing Composition Data and Models Metadata pages before booting into the firmware with the updated Composition Data and Models Metadata. The old Composition Data will then be loaded into Composition Data Pages 0, 1 and 2, while the Composition Data in the new firmware will be loaded into Composition Data Pages 128, 129 and 130. The Models Metadata for the old image will be loaded into Models Metadata Page 0, and the Models Metadata for the new image will be loaded into Models Metadata Page 128.

Limitation:

- It is not possible to change the Composition Data of the device and keep the device provisioned and working with the old firmware after the new firmware image is applied.

Start The Start procedure prepares the application for the incoming transfer. It'll contain information about which image is being updated, as well as the update metadata.

The Firmware Update Server `start` callback must return a pointer to the BLOB Writer the BLOB Transfer Server will send the BLOB to.

BLOB transfer After the setup stage, the Firmware Update Server prepares the BLOB Transfer Server for the incoming transfer. The entire firmware image is transferred to the BLOB Transfer Server, which passes the image to its assigned BLOB Writer.

At the end of the BLOB transfer, the Firmware Update Server calls its `end` callback.

Image verification After the BLOB transfer has finished, the application should verify the image in any way it can to ensure that it is ready for being applied. Once the image has been verified, the application calls `bt_mesh_dfu_srv_verified()`.

If the image can't be verified, the application calls `bt_mesh_dfu_srv_rejected()`.

Applying the image Finally, if the image was verified, the Distributor may instruct the Firmware Update Server to apply the transfer. This is communicated to the application through the `apply` callback. The application should swap the image and start running with the new firmware. The firmware image table should be updated to reflect the new firmware ID of the updated image.

When the transfer applies to the mesh application itself, the device might have to reboot as part of the swap. This restart can be performed from inside the apply callback, or done asynchronously. After booting up with the new firmware, the firmware image table should be updated before the Bluetooth Mesh subsystem is started.

The Distributor will read out the firmware image table to confirm that the transfer was successfully applied. If the metadata check indicated that the device would become unprovisioned, the Target node is not required to respond to this check.

API reference
Firmware Update Server model

Firmware Update Client The Firmware Update Client is responsible for distributing firmware updates through the mesh network. The Firmware Update Client uses the *BLOB Transfer Client* as a transport for its transfers.

API reference

Firmware Uppdate Client model

Firmware Distribution Server The Firmware Distribution Server model implements the Distributor role for the *Device Firmware Update (DFU)* subsystem. It extends the *BLOB Transfer Server*, which it uses to receive the firmware image binary from the Initiator node. It also instantiates a *Firmware Update Client*, which it uses to distribute firmware updates throughout the mesh network.

> **Note**
>
> Currently, the Firmware Distribution Server supports out-of-band (OOB) retrieval of firmware images over SMP service only.

The Firmware Distribution Server does not have an API of its own, but relies on a Firmware Distribution Client model on a different device to give it information and trigger image distribution and upload.

Firmware slots The Firmware Distribution Server is capable of storing multiple firmware images for distribution. Each slot contains a separate firmware image with metadata, and can be distributed to other mesh nodes in the network in any order. The contents, format and size of the firmware images are vendor specific, and may contain data from other vendors. The application should never attempt to execute or modify them.

The slots are managed remotely by a Firmware Distribution Client, which can both upload new slots and delete old ones. The application is notified of changes to the slots through the Firmware Distribution Server's callbacks (`bt_mesh_fd_srv_cb`). While the metadata for each firmware slot is stored internally, the application must provide a *BLOB streams* for reading and writing the firmware image.

API reference

Firmware Distribution Server model

Overview

DFU roles The Bluetooth Mesh DFU subsystem defines three different roles the mesh nodes have to assume in the distribution of firmware images:

Target node
: Target node is the receiver and user of the transferred firmware images. All its functionality is implemented by the *Firmware Update Server* model. A transfer may be targeting any number of Target nodes, and they will all be updated concurrently.

Distributor
: The Distributor role serves two purposes in the DFU process. First, it's acting as the Target node in the Upload Firmware procedure, then it distributes the uploaded image to other Target nodes as the Distributor. The Distributor does not select the parameters of the transfer, but relies on an Initiator to give it a list of Target nodes and transfer parameters. The Distributor functionality is implemented in two models, *Firmware Distribution Server* and *Firmware Update Client*. The *Firmware Distribution Server* is responsible for communicating with the Initiator, and the *Firmware Update Client* is responsible for distributing the image to the Target nodes.

Initiator
: The Initiator role is typically implemented by the same device that implements the Bluetooth Mesh *Provisioner* and *Configurator* roles. The Initiator needs a full overview of the

potential Target nodes and their firmware, and will control (and initiate) all firmware updates. The Initiator role is not implemented in the Zephyr Bluetooth Mesh DFU subsystem.

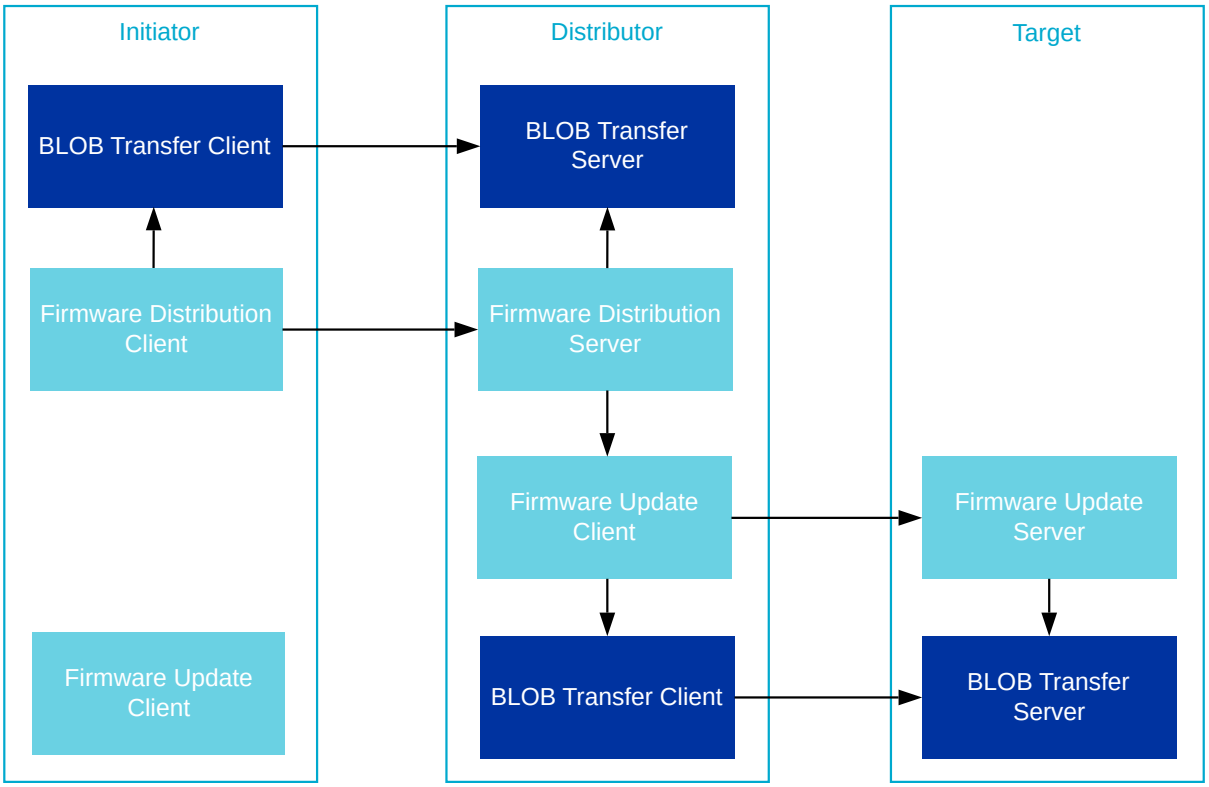

Fig. 21: DFU roles and the associated Bluetooth Mesh models

Bluetooth Mesh applications may combine the DFU roles in any way they'd like, and even take on multiple instances of the same role by instantiating the models on separate elements. For instance, the Distributor and Initiator role can be combined by instantiating the *Firmware Update Client* on the Initiator node and calling its API directly.

It's also possible to combine the Initiator and Distributor devices into a single device, and replace the Firmware Distribution Server model with a proprietary mechanism that will access the Firmware Update Client model directly, e.g. over a serial protocol.

Note

All DFU models instantiate one or more *BLOB Transfer models*, and may need to be spread over multiple elements for certain role combinations.

Stages The Bluetooth Mesh DFU process is designed to act in three stages:

Upload stage

First, the image is uploaded to a Distributor in a mesh network by an external entity, such as a phone or gateway (the Initiator). During the Upload stage, the Initiator transfers the firmware image and all its metadata to the Distributor node inside the mesh network. The Distributor stores the firmware image and its metadata persistently, and awaits further instructions from the Initiator. The time required to complete the upload process depends on the size of the image. After the upload completes, the Initiator can disconnect from the network during the much more time-consuming Distribution stage. Once the firmware has been uploaded to the Distributor, the Initiator may trigger the Distribution stage at any time.

Firmware Capability Check stage (optional)
: Before starting the Distribution stage, the Initiator may optionally check if Target nodes can accept the new firmware. Nodes that do not respond, or respond that they can't receive the new firmware, are excluded from the firmware distribution process.

Distribution stage
: Before the firmware image can be distributed, the Initiator transfers the list of Target nodes and their designated firmware image index to the Distributor. Next, it tells the Distributor to start the firmware distributon process, which runs in the background while the Initiator and the mesh network perform other duties. Once the firmware image has been transferred to the Target nodes, the Distributor may ask them to apply the firmware image immediately and report back with their status and new firmware IDs.

Firmware images All updatable parts of a mesh node's firmware should be represented as a firmware image. Each Target node holds a list of firmware images, each of which should be independently updatable and identifiable.

Firmware images are represented as a BLOB (the firmware itself) with the following additional information attached to it:

Firmware ID
: The firmware ID is used to identify a firmware image. The Initiator node may ask the Target nodes for a list of its current firmware IDs to determine whether a newer version of the firmware is available. The format of the firmware ID is vendor specific, but generally, it should include enough information for an Initiator node with knowledge of the format to determine the type of image as well as its version. The firmware ID is optional, and its max length is determined by `CONFIG_BT_MESH_DFU_FWID_MAXLEN`.

Firmware metadata
: The firmware metadata is used by the Target node to determine whether it should accept an incoming firmware update, and what the effect of the update would be. The metadata format is vendor specific, and should contain all information the Target node needs to verify the image, as well as any preparation the Target node has to make before the image is applied. Typical metadata information can be image signatures, changes to the node's Composition Data and the format of the BLOB. The Target node may perform a metadata check before accepting incoming transfers to determine whether the transfer should be started. The firmware metadata can be discarded by the Target node after the metadata check, as other nodes will never request the metadata from the Target node. The firmware metadata is optional, and its maximum length is determined by `CONFIG_BT_MESH_DFU_METADATA_MAXLEN`.

  The Bluetooth Mesh DFU subsystem in Zephyr provides its own metadata format (`bt_mesh_dfu_metadata`) together with a set of related functions that can be used by an end product. The support for it is enabled using the `CONFIG_BT_MESH_DFU_METADATA` option. The format of the metadata is presented in the table below.

Field	Size (Bytes)	Description
New firmware version	8 B	1 B: Major version 1 B: Minor version 2 B: Revision 4 B: Build number
New firmware size	3 B	Size in bytes for a new firmware
New firmware core type	1 B	Bit field: Bit 0: Application core Bit 1: Network core Bit 2: Applications specific BLOB. Other bits: RFU
Hash of incoming composition data	4 B (Optional)	Lower 4 octets of AES-CMAC (app-specific-key, composition data). This field is present, if Bit 0 is set in the New firmware core type field.
New number of elements	2 B (Optional)	Number of elements on the node after firmware is applied. This field is present, if Bit 0 is set in the New firmware core type field.
Application-specific data for new firmware	<variable> (Optional)	Application-specific data to allow application to execute some vendor-specific behaviors using this data before it can respond with a status message.

> **Note**
>
> The AES-CMAC algorithm serves as a hashing function with a fixed key and is not used for encryption in Bluetooth Mesh DFU metadata. The resulting hash is not secure since the key is known.

Firmware URI

The firmware URI gives the Initiator information about where firmware updates for the image can be found. The URI points to an online resource the Initiator can interact with to get new versions of the firmware. This allows Initiators to perform updates for any node in the mesh network by interacting with the web server pointed to in the URI. The URI must point to a resource using the `http` or `https` schemes, and the targeted web server must behave according to the Firmware Check Over HTTPS procedure defined by the specification. The firmware URI is optional, and its max length is determined by `CONFIG_BT_MESH_DFU_URI_MAXLEN`.

> **Note**
>
> The out-of-band distribution mechanism is not supported.

Firmware effect A new image may have the Composition Data Page 0 different from the one allocated on a Target node. This may have an effect on the provisioning data of the node and how the Distributor finalizes the DFU. Depending on the availability of the Remote Provisioning Server model on the old and new image, the device may either boot up unprovisioned after applying the new firmware or require to be re-provisioned. The complete list of available options is defined in `bt_mesh_dfu_effect`:

`BT_MESH_DFU_EFFECT_NONE`
: The device stays provisioned after the new firmware is programmed. This effect is chosen if the composition data of the new firmware doesn't change.

`BT_MESH_DFU_EFFECT_COMP_CHANGE_NO_RPR`
: This effect is chosen when the composition data changes and the device doesn't support the remote provisioning. The new composition data takes place only after re-provisioning.

`BT_MESH_DFU_EFFECT_COMP_CHANGE`
: This effect is chosen when the composition data changes and the device supports the remote

provisioning. In this case, the device stays provisioned and the new composition data takes place after re-provisioning using the Remote Provisioning models.

`BT_MESH_DFU_EFFECT_UNPROV`
: This effect is chosen if the composition data in the new firmware changes, the device does not support the remote provisioning, and the new composition data takes effect after applying the firmware. The effect can also be chosen, if it is necessary to unprovision the device for application-specific reasons.

When the Target node receives the Firmware Update Firmware Metadata Check message, the Firmware Update Server model calls the `bt_mesh_dfu_srv_cb.check` callback, the application can then process the metadata and provide the effect value. If the effect is `BT_MESH_DFU_EFFECT_COMP_CHANGE`, the application must call functions `bt_mesh_comp_change_prepare()` and `bt_mesh_models_metadata_change_prepare()` to prepare the Composition Data Page and Models Metadata Page contents before applying the new firmware image. See *Composition Data and Models Metadata* for more information.

DFU procedures The DFU protocol is implemented as a set of procedures that must be performed in a certain order.

The Initiator controls the Upload stage of the DFU protocol, and all Distributor side handling of the upload subprocedures is implemented in the *Firmware Distribution Server*.

The Distribution stage is controlled by the Distributor, as implemented by the *Firmware Update Client*. The Target node implements all handling of these procedures in the *Firmware Update Server*, and notifies the application through a set of callbacks.

Uploading the firmware The Upload Firmware procedure uses the *BLOB Transfer models* to transfer the firmware image from the Initiator to the Distributor. The Upload Firmware procedure works in two steps:

1. The Initiator generates a BLOB ID, and sends it to the Distributor's Firmware Distribution Server along with the firmware information and other input parameters of the BLOB transfer. The Firmware Distribution Server stores the information, and prepares its BLOB Transfer Server for the incoming transfer before it responds with a status message to the Initiator.
2. The Initiator's BLOB Transfer Client model transfers the firmware image to the Distributor's BLOB Transfer Server, which stores the image in a predetermined flash partition.

When the BLOB transfer finishes, the firmware image is ready for distribution. The Initiator may upload several firmware images to the Distributor, and ask it to distribute them in any order or at any time. Additional procedures are available for querying and deleting firmware images from the Distributor.

The following Distributor's capabilities related to firmware images can be configured using the configuration options:

- `CONFIG_BT_MESH_DFU_SLOT_CNT`: Amount of image slots available on the device.
- `CONFIG_BT_MESH_DFD_SRV_SLOT_MAX_SIZE`: Maximum allowed size for each image.
- `CONFIG_BT_MESH_DFD_SRV_SLOT_SPACE`: Available space for all images.

Populating the Distributor's receivers list Before the Distributor can start distributing the firmware image, it needs a list of Target nodes to send the image to. The Initiator gets the full list of Target nodes either by querying the potential targets directly, or through some external authority. The Initiator uses this information to populate the Distributor's receivers list with the address and relevant firmware image index of each Target node. The Initiator may send one or more Firmware Distribution Receivers Add messages to build the Distributor's receivers list, and a Firmware Distribution Receivers Delete All message to clear it.

The maximum number of receivers that can be added to the Distributor is configured through the `CONFIG_BT_MESH_DFD_SRV_TARGETS_MAX` configuration option.

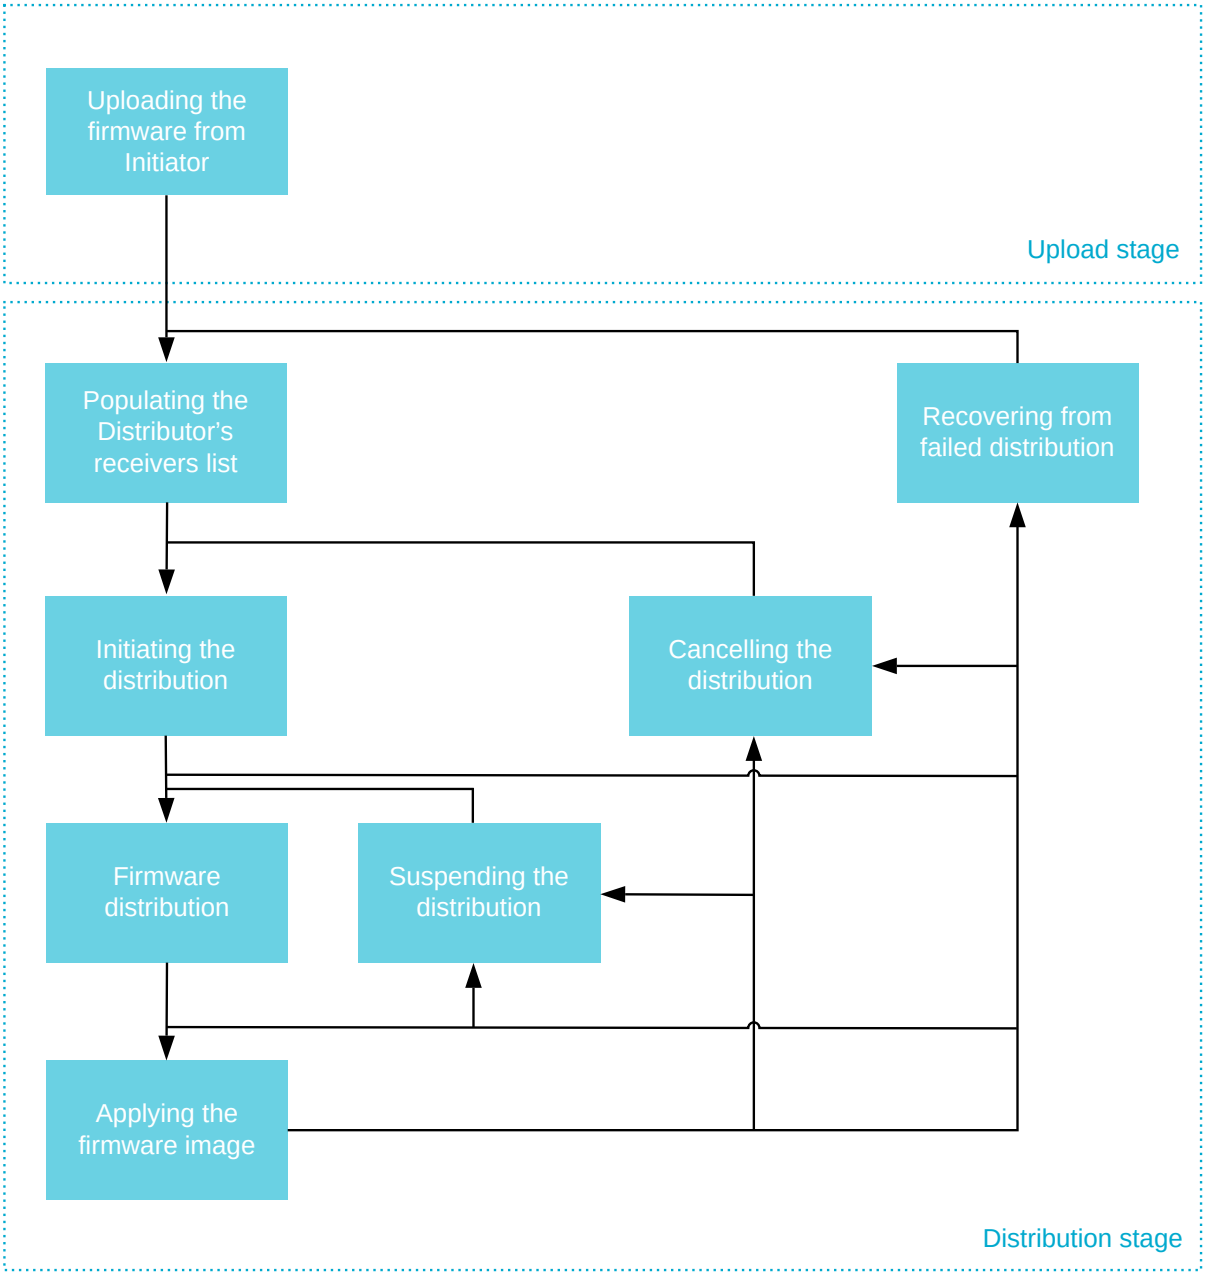

Fig. 22: DFU stages and procedures as seen from the Distributor

Initiating the distribution Once the Distributor has stored a firmware image and received a list of Target nodes, the Initiator may initiate the distribution procedure. The BLOB transfer parameters for the distribution are passed to the Distributor along with an update policy. The update policy decides whether the Distributor should request that the firmware is applied on the Target nodes or not. The Distributor stores the transfer parameters and starts distributing the firmware image to its list of Target nodes.

Firmware distribution The Distributor's Firmware Update Client model uses its BLOB Transfer Client model's broadcast subsystem to communicate with all Target nodes. The firmware distribution is performed with the following steps:

1. The Distributor's Firmware Update Client model generates a BLOB ID and sends it to each Target node's Firmware Update Server model, along with the other BLOB transfer parameters, the Target node firmware image index and the firmware image metadata. Each Target node performs a metadata check and prepares their BLOB Transfer Server model for the transfer, before sending a status response to the Firmware Update Client, indicating if the firmware update will have any effect on the Bluetooth Mesh state of the node.
2. The Distributor's BLOB Transfer Client model transfers the firmware image to all Target nodes.
3. Once the BLOB transfer has been received, the Target nodes' applications verify that the firmware is valid by performing checks such as signature verification or image checksums against the image metadata.
4. The Distributor's Firmware Update Client model queries all Target nodes to ensure that they've all verified the firmware image.

If the distribution procedure completed with at least one Target node reporting that the image has been received and verified, the distribution procedure is considered successful.

Note

The firmware distribution procedure only fails if *all* Target nodes are lost. It is up to the Initiator to request a list of failed Target nodes from the Distributor and initiate additional attempts to update the lost Target nodes after the current attempt is finished.

Suspending the distribution The Initiator can also request the Distributor to suspend the firmware distribution. In this case, the Distributor will stop sending any messages to Target nodes. When the firmware distribution is resumed, the Distributor will continue sending the firmware from the last successfully transferred block.

Applying the firmware image If the Initiator requested it, the Distributor can initiate the Apply Firmware on Target Node procedure on all Target nodes that successfully received and verified the firmware image. The Apply Firmware on Target Node procedure takes no parameters, and to avoid ambiguity, it should be performed before a new transfer is initiated. The Apply Firmware on Target Node procedure consists of the following steps:

1. The Distributor's Firmware Update Client model instructs all Target nodes that have verified the firmware image to apply it. The Target nodes' Firmware Update Server models respond with a status message before calling their application's `apply` callback.
2. The Target node's application performs any preparations needed before applying the transfer, such as storing a snapshot of the Composition Data or clearing its configuration.
3. The Target node's application swaps the current firmware with the new image and updates its firmware image list with the new firmware ID.

4. The Distributor's Firmware Update Client model requests the full list of firmware images from each Target node, and scans through the list to make sure that the new firmware ID has replaced the old.

> **Note**
>
> During the metadata check in the distribution procedure, the Target node may have reported that it will become unprovisioned after the firmware image is applied. In this case, the Distributor's Firmware Update Client model will send a request for the full firmware image list, and expect no response.

Cancelling the distribution The firmware distribution can be cancelled at any time by the Initiator. In this case, the Distributor starts the cancelling procedure by sending a cancelling message to all Target nodes. The Distributor waits for the response from all Target nodes. Once all Target nodes have replied, or the request has timed out, the distribution procedure is cancelled. After this the distribution procedure can be started again from the `Firmware distribution` section.

API reference This section lists the types common to the Device Firmware Update mesh models.

Firmware Distribution models

Bluetooth Mesh Device Firmware Update

Bluetooth Mesh Device Firmware Update (DFU) metadata

Message The Bluetooth Mesh message provides set of structures, macros and functions used for preparing message buffers, managing message and acknowledged message contexts.

API reference
Message

Segmentation and reassembly (SAR) Segmentation and reassembly (SAR) provides a way of handling larger upper transport layer messages in a mesh network, with a purpose of enhancing the Bluetooth Mesh throughput. The segmentation and reassembly mechanism is used by the lower transport layer.

The lower transport layer defines how the upper transport layer PDUs are segmented and reassembled into multiple Lower Transport PDUs, and sends them to the lower transport layer on a peer device. If the Upper Transport PDU fits, it is sent in a single Lower Transport PDU. For longer packets, which do not fit into a single Lower Transport PDU, the lower transport layer performs segmentation, splitting the Upper Transport PDU into multiple segments.

The lower transport layer on the receiving device reassembles the segments into a single Upper Transport PDU before passing it up the stack. Delivery of a segmented message is acknowledged by the lower transport layer of the receiving node, while an unsegmented message delivery is not acknowledged. However, an Upper Transport PDU that fits into one Lower Transport PDU can also be sent as a single-segment segmented message when acknowledgment by the lower transport layer is required. Set the `send rel` flag (see `bt_mesh_msg_ctx`) to use the reliable message transmission and acknowledge single-segment segmented messages.

The transport layer is able to transport up to 32 segments with its SAR mechanism, with a maximum message (PDU) size of 384 octets. To configure message size for the Bluetooth Mesh stack, use the following Kconfig options:

- `CONFIG_BT_MESH_RX_SEG_MAX` to set the maximum number of segments in an incoming message.

- `CONFIG_BT_MESH_TX_SEG_MAX` to set the maximum number of segments in an outgoing message.

The Kconfig options `CONFIG_BT_MESH_TX_SEG_MSG_COUNT` and `CONFIG_BT_MESH_RX_SEG_MSG_COUNT` define how many outgoing and incoming segmented messages can be processed simultaneously. When more than one segmented message is sent to the same destination, the messages are queued and sent one at a time.

Incoming and outgoing segmented messages share the same pool for allocation of their segments. This pool size is configured through the `CONFIG_BT_MESH_SEG_BUFS` Kconfig option. Both incoming and outgoing messages allocate segments at the start of the transaction. The outgoing segmented message releases its segments one by one as soon as they are acknowledged by the receiver, while the incoming message releases the segments first after the message is fully received. Keep this in mind when defining the size of the buffers.

SAR does not impose extra overhead on the access layer payload per segment.

Segmentation and reassembly (SAR) Configuration models With Bluetooth Mesh Protocol Specification version 1.1, it became possible to configure SAR behavior, such as intervals, timers and retransmission counters, over a mesh network using SAR Configuration models:

- *SAR Configuration Client*
- *SAR Configuration Server*

The following SAR behavior applies regardless of the presence of a SAR Configuration Server on a node.

Transmission of segments is separated by a segment transmission interval (see the *SAR Segment Interval Step* state). Other configurable time intervals and delays available for the segmentation and reassembly are:

- Interval between unicast retransmissions (see the states *SAR Unicast Retransmissions Interval Step* and *SAR Unicast Retransmissions Interval Increment*).
- Interval between multicast retransmissions (see the *SAR Multicast Retransmissions Interval Step* state).
- Segment reception interval (see the *SAR Receiver Segment Interval Step* state).
- Acknowledgment delay increment (see the *SAR Acknowledgment Delay Increment* state).

When the last segment marked as unacknowledged is transmitted, the lower transport layer starts a retransmissions timer. The initial value of the SAR Unicast Retransmissions timer depends on the value of the TTL field of the message. If the TTL field value is greater than `0`, the initial value for the timer is set according to the following formula:

$$unicast\ retransmissions\ interval\ step + unicast\ retransmissions\ interval\ increment \times (TTL - 1)$$

If the TTL field value is `0`, the initial value of the timer is set to the unicast retransmissions interval step.

The initial value of the SAR Multicast Retransmissions timer is set to the multicast retransmissions interval.

When the lower transport layer receives a message segment, it starts a SAR Discard timer. The discard timer tells how long the lower transport layer waits before discarding the segmented message the segment belongs to. The initial value of the SAR Discard timer is the discard timeout value indicated by the *SAR Discard Timeout* state.

SAR Acknowledgment timer holds the time before a Segment Acknowledgment message is sent for a received segment. The initial value of the SAR Acknowledgment timer is calculated using the following formula:

$$min(SegN + 0.5, acknowledgment\ delay\ increment) \times segment\ reception\ interval$$

The SegN field value identifies the total number of segments the Upper Transport PDU is segmented into.

Four counters are related to SAR behavior:

- Two unicast retransmissions counts (see *SAR Unicast Retransmissions Count* state and *SAR Unicast Retransmissions Without Progress Count* state)
- Multicast retransmissions count (see *SAR Multicast Retransmissions Count* state)
- Acknowledgment retransmissions count (see *SAR Acknowledgment Retransmissions Count* state)

If the number of segments in the transmission is higher than the value of the *SAR Segments Threshold* state, Segment Acknowledgment messages are retransmitted using the value of the *SAR Acknowledgment Retransmissions Count* state.

SAR states There are two states defined related to segmentation and reassembly:

- SAR Transmitter state
- SAR Receiver state

The SAR Transmitter state is a composite state that controls the number and timing of transmissions of segmented messages. It includes the following states:

- SAR Segment Interval Step
- SAR Unicast Retransmissions Count
- SAR Unicast Retransmissions Without Progress Count
- SAR Unicast Retransmissions Interval Step
- SAR Unicast Retransmissions Interval Increment
- SAR Multicast Retransmissions Count
- SAR Multicast Retransmissions Interval Step

The SAR Receiver state is a composite state that controls the number and timing of Segment Acknowledgment transmissions and the discarding of reassembly of a segmented message. It includes the following states:

- SAR Segments Threshold
- SAR Discard Timeout
- SAR Acknowledgment Delay Increment
- SAR Acknowledgment Retransmissions Count
- SAR Receiver Segment Interval Step

SAR Segment Interval Step SAR Segment Interval Step state holds a value that controls the interval between transmissions of segments of a segmented message. The interval is measured in milliseconds.

Use the CONFIG_BT_MESH_SAR_TX_SEG_INT_STEP Kconfig option to set the default value. Segment transmission interval is then calculated using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_SEG_INT_STEP} + 1) \times 10 \text{ ms}$$

SAR Unicast Retransmissions Count SAR Unicast Retransmissions Count holds a value that defines the maximum number of retransmissions of a segmented message to a unicast destination. Use the CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_COUNT Kconfig option to set the default value for this state.

SAR Unicast Retransmissions Without Progress Count This state holds a value that defines the maximum number of retransmissions of a segmented message to a unicast address that will be sent if no acknowledgment was received during the timeout, or if an acknowledgment with already confirmed segments was received. Use the Kconfig option CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_WITHOUT_PROG_COUNT to set the maximum number of retransmissions.

SAR Unicast Retransmissions Interval Step The value of this state controls the interval step used for delaying the retransmissions of unacknowledged segments of a segmented message to a unicast address. The interval step is measured in milliseconds.

Use the CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_STEP Kconfig option to set the default value. This value is then used to calculate the interval step using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_STEP} + 1) \times 25 \text{ ms}$$

SAR Unicast Retransmissions Interval Increment SAR Unicast Retransmissions Interval Increment holds a value that controls the interval increment used for delaying the retransmissions of unacknowledged segments of a segmented message to a unicast address. The increment is measured in milliseconds.

Use the Kconfig option CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_INC to set the default value. The Kconfig option value is used to calculate the increment using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_UNICAST_RETRANS_INT_INC} + 1) \times 25 \text{ ms}$$

SAR Multicast Retransmissions Count The state holds a value that controls the total number of retransmissions of a segmented message to a multicast address. Use the Kconfig option CONFIG_BT_MESH_SAR_TX_MULTICAST_RETRANS_COUNT to set the total number of retransmissions.

SAR Multicast Retransmissions Interval Step This state holds a value that controls the interval between retransmissions of all segments in a segmented message to a multicast address. The interval is measured in milliseconds.

Use the Kconfig option CONFIG_BT_MESH_SAR_TX_MULTICAST_RETRANS_INT to set the default value that is used to calculate the interval using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_TX_MULTICAST_RETRANS_INT} + 1) \times 25 \text{ ms}$$

SAR Discard Timeout The value of this state defines the time in seconds that the lower transport layer waits after receiving segments of a segmented message before discarding that segmented message. Use the Kconfig option CONFIG_BT_MESH_SAR_RX_DISCARD_TIMEOUT to set the default value. The discard timeout will be calculated using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_RX_DISCARD_TIMEOUT} + 1) \times 5 \text{ seconds}$$

SAR Acknowledgment Delay Increment This state holds a value that controls the delay increment of an interval used for delaying the transmission of an acknowledgment message after receiving a new segment. The increment is measured in segments.

Use the Kconfig option CONFIG_BT_MESH_SAR_RX_ACK_DELAY_INC to set the default value. The increment value is calculated to be CONFIG_BT_MESH_SAR_RX_ACK_DELAY_INC + 1.5.

SAR Segments Threshold SAR Segments Threshold state holds a value that defines a threshold in number of segments of a segmented message for acknowledgment retransmissions. Use the Kconfig option CONFIG_BT_MESH_SAR_RX_SEG_THRESHOLD to set the threshold.

When the number of segments of a segmented message is above this threshold, the stack will additionally retransmit every acknowledgment message the number of times given by the value of CONFIG_BT_MESH_SAR_RX_ACK_RETRANS_COUNT.

SAR Acknowledgment Retransmissions Count The SAR Acknowledgment Retransmissions Count state controls the number of retransmissions of Segment Acknowledgment messages sent by the lower transport layer. It gives the total number of retranmissions of an acknowledgment message that the stack will additionally send when the size of segments in a segmented message is above the CONFIG_BT_MESH_SAR_RX_SEG_THRESHOLD value.

Use the Kconfig option CONFIG_BT_MESH_SAR_RX_ACK_RETRANS_COUNT to set the default value for this state. The maximum number of transmissions of a Segment Acknowledgment message is CONFIG_BT_MESH_SAR_RX_ACK_RETRANS_COUNT + 1.

SAR Receiver Segment Interval Step The SAR Receiver Segment Interval Step defines the segments reception interval step used for delaying the transmission of an acknowledgment message after receiving a new segment. The interval is measured in milliseconds.

Use the Kconfig option CONFIG_BT_MESH_SAR_RX_SEG_INT_STEP to set the default value and calculate the interval using the following formula:

$$(\texttt{CONFIG_BT_MESH_SAR_RX_SEG_INT_STEP} + 1) \times 10 \text{ ms}$$

Provisioning Provisioning is the process of adding devices to a mesh network. It requires two devices operating in the following roles:

- The *provisioner* represents the network owner, and is responsible for adding new nodes to the mesh network.
- The *provisionee* is the device that gets added to the network through the Provisioning process. Before the provisioning process starts, the provisionee is an *unprovisioned device*.

The Provisioning module in the Zephyr Bluetooth Mesh stack supports both the Advertising and GATT Provisioning bearers for the provisionee role, as well as the Advertising Provisioning bearer for the provisioner role.

The Provisioning process All Bluetooth Mesh nodes must be provisioned before they can participate in a Bluetooth Mesh network. The Provisioning API provides all the functionality necessary for a device to become a provisioned mesh node. Provisioning is a five-step process, involving the following steps:

- Beaconing
- Invitation
- Public key exchange
- Authentication
- Provisioning data transfer

Beaconing To start the provisioning process, the unprovisioned device must first start broadcasting the Unprovisioned Beacon. This makes it visible to nearby provisioners, which can initiate the provisioning. To indicate that the device needs to be provisioned, call bt_mesh_prov_enable(). The device starts broadcasting the Unprovisioned Beacon with the device UUID and the OOB information field, as specified in the prov parameter passed to bt_mesh_init(). Additionally, a Uniform Resource Identifier (URI) may be specified, which can

point the provisioner to the location of some Out Of Band information, such as the device's public key or an authentication value database. The URI is advertised in a separate beacon, with a URI hash included in the unprovisioned beacon, to tie the two together.

Uniform Resource Identifier The Uniform Resource Identifier shall follow the format specified in the Bluetooth Core Specification Supplement. The URI must start with a URI scheme, encoded as a single utf-8 data point, or the special `none` scheme, encoded as `0x01`. The available schemes are listed on the Bluetooth website.

Examples of encoded URIs:

Table 28: URI encoding examples

URI	Encoded
`http://example.com`	`\x16//example.com`
`https://www.zephyrproject.org/`	`\x17//www.zephyrproject.org/`
`just a string`	`\x01just a string`

Provisioning invitation The provisioner initiates the Provisioning process by sending a Provisioning invitation. The invitations prompts the provisionee to call attention to itself using the Health Server *Attention state*, if available.

The Unprovisioned device automatically responds to the invite by presenting a list of its capabilities, including the supported Out of Band Authentication methods and algorithms.

Public key exchange Before the provisioning process can begin, the provisioner and the unprovisioned device exchange public keys, either in-band or Out of Band (OOB).

In-band public key exchange is a part of the provisioning process and always supported by the unprovisioned device and provisioner.

If the application wants to support public key exchange via OOB, it needs to provide public and private keys to the mesh stack. The unprovisioned device will reflect this in its capabilities. The provisioner obtains the public key via any available OOB mechanism (e.g. the device may advertise a packet containing the public key or it can be encoded in a QR code printed on the device packaging). Note that even if the unprovisioned device has specified the public key for the Out of Band exchange, the provisioner may choose to exchange the public key in-band if it can't retrieve the public key via OOB mechanism. In this case, a new key pair will be generated by the mesh stack for each Provisioning process.

To enable support of OOB public key on the unprovisioned device side, `CONFIG_BT_MESH_PROV_OOB_PUBLIC_KEY` needs to be enabled. The application must provide public and private keys before the Provisioning process is started by initializing pointers to `bt_mesh_prov.public_key_be` and `bt_mesh_prov.private_key_be`. The keys needs to be provided in big-endian bytes order.

To provide the device's public key obtained via OOB, call `bt_mesh_prov_remote_pub_key_set()` on the provisioner side.

Authentication After the initial exchange, the provisioner selects an Out of Band (OOB) Authentication method. This allows the user to confirm that the device the provisioner connected to is actually the device they intended, and not a malicious third party.

The Provisioning API supports the following authentication methods for the provisionee:

- **Static OOB:** An authentication value is assigned to the device in production, which the provisioner can query in some application specific way. For secure provisioning with the BTM_ECDH_P256_HMAC_SHA256_AES_CCM algorithm, the Static OOB value should contain more than 128 bits of entropy to provide adequate security against attacks.

- **Input OOB:** The user inputs the authentication value. The available input actions are listed in `bt_mesh_input_action_t`.
- **Output OOB:** Show the user the authentication value. The available output actions are listed in `bt_mesh_output_action_t`.

The application must provide callbacks for the supported authentication methods in `bt_mesh_prov`, as well as enabling the supported actions in `bt_mesh_prov.output_actions` and `bt_mesh_prov.input_actions`.

When an Output OOB action is selected, the authentication value should be presented to the user when the output callback is called, and remain until the `bt_mesh_prov.input_complete` or `bt_mesh_prov.complete` callback is called. If the action is `blink`, `beep` or `vibrate`, the sequence should be repeated after a delay of three seconds or more.

When an Input OOB action is selected, the user should be prompted when the application receives the `bt_mesh_prov.input` callback. The user response should be fed back to the Provisioning API through `bt_mesh_input_string()` or `bt_mesh_input_numeric()`. If no user response is recorded within 60 seconds, the Provisioning process is aborted.

If Provisionee wants to mandate OOB authentication, it is mandatory to use the BT_MESH_ECDH_P256_HMAC_SHA256_AES_CCM algorithm.

Data transfer After the device has been successfully authenticated, the provisioner transfers the Provisioning data:

- Unicast address
- A network key
- IV index
- Network flags
  - Key refresh
  - IV update

Additionally, a device key is generated for the node. All this data is stored by the mesh stack, and the provisioning `bt_mesh_prov.complete` callback gets called.

Provisioning security Depending on the choice of public key exchange mechanism and authentication method, the provisioning process can be secure or insecure.

On May 24th 2021, ANSSI disclosed a set of vulnerabilities in the Bluetooth Mesh provisioning protocol that showcased how the low entropy provided by the Blink, Vibrate, Push, Twist and Input/Output numeric OOB methods could be exploited in impersonation and MITM attacks. In response, the Bluetooth SIG has reclassified these OOB methods as insecure in the Bluetooth Mesh Profile Specification v1.0.1 erratum 16350, as AuthValue may be brute forced in real time. To ensure secure provisioning, applications should use a static OOB value and OOB public key transfer.

API reference

Provisioning

Proxy The Proxy feature allows legacy devices like phones to access the Bluetooth Mesh network through GATT. The Proxy feature is only compiled in if the `CONFIG_BT_MESH_GATT_PROXY` option is set. The Proxy feature state is controlled by the *Configuration Server*, and the initial value can be set with `bt_mesh_cfg_srv.gatt_proxy`.

Nodes with the Proxy feature enabled can advertise with Network Identity and Node Identity, which is controlled by the *Configuration Client*.

The GATT Proxy state indicates if the Proxy feature is supported.

Private Proxy A node supporting the Proxy feature and the *Private Beacon Server* model can advertise with Private Network Identity and Private Node Identity types, which is controlled by the *Private Beacon Client*. By advertising with this set of identification types, the node allows the legacy device to connect to the network over GATT while maintaining the privacy of the network.

The Private GATT Proxy state indicates whether the Private Proxy functionality is supported.

Proxy Solicitation In the case where both GATT Proxy and Private GATT Proxy states are disabled on a node, a legacy device cannot connect to it. A node supporting the *On-Demand Private Proxy Server* may however be solicited to advertise connectable advertising events without enabling the Private GATT Proxy state. To solicit the node, the legacy device can send a Solicitation PDU by calling the `bt_mesh_proxy_solicit()` function. To enable this feature, the device must to be compiled with the `CONFIG_BT_MESH_PROXY_SOLICITATION` option set.

Solicitation PDUs are non-mesh, non-connectable, undirected advertising messages containing Proxy Solicitation UUID, encrypted with the network key of the subnet that the legacy device wants to connect to. The PDU contains the source address of the legacy device and a sequence number. The sequence number is maintained by the legacy device and is incremented for every new Solicitation PDU sent.

Each node supporting the Solicitation PDU reception holds its own Solicitation Replay Protection List (SRPL). The SRPL protects the solicitation mechanism from replay attacks by storing solicitation sequence number (SSEQ) and solicitation source (SSRC) pairs of valid Solicitation PDUs processed by the node. The delay between updating the SRPL and storing the change to the persistent storage is defined by `CONFIG_BT_MESH_RPL_STORE_TIMEOUT`.

The Solicitation PDU RPL Configuration models, *Solicitation PDU RPL Configuration Client* and *Solicitation PDU RPL Configuration Server*, provide the functionality of saving and clearing SRPL entries. A node that supports the Solicitation PDU RPL Configuration Client model can clear a section of the SRPL on the target by calling the `bt_mesh_sol_pdu_rpl_clear()` function. Communication between the Solicitation PDU RPL Configuration Client and Server is encrypted using the application key, therefore, the Solicitation PDU RPL Configuration Client can be instantiated on any device in the network.

When the node receives the Solicitation PDU and successfully authenticates it, it will start advertising connectable advertisements with the Private Network Identity type. The duration of the advertisement can be configured by the On-Demand Private Proxy Client model.

Proxy

Heartbeat The Heartbeat feature provides functionality for monitoring Bluetooth Mesh nodes and determining the distance between nodes.

The Heartbeat feature is configured through the *Configuration Server* model.

Heartbeat messages Heartbeat messages are sent as transport control packets through the network, and are only encrypted with a network key. Heartbeat messages contain the original Time To Live (TTL) value used to send the message and a bitfield of the active features on the node. Through this, a receiving node can determine how many relays the message had to go through to arrive at the receiver, and what features the node supports.

Available Heartbeat feature flags:

- `BT_MESH_FEAT_RELAY`
- `BT_MESH_FEAT_PROXY`
- `BT_MESH_FEAT_FRIEND`
- `BT_MESH_FEAT_LOW_POWER`

Heartbeat publication Heartbeat publication is controlled through the Configuration models, and can be triggered in two ways:

Periodic publication
: The node publishes a new Heartbeat message at regular intervals. The publication can be configured to stop after a certain number of messages, or continue indefinitely.

Triggered publication
: The node publishes a new Heartbeat message every time a feature changes. The set of features that can trigger the publication is configurable.

The two publication types can be combined.

Heartbeat subscription A node can be configured to subscribe to Heartbeat messages from one node at the time. To receive a Heartbeat message, both the source and destination must match the configured subscription parameters.

Heartbeat subscription is always time limited, and throughout the subscription period, the node keeps track of the number of received Heartbeats as well as the minimum and maximum received hop count.

All Heartbeats received with the configured subscription parameters are passed to the `bt_mesh_hb_cb::recv` event handler.

When the Heartbeat subscription period ends, the `bt_mesh_hb_cb::sub_end` callback gets called.

Heartbeat

Runtime Configuration The runtime configuration API allows applications to change their runtime configuration directly, without going through the Configuration models.

Bluetooth Mesh nodes should generally be configured by a central network configurator device with a *Configuration Client* model. Each mesh node instantiates a *Configuration Server* model that the Configuration Client can communicate with to change the node configuration. In some cases, the mesh node can't rely on the Configuration Client to detect or determine local constraints, such as low battery power or changes in topology. For these scenarios, this API can be used to change the configuration locally.

Note

Runtime configuration changes before the node is provisioned will not be stored in the *persistent storage*.

API reference
Runtime Configuration

Mesh Statistic The statistic API provides runtime monitoring of Bluetooth Mesh communication.

Frame statistic The frame statistic API allows monitoring the number of received frames over different interfaces, and the number of planned and succeeded transmission and relaying attempts.

The API helps the user to estimate the efficiency of the advertiser configuration parameters and the scanning ability of the device. The number of the monitored parameters can be easily extended by customer values.

LPN timing measurement When `CONFIG_BT_MESH_LOW_POWER` is enabled, the statistic module measures LPN friendship timing parameters by timestamping protocol events:

- T1: Poll TX complete
- T2: Scanner enabled (ReceiveDelay elapsed)
- T3: Friend response received or ReceiveWindow expired

From these timestamps the module computes the measured ReceiveDelay (T2 - T1) and ReceiveWindow (T3 - T2) in microseconds. The application can use these values to evaluate the actual on-air timing against configured friendship parameters.

An application can read out and reset statistics at any time.

API reference

Statistic

Bluetooth Mesh Shell The Bluetooth Mesh shell subsystem provides a set of Bluetooth Mesh shell commands for the *Shell* module. It allows for testing and exploring the Bluetooth Mesh API through an interactive interface, without having to write an application.

The Bluetooth Mesh shell interface provides access to most Bluetooth Mesh features, including provisioning, configuration, and message sending.

Prerequisites The Bluetooth Mesh shell subsystem depends on the application to create the composition data and do the mesh initialization.

Application The Bluetooth Mesh shell subsystem is most easily used through the Bluetooth Mesh shell application under `tests/bluetooth/mesh_shell`. See *Shell* for information on how to connect and interact with the Bluetooth Mesh shell application.

Basic usage The Bluetooth Mesh shell subsystem adds a single `mesh` command, which holds a set of sub-commands. Every time the device boots up, make sure to call `mesh init` before any of the other Bluetooth Mesh shell commands can be called:

```
uart:~$ mesh init
```

This is done to ensure that all available log will be printed to the shell output.

Provisioning The mesh node must be provisioned to become part of the network. This is only necessary the first time the device boots up, as the device will remember its provisioning data between reboots.

The simplest way to provision the device is through self-provisioning. To do this the user must provision the device with the default network key and address `0x0001`, execute:

```
uart:~$ mesh prov local 0 0x0001
```

Since all mesh nodes use the same values for the default network key, this can be done on multiple devices, as long as they're assigned non-overlapping unicast addresses. Alternatively, to provision the device into an existing network, the unprovisioned beacon can be enabled with `mesh prov pb-adv on` or `mesh prov pb-gatt on`. The beacons can be picked up by an external provisioner, which can provision the node into its network.

Once the mesh node is part of a network, its transmission parameters can be controlled by the general configuration commands:

- To set the destination address, call `mesh target dst <Addr>`.
- To set the network key index, call `mesh target net <NetKeyIdx>`.

- To set the application key index, call `mesh target app <AppKeyIdx>`.

By default, the transmission parameters are set to send messages to the provisioned address and network key.

Configuration By setting the destination address to the local unicast address (`0x0001` in the `mesh prov local` command above), we can perform self-configuration through any of the *Models* commands.

A good first step is to read out the node's own composition data:

```
uart:~$ mesh models cfg get-comp
```

This prints a list of the composition data of the node, including a list of its model IDs.

Next, since the device has no application keys by default, it's a good idea to add one:

```
uart:~$ mesh models cfg appkey add 0 0
```

Message sending With an application key added (see above), the mesh node's transition parameters are all valid, and the Bluetooth Mesh shell can send raw mesh messages through the network.

For example, to send a Generic OnOff Set message, call:

```
uart:~$ mesh test net-send 82020100
```

Note

All multibyte fields model messages are in little endian, except the opcode.

The message will be sent to the current destination address, using the current network and application key indexes. As the destination address points to the local unicast address by default, the device will only send packets to itself. To change the destination address to the All Nodes broadcast address, call:

```
uart:~$ mesh target dst 0xffff
```

With the destination address set to `0xffff`, any other mesh nodes in the network with the configured network and application keys will receive and process the messages we send.

Note

To change the configuration of the device, the destination address must be set back to the local unicast address before issuing any configuration commands.

Sending raw mesh packets is a good way to test model message handler implementations during development, as it can be done without having to implement the sending model. By default, only the reception of the model messages can be tested this way, as the Bluetooth Mesh shell only includes the foundation models. To receive a packet in the mesh node, you have to add a model with a valid opcode handler list to the composition data in `subsys/bluetooth/mesh/shell.c`, and print the incoming message to the shell in the handler callback.

Parameter formats The Bluetooth Mesh shell commands are parsed with a variety of formats:

Table 29: Parameter formats

Type	Description	Example
Integers	The default format unless something else is specified. Can be either decimal or hexadecimal.	`1234`, `0xabcd01234`
Hexstrings	For raw byte arrays, like UUIDs, key values and message payloads, the parameters should be formatted as an unbroken string of hexadecimal values without any prefix.	`deadbeef01234`
Booleans	Boolean values are denoted in the API documentation as `<val(off, on)>`.	`on`, `off`, `enabled`, `disabled`, `1`, `0`

Commands The Bluetooth Mesh shell implements a large set of commands. Some of the commands accept parameters, which are mentioned in brackets after the command name. For example, `mesh lpn set <value: off, on>`. Mandatory parameters are marked with angle brackets (e.g. `<NetKeyIdx>`), and optional parameters are marked with square brackets (e.g. `[DstAddr]`).

The Bluetooth Mesh shell commands are divided into the following groups:

- *General configuration*
- *Target*
- *Low Power Node*
- *Testing*
- *Provisioning*
- *Proxy*
- *Models*
- *Configuration database*
- *Statistic*

Note

Some commands depend on specific features being enabled in the compile time configuration of the application. Not all features are enabled by default. The list of available Bluetooth mesh shell commands can be shown in the shell by calling `mesh` without any arguments.

General configuration

`mesh init`

Initialize the mesh shell. This command must be run before any other mesh command.

`mesh reset-local`

Reset the local mesh node to its initial unprovisioned state. This command will also clear the Configuration Database (CDB) if present.

Target The target commands enables the user to monitor and set the target destination address, network index and application index for the shell. These parameters are used by several commands, like provisioning, Configuration Client, etc.

`mesh target dst [DstAddr]`

Get or set the message destination address. The destination address determines where mesh packets are sent with the shell, but has no effect on modules outside the shell's control.

- `DstAddr`: If present, sets the new 16-bit mesh destination address. If omitted, the current destination address is printed.

`mesh target net [NetKeyIdx]`

Get or set the message network index. The network index determines which network key is used to encrypt mesh packets that are sent with the shell, but has no effect on modules outside the shell's control. The network key must already be added to the device, either through provisioning or by a Configuration Client.

- `NetKeyIdx`: If present, sets the new network index. If omitted, the current network index is printed.

`mesh target app [AppKeyIdx]`

Get or set the message application index. The application index determines which application key is used to encrypt mesh packets that are sent with the shell, but has no effect on modules outside the shell's control. The application key must already be added to the device by a Configuration Client, and must be bound to the current network index.

- `AppKeyIdx`: If present, sets the new application index. If omitted, the current application index is printed.

Low Power Node

`mesh lpn set <Val(off, on)>`

Enable or disable Low Power operation. Once enabled, the device will turn off its radio and start polling for friend nodes.

- `Val`: Sets whether Low Power operation is enabled.

`mesh lpn poll`

Perform a poll to the friend node, to receive any pending messages. Only available when LPN is enabled.

Testing

`mesh test net-send <HexString>`

Send a raw mesh message with the current destination address, network and application index. The message opcode must be encoded manually.

- `HexString` Raw hexadecimal representation of the message to send.

`mesh test iv-update`

Force an IV update.

`mesh test iv-update-test <Val(off, on)>`

Set the IV update test mode. In test mode, the IV update timing requirements are bypassed.

- `Val`: Enable or disable the IV update test mode.

`mesh test rpl-clear`

Clear the replay protection list, forcing the node to forget all received messages.

Warning

Clearing the replay protection list breaks the security mechanisms of the mesh node, making it susceptible to message replay attacks. This should never be performed in a real deployment.

Health Server Test

`mesh test health-srv add-fault <FaultID>`

Register a new Health Server Fault for the Linux Foundation Company ID.

- `FaultID`: ID of the fault to register (`0x0001` to `0xFFFF`)

`mesh test health-srv del-fault [FaultID]`

Remove registered Health Server faults for the Linux Foundation Company ID.

- `FaultID`: If present, the given fault ID will be deleted. If omitted, all registered faults will be cleared.

Provisioning To allow a device to broadcast connectable unprovisioned beacons, the `CONFIG_BT_MESH_PROVISIONEE` configuration option must be enabled, along with the `CONFIG_BT_MESH_PB_GATT` option.

`mesh prov pb-gatt <Val(off, on)>`

Start or stop advertising a connectable unprovisioned beacon. The connectable unprovisioned beacon allows the mesh node to be discovered by nearby GATT based provisioners, and provisioned through the GATT bearer.

- `Val`: Enable or disable provisioning with GATT

To allow a device to broadcast unprovisioned beacons, the `CONFIG_BT_MESH_PROVISIONEE` configuration option must be enabled, along with the `CONFIG_BT_MESH_PB_ADV` option.

`mesh prov pb-adv <Val(off, on)>`

Start or stop advertising the unprovisioned beacon. The unprovisioned beacon allows the mesh node to be discovered by nearby advertising-based provisioners, and provisioned through the advertising bearer.

- `Val`: Enable or disable provisioning with advertiser

To allow a device to provision devices, the `CONFIG_BT_MESH_PROVISIONER` and `CONFIG_BT_MESH_PB_ADV` configuration options must be enabled.

`mesh prov remote-adv <UUID(1-16 hex)> <NetKeyIdx> <Addr> <AttDur(s)>`

Provision a nearby device into the mesh. The mesh node starts scanning for unprovisioned beacons with the given UUID. Once found, the unprovisioned device will be added to the mesh network with the given unicast address, and given the network key indicated by `NetKeyIdx`.

- `UUID`: UUID of the unprovisioned device. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `NetKeyIdx`: Index of the network key to pass to the device.
- `Addr`: First unicast address to assign to the unprovisioned device. The device will occupy as many addresses as it has elements, and all must be available.
- `AttDur`: The duration in seconds the unprovisioned device will identify itself for, if supported. See *Attention state* for details.

To allow a device to provision devices over GATT, the `CONFIG_BT_MESH_PROVISIONER` and `CONFIG_BT_MESH_PB_GATT_CLIENT` configuration options must be enabled.

`mesh prov remote-gatt <UUID(1-16 hex)> <NetKeyIdx> <Addr> <AttDur(s)>`

Provision a nearby device into the mesh. The mesh node starts scanning for connectable advertising for PB-GATT with the given UUID. Once found, the unprovisioned device will be added to the mesh network with the given unicast address, and given the network key indicated by `NetKeyIdx`.

- `UUID`: UUID of the unprovisioned device. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `NetKeyIdx`: Index of the network key to pass to the device.
- `Addr`: First unicast address to assign to the unprovisioned device. The device will occupy as many addresses as it has elements, and all must be available.
- `AttDur`: The duration in seconds the unprovisioned device will identify itself for, if supported. See *Attention state* for details.

`mesh prov uuid [UUID(1-16 hex)]`

Get or set the mesh node's UUID, used in the unprovisioned beacons.

- `UUID`: If present, new 128-bit UUID value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the current UUID will be printed. To enable this command, the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option must be enabled.

`mesh prov input-num <Number>`

Input a numeric OOB authentication value. Only valid when prompted by the shell during provisioning. The input number must match the number presented by the other participant in the provisioning.

- `Number`: Decimal authentication number.

`mesh prov input-str <String>`

Input an alphanumeric OOB authentication value. Only valid when prompted by the shell during provisioning. The input string must match the string presented by the other participant in the provisioning.

- `String`: Unquoted alphanumeric authentication string.

`mesh prov static-oob [Val(1-32 hex)]`

Set or clear the static OOB authentication value. The static OOB authentication value must be set before provisioning starts to have any effect. The static OOB value must be same on both participants in the provisioning. To enable this command, the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option must be enabled.

- `Val`: If present, indicates the new hexadecimal value of the static OOB. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the static OOB value is cleared.

`mesh prov local <NetKeyIdx> <Addr> [IVI]`

Provision the mesh node itself. If the Configuration database is enabled, the network key must be created. Otherwise, the default key value is used.

- `NetKeyIdx`: Index of the network key to provision.
- `Addr`: First unicast address to assign to the device. The device will occupy as many addresses as it has elements, and all must be available.
- `IVI`: Indicates the current network IV index. Defaults to 0 if omitted.

`mesh prov beacon-listen <Val(off, on)>`

Enable or disable printing of incoming unprovisioned beacons. Allows a provisioner device to detect nearby unprovisioned devices and provision them. To enable this command, the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option must be enabled.

- `Val`: Whether to enable the unprovisioned beacon printing.

`mesh prov remote-pub-key <PubKey>`

Provide Device public key.

- `PubKey` - Device public key in big-endian.

`mesh prov auth-method input <Action> <Size>`

From the provisioner device, instruct the unprovisioned device to use the specified Input OOB authentication action.

- `Action` - Input action. Allowed values:
  - `0` - No input action.
  - `1` - Push action set.
  - `2` - Twist action set.
  - `4` - Enter number action set.
  - `8` - Enter String action set.
- `Size` - Authentication size.

`mesh prov auth-method output <Action> <Size>`

From the provisioner device, instruct the unprovisioned device to use the specified Output OOB authentication action.

- `Action` - Output action. Allowed values:
  - `0` - No output action.
  - `1` - Blink action set.

  - 2 - Vibrate action set.
  - 4 - Display number action set.
  - 8 - Display String action set.
- Size - Authentication size.

`mesh prov auth-method static <Val(1-16 hex)>`

From the provisioner device, instruct the unprovisioned device to use static OOB authentication, and use the given static authentication value when provisioning.

- Val - Static OOB value. Providing a hex-string shorter than 32 bytes will populate the N most significant bytes of the array and zero-pad the rest.

`mesh prov auth-method none`

From the provisioner device, don't use any authentication when provisioning new devices. This is the default behavior.

Proxy The Proxy Server module is an optional mesh subsystem that can be enabled through the CONFIG_BT_MESH_GATT_PROXY configuration option.

`mesh proxy identity-enable`

Enable the Proxy Node Identity beacon, allowing Proxy devices to connect explicitly to this device. The beacon will run for 60 seconds before the node returns to normal Proxy beacons.

The Proxy Client module is an optional mesh subsystem that can be enabled through the CONFIG_BT_MESH_PROXY_CLIENT configuration option.

`mesh proxy connect <NetKeyIdx>`

Auto-Connect a nearby proxy server into the mesh.

- NetKeyIdx: Index of the network key to connect.

`mesh proxy disconnect <NetKeyIdx>`

Disconnect the existing proxy connection.

- NetKeyIdx: Index of the network key to disconnect.

`mesh proxy solicit <NetKeyIdx>`

Begin Proxy Solicitation of a subnet. Support of this feature can be enabled through the CONFIG_BT_MESH_PROXY_SOLICITATION configuration option.

- NetKeyIdx: Index of the network key to send Solicitation PDUs to.

Models

Configuration Client The Configuration Client model is an optional mesh subsystem that can be enabled through the CONFIG_BT_MESH_CFG_CLI configuration option. This is implemented as a separate module (`mesh models cfg`) inside the `mesh models` subcommand list. This module will work on any instance of the Configuration Client model if the mentioned shell configuration options is enabled, and as long as the Configuration Client model is present in the model composition of the application. This shell module can be used for configuring itself and other nodes in the mesh network.

The Configuration Client uses general message parameters set by `mesh target dst` and `mesh target net` to target specific nodes. When the Bluetooth Mesh shell node is provisioned, given that the `CONFIG_BT_MESH_SHELL_PROV_CTX_INSTANCE` option is enabled with the shell provisioning context initialized, the Configuration Client model targets itself by default. Similarly, when another node has been provisioned by the Bluetooth Mesh shell, the Configuration Client model targets the new node. In most common use-cases, the Configuration Client is depending on the provisioning features and the Configuration database to be fully functional. The Configuration Client always sends messages using the Device key bound to the destination address, so it will only be able to configure itself and the mesh nodes it provisioned. The following steps are an example of how you can set up a device to start using the Configuration Client commands:

- Initialize the client node (`mesh init`).
- Create the CDB (`mesh cdb create`).
- Provision the local device (`mesh prov local`).
- The shell module should now target itself.
- Monitor the composition data of the local node (`mesh models cfg get-comp`).
- Configure the local node as desired with the Configuration Client commands.
- Provision other devices (`mesh prov beacon-listen`) (`mesh prov remote-adv`) (`mesh prov remote-gatt`).
- The shell module should now target the newly added node.
- Monitor the newly provisioned nodes and their addresses (`mesh cdb show`).
- Monitor the composition data of the target device (`mesh models cfg get-comp`).
- Configure the node as desired with the Configuration Client commands.

`mesh models cfg target get`

Get the target Configuration server for the Configuration Client model.

`mesh models cfg help`

Print information for the Configuration Client shell module.

`mesh models cfg reset`

Reset the target device.

`mesh models cfg timeout [Timeout(s)]`

Get and set the Config Client model timeout used during message sending.

- `Timeout`: If present, set the Config Client model timeout in seconds. If omitted, the current timeout is printed.

`mesh models cfg get-comp [Page]`

Read a composition data page. The full composition data page will be printed. If the target does not have the given page, it will return the last page before it.

- `Page`: The composition data page to request. Defaults to 0 if omitted.

`mesh models cfg beacon [Val(off, on)]`

Get or set the network beacon transmission.

- `Val`: If present, enables or disables sending of the network beacon. If omitted, the current network beacon state is printed.

`mesh models cfg ttl [TTL]`

Get or set the default TTL value.

- `TTL`: If present, sets the new default TTL value. Legal TTL values are 0x00 and 0x02-0x7f. If omitted, the current default TTL value is printed.

`mesh models cfg friend [Val(off, on)]`

Get or set the Friend feature.

- `Val`: If present, enables or disables the Friend feature. If omitted, the current Friend feature state is printed:
  - `0x00`: The feature is supported, but disabled.
  - `0x01`: The feature is enabled.
  - `0x02`: The feature is not supported.

`mesh models cfg gatt-proxy [Val(off, on)]`

Get or set the GATT Proxy feature.

- `Val`: If present, enables or disables the GATT Proxy feature. If omitted, the current GATT Proxy feature state is printed:
  - `0x00`: The feature is supported, but disabled.
  - `0x01`: The feature is enabled.
  - `0x02`: The feature is not supported.

`mesh models cfg relay [<Val(off, on)> [<Count> [Int(ms)]]]`

Get or set the Relay feature and its parameters.

- `Val`: If present, enables or disables the Relay feature. If omitted, the current Relay feature state is printed:
  - `0x00`: The feature is supported, but disabled.
  - `0x01`: The feature is enabled.
  - `0x02`: The feature is not supported.
- `Count`: Sets the new relay retransmit count if `val` is `on`. Ignored if `val` is `off`. Legal retransmit count is 0-7. Defaults to `2` if omitted.
- `Int`: Sets the new relay retransmit interval in milliseconds if `val` is `on`. Legal interval range is 10-320 milliseconds. Ignored if `val` is `off`. Defaults to `20` if omitted.

`mesh models cfg node-id <NetKeyIdx> [Identity]`

Get or Set of current Node Identity state of a subnet.

- `NetKeyIdx`: The network key index to Get/Set.
- `Identity`: If present, sets the identity of Node Identity state.

`mesh models cfg polltimeout-get <LPNAddr>`

Get current value of the PollTimeout timer of the LPN within a Friend node.

- `LPNAddr` Address of Low Power node.

`mesh models cfg net-transmit-param [<Count> <Int(ms)>]`

Get or set the network transmit parameters.

- `Count`: Sets the number of additional network transmits for every sent message. Legal retransmit count is 0-7.
- `Int`: Sets the new network retransmit interval in milliseconds. Legal interval range is 10-320 milliseconds.

`mesh models cfg netkey add <NetKeyIdx> [Key(1-16 hex)]`

Add a network key to the target node. Adds the key to the Configuration Database if enabled.

- `NetKeyIdx`: The network key index to add.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. Only valid if the key does not already exist in the Configuration Database. If omitted, the default key value is used.

`mesh models cfg netkey upd <NetKeyIdx> [Key(1-16 hex)]`

Update a network key to the target node.

- `NetKeyIdx`: The network key index to updated.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the default key value is used.

`mesh models cfg netkey get`

Get a list of known network key indexes.

`mesh models cfg netkey del <NetKeyIdx>`

Delete a network key from the target node.

- `NetKeyIdx`: The network key index to delete.

`mesh models cfg appkey add <NetKeyIdx> <AppKeyIdx> [Key(1-16 hex)]`

Add an application key to the target node. Adds the key to the Configuration Database if enabled.

- `NetKeyIdx`: The network key index the application key is bound to.
- `AppKeyIdx`: The application key index to add.
- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. Only valid if the key does not already exist in the Configuration Database. If omitted, the default key value is used.

`mesh models cfg appkey upd <NetKeyIdx> <AppKeyIdx> [Key(1-16 hex)]`

Update an application key to the target node.

- `NetKeyIdx`: The network key index the application key is bound to.
- `AppKeyIdx`: The application key index to update.

- `Key`: If present, sets the key value as a 128-bit hexadecimal value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, the default key value is used.

`mesh models cfg appkey get <NetKeyIdx>`

Get a list of known application key indexes bound to the given network key index.

- `NetKeyIdx`: Network key indexes to get a list of application key indexes from.

`mesh models cfg appkey del <NetKeyIdx> <AppKeyIdx>`

Delete an application key from the target node.

- `NetKeyIdx`: The network key index the application key is bound to.
- `AppKeyIdx`: The application key index to delete.

`mesh models cfg model app-bind <Addr> <AppKeyIdx> <MID> [CID]`

Bind an application key to a model. Models can only encrypt and decrypt messages sent with application keys they are bound to.

- `Addr`: Address of the element the model is on.
- `AppKeyIdx`: The application key to bind to the model.
- `MID`: The model ID of the model to bind the key to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model app-unbind <Addr> <AppKeyIdx> <MID> [CID]`

Unbind an application key from a model.

- `Addr`: Address of the element the model is on.
- `AppKeyIdx`: The application key to unbind from the model.
- `MID`: The model ID of the model to unbind the key from.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model app-get <ElemAddr> <MID> [CID]`

Get a list of application keys bound to a model.

- `ElemAddr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the bound keys of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model pub <Addr> <MID> [CID] [<PubAddr> <AppKeyIdx> <Cred(off, on)> <TTL> <PerRes> <PerSteps> <Count> <Int(ms)>]`

Get or set the publication parameters of a model. If all publication parameters are included, they become the new publication parameters of the model. If all publication parameters are omitted, print the current publication parameters of the model.

- `Addr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the bound keys of.

- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

Publication parameters:

- `PubAddr`: The destination address to publish to.
- `AppKeyIdx`: The application key index to publish with.
- `Cred`: Whether to publish with Friendship credentials when acting as a Low Power Node.
- `TTL`: TTL value to publish with (`0x00` to `0x07f`).
- `PerRes`: Resolution of the publication period steps:
  - `0x00`: The Step Resolution is 100 milliseconds
  - `0x01`: The Step Resolution is 1 second
  - `0x02`: The Step Resolution is 10 seconds
  - `0x03`: The Step Resolution is 10 minutes
- `PerSteps`: Number of publication period steps, or 0 to disable periodic publication.
- `Count`: Number of retransmission for each published message (`0` to 7).
- `Int` The interval between each retransmission, in milliseconds. Must be a multiple of 50.

```
mesh models cfg model pub-va <Addr> <UUID(1-16 hex)> <AppKeyIdx> <Cred(off, on)>
<TTL> <PerRes> <PerSteps> <Count> <Int(ms)> <MID> [CID]
```

Set the publication parameters of a model.

- `Addr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the bound keys of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

Publication parameters:

- `UUID`: The destination virtual address to publish to. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `AppKeyIdx`: The application key index to publish with.
- `Cred`: Whether to publish with Friendship credentials when acting as a Low Power Node.
- `TTL`: TTL value to publish with (`0x00` to `0x07f`).
- `PerRes`: Resolution of the publication period steps:
  - `0x00`: The Step Resolution is 100 milliseconds
  - `0x01`: The Step Resolution is 1 second
  - `0x02`: The Step Resolution is 10 seconds
  - `0x03`: The Step Resolution is 10 minutes
- `PerSteps`: Number of publication period steps, or 0 to disable periodic publication.
- `Count`: Number of retransmission for each published message (`0` to 7).

- `Int` The interval between each retransmission, in milliseconds. Must be a multiple of 50.

`mesh models cfg model sub-add <ElemAddr> <SubAddr> <MID> [CID]`

Subscription the model to a group address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- `ElemAddr`: Address of the element the model is on.
- `SubAddr`: 16-bit group address the model should subscribe to (`0xc000` to `0xFEFF`).
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-del <ElemAddr> <SubAddr> <MID> [CID]`

Unsubscribe a model from a group address.

- `ElemAddr`: Address of the element the model is on.
- `SubAddr`: 16-bit group address the model should remove from its subscription list (`0xc000` to `0xFEFF`).
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-add-va <ElemAddr> <LabelUUID(1-16 hex)> <MID> [CID]`

Subscribe the model to a virtual address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- `ElemAddr`: Address of the element the model is on.
- `LabelUUID`: 128-bit label UUID of the virtual address to subscribe to. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-del-va <ElemAddr> <LabelUUID(1-16 hex)> <MID> [CID]`

Unsubscribe a model from a virtual address.

- `ElemAddr`: Address of the element the model is on.
- `LabelUUID`: 128-bit label UUID of the virtual address to remove the subscription of. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-ow <ElemAddr> <SubAddr> <MID> [CID]`

Overwrite all model subscriptions with a single new group address.

- `ElemAddr`: Address of the element the model is on.
- `SubAddr`: 16-bit group address the model should added to the subscription list (`0xc000` to `0xFEFF`).
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-ow-va <ElemAddr> <LabelUUID(1-16 hex)> <MID> [CID]`

Overwrite all model subscriptions with a single new virtual address. Models only receive messages sent to their unicast address or a group or virtual address they subscribe to. Models may subscribe to multiple group and virtual addresses.

- `ElemAddr`: Address of the element the model is on.
- `LabelUUID`: 128-bit label UUID of the virtual address as the new Address to be added to the subscription list. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `MID`: The model ID of the model to add the subscription to.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-del-all <ElemAddr> <MID> [CID]`

Remove all group and virtual address subscriptions from of a model.

- `ElemAddr`: Address of the element the model is on.
- `MID`: The model ID of the model to Unsubscribe all.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg model sub-get <ElemAddr> <MID> [CID]`

Get a list of addresses the model subscribes to.

- `ElemAddr`: Address of the element the model is on.
- `MID`: The model ID of the model to get the subscription list of.
- `CID`: If present, determines the Company ID of the model. If omitted, the model is a Bluetooth SIG defined model.

`mesh models cfg krp <NetKeyIdx> [Phase]`

Get or set the key refresh phase of a subnet.

- `NetKeyIdx`: The identified network key used to Get/Set the current Key Refresh Phase state.
- `Phase`: New Key Refresh Phase. Valid phases are:
  - `0x00`: Normal operation; Key Refresh procedure is not active
  - `0x01`: First phase of Key Refresh procedure
  - `0x02`: Second phase of Key Refresh procedure

`mesh models cfg hb-sub [<Src> <Dst> <Per>]`

Get or set the Heartbeat subscription parameters. A node only receives Heartbeat messages matching the Heartbeat subscription parameters. Sets the Heartbeat subscription parameters if present, or prints the current Heartbeat subscription parameters if called with no parameters.

- `Src`: Unicast source address to receive Heartbeat messages from.
- `Dst`: Destination address to receive Heartbeat messages on.
- `Per`: Logarithmic representation of the Heartbeat subscription period:
  - `0`: Heartbeat subscription will be disabled.
  - `1` to `17`: The node will subscribe to Heartbeat messages for $2^{(\text{period} - 1)}$ seconds.

`mesh models cfg hb-pub [<Dst> <Count> <Per> <TTL> <Features> <NetKeyIdx>]`

Get or set the Heartbeat publication parameters. Sets the Heartbeat publication parameters if present, or prints the current Heartbeat publication parameters if called with no parameters.

- `Dst`: Destination address to publish Heartbeat messages to.
- `Count`: Logarithmic representation of the number of Heartbeat messages to publish periodically:
  - `0`: Heartbeat messages are not published periodically.
  - `1` to `17`: The node will periodically publish $2^{(\text{count} - 1)}$ Heartbeat messages.
  - `255`: Heartbeat messages will be published periodically indefinitely.
- `Per`: Logarithmic representation of the Heartbeat publication period:
  - `0`: Heartbeat messages are not published periodically.
  - `1` to `17`: The node will publish Heartbeat messages every $2^{(\text{period} - 1)}$ seconds.
- `TTL`: The TTL value to publish Heartbeat messages with (`0x00` to `0x7f`).
- `Features`: Bitfield of features that should trigger a Heartbeat publication when changed:
  - `Bit 0`: Relay feature.
  - `Bit 1`: Proxy feature.
  - `Bit 2`: Friend feature.
  - `Bit 3`: Low Power feature.
- `NetKeyIdx`: Index of the network key to publish Heartbeat messages with.

Health Client The Health Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_HEALTH_CLI` configuration option. This is implemented as a separate module (`mesh models health`) inside the `mesh models` subcommand list. This module will work on any instance of the Health Client model if the mentioned shell configuration options is enabled, and as long as one or more Health Client model(s) is present in the model composition of the application. This shell module can be used to trigger interaction between Health Clients and Servers on devices in a Mesh network.

By default, the module will choose the first Health Client instance in the model composition when using the Health Client commands. To choose a specific Health Client instance the user can utilize the commands `mesh models health instance set` and `mesh models health instance get-all`.

The Health Client may use the general messages parameters set by `mesh target dst`, `mesh target net` and `mesh target app` to target specific nodes. If the shell target destination address is set to

zero, the targeted Health Client will attempt to publish messages using its configured publication parameters.

`mesh models health instance set <ElemIdx>`

Set the Health Client model instance to use.

- `ElemIdx`: Element index of Health Client model.

`mesh models health instance get-all`

Prints all available Health Client model instances on the device.

`mesh models health fault-get <CID>`

Get a list of registered faults for a Company ID.

- `CID`: Company ID to get faults for.

`mesh models health fault-clear <CID>`

Clear the list of faults for a Company ID.

- `CID`: Company ID to clear the faults for.

`mesh models health fault-clear-unack <CID>`

Clear the list of faults for a Company ID without requesting a response.

- `CID`: Company ID to clear the faults for.

`mesh models health fault-test <CID> <TestID>`

Invoke a self-test procedure, and show a list of triggered faults.

- `CID`: Company ID to perform self-tests for.
- `TestID`: Test to perform.

`mesh models health fault-test-unack <CID> <TestID>`

Invoke a self-test procedure without requesting a response.

- `CID`: Company ID to perform self-tests for.
- `TestID`: Test to perform.

`mesh models health period-get`

Get the current Health Server publish period divisor.

`mesh models health period-set <Divisor>`

Set the current Health Server publish period divisor. When a fault is detected, the Health Server will start publishing is fault status with a reduced interval. The reduced interval is determined by the Health Server publish period divisor: Fault publish period = Publish period / 2^{divisor}.

- `Divisor`: The new Health Server publish period divisor.

`mesh models health period-set-unack <Divisor>`

Set the current Health Server publish period divisor. When a fault is detected, the Health Server will start publishing is fault status with a reduced interval. The reduced interval is determined by the Health Server publish period divisor: Fault publish period = Publish period / $2^{divisor}$.

- `Divisor`: The new Health Server publish period divisor.

`mesh models health attention-get`

Get the current Health Server attention state.

`mesh models health attention-set <Time(s)>`

Enable the Health Server attention state for some time.

- `Time`: Duration of the attention state, in seconds (`0` to `255`)

`mesh models health attention-set-unack <Time(s)>`

Enable the Health Server attention state for some time without requesting a response.

- `Time`: Duration of the attention state, in seconds (`0` to `255`)

Binary Large Object (BLOB) Transfer Client model The *BLOB Transfer Client* can be added to the mesh shell by enabling the `CONFIG_BT_MESH_BLOB_CLI` option, and disabling the `CONFIG_BT_MESH_DFU_CLI` option.

`mesh models blob cli target <Addr>`

Add a Target node for the next BLOB transfer.

- `Addr`: Unicast address of the Target node's BLOB Transfer Server model.

`mesh models blob cli caps [<Group> [<TimeoutBase>]]`

Retrieve transfer capabilities for Target nodes.

- `Group`: Optional group address to use when communicating with Target nodes. If omitted, the BLOB Transfer Client will address each Target node individually.
- `TimeoutBase`: Optional time to wait for responses from Target nodes, in 10-second increments.

`mesh models blob cli tx <Id> <Size> <BlockSizeLog> <ChunkSize> [<Group> [<Mode(push, pull)>]]`

Perform a BLOB transfer to Target nodes. The BLOB Transfer Client will send a dummy BLOB to all Target nodes, then post a message when the transfer is completed. Note that all Target nodes must first be configured to receive the transfer using the `mesh models blob srv rx` command.

- `Id`: 64-bit BLOB transfer ID.
- `Size`: Size of the BLOB in bytes.
- `BlockSizeLog`: Logarithmic representation of the BLOB's block size. The final block size will be `1 << block size log` bytes.
- `ChunkSize`: Chunk size in bytes.

- `Group`: Optional group address to use when communicating with Target nodes. If omitted or set to 0, the BLOB Transfer Client will address each Target node individually.
- `Mode`: BLOB transfer mode to use. Must be either `push` (Push BLOB Transfer Mode) or `pull` (Pull BLOB Transfer Mode). If omitted, `push` will be used by default.

`mesh models blob cli tx-cancel`

Cancel an ongoing BLOB transfer.

`mesh models blob cli tx-get [Group]`

Determine the progress of a previously running BLOB transfer. Can be used when not performing a BLOB transfer.

- `Group`: Optional group address to use when communicating with Target nodes. If omitted or set to 0, the BLOB Transfer Client will address each Target node individually.

`mesh models blob cli tx-suspend`

Suspend the ongoing BLOB transfer.

`mesh models blob cli tx-resume`

Resume the suspended BLOB transfer.

`mesh models blob cli instance-set <ElemIdx>`

Use the BLOB Transfer Client model instance on the specified element when using the other BLOB Transfer Client model commands.

- `ElemIdx`: The element on which to find the BLOB Transfer Client model instance to use.

`mesh models blob cli instance-get-all`

Get a list of all BLOB Transfer Client model instances on the node.

BLOB Transfer Server model The *BLOB Transfer Server* can be added to the mesh shell by enabling the `CONFIG_BT_MESH_BLOB_SRV` option. The BLOB Transfer Server model is capable of receiving any BLOB data, but the implementation in the mesh shell will discard the incoming data.

`mesh models blob srv rx <ID> [<TimeoutBase(10s steps)>]`

Prepare to receive a BLOB transfer.

- `ID`: 64-bit BLOB transfer ID to receive.
- `TimeoutBase`: Optional additional time to wait for client messages, in 10-second increments.

`mesh models blob srv rx-cancel`

Cancel an ongoing BLOB transfer.

`mesh models blob srv instance-set <ElemIdx>`

Use the BLOB Transfer Server model instance on the specified element when using the other BLOB Transfer Server model commands.

- `ElemIdx`: The element on which to find the BLOB Transfer Server model instance to use.

`mesh models blob srv instance-get-all`

Get a list of all BLOB Transfer Server model instances on the node.

Binary Large Object (BLOB) Transfer flash stream BLOB flash stream configuration can be added to the mesh shell by enabling the `CONFIG_BT_MESH_SHELL_BLOB_IO_FLASH` option. By default, the shell uses a dummy BLOB stream. This option allows the user to specify which area in the flash to use. See *Flash map* for information on how to obtain related parameters.

`mesh models blob flash-stream-set <AreaID> [<Offset>]`

Set the BLOB stream to a specified area.

- `AreaID`: Flash area ID to write/read the BLOB to/from.
- `Offset`: Optional offset into the flash area to place the BLOB at (in bytes).

`mesh models blob flash-stream-unset`

Set the BLOB stream back to the dummy stream.

Firmware Update Client model The Firmware Update Client model can be added to the mesh shell by enabling configuration options `CONFIG_BT_MESH_BLOB_CLI` and `CONFIG_BT_MESH_DFU_CLI`. The Firmware Update Client demonstrates the firmware update Distributor role by transferring a dummy firmware update to a set of Target nodes.

`mesh models dfu slot add <Size> <FwID> [<Metadata>]`

Add a virtual DFU image slot that can be transferred as a DFU image. The image slot will be assigned an image slot index, which is printed as a response, and can be used to reference the slot in other commands. To update the image slot, remove it using the `mesh models dfu slot del` shell command and then add it again.

- `Size`: DFU image slot size in bytes.
- `FwID`: Firmware ID, formatted as a hexstring.
- `Metadata`: Optional firmware metadata, formatted as a hexstring.

`mesh models dfu slot del <SlotIdx>`

Delete the DFU image slot at the given index.

- `SlotIdx`: Index of the slot to delete.

`mesh models dfu slot get <SlotIdx>`

Get all available information about a DFU image slot.

- `SlotIdx`: Index of the slot to get.

`mesh models dfu cli target <Addr> <ImgIdx>`

Add a Target node.

- `Addr`: Unicast address of the Target node.
- `ImgIdx`: Image index to address on the Target node.

`mesh models dfu cli target-state`

Check the DFU Target state of the device at the configured destination address.

`mesh models dfu cli target-imgs [<MaxCount>]`

Get a list of DFU images on the device at the configured destination address.

- `MaxCount`: Optional maximum number of images to return. If omitted, there's no limit on the number of returned images.

`mesh models dfu cli target-check <SlotIdx> <TargetImgIdx>`

Check whether the device at the configured destination address will accept a DFU transfer from the given DFU image slot to the Target node's DFU image at the given index, and what the effect would be.

- `SlotIdx`: Index of the local DFU image slot to check.
- `TargetImgIdx`: Index of the Target node's DFU image to check.

`mesh models dfu cli send <SlotIdx> [<Group>]`

Start a DFU transfer to all added Target nodes.

- `SlotIdx`: Index of the local DFU image slot to send.
- `Group`: Optional group address to use when communicating with the Target nodes. If omitted, the Firmware Update Client will address each Target node individually.

`mesh models dfu cli cancel [<Addr>]`

Cancel the DFU procedure at any state on a specific Target node or on all Target nodes. When a Target node address is provided, the Firmware Update Client model will try to cancel the DFU procedure on the provided Target node. Otherwise, the Firmware Update Client model will try to cancel the ongoing DFU procedure on all Target nodes.

- `Addr`: Optional unicast address of a Target node on which to cancel the DFU procedure.

`mesh models dfu cli apply`

Apply the most recent DFU transfer on all Target nodes. Can only be called after a DFU transfer is completed.

`mesh models dfu cli confirm`

Confirm that the most recent DFU transfer was successfully applied on all Target nodes. Can only be called after a DFU transfer is completed and applied.

`mesh models dfu cli suspend`

Suspend the ongoing DFU transfer.

`mesh models dfu cli resume`

Resume the suspended DFU transfer.

`mesh models dfu cli progress`

Check the progress of the current transfer.

`mesh models dfu cli instance-set <ElemIdx>`

Use the Firmware Update Client model instance on the specified element when using the other Firmware Update Client model commands.

- `ElemIdx`: The element on which to find the Firmware Update Client model instance to use.

`mesh models dfu cli instance-get-all`

Get a list of all Firmware Update Client model instances on the node.

Firmware Update Server model The Firmware Update Server model can be added to the mesh shell by enabling configuration options `CONFIG_BT_MESH_BLOB_SRV` and `CONFIG_BT_MESH_DFU_SRV`. The Firmware Update Server demonstrates the firmware update Target role by accepting any firmware update. The mesh shell Firmware Update Server will discard the incoming firmware data, but otherwise behave as a proper firmware update Target node.

`mesh models dfu srv applied`

Mark the most recent DFU transfer as applied. Can only be called after a DFU transfer is completed, and the Distributor has requested that the transfer is applied.

As the mesh shell Firmware Update Server doesn't actually apply the incoming firmware image, this command can be used to emulate an applied status, to notify the Distributor that the transfer was successful.

`mesh models dfu srv progress`

Check the progress of the current transfer.

`mesh models dfu srv rx-cancel`

Cancel incoming DFU transfer.

`mesh models dfu srv instance-set <ElemIdx>`

Use the Firmware Update Server model instance on the specified element when using the other Firmware Update Server model commands.

- `ElemIdx`: The element on which to find the Firmware Update Server model instance to use.

`mesh models dfu srv instance-get-all`

Get a list of all Firmware Update Server model instances on the node.

Firmware Distribution Server model The Firmware Distribution Server model commands can be added to the mesh shell by enabling the `CONFIG_BT_MESH_DFD_SRV` configuration option. The shell commands for this model mirror the messages sent to the server by a Firmware Distribution Client model. To use these commands, a Firmware Distribution Server must be instantiated by the application.

`mesh models dfd receivers-add <Addr>,<FwIdx>[;<Addr>,<FwIdx>]...`

Add receivers to the Firmware Distribution Server. Supply receivers as a list of comma-separated addr,fw_idx pairs, separated by semicolons, for example, `0x0001,0;0x0002,0;0x0004,1`. Do not use spaces in the receiver list. Repeated calls to this command will continue populating the receivers list until `mesh models dfd receivers-delete-all` is called.

- `Addr`: Address of the receiving node(s).
- `FwIdx`: Index of the firmware slot to send to `Addr`.

`mesh models dfd receivers-delete-all`

Delete all receivers from the server.

`mesh models dfd receivers-get <First> <Count>`

Get a list of info about firmware receivers.

- `First`: Index of the first receiver to get from the receiver list.
- `Count`: The number of receivers for which to get info.

`mesh models dfd capabilities-get`

Get the capabilities of the server.

`mesh models dfd get`

Get information about the current distribution state, phase and the transfer parameters.

`mesh models dfd start <AppKeyIdx> <SlotIdx> [<Group> [<PolicyApply> [<TTL> [<TimeoutBase> [<XferMode>]]]]]`

Start the firmware distribution.

- `AppKeyIdx`: Application index to use for sending. The common application key should be bound to the Firmware Update and BLOB Transfer models on the Distributor and Target nodes.
- `SlotIdx`: Index of the local image slot to send.
- `Group`: Optional group address to use when communicating with the Target nodes. If omitted, the Firmware Distribution Server will address each Target node individually. To keep addressing each Target node individually while changing other arguments, set this argument value to 0.
- `PolicyApply`: Optional field that corresponds to the update policy. Setting this to `true` will make the Firmware Distribution Server apply the image immediately after the transfer is completed.
- `TTL`: Optional. TTL value to use when sending. Defaults to configured default TTL.
- `TimeoutBase`: Optional additional value used to calculate timeout values in the firmware distribution process, in 10-second increments.. See *Transfer timeout* for information about how `timeout_base` is used to calculate the transfer timeout. Defaults to 0.
- `XferMode`: Optional BLOB transfer mode. 1 = Push mode (Push BLOB Transfer Mode), 2 = Pull mode (Pull BLOB Transfer Mode). Defaults to Push mode.

`mesh models dfd suspend`

Suspends the ongoing distribution.

`mesh models dfd cancel`

Cancel the ongoing distribution.

`mesh models dfd apply`

Apply the distributed firmware.

`mesh models dfd fw-get <FwID>`

Get information about the firmware image uploaded to the server.

- `FwID`: Firmware ID of the image to get.

`mesh models dfd fw-get-by-idx <Idx>`

Get information about the firmware image uploaded to the server in a specific slot.

- `Idx`: Index of the slot to get the image from.

`mesh models dfd fw-delete <FwID>`

Delete a firmware image from the server.

- `FwID`: Firmware ID of the image to delete.

`mesh models dfd fw-delete-all`

Delete all firmware images from the server.

`mesh models dfd instance-set <ElemIdx>`

Use the Firmware Distribution Server model instance on the specified element when using the other Firmware Distribution Server model commands.

- `ElemIdx`: The element on which to find the Firmware Distribution Server model instance to use.

`mesh models dfd instance-get-all`

Get a list of all Firmware Distribution Server model instances on the node.

DFU metadata The DFU metadata shell commands allow generating metadata that can be used by a Target node to check the firmware before accepting it. The commands are enabled through the `CONFIG_BT_MESH_SHELL_DFU_METADATA` configuration option.

`mesh models dfu metadata comp-clear`

Clear the stored composition data to be used for the Target node.

`mesh models dfu metadata comp-add <CID> <ProductID> <VendorID> <Crpl> <Features>`

Create a header of the Composition Data Page 0.

- `CID`: Company identifier assigned by Bluetooth SIG.
- `ProductID`: Vendor-assigned product identifier.
- `VendorID`: Vendor-assigned version identifier.
- `Crpl`: The size of the replay protection list.
- `Features`: Features supported by the node in bit field format:
  - `0`: Relay.
  - `1`: Proxy.
  - `2`: Friend.
  - `3`: Low Power.

`mesh models dfu metadata comp-elem-add <Loc> <NumS> <NumV> {<SigMID>|<VndCID> <VndMID>}...`

Add element description of the Target node.

- `Loc`: Element location.
- `NumS`: Number of SIG models instantiated on the element.
- `NumV`: Number of vendor models instantiated on the element.
- `SigMID`: SIG Model ID.
- `VndCID`: Vendor model company identifier.
- `VndMID`: Vendor model identifier.

`mesh models dfu metadata comp-hash-get [<Key(16 hex)>]`

Generate a hash of the stored Composition Data to be used in metadata.

- `Key`: Optional 128-bit key to be used to generate the hash. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.

`mesh models dfu metadata encode <Major> <Minor> <Rev> <BuildNum> <Size> <CoreType> <Hash> <Elems> [<UserData>]`

Encode metadata for the DFU.

- `Major`: Major version of the firmware.
- `Minor`: Minor version of the firmware.
- `Rev`: Revision number of the firmware.
- `BuildNum`: Build number.
- `Size`: Size of the signed bin file.
- `CoreType`: New firmware core type:
  - `1`: Application core.
  - `2`: Network core.
  - `4`: Applications specific BLOB.
- `Hash`: Hash of the composition data generated using `mesh models dfu metadata comp-hash-get` command.

- `Elems`: Number of elements on the new firmware.
- `UserData`: User data supplied with the metadata.

Segmentation and Reassembly (SAR) Configuration Client The SAR Configuration client is an optional mesh model that can be enabled through the `CONFIG_BT_MESH_SAR_CFG_CLI` configuration option. The SAR Configuration Client model is used to support the functionality of configuring the behavior of the lower transport layer of a node that supports the SAR Configuration Server model.

`mesh models sar tx-get`

Send SAR Configuration Transmitter Get message.

`mesh models sar tx-set <SegIntStep> <UniRetransCnt> <UniRetransWithoutProgCnt> <UniRetransIntStep> <UniRetransIntInc> <MultiRetransCnt> <MultiRetransInt>`

Send SAR Configuration Transmitter Set message.

- `SegIntStep`: SAR Segment Interval Step state.
- `UniRetransCnt`: SAR Unicast Retransmissions Count state.
- `UniRetransWithoutProgCnt`: SAR Unicast Retransmissions Without Progress Count state.
- `UniRetransIntStep`: SAR Unicast Retransmissions Interval Step state.
- `UniRetransIntInc`: SAR Unicast Retransmissions Interval Increment state.
- `MultiRetransCnt`: SAR Multicast Retransmissions Count state.
- `MultiRetransInt`: SAR Multicast Retransmissions Interval state.

`mesh models sar rx-get`

Send SAR Configuration Receiver Get message.

`mesh models sar rx-set <SegThresh> <AckDelayInc> <DiscardTimeout> <RxSegIntStep> <AckRetransCount>`

Send SAR Configuration Receiver Set message.

- `SegThresh`: SAR Segments Threshold state.
- `AckDelayInc`: SAR Acknowledgment Delay Increment state.
- `DiscardTimeout`: SAR Discard Timeout state.
- `RxSegIntStep`: SAR Receiver Segment Interval Step state.
- `AckRetransCount`: SAR Acknowledgment Retransmissions Count state.

Private Beacon Client The Private Beacon Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_PRIV_BEACON_CLI` configuration option.

`mesh models prb priv-beacon-get`

Get the target's Private Beacon state. Possible values:

- `0x00`: The node doesn't broadcast Private beacons.
- `0x01`: The node broadcasts Private beacons.

`mesh models prb priv-beacon-set <Val(off, on)> <RandInt(10s steps)>`

Set the target's Private Beacon state.

- `Val`: Control Private Beacon state.
- `RandInt`: Random refresh interval (in 10-second steps), or 0 to keep current value.

`mesh models prb priv-gatt-proxy-get`

Get the target's Private GATT Proxy state. Possible values:

- `0x00`: The Private Proxy functionality is supported, but disabled.
- `0x01`: The Private Proxy functionality is enabled.
- `0x02`: The Private Proxy functionality is not supported.

`mesh models prb priv-gatt-proxy-set <Val(off, on)>`

Set the target's Private GATT Proxy state.

- `Val`: New Private GATT Proxy value:
  - `0x00`: Disable the Private Proxy functionality.
  - `0x01`: Enable the Private Proxy functionality.

`mesh models prb priv-node-id-get <NetKeyIdx>`

Get the target's Private Node Identity state. Possible values:

- `0x00`: The node does not adverstise with the Private Node Identity.
- `0x01`: The node advertises with the Private Node Identity.
- `0x02`: The node doesn't support advertising with the Private Node Identity.
- `NetKeyIdx`: Network index to get the Private Node Identity state of.

`mesh models prb priv-node-id-set <NetKeyIdx> <State>`

Set the target's Private Node Identity state.

- `NetKeyIdx`: Network index to set the Private Node Identity state of.
- `State`: New Private Node Identity value:
  - `0x00`: Stop advertising with the Private Node Identity.
  - `0x01`: Start advertising with the Private Node Identity.

Opcodes Aggregator Client The Opcodes Aggregator client is an optional Bluetooth Mesh model that can be enabled through the `CONFIG_BT_MESH_OP_AGG_CLI` configuration option. The Opcodes Aggregator Client model is used to support the functionality of dispatching a sequence of access layer messages to nodes supporting the Opcodes Aggregator Server model.

`mesh models opagg seq-start <ElemAddr>`

Start the Opcodes Aggregator Sequence message. This command initiates the context for aggregating messages and sets the destination address for next shell commands to `elem_addr`.

- `ElemAddr`: Element address that will process the aggregated opcodes.

`mesh models opagg seq-send`

Send the Opcodes Aggregator Sequence message. This command completes the procedure, sends the aggregated sequence message to the target node and clears the context.

`mesh models opagg seq-abort`

Abort the Opcodes Aggregator Sequence message. This command clears the Opcodes Aggregator Client context.

Remote Provisioning Client The Remote Provisioning Client is an optional Bluetooth Mesh model enabled through the `CONFIG_BT_MESH_RPR_CLI` configuration option. The Remote Provisioning Client model provides support for remote provisioning of devices into a mesh network by using the Remote Provisioning Server model.

This shell module can be used to trigger interaction between Remote Provisioning Clients and Remote Provisioning Servers on devices in a mesh network.

`mesh models rpr scan <Timeout(s)> [<UUID(1-16 hex)>]`

Start scanning for unprovisioned devices.

- `Timeout`: Scan timeout in seconds. Must be at least 1 second.
- `UUID`: Device UUID to scan for. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, all devices will be reported.

`mesh models rpr scan-ext <Timeout(s)> <UUID(1-16 hex)> [<ADType> ... ]`

Start the extended scanning for unprovisioned devices.

- `Timeout`: Scan timeout in seconds. Valid values from `BT_MESH_RPR_EXT_SCAN_TIME_MIN` to `BT_MESH_RPR_EXT_SCAN_TIME_MAX`.
- `UUID`: Device UUID to start extended scanning for. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `ADType`: List of AD types to include in the scan report. Must contain 1 to `CONFIG_BT_MESH_RPR_AD_TYPES_MAX` entries.

`mesh models rpr scan-srv [<ADType> ... ]`

Start the extended scanning for the Remote Provisioning Server.

- `ADType`: List of AD types to include in the scan report. Must contain 1 to `CONFIG_BT_MESH_RPR_AD_TYPES_MAX` entries.

`mesh models rpr scan-caps`

Get the scanning capabilities of the Remote Provisioning Server.

`mesh models rpr scan-get`

Get the current scanning state of the Remote Provisioning Server.

`mesh models rpr scan-stop`

Stop any ongoing scanning on the Remote Provisioning Server.

`mesh models rpr link-get`

Get the current link status of the Remote Provisioning Server.

`mesh models rpr link-close`

Close any open links on the Remote Provisioning Server.

`mesh models rpr provision-remote <UUID(1-16 hex)> <NetKeyIdx> <Addr>`

Provision a mesh node using the PB-Remote provisioning bearer.

- `UUID`: UUID of the unprovisioned node. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `NetKeyIdx`: Network Key Index to give to the unprovisioned node.
- `Addr`: Address to assign to remote device. If `addr` is 0, the lowest available address will be chosen.

`mesh models rpr reprovision-remote <Addr> [<CompChanged(false, true)>]`

Reprovision a mesh node using the PB-Remote provisioning bearer.

- `Addr`: Address to assign to remote device. If `addr` is 0, the lowest available address will be chosen.
- `CompChanged`: The Target node has indicated that its Composition Data has changed. Defaults to false.

`mesh models rpr instance-set <ElemIdx>`

Use the Remote Provisioning Client model instance on the specified element when using the other Remote Provisioning Client model commands.

- `ElemIdx`: The element on which to find the Remote Provisioning Client model instance to use.

`mesh models rpr instance-get-all`

Get a list of all Remote Provisioning Client model instances on the node.

Large Composition Data Client The Large Composition Data Client is an optional Bluetooth Mesh model enabled through the `CONFIG_BT_MESH_LARGE_COMP_DATA_CLI` configuration option. The Large Composition Data Client model is used to support the functionality of reading pages of Composition Data that do not fit in a Config Composition Data Status message, and reading the metadata of the model instances.

`mesh models lcd large-comp-data-get <Page> <Offset>`

Send the Large Composition Data Get message to query a portion of the Composition Data state of a node.

- `Page`: Page number of the Composition Data.
- `Offset`: Offset within the page.

`mesh models lcd models-metadata-get <Page> <Offset>`

Send the Models Metadata Get message to query a portion of a page of the Models Metadata state.

- `Page`: Page number of the Models Metadata.
- `Offset`: Offset within the page.

Bridge Configuration Client The Bridge Configuration Client model is an optional Bluetooth Mesh model that can be enabled through the `CONFIG_BT_MESH_BRG_CFG_CLI` configuration option. The model provides functionality for configuring the subnet bridge functionality of a mesh node.

`mesh models brg get`

Get the current Subnet Bridge state.

`mesh models brg set <State(disable, enable)>`

Set the Subnet Bridge state.

- `State`: Disable or enable the Subnet Bridge functionality.

`mesh models brg table-size-get`

Get the current size of the Bridging Table.

`mesh models brg table-add <Directions> <NetIdx1> <NetIdx2> <Addr1> <Addr2>`

Add an entry to the Bridging Table.

- `Directions`: Allowed directions for the bridged traffic. Valid values are:
  - `0x01`: Bridging is allowed only for messages with `Addr1` as the source address and `Addr2` as the destination address.
  - `0x02`: Bridging is allowed in both directions.
- `NetIdx1`: NetKey index of the first subnet.
- `NetIdx2`: NetKey index of the second subnet.
- `Addr1`: Address of the node in the first subnet.
- `Addr2`: Address of the node in the second subnet.

`mesh models brg table-remove <NetIdx1> <NetIdx2> <Addr1> <Addr2>`

Remove an entry from the Bridging Table.

- `NetIdx1`: NetKey index of the first subnet.
- `NetIdx2`: NetKey index of the second subnet.
- `Addr1`: Address of the node in the first subnet.
- `Addr2`: Address of the node in the second subnet.

`mesh models brg subnets-get <Filter> <NetIdx> <StartIdx>`

Get a filtered set of NetKey index pairs extracted from the Bridging Table.

- `Filter`: Filter to be applied when reporting pairs of NetKey indexes extracted from the Bridging Table. Allowed values:
  - `0x00`: Report all pairs.

  - `0x01`: Report pairs in which the NetKey index of the first subnet matches `NetIdx`.
  - `0x02`: Report pairs in which the NetKey index of the second subnet matches `NetIdx`.
  - `0x03`: Report pairs in which one of the NetKey indexes matches `NetIdx`.
- `NetIdx`: NetKey index of any of the subnets.
- `StartIdx`: Start offset in units of pairs of NetKey indexes to read.

`mesh models brg table-get <NetIdx1> <NetIdx2> <StartIdx>`

Get a list of addresses and allowed traffic directions of the Bridging Table entries.

- `NetIdx1`: NetKey index of the first subnet.
- `NetIdx2`: NetKey index of the second subnet.
- `StartIdx`: Start offset to read in units of Bridging Table state entries.

Configuration database The Configuration database is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_CDB` configuration option. The Configuration database is only available on provisioner devices, and allows them to store all information about the mesh network. To avoid conflicts, there should only be one mesh node in the network with the Configuration database enabled. This node is the Configurator, and is responsible for adding new nodes to the network and configuring them.

`mesh cdb create [NetKey(1-16 hex)]`

Create a Configuration database.

- `NetKey`: Optional network key value of the primary network key (NetKeyIndex=0). Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. Defaults to the default key value if omitted.

`mesh cdb clear`

Clear all data from the Configuration database.

`mesh cdb show`

Show all data in the Configuration database.

`mesh cdb node-add <UUID(1-16 hex)> <Addr> <ElemCnt> <NetKeyIdx> [DevKey(1-16 hex)]`

Manually add a mesh node to the configuration database. Note that devices provisioned with `mesh provision` and `mesh provision-adv` will be added automatically if the Configuration Database is enabled and created.

- `UUID`: 128-bit hexadecimal UUID of the node. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest.
- `Addr`: Unicast address of the node, or 0 to automatically choose the lowest available address.
- `ElemCnt`: Number of elements on the node.
- `NetKeyIdx`: The network key the node was provisioned with.

- `DevKey`: Optional 128-bit device key value for the device. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, a random value will be generated.

`mesh cdb node-del <Addr>`

Delete a mesh node from the Configuration database. If possible, the node should be reset with `mesh reset` before it is deleted from the Configuration database, to avoid unexpected behavior and uncontrolled access to the network.

- `Addr` Address of the node to delete.

`mesh cdb subnet-add <NetKeyIdx> [<NetKey(1-16 hex)>]`

Add a network key to the Configuration database. The network key can later be passed to mesh nodes in the network. Note that adding a key to the Configuration database does not automatically add it to the local node's list of known network keys.

- `NetKeyIdx`: Key index of the network key to add.
- `NetKey`: Optional 128-bit network key value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, a random value will be generated.

`mesh cdb subnet-del <NetKeyIdx>`

Delete a network key from the Configuration database.

- `NetKeyIdx`: Key index of the network key to delete.

`mesh cdb app-key-add <NetKeyIdx> <AppKeyIdx> [<AppKey(1-16 hex)>]`

Add an application key to the Configuration database. The application key can later be passed to mesh nodes in the network. Note that adding a key to the Configuration database does not automatically add it to the local node's list of known application keys.

- `NetKeyIdx`: Network key index the application key is bound to.
- `AppKeyIdx`: Key index of the application key to add.
- `AppKey`: Optional 128-bit application key value. Providing a hex-string shorter than 16 bytes will populate the N most significant bytes of the array and zero-pad the rest. If omitted, a random value will be generated.

`mesh cdb app-key-del <AppKeyIdx>`

Delete an application key from the Configuration database.

- `AppKeyIdx`: Key index of the application key to delete.

On-Demand Private GATT Proxy Client The On-Demand Private GATT Proxy Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_OD_PRIV_PROXY_CLI` configuration option.

`mesh models od_priv_proxy od-priv-gatt-proxy [Dur(s)]`

Set the On-Demand Private GATT Proxy state on active target, or fetch the value of this state from it.

- `Dur`: If given, set the state of On-Demand Private GATT Proxy to this value in seconds. Fetch this value otherwise.

Solicitation PDU RPL Client The Solicitation PDU RPL Client model is an optional mesh subsystem that can be enabled through the `CONFIG_BT_MESH_SOL_PDU_RPL_CLI` configuration option.

`mesh models sol_pdu_rpl sol-pdu-rpl-clear <RngStart> <Ackd> [RngLen]`

Clear active target's solicitation replay protection list (SRPL) in given range of solicitation source (SSRC) addresses.

- `RngStart`: Start address of the SSRC range.
- `Ackd`: This argument decides on whether an acknowledged or unacknowledged message will be sent.
- `RngLen`: Range length for the SSRC addresses to be cleared from the solicitiation RPL list. This parameter is optional; if absent, only a single SSRC address will be cleared.

Statistic The statistic is an optional mesh module that can be enabled through the `CONFIG_BT_MESH_STATISTIC` configuration option.

`mesh stat adv_get`

Get the frame statistic. The command prints numbers of received frames, as well as numbers of planned and succeeded transmission attempts.

`mesh stat adv_clear`

Clear frame statistics collected before.

`mesh stat lpn_get`

Get the measured LPN friendship timing parameters. The command prints ReceiveDelay and ReceiveWindow values derived from timestamps taken during poll cycles. Requires `CONFIG_BT_MESH_LOW_POWER`.

`mesh stat lpn_clear`

Clear LPN timing statistics collected before. Requires `CONFIG_BT_MESH_LOW_POWER`.

Subnet Bridge With Bluetooth Mesh Protocol Specification version 1.1, the Bluetooth Mesh Subnet Bridge feature was introduced. This feature allows mesh networks to use subnets for area isolation, but to also allow communication between specific devices in different, adjacent subnets without compromising security.

The Bluetooth Mesh Subnet Bridge feature makes it possible for selected nodes in the network to act as Subnet Bridges, allowing controlled communication by relaying messages between nodes in adjacent subnets.

The Subnet Bridge feature includes two models:

- *Bridge Configuration Server*
- *Bridge Configuration Client*

The Bridge Configuration Server model is mandatory for supporting the Subnet Bridge feature. The Bridge Configuration Client model is optional and allows nodes to configure the Subnet Bridge on other nodes. These models define the necessary states, messages, and behaviors for configuring and managing the Subnet Bridge feature.

The configuration and management of the Subnet Bridge feature are handled using the Bridge Configuration Server and Client models. A node implementing the Bridge Configuration Client model can act as a *Configuration Manager* for the Subnet Bridge feature.

Concepts To get a better understanding of the Subnet Bridge feature and its capabilities, an overview of a few concepts is needed.

Subnet A subnet is a group of nodes within a mesh network that share a common network key, enabling them to communicate securely at the network layer. Each subnet operates independently, with nodes exchanging messages exclusively within that group. A node may belong to multiple subnets at the same time.

Subnet Bridge node A Subnet Bridge node is a node in a Bluetooth Mesh network that belongs to multiple subnets and has a Subnet Bridge functionality enabled. Subnet bridging can be performed only by such a node. The Subnet Bridge node connects the subnets, and allows communication between them by relaying messages across the subnet groups.

The Subnet Bridge node has a primary subnet, based on the primary NetKey, which handles the IV Update procedure and propagates updates to other subnets. The secondary subnets, on which messages are relayed, are referred to as *bridged subnets*.

Bridging Table The Bridging Table contains the entries for the subnets that are bridged by the node, and is managed by the Bridge Configuration Server model.

The maximum number of entries in the bridging table is defined by the `CONFIG_BT_MESH_BRG_TABLE_ITEMS_MAX` option, which defaults to the minimum value of 16, with a maximum possible size of 255.

Enabling or disabling the Subnet Bridge feature The Bridge Configuration Client (or Configuration Manager) can enable or disable the Subnet Bridge feature on a node by sending a **Subnet Bridge Set** message to the Bridge Configuration Server model on the target node, using the `bt_mesh_brg_cfg_cli_set()` function.

Adding or removing subnets The Bridge Configuration Client can add or remove an entry from the Bridging Table by sending a **Bridging Table Add** or **Bridging Table Remove** message to the Bridge Configuration Server model on the target node, calling the `bt_mesh_brg_cfg_cli_table_add()` or `bt_mesh_brg_cfg_cli_table_remove()` functions.

Subnet Bridge states The Subnet Bridge has the following states:

- *Subnet Bridge*: This state indicates whether the Subnet Bridge feature is enabled or disabled on the node. The Bridge Configuration Client can retrieve this information by sending a **Subnet Bridge Get** message to the Bridge Configuration Server using the `bt_mesh_brg_cfg_cli_get()` function.
- *Bridging Table*: This state holds the bridging table. The Client can request a list of entries from a Bridging Table by sending a **Bridging Table Get** message to the target node using the `bt_mesh_brg_cfg_cli_table_get()` function.

  The Client can get a list of subnets currently bridged by a Subnet Bridge by sending a **Bridged Subnets Get** message to the target Server by calling the `bt_mesh_brg_cfg_cli_subnets_get()` function.
- *Bridging Table Size*: This state reports the maximum number of entries the Bridging Table can store. The Client can retrieve this information by sending a **Bridging Table Size Get** message using the `bt_mesh_brg_cfg_cli_table_size_get()` function. This is a read-only state.

Subnet bridging and replay protection The Subnet Bridge feature enables message relaying between subnets and requires effective replay protection to ensure network security. Key considerations to take into account are described below.

Relay buffer considerations When a message is relayed between subnets by a Subnet Bridge, it is allocated from the relay buffer pool. The number of relay buffers are configurable using the `CONFIG_BT_MESH_RELAY_BUF_COUNT` Kconfig option.

When `CONFIG_BT_MESH_ADV_EXT` is enabled, messages will be transmitted using the relay advertising sets. The number of advertising sets are configurable using the `CONFIG_BT_MESH_RELAY_ADV_SETS` Kconfig option.

Both the relay buffer pool and advertising sets can be used even if the relay feature `CONFIG_BT_MESH_RELAY` is disabled.

Replay protection and Bridging Table A Subnet Bridge node must implement replay protection for all Access and Transport Control messages sent to bridged subnets.

The Replay Protection List (RPL) works with the Bridging Table to ensure security:

- The Subnet Bridge stores the latest IVISeq for each source address authorized to send messages to bridged subnets.
- Messages with an IVISeq less than or equal to the stored value are discarded, while valid messages update the stored IVISeq before being relayed.

To ensure proper operation, it is important that the RPL and Bridging Table are synchronized, as every bridged message must pass through the replay protection mechanism before being relayed.

Note

The RPL size should scale with the Bridging Table. As the number of bridged subnets grows, more source addresses and IVISeq values must be tracked, requiring a larger RPL to maintain effective replay protection.

Subnet Bridge and Directed Forwarding Bluetooth Mesh Directed Forwarding (MDF) enables efficient routing between nodes across subnets by optimizing relay paths. While MDF can enhance Subnet Bridging by handling path discovery and forwarding, the current implementation does not support this feature.

API reference This section contains types and defines common to the Bridge Configuration models.

Overview The Configuration Database (CDB) is the subsystem for Bluetooth® Mesh provisioner devices. It stores and manages information about the mesh network, including provisioned nodes, network keys, and application keys. The CDB enables a provisioner to track the network topology, assign addresses, and configure nodes systematically.

> **Note**
>
> The CDB implementation has proprietary design and does not follow the Bluetooth SIG specification.

The CDB is enabled with the `CONFIG_BT_MESH_CDB` configuration option and is typically used only on the provisioner device in the network. There should be only one device in the mesh network with CDB enabled to avoid conflicts.

Key features

- **Persistent Storage**: All CDB data is stored persistently when `CONFIG_BT_SETTINGS` is enabled, allowing the provisioner to recover network state across reboots.
- **Address Management**: Automatic allocation and tracking of unicast addresses for provisioned nodes.
- **Key Management**: Storage and synchronization of network keys and application keys.
- **Node Tracking**: Maintains information about each provisioned node including UUID, address, element count, device key, and configuration status.
- **IV Index Management**: Tracks the network's IV Index and IV Update state.

Configuration options The following Kconfig options control the CDB capacity:

- CONFIG_BT_MESH_CDB_NODE_COUNT - Maximum number of nodes the CDB can handle.
- CONFIG_BT_MESH_CDB_SUBNET_COUNT - Maximum number of subnets the CDB can handle.
- CONFIG_BT_MESH_CDB_APP_KEY_COUNT - Maximum number of application keys the CDB can handle.

Additional options:

- CONFIG_BT_MESH_CDB_KEY_SYNC - Enables automatic synchronization between mesh keys on the provisioner node and the CDB keys. If option is enabled then operations with keys performed through the *Configuration Server* are automatically mirrored to the CDB.

Data Structures The CDB was designed to handle data collected in several data structures. The structures represent nodes, subnets, application keys, and the overall database state.

Node structure

```
struct bt_mesh_cdb_node {
        /** Node UUID */
        uint8_t  uuid[16];
        /** Primary element address */
        uint16_t addr;
        /** Network key index used during provisioning */
        uint16_t net_idx;
        /** Number of elements */
        uint8_t  num_elem;
        /** Device key */
        struct bt_mesh_key dev_key;
        /** Node flags */
        ATOMIC_DEFINE(flags, BT_MESH_CDB_NODE_FLAG_COUNT);
};
```

Node flags:

- BT_MESH_CDB_NODE_CONFIGURED - Set when the node has been configured with keys and bindings.

Subnet structure

```
struct bt_mesh_cdb_subnet {
        /** Network key index */
        uint16_t net_idx;
        /** Key Refresh phase */
        uint8_t kr_phase;
        /** Old and new keys for Key Refresh */
        struct {
                struct bt_mesh_key net_key;
        } keys[2];
};
```

Application Key structure

```
struct bt_mesh_cdb_app_key {
        /** Bound network key index */
        uint16_t net_idx;
        /** Application key index */
        uint16_t app_idx;
        /** Old and new keys for Key Refresh */
        struct {
```

(continues on next page)

(continued from previous page)

```
                struct bt_mesh_key app_key;
        } keys[2];
};
```

Main CDB structure

```
struct bt_mesh_cdb {
        /** Network IV Index */
        uint32_t iv_index;
        /** Lowest available unicast address for provisioning */
        uint16_t lowest_avail_addr;
        /** Flags for CDB state (private) */
        ATOMIC_DEFINE(flags, BT_MESH_CDB_FLAG_COUNT);
        /** Nodes in the mesh network */
        struct bt_mesh_cdb_node nodes[NODE_COUNT];
        /** Subnets in the mesh network */
        struct bt_mesh_cdb_subnet subnets[SUBNET_COUNT];
        /** Application keys in the mesh network */
        struct bt_mesh_cdb_app_key app_keys[APP_KEY_COUNT];
};

/** The global CDB instance is accessible through this variable. */
extern struct bt_mesh_cdb bt_mesh_cdb;
```

Usage scenarios The following patterns demonstrate common CDB usage scenarios:

- *Provisioner initialization* - Creating and initializing the CDB
- *Provisioning and node allocation* - Managing node provisioning and addresses
- *Subnet and key management* - Managing network keys and subnets
- *Subnet lookup and removal* - Finding and removing subnets
- *Setting up application keys* - Adding application keys to the CDB
- *Application keys lookup and removal* - Finding and removing application keys
- *Node configuration* - Configuring provisioned nodes
- *Iterating over nodes* - Processing nodes with callbacks
- *Node lookup and removal* - Finding and removing nodes
- *IV Index management* - Managing IV Index updates
- *Working with device keys* - Importing/exporting device keys
- *Clearing the CDB* - Resetting the database

> **Note**
>
> The provided below source code of scenarios should be treated as conceptual patterns rather than exact implementations. They require adaptation to fit into an application context and testing. Please read the CDB API description for correct usage.

Provisioner initialization On the embedded provisioner node, the CDB must be initialized before the mesh stack is provisioned and the application can use it for key storage, node tracking, and configuration. This step establishes the primary network key, the initial subnet, and the

starting IV Index and address space, so that all later CDB operations work on a well-defined network context and can be persisted across reboots.

A typical provisioner initializes the CDB during startup:

```
#include <zephyr/bluetooth/mesh.h>

static int provisioner_init(void)
{
    uint8_t net_key[16];
    int err;

    /* Initialize Bluetooth Mesh */
    err = bt_mesh_init(&prov, &comp);
    if (err) {
        return err;
    }

    /* Load settings if persistent storage is enabled */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        settings_load();
    }

    /* Generate or use predefined network key */
    bt_rand(net_key, 16);

    /* Create CDB with primary network key */
    err = bt_mesh_cdb_create(net_key);
    if (err == -EALREADY) {
        printk("Using stored CDB\n");
    } else if (err) {
        printk("Failed to create CDB (err %d)\n", err);
        return err;
    } else {
        printk("Created new CDB\n");
    }

    return 0;
}
```

Key points:

- Call the `bt_mesh_cdb_create()` function with the primary network key.
- Returns error code if CDB already exists (loaded from persistent storage).
- The function automatically creates a subnet with `NetIdx = 0`.
- Sets the IV Index to `0` and lowest available address to `1`.

Provisioning and node allocation When you add new devices to the mesh, their addresses, device keys, and basic metadata must be recorded consistently in the provisioner's database. Automatic node allocation during PB-ADV/PB-GATT provisioning keeps CDB and the actual network in sync. When provisioning a new device, the CDB automatically allocates the node during the provisioning process.

However, you can also manually allocate nodes or check allocation. Manual node allocation is useful for advanced scenarios such as importing nodes from an external source, pre-allocating address ranges, or recovering a network from known information.

```
/* Provisioning callback - node is automatically added to CDB */
static void node_added(uint16_t idx, uint8_t uuid[16], uint16_t addr,
                       uint8_t num_elem)
{
    printk("Node added: addr=0x%04x, elements=%d\n", addr, num_elem);
    /* The CDB node is created automatically by the provisioning subsystem */
}

static const struct bt_mesh_prov prov = {
    .uuid = dev_uuid,
    .node_added = node_added,
    /* ... other callbacks ... */
};

/* Manual node allocation (if needed) */
static struct bt_mesh_cdb_node *allocate_node(const uint8_t uuid[16],
                                              uint8_t num_elem)
{
    struct bt_mesh_cdb_node *node;
    uint16_t addr;

    /* Get free address or specify one (0 = auto-allocate) */
    addr = bt_mesh_cdb_free_addr_get(num_elem);
    if (addr == BT_MESH_ADDR_UNASSIGNED) {
        printk("No free addresses available\n");
        return NULL;
    }

    /* Allocate node in CDB */
    node = bt_mesh_cdb_node_alloc(uuid, addr, num_elem, net_idx);
    if (node == NULL) {
        printk("Failed to allocate node\n");
        return NULL;
    }

    return node;
}
```

Key points:

- During normal PB-ADV/PB-GATT provisioning, nodes are automatically added to the CDB.
- The `bt_mesh_cdb_node_alloc()` function creates a CDB entry with the specified parameters.
- Pass `BT_MESH_ADDR_UNASSIGNED` as the address to let the CDB auto-assign the lowest available address.
- The `bt_mesh_cdb_free_addr_get()` function finds a free address range for a given element count.
- Address allocation checks for conflicts and ensures the unicast address validity.

Subnet and key management Large or segmented mesh networks often use multiple subnets to separate traffic domains, enable secure migration, or support the Key Refresh procedure. Managing subnets and their network keys in the CDB allows the provisioner to create new subnets, rotate keys, and derive the correct flags and IV Index when provisioning and configuring nodes.

Manage network keys and subnets in the CDB:

```
/* Add a new subnet */
static int add_subnet(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;
    uint8_t net_key[16];
    int err;

    /* Allocate subnet in CDB */
    sub = bt_mesh_cdb_subnet_alloc(net_idx);
    if (sub == NULL) {
        printk("Failed to allocate subnet\n");
        return -ENOMEM;
    }

    /* Generate network key */
    bt_rand(net_key, 16);

    /* Import key value */
    err = bt_mesh_cdb_subnet_key_import(sub, 0, net_key);
    if (err) {
        bt_mesh_cdb_subnet_del(sub, false);
        return err;
    }

    /* Store subnet */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_subnet_store(sub);
    }

    return 0;
}

/* Get subnet for provisioning */
static int get_subnet_flags(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;
    uint8_t flags;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        return -ENOENT;
    }

    flags = bt_mesh_cdb_subnet_flags(sub);
    printk("Subnet flags: KR=%d IVU=%d\n",
           !!(flags & BT_MESH_NET_FLAG_KR),
           !!(flags & BT_MESH_NET_FLAG_IVU));

    return 0;
}
```

Key points:

- The `bt_mesh_cdb_subnet_alloc()` function allocates a subnet by NetIdx.
- The `bt_mesh_cdb_subnet_key_import()` function sets the actual key value.
- The `bt_mesh_cdb_subnet_flags()` function returns flags needed for provisioning data.
- The flags include Key Refresh and IV Update state from the CDB.

Subnet lookup and removal At some point you may need to inspect an existing subnet (for diagnostics or tooling) or remove it entirely (for example when decommissioning a segment, rotating to a new subnet, or cleaning up after experimentation). The CDB provides lookup and deletion helpers so that the provisioner can keep its view of active subnets consistent with what nodes actually use.

Find and manage subnets in the CDB:

```
/* Get subnet by NetIdx */
static void lookup_subnet(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        printk("Subnet 0x%03x not found\n", net_idx);
        return;
    }

    printk("Subnet 0x%03x: kr_phase=%d\n", net_idx, sub->kr_phase);
}

/* Remove a subnet from the CDB */
static void remove_subnet(uint16_t net_idx)
{
    struct bt_mesh_cdb_subnet *sub;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        printk("Subnet not found\n");
        return;
    }

    /* First, remove the subnet from all nodes in the network */
    /* ... send NetKey Delete to all nodes using Config Client ... */

    /* Delete subnet from CDB */
    bt_mesh_cdb_subnet_del(sub, true);

    printk("Subnet 0x%03x removed\n", net_idx);
}

/* Export subnet key for external use */
static int export_subnet_key(uint16_t net_idx, int key_idx)
{
    struct bt_mesh_cdb_subnet *sub;
    uint8_t net_key[16];
    int err;

    sub = bt_mesh_cdb_subnet_get(net_idx);
    if (sub == NULL) {
        return -ENOENT;
    }

    err = bt_mesh_cdb_subnet_key_export(sub, key_idx, net_key);
    if (err) {
        printk("Failed to export subnet key (err %d)\n", err);
        return err;
```

(continues on next page)

(continued from previous page)

```
    }

    printk("NetKey[%d] for subnet 0x%03x: ", key_idx, net_idx);
    for (int i = 0; i < 16; i++) {
        printk("%02x", net_key[i]);
    }
    printk("\n");

    return 0;
}
```

Key points:

- The `bt_mesh_cdb_subnet_get()` function retrieves a subnet by its NetKeyIndex.
- Pass `true` to the `bt_mesh_cdb_subnet_del()` function to clear persistent storage.
- Always remove the subnet from all nodes before deleting it from the CDB.
- Use the `bt_mesh_cdb_subnet_key_export()` function to retrieve key material securely.
- The `key_idx` parameter (`0` or `1`) selects between old and new keys during the Key Refresh procedure.

Setting up application keys Application keys define which application traffic can be encrypted and where it can be bound. After the CDB is initialized, the provisioner must create one or more application keys so that it can bind models on nodes and enable real application-level communication (for example, lighting or sensor data).

After creating the CDB, add application keys for node configuration:

```
static void setup_cdb_keys(void)
{
    struct bt_mesh_cdb_app_key *key;
    uint8_t app_key[16];
    int err;

    /* Allocate application key in CDB */
    key = bt_mesh_cdb_app_key_alloc(net_idx, app_idx);
    if (key == NULL) {
        printk("Failed to allocate app-key\n");
        return;
    }

    /* Generate random key value */
    bt_rand(app_key, 16);

    /* Import the key into CDB */
    err = bt_mesh_cdb_app_key_import(key, 0, app_key);
    if (err) {
        printk("Failed to import appkey (err %d)\n", err);
        return;
    }

    /* Store to persistent storage */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_app_key_store(key);
    }
}
```

Key points:

- The `bt_mesh_cdb_app_key_alloc()` function allocates a slot in the CDB.
- The `bt_mesh_cdb_app_key_import()` function sets the actual key value.
- The second parameter to import (`0`) is the key index for the Key Refresh procedure (`0` = current key).
- Always store keys after creation when using persistent storage.

Application keys lookup and removal Over time, you may need to inspect which network key an application key is bound to, rotate or revoke application keys, or clean up keys that are no longer used. Proper lookup and removal through the CDB helps avoid dangling bindings and ensures that nodes and the provisioner share the same view of usable application keys.

Find and manage application keys in the CDB:

```
/* Get application key by AppIdx */
static void lookup_app_key(uint16_t app_idx)
{
    struct bt_mesh_cdb_app_key *key;

    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        printk("AppKey 0x%03x not found\n", app_idx);
        return;
    }

    printk("AppKey 0x%03x: bound to NetIdx 0x%03x\n",
           app_idx, key->net_idx);
}

/* Remove an application key from the CDB */
static void remove_app_key(uint16_t app_idx)
{
    struct bt_mesh_cdb_app_key *key;

    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        printk("AppKey not found\n");
        return;
    }

    /* First, remove the app key from all nodes in the network */
    /* ... send AppKey Delete to all nodes using Config Client ... */

    /* Delete app key from CDB */
    bt_mesh_cdb_app_key_del(key, true);

    printk("AppKey 0x%03x removed\n", app_idx);
}

/* Export application key for external use */
static int export_app_key(uint16_t app_idx, int key_idx)
{
    struct bt_mesh_cdb_app_key *key;
    uint8_t app_key[16];
    int err;
```

(continues on next page)

(continued from previous page)

```
    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        return -ENOENT;
    }

    err = bt_mesh_cdb_app_key_export(key, key_idx, app_key);
    if (err) {
        printk("Failed to export app key (err %d)\n", err);
        return err;
    }

    printk("AppKey[%d] 0x%03x: ", key_idx, app_idx);
    for (int i = 0; i < 16; i++) {
        printk("%02x", app_key[i]);
    }
    printk("\n");

    return 0;
}

/* Update application key binding */
static int update_app_key_binding(uint16_t app_idx, uint16_t new_net_idx)
{
    struct bt_mesh_cdb_app_key *key;

    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        return -ENOENT;
    }

    /* Verify the new subnet exists */
    if (bt_mesh_cdb_subnet_get(new_net_idx) == NULL) {
        printk("Target subnet 0x%03x not found\n", new_net_idx);
        return -ENOENT;
    }

    key->net_idx = new_net_idx;

    /* Store updated binding */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_app_key_store(key);
    }

    printk("AppKey 0x%03x rebound to NetIdx 0x%03x\n",
           app_idx, new_net_idx);

    return 0;
}
```

Key points:

- The `bt_mesh_cdb_app_key_get()` function retrieves an application key by its AppKeyIndex.
- Pass `true` to the `bt_mesh_cdb_app_key_del()` function to clear persistent storage.
- Always remove the app key from all nodes before deleting it from the CDB.
- Use the `bt_mesh_cdb_app_key_export()` function to retrieve key material securely.

- The `key_idx` parameter (`0` or `1`) selects between old and new keys during the Key Refresh procedure.
- Application keys are bound to a network key through the `net_idx` field.

Node configuration Provisioning only adds a node to the network; it does not make it participate in your application. After provisioning, you must configure nodes—add network/app keys, bind models, and set subscriptions/publications. The CDB stores the keys and configuration status so the provisioner can resume configuration after a reboot and avoid re-configuring already finished nodes.

After provisioning, configure the node by adding keys and binding models:

```
static void configure_node(struct bt_mesh_cdb_node *node)
{
    NET_BUF_SIMPLE_DEFINE(buf, BT_MESH_RX_SDU_MAX);
    struct bt_mesh_cdb_app_key *key;
    uint8_t app_key[16];
    uint8_t status;
    int err;

    printk("Configuring node 0x%04x\n", node->addr);

    /* Get application key from CDB */
    key = bt_mesh_cdb_app_key_get(app_idx);
    if (key == NULL) {
        printk("App-key not found\n");
        return;
    }

    /* Export key value from CDB */
    err = bt_mesh_cdb_app_key_export(key, 0, app_key);
    if (err) {
        printk("Failed to export key (err %d)\n", err);
        return;
    }

    /* Add application key to the node */
    err = bt_mesh_cfg_cli_app_key_add(net_idx, node->addr,
                                      net_idx, app_idx,
                                      app_key, &status);
    if (err || status) {
        printk("Failed to add app-key (err %d, status %d)\n",
               err, status);
        return;
    }

    /* Get composition data and bind models */
    err = bt_mesh_cfg_cli_comp_data_get(net_idx, node->addr, 0,
                                        &status, &buf);
    if (err || status) {
        printk("Failed to get composition data\n");
        return;
    }

    /* Parse composition and bind models to app key */
    /* ... model binding code ... */
```

(continues on next page)

(continued from previous page)

```
    /* Mark node as configured */
    atomic_set_bit(node->flags, BT_MESH_CDB_NODE_CONFIGURED);

    /* Persist configuration status */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_node_store(node);
    }
}
```

Key points:

- Use the `bt_mesh_cdb_app_key_get()` and the `bt_mesh_cdb_app_key_export()` functions to retrieve keys.
- The Configuration Client model is used to configure remote nodes.
- Set the `BT_MESH_CDB_NODE_CONFIGURED` flag after successful configuration.
- Always call the `bt_mesh_cdb_node_store()` function to persist the configured state.

Iterating over nodes Many management tasks involve acting on all (or a filtered subset of) nodes: checking which ones still need configuration, generating statistics, or performing bulk operations. The CDB iterator lets the provisioner traverse all known nodes in a safe, abstract way without relying on internal storage details.

The CDB provides an iterator to process all allocated nodes:

```
/* Check for unconfigured nodes */
static uint8_t check_unconfigured(struct bt_mesh_cdb_node *node,
                                  void *user_data)
{
    if (!atomic_test_bit(node->flags, BT_MESH_CDB_NODE_CONFIGURED)) {
        printk("Node 0x%04x needs configuration\n", node->addr);
        configure_node(node);
    }

    return BT_MESH_CDB_ITER_CONTINUE;
}

static void process_nodes(void)
{
    bt_mesh_cdb_node_foreach(check_unconfigured, NULL);
}

/* Example: Count nodes on a specific subnet */
static uint8_t count_subnet_nodes(struct bt_mesh_cdb_node *node,
                                  void *user_data)
{
    uint16_t *net_idx = user_data;
    static int count = 0;

    if (node->net_idx == *net_idx) {
        count++;
    }

    return BT_MESH_CDB_ITER_CONTINUE;
}
```

Key points:

- The `bt_mesh_cdb_node_foreach()` function calls the callback for each allocated node.
- Return `BT_MESH_CDB_ITER_CONTINUE` to continue iteration.
- Return `BT_MESH_CDB_ITER_STOP` to stop iteration early.
- The callback is only called for nodes with `addr != BT_MESH_ADDR_UNASSIGNED`.

Node lookup and removal Sometimes a single node must be inspected (for example, when debugging) or removed from the network (for example, when it is physically decommissioned or replaced). Using CDB node lookup and deletion keeps the logical view of the mesh consistent with the actual devices and prevents address reuse conflicts.

Find and manage nodes in the CDB:

```
/* Get node by address */
static void lookup_node(uint16_t addr)
{
    struct bt_mesh_cdb_node *node;

    node = bt_mesh_cdb_node_get(addr);
    if (node == NULL) {
        printk("Node 0x%04x not found\n", addr);
        return;
    }

    printk("Node 0x%04x: %d elements, net_idx=0x%03x\n",
           node->addr, node->num_elem, node->net_idx);
}

/* Remove a node from the network */
static void remove_node(uint16_t addr)
{
    struct bt_mesh_cdb_node *node;

    node = bt_mesh_cdb_node_get(addr);
    if (node == NULL) {
        printk("Node not found\n");
        return;
    }

    /* First, send Node Reset to the device (recommended) */
    /* ... send reset command using Config Client ... */

    /* Delete node from CDB */
    bt_mesh_cdb_node_del(node, true);

    printk("Node 0x%04x removed\n", addr);
}
```

Key points:

- The `bt_mesh_cdb_node_get()` function searches by element address (works for any element address).
- Always send a `Node Reset` command before removing a node to avoid orphaned devices.
- Pass `true` to the `bt_mesh_cdb_node_del()` function to clear persistent storage.
- Deleting a node might update the `lowest_avail_addr` if appropriate (please read CDB API for details).

IV Index management The IV Index is a core part of Bluetooth Mesh security and replay protection. When IV Update procedures occur, the provisioner must update its stored IV Index so that future provisioning and configuration use the correct value and address space. Storing this in the CDB keeps the network state coherent across reboots and between provisioning actions.

Update the network's IV Index:

```
/* Update IV Index when IV Update procedure occurs */
static void handle_iv_update(uint32_t iv_index, bool iv_update)
{
    bt_mesh_cdb_iv_update(iv_index, iv_update);

    printk("IV Index updated: %u (IV Update: %s)\n",
           iv_index, iv_update ? "in progress" : "normal");
}

/* The IV Index is automatically used during provisioning */
static void provision_with_current_iv(void)
{
    /* The provisioner automatically uses bt_mesh_cdb.iv_index
     * and bt_mesh_cdb_subnet_flags() when sending provisioning data
     */
}
```

Key points:

- The `bt_mesh_cdb_iv_update()` function updates both the IV Index and IV Update flag.
- The CDB automatically resets `lowest_avail_addr` during IV Index updates.
- The provisioner subsystem automatically uses CDB's IV Index for new nodes.

Working with device keys Device keys are sensitive information and often handled through secure key storage (for example, PSA crypto). The CDB's key import/export APIs abstract how keys are stored, allowing the application to use device keys when needed (for configuration or external tooling) without breaking the security model or relying on direct pointers into key storage.

Import and export device keys using the key management API:

```
/* Import a known device key */
static int import_dev_key(struct bt_mesh_cdb_node *node,
                          const uint8_t dev_key[16])
{
    int err;

    err = bt_mesh_cdb_node_key_import(node, dev_key);
    if (err) {
        printk("Failed to import device key (err %d)\n", err);
        return err;
    }

    /* Store updated node */
    if (IS_ENABLED(CONFIG_BT_SETTINGS)) {
        bt_mesh_cdb_node_store(node);
    }

    return 0;
}
```

(continues on next page)

(continued from previous page)

```
/* Export device key for external use */
static int export_dev_key(struct bt_mesh_cdb_node *node)
{
    uint8_t dev_key[16];
    int err;

    err = bt_mesh_cdb_node_key_export(node, dev_key);
    if (err) {
        printk("Failed to export device key (err %d)\n", err);
        return err;
    }

    /* Use the exported key */
    printk("Device key: ");
    for (int i = 0; i < 16; i++) {
        printk("%02x", dev_key[i]);
    }
    printk("\n");

    return 0;
}
```

Key points:

- Always use import/export functions when working with keys (required for PSA crypto).
- Keys are stored securely and are not be directly accessible through pointers.
- The provisioner automatically generates and imports device keys during provisioning.

Clearing the CDB For factory reset, testing, or starting a completely new network, you may need to wipe all provisioning and configuration data. Clearing the CDB resets the logical network state so you can safely recreate it from scratch, while avoiding inconsistencies with stale keys or node entries.

Reset the entire configuration database:

```
static void reset_network(void)
{
    printk("Clearing CDB...\n");

    /* Clear all CDB data */
    bt_mesh_cdb_clear();

    printk("CDB cleared\n");
}
```

Key points:

- The `bt_mesh_cdb_clear()` function removes all nodes, subnets, and app keys.
- Clears persistent storage if the `CONFIG_BT_SETTINGS` Kconfig option is enabled.
- Marks the CDB as invalid (must call the `bt_mesh_cdb_create()` function to use again).

Best practices

- **Error handling** - Check return values from all CDB functions, especially allocation functions which can fail when capacity is reached.

- **Address management** - Let the CDB manage address allocation by passing `0` to the `bt_mesh_cdb_node_alloc()` function unless you have specific addressing requirements.
- **Configuration tracking** - Always set the `BT_MESH_CDB_NODE_CONFIGURED` flag and store the node after successful configuration to avoid reconfiguring nodes unnecessarily.
- **Key security** - Never log or expose keys in production code. Use import/export functions to handle key material securely.
- **Iteration safety** - Do not modify the CDB (add/remove nodes) during `bt_mesh_cdb_node_foreach()` iteration. Collect addresses first, then modify.

Common pitfalls

CDB synchronization among multiple provisioners
If there are multiple provisioners in the network, ensure they synchronize their CDBs to avoid conflicts. Use application-level mechanisms to share CDB among multiple provisioners. There is no built-in mechanism for CDB synchronization.

Forgetting to store
CDB modifications are not automatically persisted. Always call the appropriate `_store()` function after making changes when using persistent storage.

Incorrect key index
When importing/exporting keys, the key index parameter (`0` or `1`) refers to the position in the Key Refresh key array, not the NetIdx or AppIdx.

Address conflicts
If manually specifying addresses, ensure they do not conflict with existing nodes. Use the `bt_mesh_cdb_free_addr_get()` function to find available addresses.

Over-capacity
CDB has fixed capacity defined by Kconfig. Exceeding capacity causes allocation failures. Monitor CDB usage and increase capacity if needed.

Accessing invalid nodes
Always check if returned pointers from `_get()` or `_alloc()` functions are `NULL` before dereferencing.

Core Host and drivers

Logical Link Control and Adaptation Protocol (L2CAP) L2CAP layer enables connection-oriented channels which can be enabled with the configuration option: `CONFIG_BT_L2CAP_DYNAMIC_CHANNEL`. These channels support segmentation and reassembly transparently, they also support credit based flow control making it suitable for data streams.

Channels instances are represented by the `bt_l2cap_chan` struct which contains the callbacks in the `bt_l2cap_chan_ops` struct to inform when the channel has been connected, disconnected or when the encryption has changed. In addition to that it also contains the `recv` callback which

is called whenever an incoming data has been received. Data received this way can be marked as processed by returning 0 or using `bt_l2cap_chan_recv_complete()` API if processing is asynchronous.

> **Note**
>
> The `recv` callback is called directly from RX Thread thus it is not recommended to block for long periods of time.

For sending data the `bt_l2cap_chan_send()` API can be used noting that it may block if no credits are available, and resuming as soon as more credits are available.

Servers can be registered using `bt_l2cap_server_register()` API passing the `bt_l2cap_server` struct which informs what `psm` it should listen to, the required security level `sec_level`, and the callback `accept` which is called to authorize incoming connection requests and allocate channel instances. The allocated objects must be of type `bt_l2cap_le_chan`, with the channel reference returned through the `accept` callback pointing to the object's `chan` member, as shown in the example below.

```
#define PSM 0x29 /* example PSM */

static int l2cap_recv(struct bt_l2cap_chan *chan, struct net_buf *buf);
static void l2cap_connected(struct bt_l2cap_chan *chan);
static void l2cap_disconnected(struct bt_l2cap_chan *chan);

/* ops used for every channel instance */
static struct bt_l2cap_chan_ops l2cap_ops = {
        .recv       = l2cap_recv,
        .connected  = l2cap_connected,
        .disconnected = l2cap_disconnected,
};

/* Fixed array of channel instances, one per possible connection */
static struct bt_l2cap_le_chan l2cap_chans[CONFIG_BT_MAX_CONN];

static int accept_cb(struct bt_conn *conn, struct bt_l2cap_server *server,
                     struct bt_l2cap_chan **chan)
{
        uint8_t conn_index = bt_conn_index(conn);

        /* initialize the chosen entry */
        (void)memset(&l2cap_chans[conn_index], 0, sizeof(l2cap_chans[conn_index]));
        l2cap_chans[conn_index].chan.ops = &l2cap_ops;

        *chan = &l2cap_chans[conn_index].chan;

        printk("L2CAP channel accepted, assigned chan[%d]\n", conn_index);

        return 0; /* accept */
}

static struct bt_l2cap_server server = {
        .psm = PSM,
        .sec_level = BT_SECURITY_L1,
        .accept = accept_cb,
};
```

A complete working example demonstrating L2CAP dynamic channels is available in the accep-

tor (server) sample: bluetooth_l2cap_coc_acceptor

Fixed Channels The user can also define fixed channels using the `BT_L2CAP_FIXED_CHANNEL_DEFINE` macro. Fixed channels are initialized upon connection, and do not support segmentation. Note that even though the `accept` callback passes the channel reference as a `bt_l2cap_chan`, the allocated object must be of type `bt_l2cap_le_chan`, with the reference pointing to its `chan` member. An example of how to define a fixed channel is shown below.

```
static struct bt_l2cap_le_chan fixed_chan[CONFIG_BT_MAX_CONN];

/* Callbacks are assumed to be defined prior. */
static struct bt_l2cap_chan_ops ops = {
    .recv = recv_cb,
    .sent = sent_cb,
    .connected = connected_cb,
    .disconnected = disconnected_cb,
};

static int l2cap_fixed_accept(struct bt_conn *conn, struct bt_l2cap_chan **chan)
{
    uint8_t conn_index = bt_conn_index(conn);

    fixed_chan[conn_index] = (struct bt_l2cap_le_chan){
        .chan.ops = &ops,
    };

    *chan = &fixed_chan[conn_index].chan;

    return 0;
}

BT_L2CAP_FIXED_CHANNEL_DEFINE(fixed_channel) = {
    .cid = 0x0010,
    .accept = l2cap_fixed_accept,
};
```

Client Channels Client channels can be initiated with use of `bt_l2cap_chan_connect()` API and can be disconnected with the `bt_l2cap_chan_disconnect()` API. Note that the latter can also disconnect channel instances created by servers.

See the initiator (client) sample for a complete example: bluetooth_l2cap_coc_initiator

Connection Management The Zephyr Bluetooth stack uses an abstraction called `bt_conn` to represent connections to other devices. The internals of this struct are not exposed to the application, but a limited amount of information (such as the remote address) can be acquired using

the bt_conn_get_info() API. Connection objects are reference counted, and the application is expected to use the bt_conn_ref() API whenever storing a connection pointer for a longer period of time, since this ensures that the object remains valid (even if the connection would get disconnected). Similarly the bt_conn_unref() API is to be used when releasing a reference to a connection.

A common mistake is to forget unreleasing a reference to a connection object created by functions bt_conn_le_create() and bt_conn_le_create_synced(). To protect against this, use the CONFIG_BT_CONN_CHECK_NULL_BEFORE_CREATE Kconfig option, which forces these functions return an error if the connection pointer passed to them is not NULL. This helps to spot such issues and avoid sporadic bugs caused by not releasing the connection object.

An application may track connections by registering a bt_conn_cb struct using the bt_conn_cb_register() or BT_CONN_CB_DEFINE APIs. This struct lets the application define callbacks for connection & disconnection events, as well as other events related to a connection such as a change in the security level or the connection parameters. When acting as a central the application will also get hold of the connection object through the return value of the bt_conn_le_create() API.

HCI Drivers

API Reference
Bluetooth HCI

HCI Packet Helpers Helpers for framing HCI command packets and parsing command responses in net_buf_simple buffers and packet bytes, independent of the Bluetooth Host and of

the HCI driver interface, together with a lockstep helper for HCI drivers that exchange HCI commands with the controller over their own transport, for example for vendor-specific controller initialization.

Both helpers are part of every build with `CONFIG_BT` enabled. The lockstep helper's header lives with the HCI driver API, under `include/zephyr/drivers/bluetooth/`.

These are not general application APIs: the intended users are HCI drivers and Bluetooth stack internals. Applications that need to send HCI commands alongside a running Host use the higher-level `bt_hci_cmd_alloc()`, `bt_hci_cmd_send()` and `bt_hci_cmd_send_sync()` APIs instead, which cooperate with the Host's command flow control.

Tools

This page lists and describes tools that can be used to assist during Bluetooth stack or application development in order to help, simplify and speed up the development process.

- *Mobile applications*
- *Using BlueZ with Zephyr*
- *Running on QEMU or native_sim*
  - *Using the Host System Bluetooth Controller*
  - *Using a Zephyr-based Bluetooth Controller*
  - *HCI Tracing*
- *Running on a Virtual Controller and native_sim*
  - *Android Emulator*
- *Using Zephyr-based Controllers with BlueZ*

Mobile applications It is often useful to make use of existing mobile applications to interact with hardware running Zephyr, to test functionality without having to write any additional code or requiring extra hardware.

The recommended mobile applications for interacting with Zephyr are:

- Android:
  - nRF Connect for Android
  - nRF Mesh for Android
  - LightBlue for Android
- iOS:
  - nRF Connect for iOS
  - nRF Mesh for iOS
  - LightBlue for iOS

Using BlueZ with Zephyr The Linux Bluetooth Protocol Stack, BlueZ, comes with a very useful set of tools that can be used to debug and interact with Zephyr's Bluetooth Host and Controller. In order to benefit from these tools you will need to make sure that you are running a recent version of the Linux Kernel and BlueZ:

- Linux Kernel 4.10+
- BlueZ 4.45+

Additionally, some of the BlueZ tools might not be bundled by default by your Linux distribution. If you need to build BlueZ from scratch to update to a recent version or to obtain all of its tools you can follow the steps below:

```
git clone git://git.kernel.org/pub/scm/bluetooth/bluez.git
cd bluez
./bootstrap-configure --disable-android --disable-midi
make
```

You can then find `btattach`, `btmgt` and `btproxy` in the `tools/` folder and `btmon` in the `monitor/` folder.

You'll need to enable BlueZ's experimental features so you can access its most recent Bluetooth functionality. Do this by editing the file `/lib/systemd/system/bluetooth.service` and making sure to include the `-E` option in the daemon's execution start line:

```
ExecStart=/usr/libexec/bluetooth/bluetoothd -E
```

Finally, reload and restart the daemon:

```
sudo systemctl daemon-reload
sudo systemctl restart bluetooth
```

Running on QEMU or native_sim It's possible to run Bluetooth applications using either the *QEMU emulator* or native_sim.

In either case, a Bluetooth controller needs to be exported from the host OS (Linux) to the emulator. For this purpose you will need some tools described in the *Using BlueZ with Zephyr* section.

Using the Host System Bluetooth Controller The host OS's Bluetooth controller is connected in the following manner:

- To the second QEMU serial line using a UNIX socket. This socket gets used with the help of the QEMU option `-serial unix:/tmp/bt-server-bredr`. This option gets passed to QEMU through `QEMU_EXTRA_FLAGS` automatically whenever an application has enabled Bluetooth support.
- To native_sim's BT User Channel driver through the use of a command-line option passed to the native_sim executable: `--bt-dev=hci0`

On the host side, BlueZ allows you to export its Bluetooth controller through a so-called user channel for QEMU and native_sim to use.

Note

You only need to run `btproxy` when using QEMU. native_sim handles the UNIX socket proxying automatically

If you are using QEMU, in order to make the Controller available you will need one additional step using `btproxy`:

1. Make sure that the Bluetooth controller is down
2. Use the btproxy tool to open the listening UNIX socket, type:

   ```
   sudo tools/btproxy -u -i 0
   Listening on /tmp/bt-server-bredr
   ```

   You might need to replace `-i 0` with the index of the Controller you wish to proxy.

If you see `Received unknown host packet type 0x00` when running QEMU, then add `-z` to the `btproxy` command line to ignore any null bytes transmitted at startup.

Once the hardware is connected and ready to use, you can then proceed to building and running a sample:

- Choose one of the Bluetooth sample applications located in `samples/bluetooth`.
- To run a Bluetooth application in QEMU, type:

```
west build -b qemu_x86 samples/bluetooth/<sample>
west build -t run
```

Running QEMU now results in a connection with the second serial line to the `bt-server-bredr` UNIX socket, letting the application access the Bluetooth controller.

- To run a Bluetooth application in native_sim, first build it:

```
west build -b native_sim samples/bluetooth/<sample>
```

And then run it with:

```
$ sudo ./build/zephyr/zephyr.exe --bt-dev=hci0
```

Using a Zephyr-based Bluetooth Controller Depending on which hardware you have available, you can choose between two transports when building a single-mode, Zephyr-based Bluetooth Controller:

- UART: Use the bluetooth_hci_uart sample and follow the instructions in bluetooth-hci-uart-qemu-posix.
- USB: Use the bluetooth_hci_usb sample and then treat it as a Host System Bluetooth Controller (see previous section)

HCI Tracing When running the Host on a computer connected to an external Controller, it is very useful to be able to see the full log of exchanges between the two, in the format of a *Host Controller Interface* log. In order to see those logs, you can use the built-in `btmon` tool from BlueZ:

```
$ btmon
```

The output looks like this:

```
= New Index: 00:00:00:00:00:00 (Primary,Virtual,Control)                 ␣
↪0.274200
= Open Index: 00:00:00:00:00:00                                          ␣
↪0.274500
< HCI Command: Reset (0x03|0x0003) plen 0                               #1␣
↪0.274600
> HCI Event: Command Complete (0x0e) plen 4                             #2␣
↪0.274700
      Reset (0x03|0x0003) ncmd 1
      Status: Success (0x00)
< HCI Command: Read Local Supported Features (0x04|0x0003) plen 0       #3␣
↪0.274800
> HCI Event: Command Complete (0x0e) plen 12                            #4␣
↪0.274900
      Read Local Supported Features (0x04|0x0003) ncmd 1
      Status: Success (0x00)
      Features: 0x00 0x00 0x00 0x00 0x60 0x00 0x00 0x00
         BR/EDR Not Supported
         LE Supported (Controller)
```

Embedded HCI tracing When running both Host and Controller in actual Integrated Circuits, you will only see normal log messages on the console by default, without any way of accessing the HCI traffic between the Host and the Controller. However, there is a special Bluetooth logging mode that converts the console to use a binary protocol that interleaves both normal log messages as well as the HCI traffic.

Set the following Kconfig options to enable this protocol before building your application:

```
CONFIG_BT_DEBUG_MONITOR_UART=y
CONFIG_UART_CONSOLE=n
```

- Setting `CONFIG_BT_DEBUG_MONITOR_UART` activates the formatting
- Clearing `CONFIG_UART_CONSOLE` makes the UART unavailable for the system console. E.g. for `printk` and the `boot banner`

Optionally, on boards whose monitor UART driver supports the interrupt API, setting `CONFIG_BT_DEBUG_MONITOR_UART_INTERRUPT_DRIVEN` queues complete monitor records and transmits them from the UART interrupt handler instead of blocking while each byte is transmitted. Records that do not fit in the buffer are dropped and reported in the next monitor record. The buffer size can be adjusted with `CONFIG_BT_DEBUG_MONITOR_UART_BUFFER_SIZE`.

To decode the binary protocol that will now be sent to the console UART you need to use the btmon tool from *BlueZ*:

```
$ btmon --tty <console TTY> --tty-speed 115200
```

If UART is not available (or you still want non-binary logs), you can set `CONFIG_BT_DEBUG_MONITOR_RTT` instead, which will use Segger RTT. For example, if trying to connect to a nRF52840DK with S/N 683578642:

```
$ btmon --jlink nRF52840_xxAA,683578642
```

Running on a Virtual Controller and native_sim An alternative to a Bluetooth physical controller is the use of a virtual controller. This controller can be connected over an HCI TCP server. This TCP server must support the HCI H4 protocol. In comparison to the physical controller variant, the virtual controller allows to test a Zephyr application running on the native boards without a physical Bluetooth controller.

The main use case for a virtual controller is to do Bluetooth connectivity tests without the need of Bluetooth hardware. This allows to automate Bluetooth integration tests with external applications such as a Bluetooth gateway or a mobile application.

To demonstrate this functionality an example is given to interact with a virtual controller. For this purpose, the experimental python module Bumble from Google is used as it allows to create a TCP Bluetooth virtual controller and connect with the Zephyr Bluetooth host. To install bumble follow the Bumble Getting Started Guide.

> **Note**
>
> If your Zephyr application requires the use of the HCI LE Set extended commands, install the branch `controller-extended-advertising` from Bumble.

Android Emulator You can test the virtual controller by connecting a Bluetooth Zephyr application to the Android Emulator.

To connect your application to the Android Emulator follow the next steps:

1. Build your Zephyr application and disable the HCI ACL flow control (i.e. `CONFIG_BT_HCI_ACL_FLOW_CONTROL=n`) as the virtual controller from android does not support it at the moment.

2. Install Android Emulator version >= 33.1.4.0. The easiest way to do this is by installing the latest Android Studio Preview version.
3. Create a new Android Virtual Device (AVD) with the Android Device Manager. The AVD should use at least SDK API 34.
4. Run the Android Emulator via terminal as follows:

   ```
   emulator avd YOUR_AVD -packet-streamer-endpoint default
   ```

5. Create a Bluetooth bridge between the Zephyr application and the virtual controller from Android Emulator with the Bumble utility `hci-bridge`.

   ```
   bumble-hci-bridge tcp-server:_:1234 android-netsim
   ```

   This command will create a TCP server bridge on the local host IP address `127.0.0.1` and port number `1234`.

6. Run the Zephyr application and connect to the TCP server created in the last step.

   ```
   ./zephyr.exe --bt-dev=127.0.0.1:1234
   ```

After following these steps the Zephyr application will be available to the Android Emulator over the virtual Bluetooth controller that was bridged with Bumble. You can verify that the Zephyr application can communicate over Bluetooth by opening the Bluetooth settings in your AVD and scanning for your Zephyr application device. To test this you can build the Bluetooth peripheral samples such as ble_peripheral_hr or ble_peripheral_dis.

Using Zephyr-based Controllers with BlueZ If you want to test a Zephyr-powered Bluetooth Controller using BlueZ's Bluetooth Host, you will need a few tools described in the *Using BlueZ with Zephyr* section. Once you have installed the tools you can then use them to interact with your Zephyr-based controller:

```
sudo tools/btmgmt --index 0
[hci0]# auto-power
[hci0]# find -l
```

You might need to replace `--index 0` with the index of the Controller you wish to manage. Additional information about `btmgmt` can be found in its manual pages.

Shell

The Bluetooth Shell is an application based on the *Shell* module. It offer a collection of commands made to easily interact with the Bluetooth stack.

For specific Bluetooth functionality see also the following shell documentation

Bluetooth: Basic Audio Profile Shell This document describes how to run Basic Audio Profile functionality which includes:

- Capabilities and Endpoint discovery
- Audio Stream Endpoint procedures

Commands

```
bap --help
Subcommands:
   init                  : [ase_sink_count, ase_source_count]

```

Table 30: State Machine Transitions

Command	Depends	Allowed States	Next States
init	none	any	none
discover	init	any	any
config	discover	idle/codec-configured/qos-configured	codec-configured
qos	config	codec-configured/qos-configured	qos-configured
enable	qos	qos-configured	enabling
connect	qos/enable	qos-configured/enabling	qos-configured/enabling
[start]	enable/connect	enabling	streaming
disable	enable	enabling/streaming	disabling
[stop]	disable	disabling	qos-configure/idle
release	config	any	releasing/codec-configure/idle
list	none	any	none
select_unicast	none	any	none
send	enable	streaming	none

Example Central Connect and establish a sink stream:

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ bap discover sink
uart:~$ bap config sink 0
uart:~$ bap qos
uart:~$ bap enable
uart:~$ bap connect
```

Connect and establish a source stream:

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ bap discover source
uart:~$ bap config source 0
uart:~$ bap qos
uart:~$ bap enable
uart:~$ bap connect
uart:~$ bap start
```

Disconnect and release:

```
uart:~$ bap disable
uart:~$ bap release
```

Example Peripheral Listen:

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt advertise on
```

Server initiated disable and release:

```
uart:~$ bap disable
uart:~$ bap release
```

Example Broadcast Source Create and establish a broadcast source stream:

```
uart:~$ bap init
uart:~$ bap create_broadcast
uart:~$ bap start_broadcast
```

Stop and release a broadcast source stream:

```
uart:~$ bap stop_broadcast
uart:~$ bap delete_broadcast
```

Example Broadcast Sink Scan for and establish a broadcast sink stream. The command bap `create_broadcast_sink` will either use existing periodic advertising sync (if exist) or start scanning and sync to the periodic advertising with the provided broadcast ID before syncing to the BIG.

```
uart:~$ bap init
uart:~$ bap create_broadcast_sink 0xEF6716
No PA sync available, starting scanning for broadcast_id
Found broadcaster with ID 0xEF6716 and addr R:03:47:95:75:C0:08 and sid 0x00
Attempting to PA sync to the broadcaster
PA synced to broadcast with broadcast ID 0xEF6716
Attempting to sync to the BIG
Received BASE from sink 0x20019080:

Possible indexes: 0x01 0x02
Sink 0x20019110 is ready to sync without encryption
uart:~$ bap sync_broadcast 0x01
```

Syncing to encrypted broadcast If the broadcast is encrypted, the broadcast code can be entered with the `bap sync_broadcast` command as such:

```
Sink 0x20019110 is ready to sync with encryption
uart:~$ bap sync_broadcast 0x01 bcode 0102030405060708090a0b0c0d0e0f
```

The broadcast code can be 1-16 values, either as a string or a hexadecimal value.

```
Sink 0x20019110 is ready to sync with encryption
uart:~$ bap sync_broadcast 0x01 bcode_str thisismycode
```

Stop and release a broadcast sink stream:

```
uart:~$ bap stop_broadcast_sink
uart:~$ bap term_broadcast_sink
```

Init The `init` command register local PAC records which are necessary to be able to configure stream and properly manage capabilities in use.

Table 31: State Machine Transitions

Depends	Allowed States	Next States
none	any	none

```
uart:~$ bap init
```

Discover PAC(s) and ASE(s) Once connected the `discover` command discover PAC records and ASE characteristics representing remote endpoints.

Table 32: State Machine Transitions

Depends	Allowed States	Next States
init	any	any

Note

Use command `gatt exchange-mtu` to make sure the MTU is configured properly.

```
uart:~$ gatt exchange-mtu
Exchange pending
Exchange successful
uart:~$ bap discover [type: sink, source]
uart:~$ bap discover sink

```

Configure preset The `bap preset` command can also be used to configure the preset used for the subsequent commands. It is possible to add or set (or reset) any value. To reset the preset, the command can simply be run without the `config` or `meta` parameter. The parameters are using the assigned numbers values.

```
uart:~$ bap preset sink 32_2_1

```

Configure Codec The `config` command attempts to configure a stream for the given direction using a preset codec configuration which can either be passed directly or in case it is omitted the default preset is used.

Table 33: State Machine Transitions

Depends	Allowed States	Next States
discover	idle/codec-configured/qos-configured	codec-configured

```
uart:~$ bap config <direction: sink, source> <index> [loc <loc_bits>] [preset
↪<preset_name>]
uart:~$ bap config sink 0
Setting location to 0x00000000
ASE config: preset 16_2_1
stream 0x2000df70 config operation rsp_code 0 reason 0
```

Configure Stream QoS The `stream_qos` Sets a new stream QoS.

```
uart:~$ bap stream_qos <interval> [framing] [latency] [pd] [sdu] [phy] [rtn]
uart:~$ bap stream_qos 10
```

Configure QoS The `qos` command attempts to configure the stream QoS using the preset configuration, each individual QoS parameter can be set with use optional parameters.

Table 34: State Machine Transitions

Depends	Allowed States	Next States
config	qos-configured/codec-configured	qos-configured

```
uart:~$ bap qos
```

Enable The `enable` command attempts to enable the stream previously configured.

Table 35: State Machine Transitions

Depends	Allowed States	Next States
qos	qos-configured	enabling

```
uart:~$ bap enable [context]
uart:~$ bap enable Media
```

Connect The `connect` command attempts to connect the stream previously configured. Sink streams will have to be started by the unicast server, and source streams will have to be started by the unicast client.

Table 36: State Machine Transitions

Depends	Allowed States	Next States
qos/enable	qos-configured/enabling	qos-configured/enabling

```
uart:~$ bap connect
```

Start The `start` command is only necessary when starting a source stream.

Table 37: State Machine Transitions

Depends	Allowed States	Next States
enable/connect	enabling	streaming

```
uart:~$ bap start
```

Disable The `disable` command attempts to disable the stream previously enabled, if the remote peer accepts then the ISO disconnection procedure is also initiated.

Table 38: State Machine Transitions

Depends	Allowed States	Next States
enable	enabling/streaming	disabling

```
uart:~$ bap disable
```

Stop The `stop` command is only necessary when acting as a sink as it indicates to the source the stack is ready to stop receiving data.

Table 39: State Machine Transitions

Depends	Allowed States	Next States
disable	disabling	qos-configure/idle

```
uart:~$ bap stop
```

Release The `release` command releases the current stream and its configuration.

Table 40: State Machine Transitions

Depends	Allowed States	Next States
config	any	releasing/codec-configure/idle

```
uart:~$ bap release
```

List The `list` command list the available streams.

Table 41: State Machine Transitions

Depends	Allowed States	Next States
none	any	none

```
uart:~$ bap list
*0: ase 0x01 dir 0x01 state 0x01
```

Select Unicast The `select_unicast` command set a unicast stream as default.

Table 42: State Machine Transitions

Depends	Allowed States	Next States
none	any	none

```
uart:~$ bap select <ase>
uart:~$ bap select 0x01
Default stream: 1
```

To select a broadcast stream:

```
uart:~$ bap select 0x01 broadcast
Default stream: 1 (broadcast)
```

Send The send command sends data over BAP Stream.

Table 43: State Machine Transitions

Depends	Allowed States	Next States
enable	streaming	none

```
uart:~$ bap send [count]
uart:~$ bap send
Audio sending...
```

Bluetooth: Basic Audio Profile: Broadcast Assistant Shell This document describes how to run the BAP Broadcast Assistant functionality. Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

The Broadcast Assistant is responsible for offloading scan for a resource restricted device, such that scanning does not drain the battery. The Broadcast Assistant shall support scanning for periodic advertisements and may optionally support the periodic advertisements synchronization transfer (PAST) protocol.

The Broadcast Assistant will typically be phones or laptops. The Broadcast Assistant scans for periodic advertisements and transfer information to the server.

It is necessary to have `CONFIG_BT_BAP_BROADCAST_ASSISTANT_LOG_LEVEL_DBG` enabled for using the Broadcast Assistant interactively.

When the Bluetooth stack has been initialized (`bt init`), and a device has been connected, the Broadcast Assistant can discover BASS on the connected device calling `bap_broadcast_assistant discover`, which will start a discovery for the BASS UUIDs and store the handles, and subscribe to all notifications.

```
uart:~$ bap_broadcast_assistant --help
bap_broadcast_assistant - Bluetooth BAP broadcast assistant client shell
                          commands
Subcommands:
discover           : Discover BASS on the server
scan_start         : Start scanning for broadcasters
scan_stop          : Stop scanning for BISs
add_src            : Add a source <address: P:XX:XX:XX:XX:XX:XX or
                      R:XX:XX:XX:XX:XX:XX> <adv_sid> <sync_pa> <broadcast_id>
                      [<sync_bis>] [<pa_interval>] [<metadata>]
add_broadcast_id   : Add a source by broadcast ID <broadcast_id> <sync_pa>
                      [<sync_bis>] [<metadata>]
add_broadcast_name: Add a source by broadcast name <broadcast_name> <sync_pa>
                      [<sync_bis>] [<metadata>]
add_pa_sync        : Add a PA sync as a source <sync_pa> <broadcast_id>
                      [bis_index [bis_index [bix_index [...]]]]>
mod_src            : Set sync <src_id> <sync_pa> [<pa_interval> | "unknown"]␣
↪[<sync_bis>]
                      [<metadata>]
broadcast_code     : Send a string-based broadcast code of up to 16 bytes
                      <src_id> <broadcast code>
rem_src            : Remove a source <src_id>
read_state         : Remove a source <index>
```

Example usage

Setup

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect P:xx:xx:xx:xx:xx:xx
```

When connected

Note

The Broadcast Assistant will not actually start scanning for periodic advertisements, as that feature is still, at the time of writing, not implemented.

Start scanning for periodic advertisements for a server:

```
uart:~$ bap_broadcast_assistant discover
BASS discover done with 1 recv states
uart:~$ bap_broadcast_assistant scan_start true
BASS scan start successful
Found broadcaster with ID 0x05BD38 and addr R:1E:4D:0A:AA:6E:49 and sid 0x00
```

Adding a source to the receive state with add_src:

```
uart:~$ bap_broadcast_assistant add_src P:11:22:33:44:55:66 5 1 1
BASS recv state: src_id 0, addr P:11:22:33:44:55:66, sid 5, sync_state 1,␣
↪encrypt_state 00000000000000000000000000000000
     [0]: BIS sync 0, metadata_len 0
```

Adding a source to the receive state with add_broadcast_id (recommended):

```
uart:~$ bap_broadcast_assistant add_broadcast_id 0x05BD38 true
[DEVICE]: R:1E:4D:0A:AA:6E:49, AD evt type 5, RSSI -28 Broadcast Audio Source C:0␣
↪S:0 D:0 SR:0 E:1 Prim: LE 1M, Secn: LE 2M, Interval: 0x03c0 (1200000 us), SID:␣
↪0x0
Found BAP broadcast source with address R:1E:4D:0A:AA:6E:49 and ID 0x05BD38
BASS recv state: src_id 0, addr R:1E:4D:0A:AA:6E:49, sid 0, sync_state 0,␣
↪encrypt_state 0
     [0]: BIS sync 0x0000, metadata_len 0
BASS add source successful
BASS recv state: src_id 0, addr R:1E:4D:0A:AA:6E:49, sid 0, sync_state 2,␣
↪encrypt_state 0
     [0]: BIS sync 0x0000, metadata_len 0
BASS recv state: src_id 0, addr R:1E:4D:0A:AA:6E:49, sid 0, sync_state 2,␣
↪encrypt_state 0
     [0]: BIS sync 0x0000, metadata_len 4
              Metadata length 2, type 2, data: 0100
```

Modifying a receive state:

```
uart:~$ bap_broadcast_assistant mod_src 0 true 0x03c0 0x02
BASS modify source successful
BASS recv state: src_id 0, addr R:1E:4D:0A:AA:6E:49, sid 0, sync_state 2,␣
↪encrypt_state 0
     [0]: BIS sync 0x0001, metadata_len 4
              Metadata length 2, type 2, data: 0100
```

Supplying a broadcast code:

```
uart:~$ bap_broadcast_assistant broadcast_code 0 secretCode
Sending broadcast code:
00000000: 73 65 63 72 65 74 43 6f 64 65 00 00 00 00 00 00 |secretCo de....|
uart:~$ BASS broadcast code successful
```

Bluetooth: Basic Audio Profile: Scan Delegator Shell This document describes how to run the Scan Delegator functionality, Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

The Scan Delegator may optionally support the periodic advertisements synchronization transfer (PAST) protocol.

The Scan Delegator server typically resides on devices that have inputs or outputs.

It is necessary to have `CONFIG_BT_BAP_SCAN_DELEGATOR_LOG_LEVEL_DBG` enabled for using the Scan Delegator interactively.

The Scan Delegator can currently only set the sync state of a receive state, but does not actually support syncing with periodic advertisements yet.

```
bap_scan_delegator --help
bap_scan_delegator - Bluetooth BAP Scan Delegator shell commands
Subcommands:
  init                : Initialize the service and register callbacks
  set_past_pref       : Set PAST preference <true || false>
  sync_pa             : Sync to PA <src_id>
  term_pa             : Terminate PA sync <src_id>
  add_src             : Add a PA as source <addr> <sid> <broadcast_id>
                        <enc_state> [bis_sync [metadata]]
  add_src_by_pa_sync  : Add a PA as source <broadcast_id> <enc_state> [bis_sync
                        [metadata]]
  mod_src             : Modify source <src_id> <broadcast_id> <enc_state>
                        [bis_sync [metadata]]
  rem_src             : Remove source <src_id>
  synced              : Set server scan state <src_id> <bis_syncs>
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ bap_scan_delegator init
uart:~$ bt advertise on
Advertising started
```

Adding a source

```
uart:~$ bap_scan_delegator add_src P:11:22:33:44:55:66 0 1234 0
Receive state with ID 0 updated
```

Adding a source from a PA sync

```
uart:~$ bt scan on
Found broadcaster with ID 0x681A22 and addr R:2C:44:05:82:EB:82 and sid 0x00␣
↪(looking for 0x1000000)
uart:~$ bt scan off
uart:~$ bt per-adv-sync-create R:2C:44:05:82:EB:82 0
PA 0x2003e9b0 synced
uart:~$ bap_scan_delegator add_src_by_pa_sync 0x681A22 0
Receive state with ID 0 updated
```

When connected Set sync state for a source:

```
uart:~$ bap_scan_delegator synced 0 1 3 0
```

Bluetooth: Common Audio Profile Shell This document describes how to run the Common Audio Profile functionality.

CAP Acceptor The Acceptor will typically be a resource-constrained device, such as a headset, earbud or hearing aid. The Acceptor can initialize a Coordinated Set Identification Service instance, if it is in a pair with one or more other CAP Acceptors.

Using the CAP Acceptor When the Bluetooth stack has been initialized (`bt init`), the Acceptor can be registered by calling `cap_acceptor init`, which will register the CAS and CSIS services, as well as register callbacks.

```
cap_acceptor --help
cap_acceptor - Bluetooth CAP acceptor shell commands
Subcommands:
  init          :Initialize the service and register callbacks [size <int>]
                 [rank <int>] [not-lockable] [sirk <data>]
  lock          :Lock the set
  release       :Release the set [force]
  sirk          :Set the currently used SIRK <sirk>
  get_info      :Get CSIS info
  sirk_rsp      :Set the response used in SIRK requests <accept, accept_enc,
                 reject, oob>
```

Besides initializing the CAS and the CSIS, there are also commands to lock and release the CSIS instance, as well as printing and modifying access to the SIRK of the CSIS.

Setting a new SIRK This command can modify the currently used SIRK. To get the new RSI to advertise on air, `bt adv-data` or `bt advertise` must be called again to set the new advertising data. If `CONFIG_BT_CSIP_SET_MEMBER_SIRK_NOTIFIABLE` is enabled, this will also notify connected clients.

```
uart:~$ cap_acceptor sirk 00112233445566778899aabbccddeeff
SIRK updated
```

Getting the current SIRK This command can get the currently used SIRK.

```
uart:~$ cap_acceptor get_info
Info for 0x2003b0c8
        SIRK
00000000: 20 37 0a 00 95 c4 04 20  00 00 00 00 f1 79 09 00 | 7.....  .....y..|
        Set size: 2
        Rank: 1
        Lockable: true
        Locked: false
```

CAP Initiator The Initiator will typically be a resource-rich device, such as a phone or PC. The Initiator can discover CAP Acceptors's CAS and optional CSIS services. The CSIS service can be read to provide information about other CAP Acceptors in the same Coordinated Set. The Initiator can execute stream control procedures on sets of devices, either ad-hoc or Coordinated, and thus provides an easy way to setup multiple streams on multiple devices at once.

Using the CAP Initiator When the Bluetooth stack has been initialized (`bt init`), the Initiator can discover CAS and the optionally included CSIS instance by calling (`cap_initiator discover`). The CAP initiator also supports broadcast audio as a source.

```
uart:~$ cap_initiator --help
cap_initiator - Bluetooth CAP initiator shell commands
Subcommands:
```

(continues on next page)

(continued from previous page)

```
  discover          : Discover CAS

  ac_9_ii           : Unicast audio configuration 9(ii)
  ac_10             : Unicast audio configuration 10
  ac_11_i           : Unicast audio configuration 11(i)
  ac_11_ii          : Unicast audio configuration 11(ii)
  broadcast_start   :
  broadcast_update  : <meta>
  broadcast_stop    :
  broadcast_delete  :
  ac_12             : Broadcast audio configuration 12
  ac_13             : Broadcast audio configuration 13
  ac_14             : Broadcast audio configuration 14
```

Before being able to perform any stream operation, the device must also perform the `bap discover` operation to discover the ASEs and PAC records. The `bap init` command also needs to be called.

When connected Discovering CAS and CSIS on a device:

```
uart:~$ cap_initiator discover
discovery completed with CSIS
```

Discovering ASEs and PAC records on a device:

```
uart:~$ bap discover
conn 0x81cc260: #0: codec 0x81d5b28 dir 0x01
codec 0x06 cid 0x0000 vid 0x0000 count 5
data #0: type 0x01 len 2

Conn: 0x81cc260, Source #1: ep 0x81e60e8
Discover complete: err 0
```

Both of the above commands should be done for each device that you want to use in the set. To use multiple devices, simply connect to more and then use `bt select` the device to execute the commands on.

Once all devices have been connected and the respective discovery commands have been called, the `cap_initiator unicast_start` command can be used to put one or more streams into the streaming state.

```
uart:~$ cap_initiator unicast_start sinks 1 sources 0 conns all
Setting up 1 sinks and 0 sources on each (2) conn
Starting 1 streams
Unicast start completed
```

To stop all the streams that has been started, the `cap_initiator unicast_stop` command can be used.

```
uart:~$ cap_initiator unicast_stop all
Unicast stop completed
```

When doing broadcast To start a broadcast as the CAP initiator there are a few steps to be done:

1. Create and configure an extended advertising set with periodic advertising
2. Create and configure a broadcast source
3. Setup extended and periodic advertising data

The following commands will setup a CAP broadcast source using the 16_2_1 preset (defined by BAP):

```
bt init
bap init
bt adv-create nconn-nscan ext-adv
bt per-adv-param
bap preset broadcast 16_2_1
cap_initiator ac_12
bt adv-data dev-name discov
```

(continues on next page)

(continued from previous page)

```
bt per-adv-data
cap_initiator broadcast_start
bt adv-start
bt per-adv on
```

The broadcast source is created by the `cap_initiator ac_12`, `cap_initiator ac_13`, and `cap_initiator ac_14` commands, configuring the broadcast source for the defined audio configurations from BAP. The broadcast source can then be stopped with `cap_initiator broadcast_stop` or deleted with `cap_initiator broadcast_delete`.

The metadata of the broadcast source can be updated at any time, including when it is already streaming. To update the metadata the `cap_initiator broadcast_update` command can be used. The command takes an array of data, and the only requirement (besides having valid data) is that the streaming context shall be set. For example to set the streaming context to media, the command can be used as

```
cap_initiator broadcast_update 03020400
CAP Broadcast source updated with new metadata. Update the advertised base via `bt␣
↪per-adv-data`
bt per-adv-data
```

The `bt per-adv-data` command should be used afterwards to update the data is the advertised BASE. The data must be little-endian, so in the above example the metadata `03020400` is setting the metadata entry with `03` as the length, `02` as the type (streaming context) and `0400` as the value `BT_AUDIO_CONTEXT_TYPE_MEDIA` (which has the numeric value of 0x).

CAP Commander The Commander will typically be a either co-located with a CAP Initiator or be on a separate resource-rich mobile device, such as a phone or smartwatch. The Commander can discover CAP Acceptors's CAS and optional CSIS services. The CSIS service can be read to provide information about other CAP Acceptors in the same Coordinated Set. The Commander can provide information about broadcast sources to CAP Acceptors or coordinate capture and rendering information such as mute or volume states.

Using the CAP Commander When the Bluetooth stack has been initialized (`bt init`), the Commander can discover CAS and the optionally included CSIS instance by calling (`cap_commander discover`).

```
cap_commander --help
cap_commander - Bluetooth CAP commander shell commands
Subcommands:
  discover                  :Discover CAS
  cancel                    :CAP commander cancel current procedure
  change_volume             :Change volume on all connections <volume>
  change_volume_mute        :Change volume mute state on all connections <mute>
  change_volume_offset      :Change volume offset per connection <volume_offset
                             [volume_offset [...]]>
  change_microphone_mute    :Change microphone mute state on all connections <mute>
  change_microphone_gain    :Change microphone gain per connection <gain
                             [gain [...]]>
  broadcast_reception_start : Start broadcast reception with source
                              <address: P:XX:XX:XX:XX:XX:XX or R:XX:XX:XX:XX:XX:XX>
                              <adv_sid> <broadcast_id>
                              [<pa_interval>] [<sync_bis>] [<metadata>]
  broadcast_reception_stop  : Stop broadcast reception <src_id [...]>
  distribute_broadcast_code : Distribute broadcast code <src_id [...]>
↪<broadcast_code>
```

Before being able to perform any stream operation, the device must also perform the `bap discover` operation to discover the ASEs and PAC records. The `bap init` command also needs to be called.

When connected

Discovering CAS and CSIS on a device

```
uart:~$ cap_commander discover
discovery completed with CSIS
```

Setting the volume on all connected devices

```
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$ cap_commander change_volume 15
uart:~$ cap_commander change_volume 15
Setting volume to 15 on 2 connections
VCP volume 15, mute 0
VCP vol_set done
VCP volume 15, mute 0
VCP flags 0x01
VCP vol_set done
Volume change completed
```

Setting the volume offset on one or more devices The offsets are set by connection index, so connection index 0 gets the first offset, and index 1 gets the second offset, etc.:

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ cap_commander change_volume_offset 10
Setting volume offset on 1 connections
VOCS inst 0x200140a4 offset 10
Offset set for inst 0x200140a4
Volume offset change completed
uart:~$
uart:~$ cap_commander change_volume_offset 10 15
Setting volume offset on 2 connections
Offset set for inst 0x200140a4
VOCS inst 0x20014188 offset 15
Offset set for inst 0x20014188
Volume offset change completed
```

Setting the volume mute on all connected devices

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ vcp_vol_ctlr discover
VCP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ cap_commander change_volume_mute 1
Setting volume mute to 1 on 2 connections
VCP volume 100, mute 1
VCP mute done
VCP volume 100, mute 1
VCP mute done
Volume mute change completed
uart:~$ cap_commander change_volume_mute 0
Setting volume mute to 0 on 2 connections
VCP volume 100, mute 0
VCP unmute done
VCP volume 100, mute 0
VCP unmute done
Volume mute change completed
```

Setting the microphone mute on all connected devices

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 VOCS and 1 AICS
uart:~$
uart:~$ cap_commander change_microphone_mute 1
Setting microphone mute to 1 on 2 connections
MICP microphone 100, mute 1
MICP mute done
MICP microphone 100, mute 1
MICP mute done
Microphone mute change completed
uart:~$ cap_commander change_microphone_mute 0
Setting microphone mute to 0 on 2 connections
MICP microphone 100, mute 0
MICP unmute done
MICP microphone 100, mute 0
```

(continues on next page)

(continued from previous page)

```
MICP unmute done
Microphone mute change completed
```

Setting the microphone gain on one or more devices The gains are set by connection index, so connection index 0 gets the first offset, and index 1 gets the second offset, etc.:

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 AICS
uart:~$
uart:~$ bt connect <device B>
Connected: <device B>
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ micp_mic_ctlr discover
MICP discover done with 1 AICS
uart:~$
uart:~$ cap_commander change_microphone_gain 10
Setting microphone gain on 1 connections
AICS inst 0x200140a4 state gain 10, mute 0, mode 0
Gain set for inst 0x200140a4
Microphone gain change completed
uart:~$
uart:~$ cap_commander change_microphone_gain 10 15
Setting microphone gain on 2 connections
Gain set for inst 0x200140a4
AICS inst 0x20014188 state gain 15, mute 0, mode 0
Gain set for inst 0x20014188
Microphone gain change completed
```

Starting and stopping broadcast reception

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ bap_init
uart:~$ cap_commander discover
discovery completed with CSIS
uart:~$ bap_broadcast_assistant discover
BASS discover done with 1 recv states
uart:~$ cap_commander broadcast_reception_start <device B> 0 4
Starting broadcast reception on 1 connection(s)
Broadcast reception start completed
uart:~$ cap_commander broadcast_reception_stop 0
Stopping broadcast reception on 1 connection(s)
Broadcast reception stop completed
```

Distributing the broadcast code

```
uart:~$ bt connect <device A>
Connected: <device A>
uart:~$ bap_init
uart:~$ cap_commander discover
```

(continues on next page)

(continued from previous page)

```
discovery completed with CSIS
uart:~$ bap_broadcast_assistant discover
BASS discover done with 1 recv states
uart:~$ cap_commander broadcast_reception_start <device B> 0 4
Starting broadcast reception on 1 connection(s)
Broadcast reception start completed
uart:~$ cap_commander distribute_broadcast_code 0 "BroadcastCode"
Distribute broadcast code completed
```

CAP Handover The handover procedures allow the user to switch between unicast and broadcast streams. Since broadcast streams are always unidirectional, the procedures will only work for streams with audio direction from the Initiator to the Acceptor (sink streams).

Using the CAP Handover procedures When the Bluetooth stack has been initialized (`bt init`), one or more remote CAP acceptor devices have been connected, and audio streams have been set up, the handover procedures can be used to switch between unicast and broadcast. Before any of the handover procedures can be used, the `bap discover`, `cap_initiator discover` and `bap_broadcast_assistant discover` commands must have been issued and completed.

```
cap_handover --help
cap_handover - Bluetooth CAP handover shell commands
Subcommands:
  unicast_to_broadcast  : Handover current unicast group to broadcast (unicast
                        group will be deleted) [enc <broadcast_code>] [preset
↪<preset_name>]
  broadcast_to_unicast  : Handover current broadcast source to unicast
                        (broadcast source will be deleted)
                        [conns <count>|all] [preset <preset_name>]
```

Handover unicast to broadcast This command hands over one or more unicast streams from unicast to broadcast.

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect <addr>

# Discover necessary services
uart:~$ bap discover
uart:~$ cap_initiator discover
uart:~$ bap_broadcast_assistant discover

# Setup unicast audio e.g. using the ac_1
uart:~$ cap_initiator ac_1

# Create a non-connectable and non-scannable extended advertising set for broadcast
uart:~$ bt adv-create nconn-nscan ext-adv
uart:~$ bt per-adv-param

# Perform the handover and update the advertising data to contain the broadcast ID
uart:~$ cap_handover unicast_to_broadcast
uart:~$ bt adv-data dev-name discov
uart:~$ bt per-adv-data

# Enable periodic advertising (extended advertising is enabled as part of handover)
uart:~$ bt per-adv on
```

Handover broadcast to unicast This command hands over one or more unicast streams from broadcast to unicast.

```
uart:~$ bt init
uart:~$ bap init
uart:~$ bt connect <addr>

# Discover necessary services
uart:~$ bap discover
uart:~$ cap_initiator discover
uart:~$ bap_broadcast_assistant discover

# Create a non-connectable and non-scannable extended advertising set for broadcast
uart:~$ bt adv-create nconn-nscan ext-adv
uart:~$ bt per-adv-param

# Setup broadcast audio e.g. using the ac_12
uart:~$ cap_initiator ac_12
uart:~$ cap_initiator broadcast_start

# Set advertising data and enable advertising
uart:~$ bt adv-data dev-name discov
uart:~$ bt per-adv-data
uart:~$ bt per-adv on
uart:~$ bt adv-start

# Wait for broadcast sink to self-scan, or use broadcast reception to instruct␣
↪sink to sync

# Perform the handover
uart:~$ cap_handover broadcast_to_unicast

# Terminate the advertiser (optional)
uart:~$ bt adv-stop
uart:~$ bt per-adv off
uart:~$ bt adv-delete
```

Bluetooth: Call Control Profile Shell

Call Control Server The Call Control Server is a role that typically resides on devices that can make calls, including calls from apps such as Skype, e.g. (smart)phones and PCs, which are typically GAP Central devices.

Using the Call Control Server The Server can be controlled locally, or by a remote device (when in a call). For example a remote device may initiate a call to the server, or the Server may initiate a call to remote device, without a client.

For all commands that take an optional `index`, if the index is not supplied then it defaults to `0` which is the GTBS bearer.

```
ccp_call_control_server --help
ccp_call_control_server - Bluetooth CCP Call Control Server shell commands
Subcommands:
  init                  : Initialize CCP Call Control Server
  set_bearer_name       : Set bearer name [index] <name>
  get_bearer_name       : Get bearer name [index]
```

(continues on next page)

(continued from previous page)

```
  get_bearer_uci          : Get bearer UCI [index]
  set_bearer_tech         : Set bearer technology [index] <technology>
  get_bearer_tech         : Get bearer technology [index]
  set_bearer_uri_schemes  : Set bearer URI schemes supported list [index] <URI␣
↪schemes>
                           (e.g. "tel,skype")
  get_bearer_uri_schemes  : Get bearer URI schemes supported list [index]
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ ccp_call_control_server init
Registered GTBS bearer
Registered bearer[1]
uart:~$ bt connect P:xx:xx:xx:xx:xx:xx
```

Setting and getting the bearer name

```
uart:~$ ccp_call_control_server get_bearer_name
Bearer[0] name: Generic TBS
uart:~$ ccp_call_control_server set_bearer_name "New name"
Bearer[0] name: New name
uart:~$ ccp_call_control_server get_bearer_name
Bearer[0] name: New name
uart:~$ ccp_call_control_server get_bearer_name 1
Bearer[1] name: Telephone Bearer #1
uart:~$ ccp_call_control_server set_bearer_name 1 "New TBS name"
Bearer[1] name: New TBS name
uart:~$ ccp_call_control_server get_bearer_name 1
Bearer[1] name: New TBS name
```

Getting the bearer UCI

```
uart:~$ ccp_call_control_server get_bearer_uci
Bearer[0] UCI: un999
uart:~$ ccp_call_control_server get_bearer_uci 1
Bearer[1] UCI: skype
```

Setting and getting the bearer technology

```
uart:~$ ccp_call_control_server get_bearer_tech
Bearer[0] technology: 3G (0x01)
uart:~$ ccp_call_control_server set_bearer_tech 0x02
Bearer[0] new technology: 4G (0x02)
```

Setting and getting the bearer URI supported schemes list

```
uart:~$ ccp_call_control_server get_bearer_uri_schemes
Bearer[0] URI schemes supported list: tel,skype
uart:~$ ccp_call_control_server set_bearer_uri_schemes "tel,teamspeak"
Bearer[0] new URI schemes supported list: tel,teamspeak
```

Call Control Client The Call Control Client is a role that typically resides on resource constrained devices such as earbuds or headsets.

Using the Call Control Client The Client can control a remote CCP server device. For example a remote device may have an incoming call that can be accepted by the Client.

```
uart:~$ ccp_call_control_client --help
ccp_call_control_client - Bluetooth CCP Call Control Client shell commands
Subcommands:
  discover  : Discover GTBS and TBS on remote device
```

Example Usage when connected

```
uart:~$ ccp_call_control_client discover
Discovery completed with GTBS and 1 TBS bearers
```

```
uart:~$ ccp_call_control_client read_bearer_name
Bearer 0x20046254 name: Generic TBS
uart:~$ ccp_call_control_client read_bearer_name 1
Bearer 0x20046256 name: Telephone Bearer #1
uart:~$ ccp_call_control_client read_bearer_uci
Bearer 0x20046254 UCI: un999
uart:~$ ccp_call_control_client read_bearer_uci 1
Bearer 0x20046256 UCI: skype
```

Bluetooth: Coordinated Set Identification Profile Shell This document describes how to run the coordinated set identification functionality, both as a client and as a server. Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

Set Coordinator (Client) The client will typically be a resource-rich device, such as a smartphone or a laptop. The client is able to lock and release members of a coordinated set. While the coordinated set is locked, no other clients may lock the set.

To lock a set, the client must connect to each of the set members it wants to lock. This implementation will always try to connect to all the members of the set, and at the same time. Thus if the set size is 3, then `BT_MAX_CONN` shall be at least 3.

If the locks on set members shall persists through disconnects, it is necessary to bond with the set members. If you need to bond with multiple set members, make sure that `BT_MAX_PAIRED` is correctly configured.

Using the Set Coordinator When the Bluetooth stack has been initialized (`bt init`), and a set member device has been connected, the call control client can be initialized by calling `csip_set_coordinator init`, which will start a discovery for the TBS uuids and store the handles, and optionally subscribe to all notifications (default is to subscribe to all).

Once the client has connected and discovered the handles, then it can read the set information, which is needed to identify other set members. The client can then scan for and connect to the remaining set members, and once all the members has been connected to, it can lock and release the set.

It is necessary to enable `CONFIG_BT_CSIP_SET_COORDINATOR_LOG_LEVEL_DBG` to properly use the set coordinator.

```
csip_set_coordinator --help
csip_set_coordinator - Bluetooth CSIP_SET_COORDINATOR shell commands
```

(continues on next page)

(continued from previous page)

```
Subcommands:
   init              :Initialize CSIP_SET_COORDINATOR
   discover          :Run discover for CSIS on peer device [member_index]
   discover_members  :Scan for set members <set_pointer>
   lock_set          :Lock set
   release_set       :Release set
   lock              :Lock specific member [member_index]
   release           :Release specific member [member_index]
   lock_get          :Get the lock value of the specific member and instance
                      [member_index [inst_idx]]
```

Example usage

Setup

```
uart:~$ init
uart:~$ bt connect P:xx:xx:xx:xx:xx:xx
```

When connected Discovering sets on a device:

```
uart:~$ csip_set_coordinator init
<dbg> bt_csip_set_coordinator.primary_discover_func: [ATTRIBUTE] handle 0x0048

```

Coordinated Set Member (Server) The server on devices that are part of a set, consisting of at least two devices, e.g. a pair of earbuds.

Using the Set Member

```
csip_set_member --help
csip_set_member - Bluetooth CSIP set member shell commands
   Subcommands:
   register           : Initialize the service and register callbacks [size
                        <int>] [rank <int>] [not-lockable] [sirk <data>]
   lock               : Lock the set
   release            : Release the set [force]
   sirk               : Set the currently used SIRK <sirk>
   set_size_and_rank  : Set the currently used size and rank <size> <rank>
   get_info           : Get service info
   sirk_rsp           : Set the response used in SIRK requests <accept,
                        accept_enc, reject, oob>
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ csip_set_member register
```

Setting a new SIRK This command can modify the currently used SIRK. To get the new RSI to advertise on air, `bt adv-data` or `bt advertise` must be called again to set the new advertising data. If `CONFIG_BT_CSIP_SET_MEMBER_SIRK_NOTIFIABLE` is enabled, this will also notify connected clients.

```
uart:~$ csip_set_member sirk 00112233445566778899aabbccddeeff
SIRK updated
```

Setting a new set size and rank This command can modify the set size and rank of a service instance. This shall be done for all device in the set at the same time, and all devices shall have the same set size. The rank will be ignored if the set is not lockable, else the rank shall be <= the set size, and shall be unique for this device in the set.

```
uart:~$ csip_set_member set_size_and_rank 1 1
Set size and rank updated to 1 and 1
```

Getting the current info This command can get the currently used set info.

```
uart:~$ csip_set_member get_info
Info for 0x2003b0c8
        SIRK
00000000: 20 37 0a 00 95 c4 04 20  00 00 00 00 f1 79 09 00 | 7.....  .....y..|
        Set size: 2
        Rank: 1
        Lockable: true
        Locked: false
```

Bluetooth: Gaming Audio Profile Shell This document describes how to run the Gaming Audio Profile shell functionality. Unlike most other low-layer profiles, GMAP is a profile that exists and has a service (GMAS) on all devices. Thus both the initiator and acceptor (or central and peripheral) should do a discovery of the remote device's GMAS to see what GMAP roles and features they support.

Using the GMAP Shell When the Bluetooth stack has been initialized (`bt init`), the GMAS can be registered by by calling `gmap init`. It is also strongly suggested to enable BAP via `bap init`.

```
uart:~$ gmap --help
gmap - Bluetooth GMAP shell commands
Subcommands:
  init      : [none]
  set_role  : [ugt | ugg | bgr | bgs]
  discover  : [none]
  ac_1      : Unicast audio configuration 1
  ac_2      : Unicast audio configuration 2
  ac_3      : Unicast audio configuration 3
  ac_4      : Unicast audio configuration 4
  ac_5      : Unicast audio configuration 5
  ac_6_i    : Unicast audio configuration 6(i)
  ac_6_ii   : Unicast audio configuration 6(ii)
  ac_7_ii   : Unicast audio configuration 7(ii)
  ac_8_i    : Unicast audio configuration 8(i)
  ac_8_ii   : Unicast audio configuration 8(ii)
  ac_11_i   : Unicast audio configuration 11(i)
  ac_11_ii  : Unicast audio configuration 11(ii)
  ac_12     : Broadcast audio configuration 12
```

(continues on next page)

(continued from previous page)

```
  ac_13     : Broadcast audio configuration 13
  ac_14     : Broadcast audio configuration 14
```

The `set_role` command can be used to change the role at runtime, assuming that the device supports the role (the GMAP roles depend on some BAP configurations).

Example Central with GMAP UGT role Connect and establish Gaming Audio streams using Audio Configuration (AC) 3 (some logging has been omitted for clarity):

```
uart:~$ bt init
uart:~$ bap init
uart:~$ gmap init
uart:~$ bt connect <address>
uart:~$ gatt exchange-mtu
uart:~$ bap discover

Bluetooth: Media Control Profile Shell This document describes how to run the media control functionality, using the shell, both as a client and as a server.

The media control server consists of to parts. There is a media player (mpl) that contains the logic to handle media, and there is a media control service (mcs) that serves as a GATT-based interface to the player. The media control client consists of one part, the GATT based client (mcc).

The media control server may include an object transfer service (ots) and the media control client may include an object transfer client (otc). When these are included, a richer set of functionality is available.

The media control server and client both implement the Generic Media Control Service (only), and do not use any underlying Media Control Services.

Note that in the examples below, in many cases the debug output has been removed and long outputs may have been shortened to make the examples shorter and clearer.

Also note that this documentation does not list all shell commands, it just shows examples of some of them. The set of commands is explorable from the mcc shell and the mpl shell, by typing `mcc` or `mpl` and pressing TAB. A help text for each command can be found by doing `mcc <command> help` or `mpl <command> help`.

Overview A media player has a *name* and an *icon* that allows identification of the player for the user.

The content of the media player is structured into tracks and groups. A media player has a number of groups. A group contains tracks and other groups. (In this implementation, a group only contains tracks, not other groups.) Tracks can be divided into segments.

An active player will have a *current track*. This is the track that is playing now (if the player is playing). The current track has a *title*, a *duration* (given in hundredths of a second) and a *position* - the current position of the player within the track.

There is also a *current group* (the group of the current track), a *parent group* (the parent group of the current group) and a *next track*.

The media player is in a *state*, which will be one of playing, paused, seeking or inactive. When playing, playback happens at a given *playback speed*, and the tracks are played according to the *playing order*, which is one of the *playing orders supported*. Track changes are signalled as notifications of the *track changed* characteristic. When seeking (fast forward or fast rewind), the track position is moved according to the *seeking speed*.

The *opcodes supported* tells which operations are supported by the player by writing to the *media control point*. There is also a *search control point* that allows to search for groups and tracks according to various criteria, with the result returned in the *search results*.

Finally, the *content control ID* is used to associate the media player with an audio stream.

Media Control Client (MCP) The media control client is used to control, and to get information from, a media control server. Control is done by writing to one of the two control points, or by writing to other writable characteristics. Getting information is done by reading characteristics, or by configuring the server to send notifications.

Using the media control client Before use, the media control client must be initialized by the command `mcc init`.

To achieve a connection to the peer, the `bt` commands must be used - `bt init` followed by `bt advertise on` (or `bt connect` if the server is advertising).

When the media control client is connected to a media control server, the client can discover the server's Generic Media Control Service, by giving the command `mcc discover_mcs`. This will store the handles of the service, and (optionally, but default) subscribe to all notifications.

After discovery, the media control client can read and write characteristics, including the media control point and the search control point.

Example usage

Setup

```
uart:~$ bt init
Bluetooth initialized

uart:~$ mcc init
MCC init complete

uart:~$ bt advertise on
Advertising started
Connected: R:F6:58:DC:27:F3:57
```

When connected Service discovery (GMCS and included OTS):

```
uart:~$ mcc discover_mcs
<dbg> bt_mcc.bt_mcc_discover_mcs: start discovery of MCS primary service
<dbg> bt_mcc.discover_primary_func: [ATTRIBUTE] handle 0x00ae
<dbg> bt_mcc.discover_primary_func: Primary discovery complete

<dbg> bt_otc.bt_otc_register: L2CAP psm 0x  25 sec_level 1 registered
<dbg> bt_mcc.discover_otc_char_func: Setup complete for OTS 1 / 1
uart:~$
```

Reading characteristics - the player name and the track duration as examples:

```
uart:~$ mcc read_player_name
Player name: My media player
4d 79 20 6d 65 64 69 61  20 70 6c 61 79 65 72    |My media  player

uart:~$ mcc read_track_duration
Track duration: 6300
```

Note that the value of some characteristics may be truncated due to being too long to fit in the ATT packet. Increasing the ATT MTU may help:

```
uart:~$ mcc read_track_title
Track title: Interlude #1 (Song for

uart:~$ gatt exchange-mtu
Exchange pending
Exchange successful

uart:~$ mcc read_track_title
Track title: Interlude #1 (Song for Alison)
```

Writing characteristics - track position as an example:

The track position is where the player "is" in the current track. Read the track position, change it by writing to it, confirm by reading it again.

```
uart:~$ mcc read_track_position
Track Position: 0

uart:~$ mcc set_track_position 500
Track Position: 500

uart:~$ mcc read_track_position
Track Position: 500
```

Controlling the player via the control point:

Writing to the control point allows the client to request the server to do operations like play, pause, fast forward, change track, change group and so on. Some operations (e.g. goto track) take an argument. Currently, raw opcode values are used as input to the control point shell command. These opcode values can be found in the mpl.h header file.

Send the play command (opcode "1"), the command to go to track (opcode "52") number three, and the pause command (opcode "2"):

```
uart:~$ mcc set_cp 1
Media State: 1
Operation: 1, result: 1
Operation: 1, param: 0

uart:~$ mcc set_cp 52 3
Track changed
Track title: Interlude #3 (Levanto Seventy)
Track duration: 7800
Track Position: 0
Current Track Object ID: 0x000000000104
Next Track Object ID: 0x000000000105
Operation: 52, result: 1
Operation: 52, param: 3

uart:~$ mcc set_cp 2
Media State: 2
Operation: 2, result: 1
Operation: 2, param: 0
```

Using the included object transfer client When object transfer is supported by both the client and the server, a larger set of characteristics is available. These include object IDs for the various

track and group objects. These IDs can be used to select and download the corresponding objects from the server's object transfer service.

Read the object ID of the current group object:

```
uart:~$ mcc read_current_group_obj_id
Current Group Object ID: 0x000000000107
```

Select the object with that ID:

```
uart:~$ mcc ots_select 0x107
Selecting object succeeded
```

Read the object's metadata:

```
uart:~$ mcc ots_read_metadata
Reading object metadata succeeded
<inf> bt_mcc: Object's meta data:
<inf> bt_mcc:        Current size    :35
<inf> bt_otc: --- Displaying 1 metadata records ---
<inf> bt_otc: Object ID: 0x000000000107
<inf> bt_otc: Object name: Joe Pass - Guitar Inte
<inf> bt_otc: Object Current Size: 35
<inf> bt_otc: Object Allocate Size: 35
<inf> bt_otc: Type: Group Obj Type
<inf> bt_otc: Properties:0x4
<inf> bt_otc:  - read permitted
```

Read the object itself:

The object received is a group object. It consists of a series of records consisting of a type (track or group) and an object ID.

```
uart:~$ mcc ots_read_current_group_object
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000102
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000103
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000104
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000105
<dbg> bt_mcc.on_group_content: Object type: 0, object  ID: 0x000000000106
```

Search The search control point takes as its input a sequence of search control items, each consisting of length, type (e.g. track name or artist name) and parameter (the track name or artist name to search for). If the result is successful, the search results are stored in an object in the object transfer service. The ID of the search results ID object can be read from the search results object ID characteristic. The search result object can then be downloaded as for the current group object above. (Note that the search results object ID is empty until a search has been done.)

This implementation has a working implementation of the search functionality interface and the server-side search control point parameter parsing. But the **actual searching is faked**, the same results are returned no matter what is searched for.

There are two commands for search, one (`mcc set_scp_raw`) allows to input the search control point parameter (the sequence of search control items) as a string. The other (`mcc set_scp_ioptest`) does preset IOP test searches and takes the round number of the IOP search control point test as a parameter.

Before the search, the search results object ID is empty

```
uart:~$ mcc read_search_results_obj_id
Search Results Object ID: 0x000000000000
<dbg> bt_mcc.mcc_read_search_results_obj_id_cb: Zero-length Search Results Object␣
↪ID
```

Run the search corresponding to the fourth round of the IOP test:

The search control point parameter generated by this command and parameter has one search control item. The length field (first octet) is 16 (0x10). (The length of the length field itself is not included.) The type field (second octet) is 0x04 (search for a group name). The parameter (the group name to search for) is "TSPX_Group_Name".

```
uart:~$ mcc set_scp_ioptest 4
Search string:
00000000: 10 04 54 53 50 58 5f 47  72 6f 75 70 5f 4e 61 6d |..TSPX_G roup_Nam|
00000010: 65                                              |e                |
Search control point notification result code: 1
Search Results Object ID: 0x000000000107
Search Control Point set
```

After the successful search, the search results object ID has a value:

```
uart:~$ mcc read_search_results_obj_id
Search Results Object ID: 0x000000000107
```

Media Control Service (MCS) The media control service (mcs) and the associated media player (mpl) typically reside on devices that can provide access to, and serve, media content, like PCs and smartphones.

As mentioned above, the media player (mpl) has the player logic, while the media control service (mcs) has the GATT-based interface. This separation is done so that the media player can also be used without the GATT-based interface.

Using the media control service and the media player The media control service and the media player are in general controlled remotely, from the media control client.

Before use, the media control client must be initialized by the command `mpl init`.

As for the client, the `bt` commands are used for connecting - `bt init` followed by `bt connect <address> <address type>` (or `bt advertise on` if the server is advertising).

Example Usage

Setup

```
uart:~$ bt init
Bluetooth initialized

uart:~$ mpl init
[Large amounts of debug output]

uart:~$ bt connect R:F9:33:3B:67:D2:A7
Connection pending
Connected: R:F9:33:3B:67:D2:A7
```

When connected Control is done from the client.

The server will give debug output related to the various operations performed by the client.

Example: Debug output by the server when the client gives the "next track" command:

```
[00:13:29.932,373] <dbg> bt_mcs.control_point_write: Opcode: 49
[00:13:29.932,403] <dbg> bt_mpl.mpl_operation_set: opcode: 49, param: 536880068
[00:13:29.932,403] <dbg> bt_mpl.paused_state_operation_handler: Operation opcode:␣
↪49
[00:13:29.932,495] <dbg> bt_mpl.do_next_track: Track ID before: 0x000000000104
[00:13:29.932,586] <dbg> bt_mpl.do_next_track: Track ID after: 0x000000000105
[00:13:29.932,617] <dbg> bt_mcs.mpl_track_changed_cb: Notifying track change
[00:13:29.932,708] <dbg> bt_mcs.mpl_track_title_cb: Notifying track title:␣
↪Interlude #4 (Vesper Dreams)
[00:13:29.932,800] <dbg> bt_mcs.mpl_track_duration_cb: Notifying track duration:␣
↪13500
[00:13:29.932,861] <dbg> bt_mcs.mpl_track_position_cb: Notifying track position: 0
[00:13:29.933,044] <dbg> bt_mcs.mpl_current_track_id_cb: Notifying current track␣
↪ID: 0x000000000105
[00:13:29.933,258] <dbg> bt_mcs.mpl_next_track_id_cb: Notifying next track ID:␣
↪0x000000000106
[00:13:29.933,380] <dbg> bt_mcs.mpl_operation_cb: Notifying control point -␣
↪opcode: 49, result: 1
```

Some server commands are available. These commands force notifications of the various characteristics, for testing that the client receives notifications. The values sent in the notifications caused by these testing commands are independent of the media player, so they do not correspond the actual values of the characteristics nor to the actual state of the media player.

Example: Force (fake value) notification of the track duration:

```
uart:~$ mpl duration_changed_cb
[00:15:17.491,058] <dbg> bt_mcs.mpl_track_duration_cb: Notifying track duration:␣
↪12000
```

Bluetooth: Telephone Bearer Service Shell This document describes how to run the call control functionality, both as a client and as a (telephone bearer service (TBS)) server. Note that in the examples below, some lines of debug have been removed to make this shorter and provide a better overview.

Telephone Bearer Service Client The telephone bearer service client will typically exist on a resource restricted device, such as headphones, but may also exist on e.g. phones or laptops. The call control client will also thus typically be the advertiser. The client can control the states of calls on a server using the call control point.

It is necessary to have `CONFIG_BT_TBS_CLIENT_LOG_LEVEL_DBG` enabled for using the client interactively.

Using the telephone bearer service client When the Bluetooth stack has been initialized (`bt init`), and a device has been connected, the telephone bearer service client can discover TBS on the connected device calling `tbs_client discover`, which will start a discovery for the TBS UUIDs and store the handles, and optionally subscribe to all notifications (default is to subscribe to all).

Since a server may have multiple TBS instances, most of the tbs_client commands will take an index (starting from 0) as input. Joining calls require at least 2 call IDs, and all call indexes shall be on the same TBS instance.

A server will also have a GTBS instance, which is an abstraction layer for all the telephone bearers on the server. If the server has both GTBS and TBS, the client may subscribe and use either when sending requests if `BT_TBS_CLIENT_GTBS` is enabled.

```
tbs_client --help
tbs_client - Bluetooth TBS_CLIENT shell commands
Subcommands:
   discover                        :Discover TBS [subscribe]
   set_signal_reporting_interval   :Set the signal reporting interval
                                    [<{instance_index, gtbs}>] <interval>
   originate                       :Originate a call [<{instance_index, gtbs}>]
                                    <uri>
   terminate                       :terminate a call [<{instance_index, gtbs}>]
                                    <id>
   accept                          :Accept a call [<{instance_index, gtbs}>] <id>
   hold                            :Place a call on hold [<{instance_index,
                                    gtbs}>] <id>
   retrieve                        :Retrieve a held call [<{instance_index,
                                    gtbs}>] <id>
   read_provider_name              :Read the bearer name [<{instance_index,
                                    gtbs}>]
   read_bearer_uci                 :Read the bearer UCI [<{instance_index, gtbs}>]
   read_technology                 :Read the bearer technology [<{instance_index,
                                    gtbs}>]
   read_uri_list                   :Read the bearer's supported URI list
                                    [<{instance_index, gtbs}>]
   read_signal_strength            :Read the bearer signal strength
                                    [<{instance_index, gtbs}>]
   read_signal_interval            :Read the bearer signal strength reporting
                                    interval [<{instance_index, gtbs}>]
   read_current_calls              :Read the current calls [<{instance_index,
                                    gtbs}>]
   read_ccid                       :Read the CCID [<{instance_index, gtbs}>]
   read_status_flags               :Read the in feature and status value
                                    [<{instance_index, gtbs}>]
   read_uri                        :Read the incoming call target URI
                                    [<{instance_index, gtbs}>]
   read_call_state                 :Read the call state [<{instance_index, gtbs}>]
   read_remote_uri                 :Read the incoming remote URI
                                    [<{instance_index, gtbs}>]
   read_friendly_name              :Read the friendly name of an incoming call
                                    [<{instance_index, gtbs}>]
   read_optional_opcodes           :Read the optional opcodes [<{instance_index,
                                    gtbs}>]
```

In the following examples, notifications from GTBS are ignored, unless otherwise specified.

Example usage

Setup

```
uart:~$ bt init
uart:~$ bt advertise on
Advertising started
```

When connected Placing a call:

```
uart:~$ tbs_client discover
<dbg> bt_tbs_client.primary_discover_func: Discover complete, found 1 instances␣
↪(GTBS found)
```

(continues on next page)

(continued from previous page)

```
<dbg> bt_tbs_client.discover_func: Setup complete for 1 / 1 TBS
<dbg> bt_tbs_client.discover_func: Setup complete GTBS
uart:~$ tbs_client originate 0 tel:123
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the dialing␣
↪state with URI tel:123
<dbg> bt_tbs_client.call_cp_notify_handler: Status: success for the originate␣
↪opcode for call 0x00
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the alerting␣
↪state with URI tel:123
<call answered by peer device, and status notified by TBS server>
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the active state␣
↪with URI tel:123
```

Placing a call on GTBS:

```
uart:~$ tbs_client originate 0 tel:123
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the dialing␣
↪state with URI tel:123
<dbg> bt_tbs_client.call_cp_notify_handler: Status: success for the originate␣
↪opcode for call 0x00
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the alerting␣
↪state with URI tel:123
<call answered by peer device, and status notified by TBS server>
<dbg> bt_tbs_client.notify_handler: Index 0
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x01 is in the active state␣
↪with URI tel:123
```

It is necessary to set an outgoing caller ID before placing a call.

Accepting incoming call from peer device:

```
<dbg> bt_tbs_client.incoming_uri_notify_handler: tel:123
<dbg> bt_tbs_client.in_call_notify_handler: tel:456
<dbg> bt_tbs_client.friendly_name_notify_handler: Peter
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x05 is in the incoming␣
↪state with URI tel:456
uart:~$ tbs_client accept 0 5
<dbg> bt_tbs_client.call_cp_callback_handler: Status: success for the accept␣
↪opcode for call 0x05
<dbg> bt_tbs_client.current_calls_notify_handler: Call 0x05 is in the active state␣

```

Telephone Bearer Service (TBS) The telephone bearer service is a service that typically resides on devices that can make calls, including calls from apps such as Skype, e.g. (smart)phones

and PCs.

It is necessary to have CONFIG_BT_TBS_LOG_LEVEL_DBG enabled for using the TBS server interactively.

Using the telephone bearer service TBS can be controlled locally, or by a remote device (when in a call). For example a remote device may initiate a call to the device with the TBS server, or the TBS server may initiate a call to remote device, without a TBS_CLIENT client. The TBS implementation is capable of fully controlling any call. Omitting an index for commands where a <instance_index> can be supplied, defaults to the GTBS bearer.

```
tbs --help
tbs - Bluetooth TBS shell commands
Subcommands:
   init                        :Initialize TBS
   authorize                   :Authorize the current connection
   accept                      :Accept call <call_index>
   terminate                   :Terminate call <call_index>
   hold                        :Hold call <call_index>
   retrieve                    :Retrieve call <call_index>
   originate                   :Originate call [<instance_index>] <uri>
   join                        :Join calls <id> <id> [<id> [<id> [...]]]
   incoming                    :Simulate incoming remote call [<{instance_index,
                                gtbs}>] <local_uri> <remote_uri>
                                <remote_friendly_name>
   remote_answer               :Simulate remote answer outgoing call <call_index>
   remote_retrieve             :Simulate remote retrieve <call_index>
   remote_terminate            :Simulate remote terminate <call_index>
   remote_hold                 :Simulate remote hold <call_index>
   set_bearer_provider_name    :Set the bearer provider name [<{instance_index,
                                gtbs}>] <name>
   set_bearer_technology       :Set the bearer technology [<{instance_index,
                                gtbs}>] <technology>
   set_bearer_signal_strength  :Set the bearer signal strength [<{instance_index,
                                gtbs}>] <strength>
   set_status_flags            :Set the bearer feature and status value
                                [<{instance_index, gtbs}>] <feature_and_status>
   set_uri_scheme              :Set the URI prefix list <bearer_idx>
↪<uri1[,uri2[,uri3[,...]]]>
   print_calls                 :Output all calls in the debug log
```

Example Usage

Setup

```
uart:~$ bt init
uart:~$ bt connect P:xx:xx:xx:xx:xx:xx
```

When connected Answering a call for a peer device originated by a client:

```
<dbg> bt_tbs.write_call_cp: Index 0: Processing the originate opcode
<dbg> bt_tbs.originate_call: New call with call index 1
<dbg> bt_tbs.write_call_cp: Index 0: Processed the originate opcode with status␣
↪success for call index 1
uart:~$ tbs remote_answer 1
TBS succeeded for call_id: 1
```

Incoming call from a peer device, accepted by client:

```
uart:~$ tbs incoming 0 tel:123 tel:456 Peter
TBS succeeded for call_id: 4
<dbg> bt_tbs.bt_tbs_remote_incoming: New call with call index 4
<dbg> bt_tbs.write_call_cp: Index 0: Processed the accept opcode with status␣
↪success for call index 4
```

Bluetooth: Telephone and Media Audio Profile Shell This document describes how to run the Telephone and Media Audio Profile functionality. Unlike most other low-layer profiles, TMAP is a profile that exists and has a service (TMAS) on all devices. Thus both the initiator and acceptor (or central and peripheral) should do a discovery of the remote device's TMAS to see what TMAP roles they support.

Using the TMAP Shell When the Bluetooth stack has been initialized (`bt init`), the TMAS can be registered by calling `tmap init`.

```
tmap --help
tmap - Bluetooth TMAP shell commands
Subcommands:
  init          :Initialize and register the TMAS
  discover      :Discover TMAS on remote device
```

Bluetooth: Public Broadcast Profile Shell This document describes how to run the Public Broadcast Profile functionality. PBP does not have an associated service. Its purpose is to enable a faster, more efficient discovery of Broadcast Sources that are transmitting audio with commonly used codec configurations.

Using the PBP Shell When the Bluetooth stack has been initialized (`bt init`), the Public Broadcast Profile is ready to run. To set the Public Broadcast Announcement features call `pbp set_features`.

```
pbp --help
pbp - Bluetooth PBP shell commands
Subcommands:
  set_features    :Set the Public Broadcast Announcement features
```

Bluetooth: A2DP Shell The `a2dp` command exposes parts of the A2DP API.

The following examples assume that you have two devices already connected.

A2DP Connection Demonstrate the flow of creating an A2DP connection:

- Both sides register A2DP callbacks using `a2dp register_cb`.
- Either side establishes an A2DP connection, which will create the AVDTP Signaling channel, using `a2dp connect`.
- Either side can get the ACL connection using `a2dp get_conn`.
- Either side can disconnect the A2DP connection using `a2dp disconnect`.

Device A (initiator)

```
uart:~$ a2dp register_cb
success
uart:~$ a2dp connect
```

(continues on next page)

(continued from previous page)

```
Bonded with XX:XX:XX:XX:XX:XX
Security changed: XX:XX:XX:XX:XX:XX level 2
a2dp connected
uart:~$ a2dp get_conn
a2dp conn is: 0xXXXXXXXX
uart:~$ a2dp disconnect
a2dp disconnected
```

Device B (acceptor)

```
uart:~$ a2dp register_cb
success
<input `a2dp connect` in initiator side>
Connected: XX:XX:XX:XX:XX:XX
Bonded with XX:XX:XX:XX:XX:XX
Security changed: XX:XX:XX:XX:XX:XX level 2
a2dp connected
<input `a2dp disconnect` in initiator side>
a2dp disconnected
```

Basic A2DP Operations Demonstrate the flow of basic A2DP operations:

- Source and Sink sides register stream endpoints using `a2dp register_ep source sbc` and `a2dp register_ep sink sbc`.
- Create an A2DP connection based on *a2dp connection*.
- Initiator discovers remote device's stream endpoints using `a2dp discover_peer_eps 0x0104`.
- Initiator configures the stream to create the stream after discovering remote endpoints using `a2dp configure`.
- Initiator establishes the stream using `a2dp establish`.
- Sink sends delay report using `a2dp send_delay_report`.
- Initiator starts the media using `a2dp start`.
- Source tests media sending using `a2dp send_media` to send one test packet data.
- Initiator suspends the media using `a2dp suspend`.
- Initiator releases the media using `a2dp release`.

Note

The initiator is the A2DP source role and the acceptor is the A2DP sink role in the following logs. The delay report can only be sent by the sink role. The media data can only be sent by the source role.

Device A (initiator)

```
uart:~$ a2dp register_ep source sbc
SBC source endpoint is registered
uart:~$ a2dp discover_peer_eps 0x0104
endpoint id: 1, (sink), (idle):
  codec type: SBC
  sample frequency:
          44100
```

(continues on next page)

(continued from previous page)

```
          48000
  channel mode:
          Mono
          Stereo
          Joint-Stereo
  Block Length:
          16
  Subbands:
          8
  Allocation Method:
          Loudness
  Bitpool Range: 18 - 35
uart:~$ a2dp configure
success to configure
stream configured
uart:~$ a2dp establish
success to establish
stream established
<input `a2dp send_delay_report` in sink side>
receive delay report and accept
received delay report: 1 1/10ms
uart:~$ a2dp start
success to start
stream started
uart:~$ a2dp send_media
frames num: 1, data length: 160
data: 1, 2, 3, 4, 5, 6 ......
uart:~$ a2dp suspend
success to suspend
stream suspended
uart:~$ a2dp release
success to release
stream released
```

Device B (acceptor)

```
uart:~$ a2dp register_ep sink sbc
SBC sink endpoint is registered
<input `a2dp configure` in initiator side>
receive requesting config and accept
sample rate 44100Hz
stream configured
<input `a2dp establish` in initiator side>
receive requesting establishment and accept
stream established
uart:~$ a2dp send_delay_report
success to send report delay
<input `a2dp start` in initiator side>
receive requesting start and accept
stream started
<input `a2dp send_media` in source side>
received, num of frames: 1, data length: 160
data: 1, 2, 3, 4, 5, 6 ......
<input `a2dp suspend` in initiator side>
receive requesting suspend and accept
stream suspended
```

(continues on next page)

(continued from previous page)

```
<input `a2dp release` in initiator side>
receive requesting release and accept
stream released
```

Abort Operation Demonstrate the abort operation:

- Establish an A2DP stream based on *basic a2dp operations*.
- Initiator aborts the stream using `a2dp abort`.

Device A (initiator)

```
uart:~$ a2dp abort
success to abort
stream released
```

Device B (acceptor)

```
<input `a2dp abort` in initiator side>
receive requesting abort and accept
stream released
```

Get Configuration and Reconfigure Operation Demonstrate the get configuration and reconfigure operations:

- Establish an A2DP stream based on *basic a2dp operations*.
- Initiator gets configuration using `a2dp get_config`.
- Initiator reconfigures the stream using `a2dp reconfigure`.

Device A (initiator)

```
uart:~$ a2dp get_config
get config result: 0
sample rate 44100Hz
uart:~$ a2dp reconfigure
success to configure
stream configured
```

Device B (acceptor)

```
<input `a2dp get_config` in initiator side>
receive get config request and accept
<input `a2dp reconfigure` in initiator side>
receive requesting reconfig and accept
sample rate 44100Hz
stream configured
```

Bluetooth: Classic: AVRCP Shell This document describes how to use the Bluetooth Classic AVRCP (Audio/Video Remote Control Profile) functionality via shell commands. The `avrcp` command exposes both Controller (CT) and Target (TG) roles for exercising AVRCP control and browsing features.

There are two sub-commands: `avrcp ct` and `avrcp tg`. The `avrcp ct` sub-command provides **Controller (CT)** functionality, and `avrcp tg` sub-command provides **Target (TG)** functionality.

Prerequisites Before running the `avrcp` shell, make sure your build enables Bluetooth Classic and the shell. An ACL BR/EDR connection to the peer device must be established first (typically via the general `bt` shell commands) before AVRCP control or browsing connections can be created.

Commands All commands can only be used after the ACL connection has been established except `avrcp ct register_cb` and `avrcp tg register_cb`.

The `avrcp` commands:

```
uart:~$ avrcp
avrcp - Bluetooth AVRCP shell commands
Subcommands:
  connect               : connect AVRCP
  disconnect            : disconnect AVRCP
  browsing_connect      : connect browsing AVRCP
  browsing_disconnect   : disconnect browsing AVRCP
  ct                    : AVRCP CT shell commands
  tg                    : AVRCP TG shell commands
```

The `avrcp ct` commands:

```
uart:~$ avrcp ct
ct - AVRCP CT shell commands
Subcommands:
  register_cb                : register avrcp ct callbacks
  get_unit                   : get unit info
  get_subunit                : get subunit info
  get_caps                   : get capabilities <cap_id: company or events>
  play                       : request a play at the remote player
  pause                      : request a pause at the remote player
  register_notification      : register notify <event_id> [playback_interval]
  set_browsed_player         : set browsed player <player_id>
  get_folder_items           : [none]
  change_path                : [none]
  get_item_attrs             : get item attrs [scope]
  get_total_number_of_items  : get total number of items [scope]
  search                     : search [search_string]
  list_app_attrs             : [none]
  list_app_vals              : List App vals <attr_id>
  get_app_curr               : Get curr player app setting val [attr1] [attr2] ...
  set_app_val                : Set app setting Val <attr1> <val1> [<attr2>
↪<val2>] ...
  get_app_attr_text          : Get app setting attrs text <attr1> [attr2] ...
  get_app_val_text           : Get setting vals Text <attr_id> <val1> [val2] ...
  inform_displayable_char    : Inform Displayable Character Set <charset_id1>␣
↪[charset_id2] ...
  inform_batt                : Inform Battery Status Of CT <Battery status>
  set_absolute_volume        : set absolute volume <volume>
  get_element_attrs          : get element attrs [identifier] [attr1] [attr2] ...
  get_play_status            : [none]
  set_addressed_player       : set addressed player <player_id>
  play_item                  : PlayItem <scope> <uid_hex> <uid_counter>
  add_to_now_playing         : AddToNowPlaying <scope> <uid_hex> <uid_counter>
```

The `avrcp tg` commands:

```
uart:~$ avrcp tg
tg - AVRCP TG shell commands
Subcommands:
  register_cb                              : register avrcp tg callbacks
  send_unit_rsp                            : send unit info response
  send_subunit_rsp                         : [none]
  send_get_caps_rsp                        : send get capabilities response␣
↪[status]
  send_notification_rsp                    : send notify rsp <event_id> <type>␣
↪[value...]
  send_browsed_player_rsp                  : Send SetBrowsedPlayer response
  send_get_folder_items_rsp                : send get folder items [status]
  send_change_path_rsp                     : send change path [status]
  send_get_item_attrs_rsp                  : send get item attrs [status]
  send_get_total_number_of_items_rsp       : send get total number of items␣
↪[status]
  send_search_rsp                          : search [status]
  send_browsing_general_reject             : send browsing general reject␣
↪[reason]
  send_passthrough_rsp                     : send_passthrough_rsp <op/opvu>
↪<opid> <state>
  send_list_player_app_setting_attrs_rsp   : send attrs rsp <num> [attr_id...]
  send_list_player_app_setting_vals_rsp    : send vals rsp <num> [val_id...]
  send_get_curr_player_app_setting_val_rsp : send current vals rsp <num_pairs>␣
↪[attr val]...
  send_set_player_app_setting_val_rsp      : set app setting val rsp [status]
  send_get_player_app_setting_attr_text_rsp : send get player app setting attr␣
↪text rsp [status]
  send_get_player_app_setting_val_text_rsp : send get player app setting val␣
↪text rsp [status]
  send_inform_displayable_char_rsp         : send displayable char rsp [status]
  send_inform_batt_status_of_ct_rsp        : send inform batt rsp [status]
  send_get_element_attrs_rsp               : send get element attrs␣
↪response<large: 1>
  send_absolute_volume_rsp                 : send absolute volume rsp <volume>
  send_get_play_status_rsp                 : send get play status [status]
  send_set_addressed_player_rsp            : send set addressed player rsp␣
↪[status]
  send_play_item_rsp                       : send play item rsp [status]
  send_add_to_now_playing_rsp              : send add to now playing rsp [status]
```

Basic AVRCP Operations

Demonstrate the flow of basic AVRCP operations:

- Both sides register AVRCP callbacks using `avrcp ct register_cb` and `avrcp tg register_cb`.
- Create an AVRCP connection using `avrcp connect`.
- CT gets capabilities from TG using `avrcp ct get_caps events`.
- CT registers for notifications using `avrcp ct register_notification 0x01`.
- CT requests playback control using `avrcp ct play`.
- CT gets current play status using `avrcp ct get_play_status`.
- CT gets element attributes (metadata) using `avrcp ct get_element_attrs`.
- CT sets volume using `avrcp ct set_absolute_volume 50`.

- CT pauses playback using `avrcp ct pause`.

> **Note**
>
> CT (Controller) sends commands and TG (Target) responds. For notification-capable events, TG typically sends an **INTERIM** response immediately after registration to indicate the current value, and later a **CHANGED** response when the value actually changes.

Device A (CT - Controller)

```
uart:~$ avrcp ct register_cb
AVRCP CT callbacks registered
uart:~$ avrcp connect
AVRCP CT connected
uart:~$ avrcp ct get_caps events
GetCapabilities : status=0x04
Remote supported EventID = 0x01
Remote supported EventID = 0x02
Remote supported EventID = 0x0d
uart:~$ avrcp ct register_notification 0x01
Get capabilities command sent successfully: cap_id=events
Sent register notification event_id=0x01
AVRCP notification rsp: tid=0x01, status=0x04, event_id=0x01
 Notification type: INTERIM
 PLAYBACK_STATUS_CHANGED: status=0x00
uart:~$ avrcp ct play
Passthrough PRESSED command sent successfully: opid=0x44
Passthrough RELEASED command sent successfully: opid=0x44
<input `avrcp tg send_passthrough_rsp op play pressed` in TG side>
AVRCP passthrough command accepted, operation id = 0x44, state = 0
<input `avrcp tg send_passthrough_rsp op play released` in TG side>
AVRCP passthrough command accepted, operation id = 0x44, state = 1
<input `avrcp tg send_notification_rsp 0x01 changed 1` in TG side>
AVRCP notification rsp: tid=0x01, status=0x04, event_id=0x01
 Notification type: CHANGED
 PLAYBACK_STATUS_CHANGED: status=0x01
uart:~$ avrcp ct get_play_status
AVRCP GetPlayStatus
getplaystatus : status=0x04
GetPlayStatus: len=180000 ms, pos=30000 ms, status=0x01
 status: PLAYING
uart:~$ avrcp ct get_element_attrs
Requesting element attributes: identifier=0x0000000000000000, num_attrs=0
AVRCP CT get element attrs command sent
GetElementAttributes : status=0x04
AVRCP GetElementAttributes response received, tid=0x05, num_attrs=7
 Attr[0]: ID=0x00000001 (TITLE), charset=0x006a, len=11
   Value: "Test Title"
 Attr[1]: ID=0x00000002 (ARTIST), charset=0x006a, len=11
   Value: "Test Artist"
uart:~$ avrcp ct set_absolute_volume 50
set absolute volume absolute_volume=0x32
AVRCP set absolute volume rsp: tid=0x02, status=0x04, volume=0x32
uart:~$ avrcp ct pause
Passthrough PRESSED command sent successfully: opid=0x46
Passthrough RELEASED command sent successfully: opid=0x46
```

(continues on next page)

(continued from previous page)

```
<input `avrcp tg send_passthrough_rsp op pause pressed` in TG side>
AVRCP passthrough command accepted, operation id = 0x46, state = 0
<input `avrcp tg send_passthrough_rsp op pause released` in TG side>
AVRCP passthrough command accepted, operation id = 0x46, state = 1
```

Device B (TG - Target)

```
uart:~$ avrcp tg register_cb
AVRCP TG callbacks registered
<input `avrcp connect` in CT side>
AVRCP TG connected
<input `avrcp ct get_caps events` in CT side>
AVRCP get capabilities command received: cap_id 0x03 (EVENTS_SUPPORTED)
uart:~$ avrcp tg send_get_caps_rsp
Get capabilities response sent successfully
<input `avrcp ct register_notification 0x01` in CT side>
receive register notification request event_id=0x01
uart:~$ avrcp tg send_notification_rsp 0x01 interim 0
Sent notification rsp event_id=0x01 type=interim
<input `avrcp ct play` in CT side>
receive passthrough command: op_id=0x44 (PLAY)
uart:~$ avrcp tg send_passthrough_rsp op play pressed
Passthrough opid=0x44 (STANDARD), state=pressed sent successfully
uart:~$ avrcp tg send_passthrough_rsp op play released
Passthrough opid=0x44 (STANDARD), state=released sent successfully
uart:~$ avrcp tg send_notification_rsp 0x01 changed 1
Sent notification rsp event_id=0x01 type=changed
<input `avrcp ct get_play_status` in CT side>
receive get play status request
uart:~$ avrcp tg send_get_play_status_rsp
GetPlayStatus rsp sent
<input `avrcp ct get_element_attrs` in CT side>
AVRCP GetElementAttributes command received
uart:~$ avrcp tg send_get_element_attrs_rsp 0
Sending standard GetElementAttributes response (7 attrs)
GetElementAttributes response sent successfully
<input `avrcp ct set_absolute_volume 50` in CT side>
AVRCP set_absolute_volume_req: tid=0x06, absolute_volume=0x32
uart:~$ avrcp tg send_absolute_volume_rsp 50
Set absolute volume response sent successfully
<input `avrcp ct pause` in CT side>
AVRCP passthrough command received: opid = 0x46
uart:~$ avrcp tg send_passthrough_rsp op pause pressed
send passthrough response
uart:~$ avrcp tg send_passthrough_rsp op pause released
send passthrough response
```

AVRCP Connection The AVRCP profile supports both control and browsing connections. The control connection is used for basic remote control functionality, while the browsing connection allows browsing of media content.

Control Connection Establish AVRCP control connection:

1. Register callbacks (CT side):

```
uart:~$ avrcp ct register_cb
AVRCP CT callbacks registered
```

2. Register callbacks (TG side):

```
uart:~$ avrcp tg register_cb
AVRCP TG callbacks registered
```

3. Connect AVRCP:

```
uart:~$ avrcp connect
AVRCP CT connected
AVRCP TG connected
```

4. Disconnect AVRCP:

```
uart:~$ avrcp disconnect
AVRCP CT disconnected
AVRCP TG disconnected
```

Browsing Connection After control connection is established, browsing connection can be initiated:

1. Connect browsing:

```
uart:~$ avrcp browsing_connect
AVRCP browsing connect request sent
AVRCP CT browsing connected
AVRCP TG browsing connected
```

2. Disconnect browsing:

```
uart:~$ avrcp browsing_disconnect
AVRCP browsing disconnect request sent
AVRCP CT browsing disconnected
AVRCP TG browsing disconnected
```

Basic Playback Control Control playback from CT side:

Play Command

```
uart:~$ avrcp ct play
Passthrough PRESSED command sent successfully: opid=0x44
Passthrough RELEASED command sent successfully: opid=0x44
```

Pause Command

```
uart:~$ avrcp ct pause
Passthrough PRESSED command sent successfully: opid=0x46
Passthrough RELEASED command sent successfully: opid=0x46
```

Get Capabilities Query supported capabilities:

Company ID

```
uart:~$ avrcp ct get_caps company
Get capabilities command sent successfully: cap_id=company
```

(continues on next page)

(continued from previous page)

```
GetCapabilities : status=0x04
Remote CompanyID = 0x001958
```

Events Supported

```
uart:~$ avrcp ct get_caps events
Get capabilities command sent successfully: cap_id=events
GetCapabilities : status=0x04
Remote supported EventID = 0x01
Remote supported EventID = 0x02
Remote supported EventID = 0x03
Remote supported EventID = 0x04
Remote supported EventID = 0x0d
```

TG Response

```
uart:~$ avrcp tg send_get_caps_rsp
Sending company ID capability rsp: 0x001958
```

Media Metadata Operations

Get Element Attributes Retrieve metadata for the currently playing media:

CT Request

```
uart:~$ avrcp ct get_element_attrs
Requesting element attributes: identifier=0x0000000000000000, num_attrs=0
AVRCP CT get element attrs command sent
GetElementAttributes : status=0x04
AVRCP GetElementAttributes response received, tid=0x00, num_attrs=7
 Attr[0]: ID=0x00000001 (TITLE), charset=0x006a, len=11
   Value: "Test Title"
 Attr[1]: ID=0x00000002 (ARTIST), charset=0x006a, len=11
   Value: "Test Artist"
 Attr[2]: ID=0x00000003 (ALBUM), charset=0x006a, len=10
   Value: "Test Album"
 Attr[3]: ID=0x00000004 (TRACK_NUMBER), charset=0x006a, len=1
   Value: "1"
 Attr[4]: ID=0x00000005 (TOTAL_TRACKS), charset=0x006a, len=2
   Value: "10"
 Attr[5]: ID=0x00000006 (GENRE), charset=0x006a, len=4
   Value: "Rock"
 Attr[6]: ID=0x00000007 (PLAYING_TIME), charset=0x006a, len=6
   Value: "240000"
```

TG Response

```
uart:~$ avrcp tg send_get_element_attrs_rsp 0
Sending standard GetElementAttributes response (7 attrs)
GetElementAttributes response sent successfully
```

Play Status Get current playback status:

CT Request

```
uart:~$ avrcp ct get_play_status
AVRCP GetPlayStatus
getplaystatus : status=0x04
GetPlayStatus: len=180000 ms, pos=30000 ms, status=0x01
 status: PLAYING
```

TG Response

```
uart:~$ avrcp tg send_get_play_status_rsp
GetPlayStatus rsp sent
```

Volume Control Set absolute volume:

CT Set Volume

```
uart:~$ avrcp ct set_absolute_volume 50
set absolute volume absolute_volume=0x32
AVRCP set absolute volume rsp: tid=0x01, status=0x04, volume=0x32
```

TG Response

```
uart:~$ avrcp tg send_absolute_volume_rsp 50
Set absolute volume response sent successfully
```

Event Notifications Register for notifications and handle events:

Register for Volume Change Notification CT Register

```
uart:~$ avrcp ct register_notification 0x0d
Sent register notification event_id=0x0d
AVRCP notification rsp: tid=0x02, status=0x04, event_id=0x0d
 Notification type: INTERIM
 VOLUME_CHANGED: absolute_volume=0x0a
AVRCP notify_changed_cb received: event_id=0x0d
 Notification type: CHANGED
 VOLUME_CHANGED: absolute_volume=0x14
```

TG Send Notification

```
uart:~$ avrcp tg send_notification_rsp 0x0d interim 10
Sent notification rsp event_id=0x0d type=interim

uart:~$ avrcp tg send_notification_rsp 0x0d changed 20
Sent notification rsp event_id=0x0d type=changed
```

Browsing Operations

Set Browsed Player CT Request

```
uart:~$ avrcp ct set_browsed_player 1
AVRCP send set browsed player req
AVRCP set browsed player success, tid = 0
  UID Counter: 1
  Number of Items: 100
  Charset ID: 0x006A
```

(continues on next page)

(continued from previous page)

```
  Folder Depth: 1
  charset_id  : 0x006A
  Get folder Name (hex)  :
00000000: 4d 75 73 69 63                                  |Music           |
```

TG Response

```
uart:~$ avrcp tg send_browsed_player_rsp
Send set browsed player response, status = 0x04
```

Get Folder Items CT Request

```
uart:~$ avrcp ct get_folder_items
Sent GetFolderItems command
AVRCP get folder items success, tid = 1
  UID Counter: 1
  Number of Items: 1
Media Player Item:
  item_len   : 28
  player_id   : 1
  major_type  : 0x01
  sub_type    : 0x00000000
  play_status : 0x00
  charset_id  : 0x006A
  name_len    : 4
  charset_id  : 0x006A
  Name (hex)  :
00000000: 44:65:6d:6f                                     |Demo
```

TG Response

```
uart:~$ avrcp tg send_get_folder_items_rsp
TG: Sent GetFolderItems response
```

Player Application Settings List and get configure player application settings:

List Available Settings CT Request

```
uart:~$ avrcp ct list_app_attrs
Sent list player app setting attrs
list player app setting attrs : status=0x04
attr =0x01 (EQUALIZER)
attr =0x02 (REPEAT_MODE)
```

TG Response

```
uart:~$ avrcp tg send_list_player_app_setting_attrs_rsp 2 0x01 0x02
TG: Sent list player app setting attrs response
```

Get Current Settings CT Request

```
uart:~$ avrcp ct get_app_curr 1 2
Sent get_curr_player_app_setting_val num=2
get curr player app setting val : status=0x04
```

(continues on next page)

(continued from previous page)

```
attr_id :1 val 1
attr_id :2 val 1
```

TG Response

```
uart:~$ avrcp tg send_get_curr_player_app_setting_val_rsp 2 0x01 0x01 0x02 0x02
TG: Send get curr player app setting val rsp (num=2)
```

Bluetooth: Classic: GOEP Shell This document describes how to run the Bluetooth Classic GOEP functionality. The goep command exposes the Bluetooth Classic GOEP Shell commands.

Commands The goep commands:

```
uart:~$ goep
goep - Bluetooth GOEP shell commands
Subcommands:
  register-rfcomm    : <channel>
  connect-rfcomm     : <channel>
  disconnect-rfcomm  :
  register-l2cap     : <psm>
  connect-l2cap      : <psm>
  disconnect-l2cap   :
  alloc-buf          : Alloc tx buffer
  release-buf        : Free allocated tx buffer
  add-header         : Adding header sets
  client             : Client sets
  server             : Server sets
```

The `goep client` commands:

```
uart:~$ goep client
client - Client sets
Subcommands:
  conn     : <mopl>
  disconn  :
  put      : <final: true, false>
  get      : <final: true, false>
  abort    :
  setpath  : [parent] [create]
  action   : <final: true, false>
```

The `goep server` commands:

```
uart:~$ goep server
server - Server sets
Subcommands:
  reg      : [UUID 128]
  unreg    :
  conn     : <rsp: continue, success, error> <mopl> [rsp_code]
  disconn  : <rsp: continue, success, error> [rsp_code]
  put      : <rsp: continue, success, error> [rsp_code]
  get      : <rsp: continue, success, error> [rsp_code]
  abort    : <rsp: continue, success, error> [rsp_code]
  setpath  : <rsp: continue, success, error> [rsp_code]
  action   : <rsp: continue, success, error> [rsp_code]
```

Connect GOEP Transport The ACL connection should be established before creating the GOEP transport connection.

The transport is based on L2CAP Channel:

L2CAP Server

```
uart:~$ goep register-l2cap 0
L2CAP server (psm 1001) is registered
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

L2CAP Client

```
uart:~$ goep connect-l2cap 1001
GOEP L2CAP connection pending
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

The transport is based on RFCOMM Channel:

RFCOMM Server

```
uart:~$ goep register-rfcomm 0
RFCOMM server (channel 06) is registered
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

RFCOMM Client

```
uart:~$ goep connect-rfcomm 6
GOEP RFCOMM connection pending
Security changed: XX:XX:XX:XX:XX:XX level 2
GOEP 0x20005600 transport connected on 0x20004dc8
uart:~$
```

Disconnect GOEP transport The transport is based on L2CAP Channel:

One Side

```
GOEP 0x20005600 transport disconnected
uart:~$
```

Another Side

```
uart:~$ goep disconnect-l2cap
GOEP L2CAP disconnection pending
GOEP 0x20005600 transport disconnected
uart:~$
```

The transport is based on RFCOMM Channel:

One Side

```
GOEP 0x20005600 transport disconnected
uart:~$
```

Another Side

```
uart:~$ goep disconnect-rfcomm
GOEP RFCOMM disconnection pending
GOEP 0x20005600 transport disconnected
uart:~$
```

Connect to OBEX Server OBEX Server

```
uart:~$ goep server reg
uart:~$
OBEX server 0x20005850 conn req, version 10, mopl 00ff
uart:~$ goep server conn success 255
uart:~$
```

OBEX Client

```
uart:~$ goep client conn 255
OBEX client 0x20005818 conn rsp, rsp_code Success, version 10, mopl 00ff
uart:~$
```

Disconnect from OBEX Server OBEX Server

```
OBEX server 0x20005850 disconn req
uart:~$ goep server disconn success
uart:~$
```

OBEX Client

```
uart:~$ goep client disconn
OBEX client 0x20005818 disconn rsp, rsp_code Success
uart:~$
```

uart:~$
```

Bluetooth: Classic: HFP Shell This document describes how to run the Bluetooth Classic HFP functionality. The `hfp` command exposes the Bluetooth Classic HFP Shell commands.

There are two sub-commands, `hfp hf` and `hfp ag`.

The `hfp hf` is for Hands-Free Profile (HF) functionality, and the `hfp ag` is for Audio Gateway (AG) functionality.

Commands All commands can only be used after the ACL connection has been established except `hfp hf reg` and `hfp ag reg`.

The `hfp` commands:

```
uart:~$ hfp
hfp - Bluetooth HFP shell commands
Subcommands:
  hf  : HFP HF shell commands
  ag  : HFP AG shell commands
```

The `hfp hf` commands:

```
uart:~$ hfp hf
hf - HFP HF shell commands
Subcommands:
  reg                           : [none]
  connect                       : <channel>
```

(continues on next page)

(continued from previous page)

```
  disconnect                    : [none]
  sco_disconnect                : [none]
  cli                           : <enable/disable>
  vgm                           : <gain>
  vgs                           : <gain>
  operator                      : [none]
  audio_connect                 : [none]
  auto_select_codec             : <enable/disable>
  select_codec                  : Codec ID
  set_codecs                    : Codec ID Map
  accept                        : <call index>
  reject                        : <call index>

```

HFP AG SLC The `hfp ag` subcommand provides functionality for HFP AG in Bluetooth Classic.

1. Register HFP AG:

```
uart:~$ hfp ag reg
```

2. Connect to HFP HF:

```
uart:~$ hfp ag connect 1
```

3. Connection is established with the HF device:

```
Security changed: XX:XX:XX:XX:XX:XX level 2
AG received codec id bit map 2
AG connected
AG received vgm 0
AG received vgs 0
```

4. Disconnect from HFP HF:

```
uart:~$ hfp ag disconnect
```

5. Connection is broken:

```
AG disconnected
```

HFP HF SLC The `hfp hf` subcommand provides functionality for HFP HF in Bluetooth Classic.

1. Register HFP HF:

```
uart:~$ hfp hf reg
```

2. Connect to HFP AG:

```
uart:~$ hfp hf connect 2
```

3. Connection is established with the AG device:

```
Security changed: XX:XX:XX:XX:XX:XX level 2
HF service 0
HF signal 0
HF roam 0
HF battery 0
HF ring: in-band
HF connected
```

4. Disconnect from HFP HF:

```
uart:~$ hfp hf disconnect
```

5. Connection is broken:

```
HF disconnected
```

Call outgoing Place a call with the Phone number supplied by the AG:

Outgoing Call Sequence on AG side

```
uart:~$ hfp ag outgoing 123456
AG outgoing call 0x20007690, number 123456
AG SCO connected 0x20005248
AG SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
uart:~$ hfp ag remote_ringing 0
AG call 0x20007690 start ringing mode 1
uart:~$ hfp ag remote_accept 0
AG call 0x20007690 accept
```

Outgoing Call Sequence on HF side

```
uart:~$ hfp hf auto_select_codec enable
HF call 0x20007408 outgoing
codec negotiation: 1
codec auto selected: id 1
HF SCO connected 0x20005248
HF SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
HF remote call 0x20007408 start ringing
HF call 0x20007408 accepted
```

Place a call with the Phone number supplied by the HF:

Outgoing Call Sequence on AG side

```
uart:~$
AG number call
AG outgoing call 0x20007690, number 123456789
AG SCO connected 0x20005248
AG SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
```

(continues on next page)

(continued from previous page)

```
uart:~$ hfp ag remote_ringing 0
AG call 0x20007690 start ringing mode 1
uart:~$ hfp ag remote_accept 0
AG call 0x20007690 accept
```

Outgoing Call Sequence on HF side

```
uart:~$ hfp hf auto_select_codec enable
uart:~$ hfp hf number_call 123456789
HF start dialing call: err 0
HF call 0x20007408 outgoing
codec negotiation: 1

HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 accepted
```

Answer incoming call from the HF:

Incoming Call Sequence on AG side

```
uart:~$ hfp ag remote_incoming 123456
AG incoming call 0x20007690, number 123456
AG codec negotiation result 0
AG call 0x20007690 start ringing mode 1
AG SCO connected 0x20005248
AG SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
AG call 0x20007690 accept
```

Incoming Call Sequence on HF side

```
uart:~$ hfp hf auto_select_codec enable
HF call 0x20007408 incoming
codec negotiation: 1
codec auto selected: id 1
HF SCO connected 0x20005248
HF SCO info:
  SCO handle 0x0008
  SCO air mode 2
  SCO link type 2
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
HF call 0x20007408 ring
HF call 0x20007408 CLIP 123456 0
uart:~$ hfp hf accept 0
HF call 0x20007408 accepted
```

Call termination After the call (outgoing or incoming) is accepted, it can be terminated from either the AG (Audio Gateway) or HF (Hands-Free) side.

Terminate a call process from the AG:

Call termination on AG side

```
uart:~$ hfp ag terminate 0
AG call 0x20007690 terminate
AG SCO disconnected 0x20005248 (reason 22)
```

Call termination on HF side

```
HF call 0x20007408 terminated
HF SCO disconnected 0x20005248 (reason 22)
```

Terminate a call process from the HF:

Call termination on AG side

```
AG call 0x20007690 terminate
AG SCO disconnected 0x20005248 (reason 22)
```

Call termination on HF side

```
uart:~$ hfp hf terminate 0
HF call 0x20007408 terminated
HF SCO disconnected 0x20005248 (reason 22)
```

Terminate a call process from the remote:

Call termination on AG side

```
uart:~$ hfp ag remote_terminate 0
AG call 0x20007690 terminate
AG SCO disconnected 0x20005248 (reason 22)
```

Call termination on HF side

```
HF call 0x20007408 terminated
HF SCO disconnected 0x20005248 (reason 22)
```

Bluetooth: Classic: L2CAP Shell This document describes how to run the Bluetooth Classic L2CAP functionality. The `br l2cap` command exposes the Bluetooth Classic L2CAP Shell commands.

Commands The `br l2cap` commands:

```
uart:~$ br l2cap
l2cap - [none]
Subcommands:
  register    : <psm> <mode: none, ret, fc, eret, stream> [hold_credit]
                [mode_optional] [extended_control]
  connect     : <psm> <mode: none, ret, fc, eret, stream> [hold_credit]
                [mode_optional] [extended_control]
  disconnect  : [none]
  send        : [number of packets] [length of packet(s)]
  credits     : [none]
  echo        : L2CAP BR ECHO commands
  connless    : L2CAP connectionless commands
```

The `br l2cap echo` commands:

```
uart:~$ br l2cap echo
echo - L2CAP BR ECHO commands
```

(continues on next page)

(continued from previous page)

```
Subcommands:
  register    : [none]
  unregister  : [none]
  req         : <length of data>
  rsp         : <identifier> <length of data>
```

The `br l2cap connless` commands:

```
uart:~$ br l2cap connless
connless - L2CAP connectionless commands
Subcommands:
  register    : <psm> [sec level]
  unregister  : [none]
  send        : <psm> <length of data>
```

Connection-oriented L2CAP

1. [Server] Register L2CAP Server:

When the Bluetooth stack has been initialized (`bt init`), the L2CAP server can be registered by calling `br l2cap register`.

```
uart:~$ br l2cap register 1001 none
L2CAP psm 4097 registered
```

2. [Client] Create L2CAP connection:

The command can only be used after the ACL connection has been established.

```
uart:~$ br l2cap connect 1001 none
L2CAP connection pending
```

3. L2CAP connection is established:

```
uart:~$
Security changed: XX:XX:XX:XX:XX:XX level 2
Incoming BR/EDR conn 0x20004848
Channel 0x20000b18 connected
It is basic mode
```

3. Send L2CAP data to remote:

```
uart:~$ br l2cap send
Rem 0
```

4. L2CAP data is received:

```
uart:~$
Incoming data channel 0x20000b18 len 200
00000000: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000010: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000020: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000030: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000040: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000050: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000060: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000070: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
00000080: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
```

(continues on next page)

(continued from previous page)

```
00000090: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
000000A0: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
000000B0: 00 00 00 00 00 00 00 00  00 00 00 00 00 00 00 00 |........ ........|
000000C0: 00 00 00 00 00 00 00 00                          |........         |
```

5. Disconnect L2CAP connection:

```
uart:~$ br l2cap disconnect
```

6. L2CAP connection is broken:

```
Channel 0x20000b18 disconnected
```

L2CAP echo The echo subcommand provides functionality for L2CAP echo requests and responses in Bluetooth Classic.

The commands can only be used after the ACL connection has been established.

1. Listen for L2CAP echo request an L2CAP echo response:

```
uart:~$ br l2cap echo register
```

2. Stop listening for L2CAP echo request an L2CAP echo response:

```
uart:~$ br l2cap echo unregister
```

3. Send L2CAP echo request:

```
uart:~$ br l2cap echo req 1
```

4. Echo request is received:

```
Incoming ECHO REQ data identifier 4 len 1
00000000: 00                                               |.                |
```

5. Send L2CAP echo response:

```
uart:~$ br l2cap echo rsp 4 1
```

6. Echo response is received:

```
uart:~$
Incoming ECHO RSP data len 1
00000000: 00                                               |.                |
```

Connectionless L2CAP The connless subcommand provides functionality for connectionless L2CAP communication in Bluetooth Classic, allowing packet transmission without establishing a L2CAP connection.

The subcommand is controlled by `CONFIG_BT_L2CAP_CONNLESS`.

The commands can only be used after the ACL connection has been established.

1. Listen for connectionless L2CAP packets:

```
uart:~$ br l2cap connless register 1001
Register connectionless callbacks with PSM 0x1001
```

2. Send data

```
uart:~$ br l2cap connless send 1001 1
Sending connectionless data with PSM 0x1001
```

3. Connectionless data is received:

```
Incoming connectionless data psm 0x1001 len 1
00000000: 00                                              |.               |
```

Bluetooth: MAP Shell This document describes how to run the Bluetooth Classic MAP (Message Access Profile) shell functionality. The `map` command exposes the Bluetooth Classic MAP shell commands.

Commands

Main Commands

The `map` commands:

```
uart:~$ map
map - Bluetooth MAP shell commands
Subcommands:
  add_header  : Adding header sets
  mce         : MCE commands
  mse         : MSE commands
```

MCE Commands

The `map mce` commands:

```
uart:~$ map mce
mce - MCE commands
Subcommands:
  mas  : MCE MAS commands
  mns  : MCE MNS commands
```

MCE MAS Commands

The `map mce mas` commands:

```
uart:~$ map mce mas
mas - MCE MAS commands
Subcommands:
  discover            : [none]
  select              : <instance_id>
  rfcomm_connect      : <channel> <instance_id> [supported_features]
  rfcomm_disconnect   : [none]
  l2cap_connect       : <psm> <instance_id> [supported_features]
  l2cap_disconnect    : [none]
  connect             : [none]
  disconnect          : [none]
  abort               : [none]
  set_folder          : <path: "/" | ".." | "../folder" | "folder">
  set_ntf_reg         : [none]
  get_folder_listing  : [srmp]
  get_msg_listing     : [name <folder_name>] [srmp]
  get_msg             : <msg_handle> [srmp]
  set_msg_status      : <msg_handle>
  push_msg            : [folder_name]
  update_inbox        : [none]
  get_mas_inst_info   : [srmp]
```

(continues on next page)

(continued from previous page)

```
  set_owner_status    : [none]
  get_owner_status    : [srmp]
  get_convo_listing   : [srmp]
  set_ntf_filter      : [none]
```

MCE MNS Commands The `map mce mns` commands:

```
uart:~$ map mce mns
mns - MCE MNS commands
Subcommands:
  register           : [none]
  rfcomm_register    : [none]
  rfcomm_disconnect  : [none]
  l2cap_register     : [none]
  l2cap_disconnect   : [none]
  connect            : <rsp: success, error> [rsp_code]
  disconnect         : <rsp: success, error> [rsp_code]
  abort              : <rsp: success, error> [rsp_code]
  send_event         : <rsp: noerror, error> [rsp_code] [srmp]
```

MSE Commands The `map mse` commands:

```
uart:~$ map mse
mse - MSE commands
Subcommands:
  mas  : MSE MAS commands
  mns  : MSE MNS commands
```

MSE MAS Commands The `map mse mas` commands:

```
uart:~$ map mse mas
mas - MSE MAS commands
Subcommands:
  select              : <instance_id>
  register            : [none]
  rfcomm_register     : [none]
  rfcomm_disconnect   : [none]
  l2cap_register      : [none]
  l2cap_disconnect    : [none]
  connect             : <rsp: success, error> [rsp_code]
  disconnect          : <rsp: success, error> [rsp_code]
  abort               : <rsp: success, error> [rsp_code]
  set_folder          : <rsp: success, error> [rsp_code]
  set_ntf_reg         : <rsp: noerror, error> [rsp_code]
  get_folder_listing  : <rsp: noerror, error> [rsp_code] [srmp]
  get_msg_listing     : <rsp: noerror, error> [rsp_code] [srmp]
  get_msg             : <rsp: noerror, error> [rsp_code] [srmp]
  set_msg_status      : <rsp: noerror, error> [rsp_code]
  push_msg            : <rsp: noerror, error> [rsp_code] [srmp]
  update_inbox        : <rsp: noerror, error> [rsp_code]
  get_mas_inst_info   : <rsp: noerror, error> [rsp_code] [srmp]
  set_owner_status    : <rsp: noerror, error> [rsp_code]
  get_owner_status    : <rsp: noerror, error> [rsp_code] [srmp]
  get_convo_listing   : <rsp: noerror, error> [rsp_code] [srmp]
  set_ntf_filter      : <rsp: noerror, error> [rsp_code]
```

MSE MNS Commands The `map mse mns` commands:

```
uart:~$ map mse mns
mns - MSE MNS commands
Subcommands:
  discover            : [none]
  rfcomm_connect      : <channel> [supported_features]
  rfcomm_disconnect   : [none]
  l2cap_connect       : <psm> [supported_features]
  l2cap_disconnect    : [none]
  connect             : [none]
  disconnect          : [none]
  abort               : [none]
  send_event          : [none]
```

Application Parameter Commands The `map add_header app_param` commands:

```
uart:~$ map add_header app_param
app_param - Application parameter commands
Subcommands:
  list                          : List all added application parameters
  clear                         : Clear all application parameters
  max_list_count                : <count: 0-65535>
  list_start_offset             : <offset: 0-65535>
  filter_msg_type               : <type_mask: hex>
  filter_period_begin           : <time: YYYYMMDDTHHMMSS[+/-HHMM]>
  filter_period_end             : <time: YYYYMMDDTHHMMSS[+/-HHMM]>
  filter_read_status            : <no_filter/unread/read>
  filter_recipient              : <recipient_address>
  filter_originator             : <originator_address>
  filter_priority               : <no_filter/high/non_high>
  attachment                    : <on/off>
  transparent                   : <on/off>
  retry                         : <on/off>
  new_message                   : <on/off>
  notification_status           : <on/off>
  mas_instance_id               : <id: 0-255>
  parameter_mask                : <mask: hex>
  folder_listing_size           : <size: 0-65535>
  listing_size                  : <size: 0-65535>
  subject_length                : <length: 0-255>
  charset                       : <native/utf8>
  fraction_request              : <first/next>
  fraction_deliver              : <more/last>
  status_indicator              : <read/deleted/extended>
  status_value                  : <yes/no>
  mse_time                      : <time: YYYYMMDDTHHMMSS[+/-HHMM]>

  map_supported_features        : [none]
  message_handle                : <handle_string: max 16 chars>
  modify_text                   : <prepend/replace>
```

Usage Examples

SDP Discovery

MCE Discover MSE The MCE can discover MSE services on the remote device:

```
uart:~$ map mce mas discover
Found RFCOMM channel 0x06
Found GOEP L2CAP PSM 0x1003
Found MAP profile version 0x0104
Found MAP features 0x007fffff
Found service name: MAP MAS 0
Found MAP instance ID 0
Found MAP MSG type 0x1f
uart:~$
```

MSE Discover MCE The MSE can discover MCE services on the remote device:

```
uart:~$ map mse mns discover
Found RFCOMM channel 0x06
Found GOEP L2CAP PSM 0x1003
Found MAP profile version 0x0104
Found MAP features 0x0077ffff
Found service name: MAP MNS
uart:~$
```

Connect MAP Transport The ACL connection should be established before creating the MAP transport connection.

MAS Transport Connection

RFCOMM Transport MCE

```
uart:~$ map mce mas rfcomm_connect 6 0 7fffff
Security changed: XX:XX:XX:XX:XX:XX level 2
MCE MAS RFCOMM connected: 0x20005a00, addr: XX:XX:XX:XX:XX:XX, instance_id: 0
Selected MCE MAS instance_id 0 as default
uart:~$
```

MSE

```
uart:~$ map mse mas register
MSE MAS server(s) registered
```

(continues on next page)

(continued from previous page)

```
uart:~$ map mse mas rfcomm_register
RFCOMM server (channel 06, mas_instance_id 0, map_supported_features 007fffff) is␣
↪registered
MSE MAS SDP record 0 registered
RFCOMM server (channel 07, mas_instance_id 1, map_supported_features 007fffff) is␣
↪registered
MSE MAS SDP record 1 registered
Security changed: XX:XX:XX:XX:XX:XX level 2
MSE MAS RFCOMM connected: 0x20005c00, addr: XX:XX:XX:XX:XX:XX, instance_id: 0
Selected MSE MAS instance_id 0 as default
uart:~$
```

L2CAP Transport MCE

```
uart:~$ map mce mas l2cap_connect 1003 0 7fffff
Security changed: XX:XX:XX:XX:XX:XX level 2
MCE MAS L2CAP connected: 0x20005a00, addr: XX:XX:XX:XX:XX:XX, instance_id: 0
Selected MCE MAS instance_id 0 as default
uart:~$
```

MSE

```
uart:~$ map mse mas register
MSE MAS server(s) registered
uart:~$ map mse mas l2cap_register
L2CAP server (psm 1003, mas_instance_id 0, map_supported_features 007fffff) is␣
↪registered
MSE MAS SDP record 0 registered
L2CAP server (psm 1005, mas_instance_id 1, map_supported_features 007fffff) is␣
↪registered
MSE MAS SDP record 1 registered
Security changed: XX:XX:XX:XX:XX:XX level 2
MSE MAS L2CAP connected: 0x20005c00, addr: XX:XX:XX:XX:XX:XX, instance_id: 0
Selected MSE MAS instance_id 0 as default
uart:~$
```

MNS Transport Connection

RFCOMM Transport MCE

```
uart:~$ map mce mns register
MCE MNS server(s) registered
uart:~$ map mce mns rfcomm_register
RFCOMM server (channel 06, map_supported_features 0077ffff) is registered
MCE MNS SDP record registered
MCE MNS RFCOMM connected: 0x20005b00, addr: XX:XX:XX:XX:XX:XX
uart:~$
```

MSE

```
uart:~$ map mse mns rfcomm_connect 6 77ffff
MSE MNS RFCOMM connected: 0x20005d00, addr: XX:XX:XX:XX:XX:XX
uart:~$
```

L2CAP Transport MCE

```
uart:~$ map mce mns register
MCE MNS server(s) registered
uart:~$ map mce mns l2cap_register
L2CAP server (psm 1003, map_supported_features 0077ffff) is registered
MCE MNS SDP record registered
MCE MNS L2CAP connected: 0x20005b00, addr: XX:XX:XX:XX:XX:XX
uart:~$
```

MSE

```
uart:~$ map mse mns l2cap_connect 1003 77ffff
MSE MNS L2CAP connected: 0x20005d00, addr: XX:XX:XX:XX:XX:XX
uart:~$
```

Disconnect MAP Transport

MAS Transport Disconnection

RFCOMM Transport (MCE initiates) MCE

```
uart:~$ map mce mas rfcomm_disconnect
MCE MAS RFCOMM disconnected: 0x20005a00
No connected MCE MAS instance available for conn XX:XX:XX:XX:XX:XX
uart:~$
```

MSE

```

uart:~$ map mce mns send_event noerror
uart:~$
```

Application Parameters The MAP shell provides commands to add application parameters to requests. These parameters must be added before sending the corresponding operation command.

Adding Application Parameters Application parameters can be added using the `map add_header app_param` commands:

```
uart:~$ map add_header app_param max_list_count 10
Added MaxListCount: 10
uart:~$ map add_header app_param list_start_offset 0
Added ListStartOffset: 0
uart:~$ map add_header app_param charset utf8
Added Charset: utf8 (1)
uart:~$
```

Listing Application Parameters To view all added application parameters:

```
uart:~$ map add_header app_param list
Added application parameters (3):
  [0] Tag=0x01, Len=2
00000000: 00 0a                                           |..              |
  [1] Tag=0x02, Len=2
00000000: 00 00                                           |..              |
  [2] Tag=0x14, Len=1
00000000: 01                                              |.               |
uart:~$
```

Clearing Application Parameters To clear all added application parameters:

```
uart:~$ map add_header app_param clear
Cleared all application parameters
uart:~$
```

Example: Get Message Listing with Filters

```
uart:~$ map add_header app_param max_list_count 10
Added MaxListCount: 10
uart:~$ map add_header app_param filter_msg_type 1f
Added FilterMessageType: 0x1f
  EMAIL=Y, SMS_GSM=Y, SMS_CDMA=Y, MMS=Y, IM=Y
uart:~$ map add_header app_param filter_read_status unread
Added FilterReadStatus: unread (1)
uart:~$ map mce mas get_msg_listing
MCE MAS 0x20005a00 get_msg_listing rsp, rsp_code Continue, data len 252
```

(continues on next page)

(continued from previous page)

```
...
uart:~$ map add_header app_param clear
Cleared all application parameters
uart:~$
```

Additional Information

RFCOMM vs L2CAP Transport

RFCOMM Transport For GET or PUT operations, the same shell command must be called multiple times until the complete message is delivered.

L2CAP Transport with SRM When SRM (Single Response Mode) is enabled, GET requests do not need to be repeated, and the server sends all response packets. For PUT operations, the client sends all request packets without waiting for intermediate responses, and the server sends a single response upon receiving the final PUT request.

L2CAP Transport with SRM and SRMP When both SRM and SRMP (Single Response Mode Parameter) are enabled, GET requests and PUT responses need to continue sending until SRMP is disabled.

SRM (Single Response Mode) SRM is automatically enabled on L2CAP transport (GOEP v2.0).

GET Operations When SRM is enabled for GET operations:

- The client sends a single GET request.
- The server sends multiple response packets without waiting for additional requests.
- The `srmp` parameter can be used to control the flow (wait for next request).

PUT Operations When SRM is enabled for PUT operations:

- The client sends multiple PUT requests without waiting for additional responses.
- The server sends a single PUT response when receiving the final PUT request.
- The `srmp` parameter can be used to control the flow (wait for next response).

Multiple Instance Support The MAP shell supports multiple MAS instances:

- MCE can connect to multiple MSE MAS instances simultaneously
- MSE can register multiple MAS instances with different instance IDs
- Use the `select` command to switch between instances

```
uart:~$ map mce mas select 0
Selected MCE MAS instance_id 0 as default
uart:~$
```

Bluetooth: Classic: PBAP Shell This document describes how to run the Bluetooth Classic PBAP (Phonebook Access Profile) functionality. The `pbap` command exposes the Bluetooth Classic PBAP Shell commands.

There are two sub-commands, `pbap pce` and `pbap pse`.

The `pbap pce` is for Phonebook Client Equipment (PCE) functionality, and the `pbap pse` is for Phonebook Server Equipment (PSE) functionality.

Commands All commands can only be used after the ACL connection has been established except `pbap pce sdp_reg` and `pbap pse rfcomm_register` and `pbap pse l2cap_register`.

The `pbap` commands:

```
uart:~$ pbap
pbap - Bluetooth pbap shell commands
Subcommands:
  alloc_buf                       : Alloc tx buffer
  release_buf                     : Free allocated tx buffer
  pce                             : Client sets
  pse                             : Server sets
  add_header_auth_challenge       : <password>
  add_header_auth_response        : <password>
  add_ap                          : add application param
```

The `pbap pce` commands:

```
uart:~$ pbap pce
pce - Client sets
Subcommands:
  sdp_reg                         : [none]
  sdp_discover                    : [none]
  connect_rfcomm                  : <channel>
  disconnect_rfcomm               : [none]
  connect_l2cap                   : <channel>
  disconnect_l2cap                : [none]
  connect                         : <mopl>
  disconnect                      : [none]
  pull_pb                         : <name> [srmp]
  pull_vcard_listing              : <name> [srmp]
  pull_vcard_entry                : <name> [srmp]
  set_phone_book                  : <Flags> [name]
  abort                           : [none]
```

The `pbap pse` commands:

```
uart:~$ pbap pse
pse - Server sets
Subcommands:
  rfcomm_register                 : [none]
  l2cap_register                  : [none]
  register                        : [none]
  connect_rsp                     : <mopl> <rsp: unauth,success,error> [rsp_code]
  disconnect_rsp                  : <rsp: success,error> [rsp_code]
  pull_phone_book_rsp             : <rsp: noerror, error> [rsp_code] [srmp]
  pull_vcard_listing_rsp          : <rsp: noerror, error> [rsp_code] [srmp]
  pull_vcard_entry_rsp            : <rsp: noerror, error> [rsp_code] [srmp]
  set_phone_book_rsp              : <rsp: success, error> [rsp_code]
  abort_rsp                       : <rsp: success, error> [rsp_code]
```

The pbap add_ap (Application Parameters) commands:

```
uart:~$ pbap add_ap
add_ap - add application param
Subcommands:
  Order                          : <indexed/alphanumeric/phonetic>
  SearchValue                    : <text>
  SearchAttribute                : <name/number/sound>
  MaxListCount                   : <0x0000-0xffff>
  ListStartOffset                : <0x0000-0xffff>
  PropertySelector               : <64 bits mask :␣
↪bt_pbap_appl_param_property_mask>
  Format                         : <v2.1/v3.0>
  PhonebookSize                  : <0x0000-0xffff>
  NewMissedCalls                 : <0x00-0xff>
  PrimaryFolderVersion           : <16bytes>
  SecondaryFolderVersion         : <16bytes>
  vCardSelector                  : <64 bits mask :␣
↪bt_pbap_appl_param_property_mask>
  DatabaseIdentifier             : <16bytes>
  vCardSelectorOperator          : <or/and>
  ResetNewMissedCalls            :
  PbapSupportedFeatures          : [supported features]
```

PBAP PCE SLC The pbap pce subcommand provides functionality for PBAP PCE (Phonebook Client Equipment) in Bluetooth Classic.

1. Register PCE SDP:

```
uart:~$ pbap pce sdp_reg
```

2. Discover PSE SDP:

```
uart:~$ pbap pce sdp_discover
SDP PBAP data@0x2000d4a0 (len 54) hint 0 from remote XX:XX:XX:XX:XX:XX
PSE rfcomm channel param 0x0001
PSE l2cap psm param 0x0019
PSE feature param 0x00000019
```

3. Connect to PSE via RFCOMM:

```
uart:~$ pbap pce connect_rfcomm 0x01
PBAP PCE rfcomm transport connected on 0x20005dd8
```

4. Establish OBEX connection:

```
uart:~$ pbap alloc_buf
uart:~$ pbap pce connect 300
pbap connect result Success, mopl 256
Connection ID: 0x00000001
Processing successful connection...
Connection established successfully (no auth required)
```

5. Disconnect from PSE:

```
uart:~$ pbap pce disconnect
pbap disconnect result OK
PBAP PCE rfcomm transport disconnected
```

PBAP PSE SLC The pbap pse subcommand provides functionality for PBAP PSE (Phonebook Server Equipment) in Bluetooth Classic.

1. Register PSE RFCOMM server:

```
uart:~$ pbap pse rfcomm_register
RFCOMM server (channel 01) is registered
```

2. Register PSE L2CAP server:

```
uart:~$ pbap pse l2cap_register
L2cap server (psm 01) is registered
```

3. Register PSE:

```
uart:~$ pbap pse register
```

4. Accept PCE connection and respond:

```
uart:~$ pbap alloc_buf
uart:~$ pbap pse connect_rsp 300 success
pbap connect version 1, mopl 256
Connection established with authentication
```

5. Disconnect from PCE:

```
uart:~$ pbap alloc_buf
uart:~$ pbap pse disconnect_rsp success
pbap disconnect requested by pce
```

Pull Phonebook Pull complete phonebook from PSE:

PCE side

```
uart:~$ pbap alloc_buf
uart:~$ pbap pce pull_pb "telecom/pb"
pbap pull phonebook result Continue
Application Parameters (length: 2):
  PhonebookSize: 0x0002 (2)

=========body=========
BEGIN:VCARD
VERSION:2.1
FN;CHARSET=UTF-8:descvs
N;CHARSET=UTF-8:descvs
END:VCARD
=========body=========

please send pull cmd again
uart:~$ pbap pce pull_pb "telecom/pb"
pbap pull phonebook result Success
Application Parameters (length: 2):
  PhonebookSize: 0x0002 (2)

=========body=========
BEGIN:VCARD
VERSION:2.1
FN;CHARSET=UTF-8:descvs
N;CHARSET=UTF-8:descvs
```

(continues on next page)

(continued from previous page)

```
END:VCARD
=========body=========
```

PSE side

```
uart:~$ pbap alloc_buf
pbap_pse get pull_phone_book request
name = telecom/pb
Application Parameters (length: 0):

uart:~$ pbap alloc_buf
uart:~$ pbap pse pull_phone_book_rsp noerror
Suspend after sending a single response and await the PCE request

uart:~$ pbap alloc_buf
uart:~$ pbap pse pull_phone_book_rsp noerror
Keep sending responses continuously until rsp_code is success
```

Pull vCard Listing Pull vCard listing to discover contacts:

PCE side

```
uart:~$ pbap alloc_buf
uart:~$ pbap add_ap MaxListCount 0x0005
uart:~$ pbap add_ap ListStartOffset 0x0000
uart:~$ pbap pce pull_vcard_listing "telecom/pb"
pbap pull vcard_listing result Continue
Application Parameters (length: 6):
  MaxListCount: 0x0005 (5)
  ListStartOffset: 0x0000 (0)

=========body=========
<?xml version="1.0"?><!DOCTYPE vcard-listing SYSTEM "vcard-listing.dtd">
<vCard-listing version="1.0"><card handle="1.vcf" name="qwe"/>
<card handle="2.vcf" name="qwe"/>
=========body=========

please send pull cmd again
uart:~$ pbap pce pull_vcard_listing "telecom/pb"
pbap pull vcard_listing result Success
=========body=========
<card handle="1.vcf" name="qwe"/><card handle="2.vcf" name="qwe"/>
/<vCard-listing>
=========body=========
```

PSE side

```
uart:~$ pbap alloc_buf
pbap_pse get pull_vcard_listing request
name = telecom/pb
Application Parameters (length: 6):
  MaxListCount: 0x0005 (5)
  ListStartOffset: 0x0000 (0)

uart:~$ pbap alloc_buf
uart:~$ pbap pse pull_vcard_listing_rsp noerror
```

(continues on next page)

(continued from previous page)

```
Suspend after sending a single response and await the PCE request

uart:~$ pbap alloc_buf
uart:~$ pbap pse pull_vcard_listing_rsp noerror
```

Pull vCard Entry Pull a specific vCard entry:

PCE side

```
uart:~$ pbap alloc_buf
uart:~$ pbap add_ap Format v2.1
uart:~$ pbap pce pull_vcard_entry "telecom/pb/1.vcf"
pbap pull vcard_entry result Continue
Application Parameters (length: 1):
  Format: 0x00 (vCard 2.1)

=========body=========
BEGIN:VCARD
VERSION:2.1
FN:
N:
TEL;X-0:1155
=========body=========

uart:~$ pbap pce pull_vcard_entry "telecom/pb/1.vcf"
pbap pull vcard_entry result Success

=========body=========
X-IRMC-CALL-DATETIME;DIALED:20220913T110607
END:VCARD
=========body=========
```

PSE side

```
uart:~$ pbap alloc_buf
pbap_pse get pull_vcard_entry request
name = telecom/pb/1.vcf
Application Parameters (length: 1):
  Format: 0x00 (vCard 2.1)

uart:~$ pbap alloc_buf
uart:~$ pbap pse pull_vcard_entry_rsp noerror
Suspend after sending a single response and await the PCE request

uart:~$ pbap alloc_buf
uart:~$ pbap pse pull_vcard_entry_rsp noerror
```

Set Phone Book Change the current phonebook directory:

PCE side

```
uart:~$ pbap alloc_buf
uart:~$ pbap pce set_phone_book 0x02 "telecom"
PBAP set phonebook result OK

uart:~$ pbap alloc_buf
```

(continues on next page)

(continued from previous page)

```
uart:~$ pbap pce set_phone_book 0x02 "pb"
PBAP set phonebook result OK

uart:~$ pbap alloc_buf
uart:~$ pbap pce set_phone_book 0x02
PBAP set phonebook result OK
```

PSE side

```
uart:~$ pbap alloc_buf
pbap_pse get set_phone_book request
set phonebook to children telecom folder

uart:~$ pbap alloc_buf
uart:~$ pbap pse set_phone_book_rsp success

uart:~$ pbap alloc_buf
pbap_pse get set_phone_book request
set phonebook to children pb folder

uart:~$ pbap alloc_buf
uart:~$ pbap pse set_phone_book_rsp success

uart:~$ pbap alloc_buf
pbap_pse get set_phone_book request
set phonebook to parent folder

uart:~$ pbap alloc_buf
uart:~$ pbap pse set_phone_book_rsp success
```

Abort Operation Abort an ongoing operation:

PCE side

```
uart:~$ pbap pce abort
abort success.
```

PSE side

```
uart:~$ pbap alloc_buf
pbap_pse get receive abort req

uart:~$ pbap pse abort_rsp success
```

Authentication PBAP can use OBEX authentication for secure connections. The authentication process involves challenge-response mechanism.

PCE with authentication challenge:

PCE side

```
uart:~$ pbap alloc_buf
uart:~$ pbap add_header_auth_challenge "password123"
uart:~$ pbap pce connect 255
pbap connect result Unauthorized, mopl 255
PSE requires authentication
Action required:
```

(continues on next page)

(continued from previous page)

```
  1. Allocate new tx_buf (pbap alloc_buf)
  2. Add auth_response header (pbap add_header_auth_response <password>)
  3. Add original auth_challenge header (pbap add_header_auth_challenge <password>)
  4. Re-send connect request (pbap pce connect <mopl>)

uart:~$ pbap alloc_buf
uart:~$ pbap add_header_auth_response "password123"
uart:~$ pbap add_header_auth_challenge "password123"
uart:~$ pbap pce connect 255
pbap connect result Success, mopl 255
Connection ID: 0x00000001
Authentication verified successfully
Connection established with authentication
```

PSE side

```
uart:~$ pbap alloc_buf
uart:~$ pbap pse register

uart:~$ pbap alloc_buf
pbap connect version 1, mopl 255
PCE authentication required - add auth_response to connect_rsp tx_buf

uart:~$ pbap alloc_buf
uart:~$ pbap add_header_auth_challenge "password123"

Bluetooth: Classic: SPP Shell This document describes how to run the Bluetooth Classic SPP functionality. The spp command exposes the Bluetooth Classic SPP Shell commands.

Commands The spp commands:

```
uart:~$ spp
spp - Bluetooth SPP sh commands
Subcommands:
  register_with_channel  : <channel> [limited credit value] [hold_credit]
  register_with_uuid     : <bt-uuid16(e.g. 1101)|bt-uuid32|bt-uuid128(e.g.
                           00001101-0000-1000-8000-00805F9B34FB)> [limited
                           credit value] [hold_credit]
  connect_by_channel     : <channel> [limited credit value] [hold_credit]
  connect_by_uuid        : <bt-uuid16(e.g. 1101)|bt-uuid32|bt-uuid128(e.g.
                           00001101-0000-1000-8000-00805F9B34FB)> [limited
                           credit value] [hold_credit]
  send                   : send [length of packet(s)]
  rls                    : [overrun|parity|framing]
  disconnect             : [none]
  recv_complete          : [none]
```

Server Register Register with channel

```
uart:~$ spp register_with_channel 9
SPP: server registered (channel=9)
```

Register with UUID

```
uart:~$ spp register_with_uuid 00001101-0000-1000-8000-00805F9B34FB
SPP: server registered (uuid=00001101-0000-1000-8000-00805f9b34fb, channel=9)
```

Connect The ACL connection should be established before creating the SPP connection.

Server (incoming)

```
uart:~$ spp register_with_channel 9
SPP: server registered (channel=9)
SPP: accepted incoming connection (conn=0x20004dc8)
SPP: connected (ep=0x20000d20, channel=9)
```

Client by channel

```
uart:~$ spp connect_by_channel 9
SPP: connect started (channel=9)
SPP: connected (ep=0x20000d20, channel=9)
```

Client by UUID

```
uart:~$ spp connect_by_uuid 00001101-0000-1000-8000-00805F9B34FB
SPP: connect started (uuid=00001101-0000-1000-8000-00805f9b34fb)
SPP: connected (ep=0x20000d20, channel=9)
```

Send Data

```
uart:~$ spp send 5
SPP: tx data (len=5)
```

Disconnect

```
uart:~$ spp disconnect
SPP: disconnecting...
SPP: disconnected (ep=0x20000d20)
```

Flow Control Server

```
uart:~$ spp register_with_channel 0 1 hold_credit
SPP: server registered (channel=6)
SPP: accepted incoming connection (conn=0x20005c70)
SPP: connected (ep=0x20006508, channel=6)
SPP: rx data (ep=0x20006508, len=10)
00000000: ff ff ff ff ff ff ff ff  ff ff                  |........ ..      |
uart:~$ spp recv_complete
SPP: rx data (ep=0x20006508, len=10)
00000000: ff ff ff ff ff ff ff ff  ff ff                  |........ ..      |
uart:~$ spp recv_complete
uart:~$ spp recv_complete
SPP: no inprogress buffer
uart:~$ spp send 10
```

(continues on next page)

(continued from previous page)

```
SPP: tx data (len=10)
uart:~$ spp send 10
SPP: tx data (len=10)
```

Client

```
uart:~$ spp connect_by_channel 6 1 hold_credit
SPP: connect started (channel=6)
Security changed: A0:CD:F3:77:F3:A0 level 2
SPP: connected (ep=0x20006448, channel=6)
uart:~$ spp send 10
SPP: tx data (len=10)
uart:~$ spp send 10
SPP: tx data (len=10)
uart:~$
uart:~$ spp recv_complete
SPP: rx data (ep=0x20006448, len=10)
00000000: ff ff ff ff ff ff ff ff  ff ff                  |........ ..      |
uart:~$ spp recv_complete
SPP: rx data (ep=0x20006448, len=10)
00000000: ff ff ff ff ff ff ff ff  ff ff                  |........ ..      |
uart:~$ spp recv_complete
uart:~$ spp recv_complete
SPP: no inprogress buffer
```

Bluetooth: GAP Shell The GAP shell is the "main" shell of Bluetooth and handles connection management, scanning, advertising, and more.

Identities Identities are a Zephyr host concept, allowing a single physical device to behave like multiple logical Bluetooth devices.

The shell allows the creation of multiple identities, to a maximum that is set by the Kconfig symbol `CONFIG_BT_ID_MAX`. To create a new identity, use `bt id-create` command. You can then use it by selecting it with its ID `bt id-select <id>`. Finally, you can list all the available identities with `id-show`.

Scan for devices Start scanning by using the `bt scan on` command. Depending on the environment you're in, you may see a lot of lines printed on the shell. To stop the scan, run `bt scan off`, the scrolling should stop.

Here is an example of what you can expect:

```
uart:~$ bt scan on
Bluetooth active scan enabled
[DEVICE]: R:CB:01:1A:2D:6E:AE, AD evt type 0, RSSI -78  C:1 S:1 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: R:20:C2:EE:59:85:5B, AD evt type 3, RSSI -62  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: R:E3:72:76:87:2F:E8, AD evt type 3, RSSI -74  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: R:1E:19:25:8A:CB:84, AD evt type 3, RSSI -67  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: R:26:42:F3:D5:A0:86, AD evt type 3, RSSI -73  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: R:0C:61:D1:B9:5D:9E, AD evt type 3, RSSI -87  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
```

(continues on next page)

(continued from previous page)

```
[DEVICE]: R:20:C2:EE:59:85:5B, AD evt type 3, RSSI -66  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
[DEVICE]: R:25:3F:7A:EE:0F:55, AD evt type 3, RSSI -83  C:0 S:0 D:0 SR:0 E:0 Prim:␣
↪LE 1M, Secn: No packets, Interval: 0x0000 (0 us), SID: 0xff
uart:~$ bt scan off
Scan successfully stopped
```

As you can see, this can lead to a high number of results. To reduce that number and easily find a specific device, you can enable scan filters. There are four types of filters: by name, by RSSI, by address and by periodic advertising interval. To apply a filter, use the `bt scan-set-filter` command followed by the type of filters. You can add multiple filters by using the commands again.

For example, if you want to look only for devices with the name *test shell*:

```
uart:~$ bt scan-filter-set name "test shell"
```

Or if you want to look for devices at a very close range:

```
uart:~$ bt scan-filter-set rssi -40
RSSI cutoff set at -40 dB
```

Finally, if you want to remove all filters:

```
uart:~$ bt scan-filter-clear all
```

You can use the command `bt scan on` to create an *active* scanner, meaning that the scanner will ask the advertisers for more information by sending a *scan request* packet. Alternatively, you can create a *passive scanner* by using the `bt scan passive` command, so the scanner will not ask the advertiser for more information.

With `CONFIG_BT_SCAN_EXT_FILTER_POLICY` enabled, the `bt scan --ext-filter-policy on` command starts the scanner with the extended scanner filter policy. The Controller then also reports directed advertisements whose target address is a resolvable private address it was unable to resolve. The target address of a directed advertisement is printed on its own line. This requires a Controller that supports the Extended Scanner Filter Policies, and the command fails otherwise.

Connecting to a device To connect to a device, you need to know its address and type of address and use the `bt connect` command with the address and the type as arguments.

Here is an example:

```
uart:~$ bt connect R:52:84:F6:BD:CE:48
Connection pending
Connected: R:52:84:F6:BD:CE:48
Remote LMP version 5.3 (0x0c) subversion 0xffff manufacturer 0x05f1
LE Features: 0x000000000001412f
LE PHY updated: TX PHY LE 2M, RX PHY LE 2M
LE conn  param req: int (0x0018, 0x0028) lat 0 to 42
LE conn param updated: int 0x0028 lat 0 to 42
```

You can list the active connections of the shell using the `bt connections` command. The shell maximum number of connections is defined by `CONFIG_BT_MAX_CONN`. You can disconnect from a connection with the `bt disconnect <address: P:XX:XX:XX:XX:XX:XX or R:XX:XX:XX:XX:XX:XX>` command.

Note

If you were scanning just before, you can connect to the last scanned device by simply running the `bt connect` command.

Alternatively, you can use the `bt connect-name <name>` command to automatically enable scanning with a name filter and connect to the first match.

Advertising Begin advertising by using the `bt advertise on` command. This will use the default parameters and advertise a resolvable private address with the name of the device. You can choose to use the identity address instead by running the `bt advertise on identity` command. To stop advertising use the `bt advertise off` command.

To enable more advanced features of advertising, you should create an advertiser using the `bt adv-create` command. Parameters for the advertiser can be passed either at the creation of it or by using the `bt adv-param` command. To begin advertising with this newly created advertiser, use the `bt adv-start` command, and then the `bt adv-stop` command to stop advertising.

When using the custom advertisers, you can choose if it will be connectable or scannable. This leads to four options: `conn-scan`, `conn-nscan`, `nconn-scan` and `nconn-nscan`. Those parameters are mandatory when creating an advertiser or updating its parameters.

For example, if you want to create a connectable and scannable advertiser and start it:

```
uart:~$ bt adv-create conn-scan
Created adv id: 0, adv: 0x200022f0
uart:~$ bt adv-start
Advertiser[0] 0x200022f0 set started
```

You may notice that with this, the custom advertiser does not advertise the device name; you need to add it. Continuing from the previous example:

```
uart:~$ bt adv-stop
Advertiser set stopped
uart:~$ bt adv-data dev-name
uart:~$ bt adv-start
Advertiser[0] 0x200022f0 set started
```

You should now see the name of the device in the advertising data. You can also set a custom name by using `name <custom name>` instead of `dev-name`. It is also possible to set the advertising data manually with the `bt adv-data` command. The following example shows how to set the advertiser name with it using raw advertising data:

```
uart:~$ bt adv-create conn-scan
Created adv id: 0, adv: 0x20002348
uart:~$ bt adv-data 1009426C7565746F6F74682D5368656C6C
uart:~$ bt adv-start
Advertiser[0] 0x20002348 set started
```

The data must be formatted according to the Bluetooth Core Specification (see version 5.3, vol. 3, part C, 11). In this example, the first octet is the size of the data (the data and one octet for the data type), the second one is the type of data, `0x09` is the Complete Local Name and the remaining data are the name in ASCII. So, on the other device you should see the name *Bluetooth-Shell*.

When advertising, if others devices use an *active* scanner, you may receive *scan request* packets. To visualize those packets, you can add `scan-reports` to the parameters of your advertiser.

Directed Advertising It is possible to use directed advertising on the shell if you want to reconnect to a device. The following example demonstrates how to create a directed advertiser

with the address specified right after the parameter `directed`. The `low` parameter indicates that we want to use the low duty cycle mode, and the `dir-rpa` parameter is required if the remote device is privacy-enabled and supports address resolution of the target address in directed advertisement.

```
uart:~$ bt adv-create conn-scan directed R:D7:54:03:CE:F3:B4 low dir-rpa
Created adv id: 0, adv: 0x20002348
```

After that, you can start the advertiser and then the target device will be able to reconnect.

Extended Advertising Let's now have a look at some extended advertising features. To enable extended advertising, use the `ext-adv` parameter.

```
uart:~$ bt adv-create conn-nscan ext-adv
Created adv id: 0, adv: 0x200022f0
uart:~$ bt adv-start
Advertiser[0] 0x200022f0 set started
```

This will create an extended advertiser, that is connectable and non-scannable.

Encrypted Advertising Data Zephyr has support for the Encrypted Advertising Data feature. The `bt encrypted-ad` sub-commands allow managing the advertising data of a given advertiser.

To encrypt the advertising data, key materials need to be provided, that can be done with `bt encrypted-ad set-keys <session key> <init vector>`. The session key is 16 bytes long and the initialisation vector is 8 bytes long.

You can add advertising data by using `bt encrypted-ad add-ad` and `bt encrypted-ad add-ead`. The former will take add one advertising data structure (as defined in the Core Specification), when the later will read the given data, encrypt them and then add the generated encrypted advertising data structure. It's possible to mix encrypted and non-encrypted data, when done adding advertising data, `bt encrypted-ad commit-ad` can be used to apply the change to the data to the selected advertiser. After that the advertiser can be started as described previously. It's possible to clear the advertising data by using `bt encrypted-ad clear-ad`.

On the Central side, it's possible to decrypt the received encrypted advertising data by setting the correct keys material as described earlier and then enabling the decrypting of the data with `bt encrypted-ad decrypt-scan on`.

Note

To see the advertising data in the scan report `bt scan-verbose-output` need to be enabled.

Note

It's possible to increase the length of the advertising data by increasing the value of `CONFIG_BT_CTLR_ADV_DATA_LEN_MAX` and `CONFIG_BT_CTLR_SCAN_DATA_LEN_MAX`.

Here is a simple example demonstrating the usage of EAD:

Peripheral

```
uart:~$ bt init
...
uart:~$ bt adv-create conn-nscan ext-adv
Created adv id: 0, adv: 0x81769a0
uart:~$ bt encrypted-ad set-keys 9ba22d3824efc70feb800c80294cba38 2e83f3d4d47695b6
```

(continues on next page)

(continued from previous page)

```
session key set to:
00000000: 9b a2 2d 38 24 ef c7 0f  eb 80 0c 80 29 4c ba 38 |..-8$... ....)L.8|
initialisation vector set to:
00000000: 2e 83 f3 d4 d4 76 95 b6                          |.....v..         |
uart:~$ bt encrypted-ad add-ad 06097368656C6C
uart:~$ bt encrypted-ad add-ead 03ffdead03ffbeef
uart:~$ bt encrypted-ad commit-ad
Advertising data for Advertiser[0] 0x81769a0 updated.
uart:~$ bt adv-start
Advertiser[0] 0x81769a0 set started
```

Central

```
uart:~$ bt init
...
uart:~$ bt scan-verbose-output on
uart:~$ bt encrypted-ad set-keys 9ba22d3824efc70feb800c80294cba38 2e83f3d4d47695b6
session key set to:
00000000: 9b a2 2d 38 24 ef c7 0f  eb 80 0c 80 29 4c ba 38 |..-8$... ....)L.8|
initialisation vector set to:
00000000: 2e 83 f3 d4 d4 76 95 b6                          |.....v..         |
uart:~$ bt encrypted-ad decrypt-scan on
Received encrypted advertising data will now be decrypted using provided key␣
↪materials.
uart:~$ bt scan on
Bluetooth active scan enabled
[DEVICE]: R:68:49:30:68:49:30, AD evt type 5, RSSI -59   shell C:1 S:0 D:0 SR:0␣
↪E:1 Prim: LE 1M, Secn: LE 2M, Interval: 0x0000 (0 us), SID: 0x0
        [SCAN DATA START - EXT_ADV]
        Type 0x09:    shell
        Type 0x31: Encrypted Advertising Data: 0xe2, 0x17, 0xed, 0x04, 0xe7, 0x02,␣
↪0x1d, 0xc9, 0x40, 0x07, uart:~0x18, 0x90, 0x6c, 0x4b, 0xfe, 0x34, 0xad
        [START DECRYPTED DATA]
        Type 0xff: 0xde, 0xad
        Type 0xff: 0xbe, 0xef
        [END DECRYPTED DATA]
        [SCAN DATA END]
...
```

Filter Accept List It's possible to create a list of allowed addresses that can be used to connect to those addresses automatically. Here is how to do it:

```
uart:~$ bt fal-add R:47:38:76:EA:29:36
uart:~$ bt fal-add R:66:C8:80:2A:05:73
uart:~$ bt fal-connect on
```

The shell will then connect to the first available device. In the example, if both devices are advertising at the same time, we will connect to the first address added to the list.

The Filter Accept List can also be used for scanning or advertising by using the option `fal`. For example, if we want to scan for a bunch of selected addresses, we can set up a Filter Accept List:

```
uart:~$ bt fal-add R:65:4B:9E:83:AF:73
uart:~$ bt fal-add R:73:72:82:B4:8F:B9
uart:~$ bt fal-add R:5D:85:50:1C:72:64
uart:~$ bt scan on fal
```

You should see only those three addresses reported by the scanner.

Enabling security When connected to a device, you can enable multiple levels of security, here is the list for Bluetooth LE:

- **1** No encryption and no authentication;
- **2** Encryption and no authentication;
- **3** Encryption and authentication;
- **4** Bluetooth LE Secure Connection.

To enable security, use the `bt security <level>` command. For levels requiring authentication (level 3 and above), you must first set the authentication method. To do it, you can use the `bt auth all` command. After that, when you will set the security level, you will be asked to confirm the passkey on both devices. On the shell side, do it with the command `bt auth-passkey-confirm`.

Pairing Enabling authentication requires the devices to be bondable. By default the shell is bondable. You can make the shell not bondable using `bt bondable off`. You can list all the devices you are paired with using the command `bt bonds`.

The maximum number of paired devices is set using `CONFIG_BT_MAX_PAIRED`. You can remove a paired device using `bt clear <address: P:XX:XX:XX:XX:XX:XX or R:XX:XX:XX:XX:XX:XX>` or remove all paired devices with the command `bt clear all`.

Bluetooth: GATT Shell The following examples assume that you have two devices already connected.

To perform service discovery on the client side, use the `gatt discover` command. This should print all the services that are available on the GATT server.

On the server side, you can register pre-defined test services using the `gatt register` command. When done, you should see the newly added services on the client side when running the discovery command.

You can now subscribe to those new services on the client side. Here is an example on how to subscribe to the test service:

```
uart:~$ gatt subscribe 26 25
Subscribed
```

The server can now notify the client with the command `gatt notify`.

Another option available through the GATT command is initiating the MTU exchange. To do it, use the `gatt exchange-mtu` command. To update the shell maximum MTU, you need to update Kconfig symbols in the configuration file of the shell. For more details, see bluetooth_mtu_update.

Bluetooth: Isochronous Channels Shell

Commands

```
iso --help
iso - Bluetooth ISO shell commands
Subcommands:
   cig_create  :[dir=tx,rx,txrx] [interval] [packing] [framing] [latency] [sdu]
                [phy] [rtn]
   cig_term    :Terminate the CIG
   connect     :Connect ISO Channel
   listen      :<dir=tx,rx,txrx> [security level]
```

(continues on next page)

(continued from previous page)

```
   send        :Send to ISO Channel [count]
   disconnect  :Disconnect ISO Channel
   create-big  :Create a BIG as a broadcaster [enc <broadcast code>]
   broadcast   :Broadcast on ISO channels
   sync-big    :Synchronize to a BIG as a receiver <BIS bitfield> [mse] [timeout]
                [enc <broadcast code>]
   term-big    :Terminate a BIG
```

Unicast examples

1. [Central] Create CIG:

Requires to be connected:

```
uart:~$ iso cig_create
CIG created
```

2. [Peripheral] Listen to ISO connections

```
uart:~$ iso listen txrx
```

3. [Central] Connect ISO channel:

```
uart:~$ iso connect
ISO Connect pending...
ISO Channel 0x20000f88 connected
```

4. Send data:

```
uart:~$ iso send
send: 40 bytes of data
ISO sending...
```

5. Disconnect ISO channel:

```
uart:~$ iso disconnect
ISO Disconnect pending...
ISO Channel 0x20000f88 disconnected with reason 0x16
```

Broadcast examples

Setting up broadcaster

```
uart:~$ bt init
Bluetooth initialized
uart:~$ bt adv-create nconn-nscan ext-adv
Created adv id: 0, adv: 0x200025d0
uart:~$ bt per-adv-param
uart:~$ iso create-big
BIG created
ISO Channel 0x200008c0 connected
uart:~$
uart:~$ bt adv-start
Advertiser[0] 0x200025d0 set started
uart:~$
uart:~$ bt per-adv on
Periodic advertising started
```

(continues on next page)

(continued from previous page)

```
uart:~$
uart:~$ iso broadcast
send: 247 bytes of data with PSN 4350
ISO broadcasting...
```

If encrypted broadcast is required, then a broadcast code can be provided as

```
uart:~$ iso create-big enc 00112233445566778899aabbccddffff
BIG created
```

Setting up sync receiver

```
uart:~$ bt init
Bluetooth initialized
uart:~$ bt scan on
[DEVICE]: R:42:0F:7A:40:AE:21, AD evt type 5, RSSI -27  C:0 S:0 D:0 SR:0 E:1 Prim:␣
↪LE 1M, Secn: LE 2M, Interval: 0x0780 (2400000 us), SID: 0x0
uart:~$ bt per-adv-sync-create R:42:0F:7A:40:AE:21 0
Per adv sync pending
PER_ADV_SYNC[0]: [DEVICE]: R:42:0F:7A:40:AE:21 synced, Interval 0x0780 (2400000␣
↪us), PHY LE 2M, SD 0x0000, PAST peer not present

uart:~$ iso sync-big 1
BIG syncing
ISO Channel 0x200008c0 connected
```

If encrypted broadcast is required, then a broadcast code can be provided as

```
uart:~$ iso sync-big 1 enc 00112233445566778899aabbccddffff
BIG syncing
ISO Channel 0x200008c0 connected
```

Bluetooth: L2CAP Shell The `l2cap` command exposes parts of the L2CAP API. The following example shows how to register a LE PSM, connect to it from another device and send 3 packets of 14 octets each.

The example assumes that the two devices are already connected.

On device A, register the LE PSM:

```
uart:~$ l2cap register 29
L2CAP psm 41 sec_level 1 registered
```

On device B, connect to the registered LE PSM and send data:

```
uart:~$ l2cap connect 29
Chan sec: 1
L2CAP connection pending
Channel 0x20000210 connected
Channel 0x20000210 status 1
uart:~$ l2cap send 3 14
Rem 2
Rem 1
```

(continues on next page)

(continued from previous page)

```
Rem 0
Outgoing data channel 0x20000210 transmitted
Outgoing data channel 0x20000210 transmitted
Outgoing data channel 0x20000210 transmitted
```

On device A, you should have received the data:

```
Incoming conn 0x20002398
Channel 0x20000210 status 1
Channel 0x20000210 connected
Channel 0x20000210 requires buffer
Incoming data channel 0x20000210 len 14
00000000: ff ff ff ff ff ff ff ff  ff ff ff ff ff ff       |........ ......  |
Channel 0x20000210 requires buffer
Incoming data channel 0x20000210 len 14
00000000: ff ff ff ff ff ff ff ff  ff ff ff ff ff ff       |........ ......  |
Channel 0x20000210 requires buffer
Incoming data channel 0x20000210 len 14
00000000: ff ff ff ff ff ff ff ff  ff ff ff ff ff ff       |........ ......  |
```

Bluetooth Shell Setup and Usage First you need to build and flash your board with the Bluetooth shell. For how to do that, see the *Getting Started Guide*. The Bluetooth shell itself is located in tests/bluetooth/shell/.

When it's done, connect to the CLI using your favorite serial terminal application. You should see the following prompt:

```
uart:~$
```

For more details on general usage of the shell, see *Shell*.

The first step is enabling Bluetooth. To do so, use the `bt init` command. The following message is printed to confirm Bluetooth has been initialized.

```
uart:~$ bt init
Bluetooth initialized

```

Logging You can configure the logging level per module at runtime. This depends on the maximum logging level that is compiled in. To configure, use the `log` command. Here are some examples:

- List the available modules and their current logging level

```
uart:~$ log status
```

- Disable logging for *bt_hci_core*

```
uart:~$ log disable bt_hci_core
```

- Enable error logs for *bt_att* and *bt_smp*

```
uart:~$ log enable err bt_att bt_smp
```

- Disable logging for all modules

```
uart:~$ log disable
```

- Enable warning logs for all modules

```
uart:~$ log enable wrn
```

4.1.3 USB

Legacy USB device support

USB device support (deprecated)

- *Overview*
- *Supported USB classes*
  - *Audio*
  - *Bluetooth HCI USB transport layer*
  - *CDC ACM*
    - *Console over CDC ACM UART*
    - *CDC ACM UART as backend*
    - *POSIX default tty ECHO mitigation*
  - *DFU*
  - *USB Human Interface Devices (HID) support*
  - *Mass Storage Class*
  - *Networking*
- *Binary Device Object Store (BOS) support*
- *Interface number and endpoint address assignment*
- *Testing over USBIP in native_sim*
- *USB Vendor and Product identifiers*

Overview The USB device stack is a hardware independent interface between USB device controller driver and USB device class drivers or customer applications. It is a port of the LPCUSB device stack and has been modified and expanded over time. It provides the following functionalities:

- Uses the *USB device controller driver API (deprecated)* provided by the device controller drivers to interact with the USB device controller.
- Responds to standard device requests and returns standard descriptors, essentially handling 'Chapter 9' processing, specifically the standard device requests in table 9-3 from the universal serial bus specification revision 2.0.
- Provides a programming interface to be used by USB device classes or customer applications. The APIs is described in include/zephyr/usb/usb_device.h

Note

All APIs listed in *USB device support APIs (deprecated)* and the functions that depend on them are deprecated and will be remove in v4.5.0. Please use the new USB device support represented by the APIs in *USB device support APIs*.

Supported USB classes

Audio There is an experimental implementation of the Audio class. It follows specification version 1.00 (`bcdADC 0x0100`) and supports synchronous synchronisation type only. See usb-audio-headphones-microphone and usb-audio-headset samples for reference.

Bluetooth HCI USB transport layer Bluetooth HCI USB transport layer implementation uses *HCI RAW channel* to expose HCI interface to the host. It is not fully in line with the description in the Bluetooth specification and consists only of an interface with the endpoint configuration:

- HCI commands through control endpoint (host-to-device only)
- HCI events through interrupt IN endpoint
- ACL data through one bulk IN and one bulk OUT endpoints

A second interface for the voice channels has not been implemented as there is no support for this type in *Bluetooth*. It is not a big problem under Linux if HCI USB transport layer is the only interface that appears in the configuration, the btusb driver would not try to claim a second (isochronous) interface. The consequence is that if HCI USB is used in a composite configuration and is the first interface, then the Linux btusb driver will claim both the first and the next interface, preventing other composite functions from working. Because of this problem, HCI USB should not be used in a composite configuration. This problem is fixed in the implementation for new USB support.

See bluetooth_hci_usb sample for reference.

CDC ACM The CDC ACM class is used as backend for different subsystems in Zephyr. However, its configuration may not be easy for the inexperienced user. Below is a description of the different use cases and some pitfalls.

The interface for CDC ACM user is *Universal Asynchronous Receiver-Transmitter (UART)* driver API. But there are two important differences in behavior to a real UART controller:

- Data transfer is only possible after the USB device stack has been initialized and started, until then any data is discarded
- If device is connected to the host, it still needs an application on the host side which requests the data
- The CDC ACM poll out implementation follows the API and blocks when the TX ring buffer is full only if the hw-flow-control property is enabled and called from a non-ISR context.

The devicetree compatible property for CDC ACM UART is `zephyr,cdc-acm-uart`. CDC ACM support is automatically selected when USB device support is enabled and a compatible node in the

devicetree sources is present. If necessary, CDC ACM support can be explicitly disabled by CONFIG_USB_CDC_ACM. About four CDC ACM UART instances can be defined and used, limited by the maximum number of supported endpoints on the controller.

CDC ACM UART node is supposed to be child of a USB device controller node. Since the designation of the controller nodes varies from vendor to vendor, and our samples and application should be as generic as possible, the default USB device controller is usually assigned an zephyr_udc0 node label. Often, CDC ACM UART is described in a devicetree overlay file and looks like this:

```
&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

Sample usb-cdc-acm has similar overlay files. And since no special properties are present, it may seem overkill to use devicetree to describe CDC ACM UART. The motivation behind using devicetree is the easy interchangeability of a real UART controller and CDC ACM UART in applications.

Console over CDC ACM UART With the CDC ACM UART node from above and zephyr,console property of the chosen node, we can describe that CDC ACM UART is to be used with the console. A similar overlay file is used by the usb-cdc-acm-console sample.

```
/ {
        chosen {
                zephyr,console = &cdc_acm_uart0;
        };
};

&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

Before the application uses the console, it is recommended to wait for the DTR signal:

```
const struct device *const dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_console));
uint32_t dtr = 0;

if (usb_enable(NULL)) {
        return;
}

while (!dtr) {
        uart_line_ctrl_get(dev, UART_LINE_CTRL_DTR, &dtr);
        k_sleep(K_MSEC(100));
}

printk("nuqneH\n");
```

CDC ACM UART as backend As for the console sample, it is possible to configure CDC ACM UART as backend for other subsystems by setting *Chosen nodes* properties.

List of few Zephyr specific chosen properties which can be used to select CDC ACM UART as backend for a subsystem or application:

- `zephyr,bt-c2h-uart` used in Bluetooth, for example see bluetooth_hci_uart
- `zephyr,ot-uart` used in OpenThread, for example see openthread-coprocessor
- `zephyr,shell-uart` used by shell for serial backend, for example see samples/subsys/shell/shell_module
- `zephyr,uart-mcumgr` used by smp-svr sample

POSIX default tty ECHO mitigation POSIX systems, like Linux, default to enabling ECHO on tty devices. Host side application can disable ECHO by calling `open()` on the tty device and issuing `ioctl()` (preferably via `tcsetattr()`) to disable echo if it is not desired. Unfortunately, there is an inherent race between the `open()` and `ioctl()` where the ECHO is enabled and any characters received (even if host application does not call `read()`) will be echoed back. This issue is especially visible when the CDC ACM port is used without any real UART on the other side because there is no arbitrary delay due to baud rate.

To mitigate the issue, Zephyr CDC ACM implementation arms IN endpoint with ZLP after device is configured. When the host reads the ZLP, which is pretty much the best indication that host application has opened the tty device, Zephyr will force `CONFIG_CDC_ACM_TX_DELAY_MS` millisecond delay before real payload is sent. This should allow sufficient time for first, and only first, application that opens the tty device to disable ECHO if ECHO is not desired. If ECHO is not desired at all from CDC ACM device it is best to set up udev rule to disable ECHO as soon as device is connected.

ECHO is particurarly unwanted when CDC ACM instance is used for Zephyr shell, because the control characters to set color sent back to shell are interpreted as (invalid) command and user will see garbage as a result. While minicom does disable ECHO by default, on exit with reset it will restore the termios settings to whatever was set on entry. Therefore, if minicom is the first application to open the tty device, the exit with reset will enable ECHO back and thus set up a problem for the next application (which cannot be mitigated at Zephyr side). To prevent the issue it is recommended either to leave minicom without reset or to disable ECHO before minicom is started.

DFU USB DFU class implementation is tightly coupled to *Device Firmware Upgrade* and *MCUBoot API*. This means that the target platform must support the *Flash Image* API.

See legacy-usb-dfu sample for reference.

USB Human Interface Devices (HID) support HID support abuses *Device Driver Model* simply to allow applications to use the `device_get_binding()`. Note that there is no HID device API as such, instead the interface is provided by `hid_ops`. The default instance name is `HID_n`, where n can be {0, 1, 2, ...} depending on the `CONFIG_USB_HID_DEVICE_COUNT`.

Each HID instance requires a HID report descriptor. The interface to the core and the report descriptor must be registered using `usb_hid_register_device()`.

As the USB HID specification is not only used by the USB subsystem, the USB HID API reference is split into two parts, *Human Interface Devices (HID)* and *USB HID Class API (deprecated)*. HID helper macros from *Human Interface Devices (HID)* should be used to compose a HID report descriptor. Macro names correspond to those used in the USB HID specification.

For the HID class interface, an IN interrupt endpoint is required for each instance, an OUT interrupt endpoint is optional. Thus, the minimum implementation requirement for `hid_ops` is to provide `int_in_ready` callback.

```
#define REPORT_ID               1
static bool configured;
static const struct device *hdev;

static void int_in_ready_cb(const struct device *dev)
```

(continues on next page)

(continued from previous page)

```
{
        static uint8_t report[2] = {REPORT_ID, 0};

        if (hid_int_ep_write(hdev, report, sizeof(report), NULL)) {
                LOG_ERR("Failed to submit report");
        } else {
                report[1]++;
        }
}

static void status_cb(enum usb_dc_status_code status, const uint8_t *param)
{
        if (status == USB_DC_RESET) {
                configured = false;
        }

        if (status == USB_DC_CONFIGURED && !configured) {
                int_in_ready_cb(hdev);
                configured = true;
        }
}

static const uint8_t hid_report_desc[] = {
        HID_USAGE_PAGE(HID_USAGE_GEN_DESKTOP),
        HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
        HID_COLLECTION(HID_COLLECTION_APPLICATION),
        HID_LOGICAL_MIN8(0x00),
        HID_LOGICAL_MAX16(0xFF, 0x00),
        HID_REPORT_ID(REPORT_ID),
        HID_REPORT_SIZE(8),
        HID_REPORT_COUNT(1),
        HID_USAGE(HID_USAGE_GEN_DESKTOP_UNDEFINED),
        HID_INPUT(0x02),
        HID_END_COLLECTION,
};

static const struct hid_ops my_ops = {
        .int_in_ready = int_in_ready_cb,
};

int main(void)
{
        int ret;

        hdev = device_get_binding("HID_0");
        if (hdev == NULL) {
                return -ENODEV;
        }

        usb_hid_register_device(hdev, hid_report_desc, sizeof(hid_report_desc),
                                &my_ops);

        ret = usb_hid_init(hdev);
        if (ret) {
                return ret;
        }
```

(continues on next page)

(continued from previous page)

```
        return usb_enable(status_cb);
}
```

If the application wishes to receive output reports via the OUT interrupt endpoint, it must enable `CONFIG_ENABLE_HID_INT_OUT_EP` and provide `int_out_ready` callback. The disadvantage of this is that Kconfig options such as `CONFIG_ENABLE_HID_INT_OUT_EP` or `CONFIG_HID_INTERRUPT_EP_MPS` apply to all instances. This design issue will be fixed in the HID class implementation for the new USB support.

See usb-hid-mouse sample for reference.

Mass Storage Class MSC follows Bulk-Only Transport specification and uses *Disk Access* to access and expose a RAM disk, emulated block device on a flash partition, or SD Card to the host. Only one disk instance can be exported at a time.

The disc to be used by the implementation is set by the `CONFIG_MASS_STORAGE_DISK_NAME` and should be the same as the name used by the disc access driver that the application wants to expose to the host. Flash, RAM, and SDMMC/MMC disk drivers use node property `disk-name` to set the disk name.

For the emulated block device on a flash partition, the flash partition and flash disk to be used must be described in the devicetree. If a storage partition is already described at the board level, application devicetree overlay must also delete `storage_partition` node first. `CONFIG_MASS_STORAGE_DISK_NAME` should be the same as `disk-name` property.

```
/delete-node/ &storage_partition;

&mx25r64 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                storage_partition: partition@0 {
                        label = "storage";
                        reg = <0x00000000 0x00020000>;
                };
        };
};

/ {
        msc_disk0 {
                compatible = "zephyr,flash-disk";
                partition = <&storage_partition>;
                disk-name = "NAND";
                cache-size = <4096>;
        };
};
```

The `disk-property` “NAND” may be confusing, but it is simply how some file systems identifies the disc. Therefore, if the application also accesses the file system on the exposed disc, default names should be used, see usb-mass sample for reference.

Networking There are three implementations that work in a similar way, providing a virtual Ethernet connection between the remote (USB host) and Zephyr network support.

- CDC ECM class, enabled with `CONFIG_USB_DEVICE_NETWORK_ECM`

- CDC EEM class, enabled with `CONFIG_USB_DEVICE_NETWORK_EEM`
- RNDIS support, enabled with `CONFIG_USB_DEVICE_NETWORK_RNDIS`

See legacy-netusb sample for reference.

Applications using RNDIS support should enable `CONFIG_USB_DEVICE_OS_DESC` for a better user experience on a host running Microsoft Windows OS.

Binary Device Object Store (BOS) support BOS handling can be enabled with Kconfig option `CONFIG_USB_DEVICE_BOS`. This option also has the effect of changing device descriptor `bcdUSB` to `0210`. The application should register descriptors such as Capability Descriptor using `usb_bos_register_cap()`. Registered descriptors are added to the root BOS descriptor and handled by the stack.

See legacy-webusb sample for reference.

Interface number and endpoint address assignment In USB terminology, a `function` is a device that provides a capability to the host, such as a HID class device that implements a keyboard. A function contains a collection of `interfaces`; at least one interface is required. An interface may contain device `endpoints`; for example, at least one input endpoint is required to implement a HID class device, and no endpoints are required to implement a USB DFU class. A USB device that combines functions is a multifunction USB device, for example, a combination of a HID class device and a CDC ACM device.

With Zephyr RTOS USB support, various combinations are possible with built-in USB classes/functions or custom user implementations. The limitation is the number of available device endpoints. Each device endpoint is uniquely addressable. The endpoint address is a combination of endpoint direction and endpoint number, a four-bit value. Endpoint number zero is used for the default control method to initialize and configure a USB device. By specification, a maximum of `15 IN` and `15 OUT` device endpoints are also available for use in functions. The actual number depends on the device controller used. Not all controllers support the maximum number of endpoints and all endpoint types. For example, a device controller might support one IN and one OUT isochronous endpoint, but only for endpoint number 8, resulting in endpoint addresses 0x88 and 0x08. Also, one controller may be able to have IN/OUT endpoints on the same endpoint number, interrupt IN endpoint 0x81 and bulk OUT endpoint 0x01, while the other may only be able to handle one endpoint per endpoint number. Information about the number of interfaces, interface associations, endpoint types, and addresses is provided to the host by the interface, interface specific, and endpoint descriptors.

Host driver for specific function, uses interface and endpoint descriptor to obtain endpoint addresses, types, and other properties. This allows function host drivers to be generic, for example, a multi-function device consisting of one or more CDC ACM and one or more CDC ECM class implementations is possible and no specific drivers are required.

Interface and endpoint descriptors of built-in USB class/function implementations in Zephyr RTOS typically have default interface numbers and endpoint addresses assigned in ascending order. During initialization, default interface numbers may be reassigned based on the number of interfaces in a given configuration. Endpoint addresses are reassigned based on controller capabilities, since certain endpoint combinations are not possible with every controller, and the number of interfaces in a given configuration. This also means that the device side class/function in the Zephyr RTOS must check the actual interface and endpoint descriptor values at runtime. This mechanism also allows as to provide generic samples and generic multifunction samples that are limited only by the resources provided by the controller, such as the number of endpoints and the size of the endpoint FIFOs.

There may be host drivers for a specific function, for example in the Linux Kernel, where the function driver does not read interface and endpoint descriptors to check interface numbers or endpoint addresses, but instead uses hardcoded values. Therefore, the host driver cannot be used in a generic way, meaning it cannot be used with different device controllers and different device configurations in combination with other functions. This may also be because the driver

is designed for a specific hardware and is not intended to be used with a clone of this specific hardware. On the contrary, if the driver is generic in nature and should work with different hardware variants, then it must not use hardcoded interface numbers and endpoint addresses. It is not possible to disable endpoint reassignment in Zephyr RTOS, which may prevent you from implementing a hardware-clone firmware. Instead, if possible, the host driver implementation should be fixed to use values from the interface and endpoint descriptor.

Testing over USBIP in native_sim A virtual USB controller implemented through USBIP might be used to test the USB device stack. Follow the general build procedure to build the USB sample for the native_sim configuration.

Run built sample with:

```
west build -t run
```

In a terminal window, run the following command to list USB devices:

```
$ usbip list -r localhost
Exportable USB devices
======================
 - 127.0.0.1
        1-1: unknown vendor : unknown product (2fe3:0100)
           : /sys/devices/pci0000:00/0000:00:01.2/usb1/1-1
           : (Defined at Interface level) (00/00/00)
           :  0 - Vendor Specific Class / unknown subclass / unknown protocol␣
↪(ff/00/00)
```

In a terminal window, run the following command to attach the USB device:

```
$ sudo usbip attach -r localhost -b 1-1
```

The USB device should be connected to your Linux host, and verified with the following commands:

```
$ sudo usbip port
Imported USB devices
====================
Port 00: <Port in Use> at Full Speed(12Mbps)
       unknown vendor : unknown product (2fe3:0100)
       7-1 -> usbip://localhost:3240/1-1
           -> remote bus/dev 001/002
$ lsusb -d 2fe3:0100
Bus 007 Device 004: ID 2fe3:0100
```

USB Vendor and Product identifiers The USB Vendor ID for the Zephyr project is `0x2FE3`. This USB Vendor ID must not be used when a vendor integrates Zephyr USB device support into its own product.

Each USB sample has its own unique Product ID. The USB maintainer, if one is assigned, or otherwise the Zephyr Technical Steering Committee, may allocate other USB Product IDs based on well-motivated and documented requests.

The following Product IDs are currently used:

Sample	PID
usb-cdc-acm	0x0001
Reserved (previously: usb-cdc-acm-composite)	0x0002
Reserved (previously: usb-hid-cdc)	0x0003
usb-cdc-acm-console	0x0004
usb-dfu (Run-Time)	0x0005
Reserved (previously: usb-hid)	0x0006
usb-hid-mouse	0x0007
usb-mass	0x0008
testusb-app	0x0009
webusb	0x000A
bluetooth_hci_usb	0x000B
Reserved (previously: bluetooth_hci_usb_h4)	0x000C
Reserved (previously: wpan-usb)	0x000D
uac2-explicit-feedback	0x000E
uac2-implicit-feedback	0x000F
uvc	0x0011
usb-dfu (DFU Mode)	0xFFFF

The USB device descriptor field `bcdDevice` (Device Release Number) represents the Zephyr kernel major and minor versions as a binary coded decimal value.

USB device support APIs (deprecated)

USB device controller driver API (deprecated) The USB device controller driver API is described in include/zephyr/drivers/usb/usb_dc.h and sometimes referred to as the `usb_dc` API.

This API has some limitations by design, it does not follow *Device Driver Model* and is being replaced by *USB device controller (UDC) driver API*.

API reference

USB Device Controller API

USB device stack API (deprecated)

API reference There are two ways to transmit data, using the 'low' level read/write API or the 'high' level transfer API.

Low level API
: To transmit data to the host, the class driver should call usb_write(). Upon completion the registered endpoint callback will be called. Before sending another packet the class driver should wait for the completion of the previous write. When data is received, the registered endpoint callback is called. usb_read() should be used for retrieving the received data. For CDC ACM sample driver this happens via the OUT bulk endpoint handler (cdc_acm_bulk_out) mentioned in the endpoint array (cdc_acm_ep_data).

High level API
: The usb_transfer method can be used to transfer data to/from the host. The transfer API will automatically split the data transmission into one or more USB transaction(s), depending endpoint max packet size. The class driver does not have to implement endpoint callback and should set this callback to the generic usb_transfer_ep_callback.

USB support

Common guidelines for USB tests and samples

Overview In general, all USB samples and tests are platform agnostic and should not require a platform-specific overlay. Though there may be exceptions to that already in the tree, the goal is to avoid platform-specific overlays. There is no obligation for a USB sample or USB test to support a specific platform.

Board configuration

Default USB device and host controller USB support uses the `zephyr_udc0` node label to assign the default USB device controller and the `zephyr_uhc0` node label to assign the default USB host controller. Depending on what a board supports, it has to assign these node labels to be able to execute samples and tests in the tree.

Supported features for the board metadata There are only two supported features for the board metadata file that are used by Twister to pick up a sample or a test. For a board with a USB controller supporting device mode, the feature is `usbd`. For a board with a USB controller supporting host mode, the feature is `usbh`.

See *Board Configuration* for more details.

Deprecated features The feature `usb_device` should not be used anymore. This feature belongs to the legacy USB device stack, which is deprecated and will be removed.

Tests Twister configuration USB tests may require additional hardware or software setup. These tests should use *fixtures* described in the table below.

Fixture	Use case
`usb_host_connec`	The test implements USB device functionality, and requires a USB host to be connected to the board under test.
`usb_device_conn`	The test implements USB host functionality, and requires a USB device to be connected to the board under test.

USB device support

Overview USB device support consists of the USB device controller (UDC) drivers , *USB device controller (UDC) driver API*, and USB device stack, *USB device stack API*. The *USB device controller (UDC) driver API* provides a generic and vendor independent interface to USB device controllers, and although, there is a clear separation between these layers, the purpose of *USB device controller (UDC) driver API* is to serve Zephyr's USB device stack exclusively.

The device stack supports multiple device controllers, meaning that if a SoC has multiple controllers, they can be used simultaneously. Full and high-speed device controllers are supported. It also provides support for registering multiple function or class instances to a configuration at runtime, or changing the configuration later. It has built-in support for several USB classes and provides an API to implement custom USB functions.

Samples

- usb-hid-keyboard
- uac2-explicit-feedback
- uac2-implicit-feedback
- uvc
- bluetooth_hci_usb
- usb-cdc-acm
- usb-cdc-acm-console
- usb-mass
- usb-hid-mouse
- zperf To build the sample for the device support, set the configuration overlay file `-DEXTRA_CONF_FILE=overlay-usbd.conf` and devicetree overlay file `-DDTC_OVERLAY_FILE=usbd_cdc_ecm.overlay` either directly or via `west`.

How to configure and enable USB device support For the USB device support samples in the Zephyr project repository, we have a common file for instantiation, configuration and initialization, samples/subsys/usb/common/sample_usbd_init.c. The following code snippets from this file are used as examples. USB Samples Kconfig options used in the USB samples and prefixed with SAMPLE_USBD_ have default values specific to the Zephyr project and the scope is limited to the project samples. In the examples below, you will need to replace these Kconfig options and other defaults with values appropriate for your application or hardware.

The USB device stack requires a context structure to manage its properties and runtime data. The preferred way to define a device context is to use the USBD_DEVICE_DEFINE macro. This creates a static usbd_context variable with a given name. Any number of contexts may be instantiated. A USB controller device can be assigned to multiple contexts, but only one context can be initialized and used at a time. Context properties must not be directly accessed or manipulated by the application.

```
/*
 * Instantiate a context named sample_usbd using the default USB device
 * controller, the Zephyr project vendor ID, and the sample product ID.
 * Zephyr project vendor ID must not be used outside of Zephyr samples.
 */
USBD_DEVICE_DEFINE(sample_usbd,
                   DEVICE_DT_GET(DT_NODELABEL(zephyr_udc0)),
                   CONFIG_SAMPLE_USBD_VID, CONFIG_SAMPLE_USBD_PID);
```

Your USB device may have manufacturer, product, and serial number string descriptors. To instantiate these string descriptors, the application should use the appropriate USBD_DESC_MANUFACTURER_DEFINE, USBD_DESC_PRODUCT_DEFINE, and USBD_DESC_SERIAL_NUMBER_DEFINE macros. String descriptors also require a single instantiation of the language descriptor using the USBD_DESC_LANG_DEFINE macro.

```
USBD_DESC_LANG_DEFINE(sample_lang);
USBD_DESC_MANUFACTURER_DEFINE(sample_mfr, CONFIG_SAMPLE_USBD_MANUFACTURER);
USBD_DESC_PRODUCT_DEFINE(sample_product, CONFIG_SAMPLE_USBD_PRODUCT);
IF_ENABLED(CONFIG_HWINFO, (USBD_DESC_SERIAL_NUMBER_DEFINE(sample_sn)));
```

String descriptors must be added to the device context at runtime before initializing the USB device with usbd_add_descriptor().

```
err = usbd_add_descriptor(&sample_usbd, &sample_lang);
if (err) {
        LOG_ERR("Failed to initialize language descriptor (%d)", err);
        return NULL;
}

err = usbd_add_descriptor(&sample_usbd, &sample_mfr);
if (err) {
        LOG_ERR("Failed to initialize manufacturer descriptor (%d)", err);
        return NULL;
}

err = usbd_add_descriptor(&sample_usbd, &sample_product);
if (err) {
        LOG_ERR("Failed to initialize product descriptor (%d)", err);
        return NULL;
}

IF_ENABLED(CONFIG_HWINFO, (
        err = usbd_add_descriptor(&sample_usbd, &sample_sn);
```

(continues on next page)

(continued from previous page)

```
))
if (err) {
        LOG_ERR("Failed to initialize SN descriptor (%d)", err);
        return NULL;
}
```

USB device requires at least one configuration instance per supported speed. The application should use USBD_CONFIGURATION_DEFINE to instantiate a configuration. Later, USB device functions are assigned to a configuration.

```
static const uint8_t attributes = (IS_ENABLED(CONFIG_SAMPLE_USBD_SELF_POWERED) ?
                                   USB_SCD_SELF_POWERED : 0) |
                                  (IS_ENABLED(CONFIG_SAMPLE_USBD_REMOTE_WAKEUP) ?
                                   USB_SCD_REMOTE_WAKEUP : 0);

/* Full speed configuration */
USBD_CONFIGURATION_DEFINE(sample_fs_config,
                          attributes,
                          CONFIG_SAMPLE_USBD_MAX_POWER, &fs_cfg_desc);

/* High speed configuration */
USBD_CONFIGURATION_DEFINE(sample_hs_config,
                          attributes,
                          CONFIG_SAMPLE_USBD_MAX_POWER, &hs_cfg_desc);
```

Each configuration instance for a specific speed must be added to the device context at runtime before the USB device is initialized using usbd_add_configuration(). Note USBD_SPEED_FS and USBD_SPEED_HS. The first full-speed or high-speed configuration will get bConfigurationValue one, and then further upward.

```
err = usbd_add_configuration(&sample_usbd, USBD_SPEED_FS,
                             &sample_fs_config);
if (err) {
        LOG_ERR("Failed to add Full-Speed configuration");
        return NULL;
}
```

Although we have already done a lot, this USB device has no function. A device can have multiple configurations with different set of functions at different speeds. A function or class can be registered on a USB device before it is initialized using usbd_register_class(). The desired configuration is specified using USBD_SPEED_FS or USBD_SPEED_HS and the configuration number. For simple cases, usbd_register_all_classes() can be used to register all available instances.

```
err = usbd_register_all_classes(&sample_usbd, USBD_SPEED_FS, 1, blocklist);
if (err) {
        LOG_ERR("Failed to add register classes");
        return NULL;
}
```

The last step in the preparation is to initialize the device with usbd_init(). After this, the configuration of the device cannot be changed. A device can be deinitialized with usbd_shutdown() and all instances can be reused, but the previous steps must be repeated. So it is possible to shutdown a device, register another type of configuration or function, and initialize it again. At the USB controller level, usbd_init() does only what is necessary to detect VBUS changes. There are controller types where the next step is only possible if a VBUS signal is present.

A function or class implementation may require its own specific configuration steps, which should be performed prior to initializing the USB device.

```
err = usbd_init(&sample_usbd);
if (err) {
        LOG_ERR("Failed to initialize device support");
        return NULL;
}
```

The final step to enable the USB device is `usbd_enable()`, after that, if the USB device is connected to a USB host controller, the host can start enumerating the device. The application can disable the USB device using `usbd_disable()`.

```
ret = usbd_enable(sample_usbd);
if (ret) {
        LOG_ERR("Failed to enable device support");
        return ret;
}
```

USB Message notifications The application can register a callback using `usbd_msg_register_cb()` to receive message notification from the USB device support subsystem. The messages are mostly about the common device state changes, and a few specific types from the USB CDC ACM implementation.

```
err = usbd_msg_register_cb(&sample_usbd, msg_cb);
if (err) {
        LOG_ERR("Failed to register message callback");
        return NULL;
}
```

The helper function `usbd_msg_type_string()` can be used to convert `usbd_msg_type` to a human readable form for logging.

If the controller supports VBUS state change detection, the battery-powered application may want to enable the USB device only when it is connected to a host. A generic application should use `usbd_can_detect_vbus()` to check for this capability.

```
static void msg_cb(struct usbd_context *const usbd_ctx,
                   const struct usbd_msg *const msg)
{
        LOG_INF("USBD message: %s", usbd_msg_type_string(msg->type));

        if (msg->type == USBD_MSG_CONFIGURATION) {
                LOG_INF("\tConfiguration value %d", msg->status);
        }

        if (usbd_can_detect_vbus(usbd_ctx)) {
                if (msg->type == USBD_MSG_VBUS_READY) {
                        if (usbd_enable(usbd_ctx)) {
                                LOG_ERR("Failed to enable device support");
                        }
                }

                if (msg->type == USBD_MSG_VBUS_REMOVED) {
                        if (usbd_disable(usbd_ctx)) {
                                LOG_ERR("Failed to disable device support");
                        }
                }
        }
}
```

Built-in functions The USB device stack has built-in USB functions. Some can be used directly in the user application through a special API, such as HID or Audio class devices, while others use a general Zephyr RTOS driver API, such as MSC and CDC class implementations. The *Identification string* identifies a class or function instance (`n`) and is used as an argument to the `usbd_register_class()`.

Class or function	User API (if any)	Identification string
USB Audio 2 class	*Audio Class 2 device API*	`uac2_n`
USB CDC ACM class	*Universal Asynchronous Receiver-Transmitter (UART)*	`cdc_acm_n`
USB CDC ECM class	Ethernet device	`cdc_ecm_n`
USB Mass Storage Class (MSC)	*USB Mass Storage Class device API*	`msc_n`
USB Human Interface Devices (HID)	*HID device API*	`hid_n`
Bluetooth HCI USB transport layer	*HCI RAW channel*	`bt_hci_n`
USB Video Class (UVC)	Video device	`uvc_n`

USB Vendor and Product identifiers

The USB Vendor ID for the Zephyr project is `0x2FE3`. Zephyr USB Vendor ID must not be used when a vendor integrates Zephyr USB device support into its own product.

Each USB sample has its own unique Product ID. The USB maintainer, if one is assigned, or otherwise the Zephyr Technical Steering Committee, may allocate other USB Product IDs based on well-motivated and documented requests.

The following Product IDs are currently used:

Sample	PID
usb-cdc-acm	0x0001
Reserved (previously: usb-cdc-acm-composite)	0x0002
Reserved (previously: usb-hid-cdc)	0x0003
usb-cdc-acm-console	0x0004
usb-dfu (Run-Time)	0x0005
Reserved (previously: usb-hid)	0x0006
usb-hid-mouse	0x0007
usb-mass	0x0008
testusb-app	0x0009
webusb	0x000A

fido2	0x0012
i2c-tiny-usb	0x0013
usb-dfu (DFU Mode)	0xFFFF

USB device CDC ACM

The CDC ACM function provided by the USB device stack only implements Abstract Control Model Serial Emulation. Its sole purpose is to emulate serial lines, as its name suggests. Most modern operating systems should provide support for it out of the box.

The CDC ACM function is represented as a serial interface on both the host and device sides, while the user or application interface is the *Universal Asynchronous Receiver-Transmitter (UART)* driver API. This allows applications that already use the UART API to use the serial interface provided by the CDC ACM function without changing the code responsible for data communication. Only additional configuration and USB device stack initialization are required.

CDC ACM UART configuration Like the real UART controller, the virtual CDC ACM UART is described in the device tree. The devicetree compatible property for CDC ACM UART is `zephyr,cdc-acm-uart`.

CDC ACM support is automatically selected when USB device support is enabled and a compatible node in the devicetree sources is present. If necessary, CDC ACM support can be explicitly disabled by `CONFIG_USBD_CDC_ACM_CLASS`. The number of possible CDC ACM instances depends on the number of supported endpoints on the USB device controller. Each CDC ACM instance requires three endpoints: two bulk endpoints (one IN, one OUT) and one interrupt IN with a MaxPacketSize of 16. The CDC ACM node can use the `label` property to distinguish different interfaces on the host side. Below is an example of the devicetree overlay file.

```
&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

Before the application uses CDC ACM UART, it may want to wait for the DTR signal. Please refer to usb-cdc-acm on how to implement this functionality.

Note

To communicate with the host, beside the UART configuration, the application must enable USB device stack, for that please refer to *How to configure and enable USB device support* and read carefully the next chapter. For users and applications migrating from the legacy stack, this is the only part they need to adapt.

CDC ACM UART as serial backend Using the example above and the `zephyr,console` chosen node property, you can configure the CDC ACM UART as the console device.

```
/ {
        chosen {
                zephyr,console = &cdc_acm_uart0;
        };
};

&zephyr_udc0 {
        cdc_acm_uart0: cdc_acm_uart0 {
                compatible = "zephyr,cdc-acm-uart";
                label = "CDC_ACM_0";
        };
};
```

In the same way that the console in the above example is configured to use the CDC ACM UART, `zephyr,shell-uart` chosen node property can be used to configure the shell to use the CDC ACM UART as the serial backend. See sample shell-module and *chosen nodes documentation*.

Since the use case as a serial backend is very common and no configuration is necessary at runtime for the CDC ACM UART, the stack offers a helper that performs the steps described in *How to configure and enable USB device support*. The helper is enabled by the `CON-`

FIG_CDC_ACM_SERIAL_INITIALIZE_AT_BOOT and initializes the USB device stack with a single CDC ACM instance. Sample usb-cdc-acm-console demonstrates how to use it.

CONFIG_CDC_ACM_SERIAL_INITIALIZE_AT_BOOT should also be used by the boards like nrf52840dongle, which do not have a debug adapter but a USB device controller, and want to use CDC ACM UART as default serial backend for logging and shell. As the configuration would be identical for any board, there are common devicetree file and Kconfig file that must be included in the board's devicetree and Kconfig.defconfig files.

Using CDC ACM UART in the application CDC ACM implements a virtual UART controller and provides Interrupt-driven UART API and Polling UART API. The ASYNC API is not supported yet. If the application wants to communicate over CDC ACM UART, the preferable way is to use Interrupt-driven UART API. It is essential to understand API documentation, nevertheless, some notes below.

Interrupt-driven UART API Internally the CDC ACM UART implementation uses two ring-buffers. These take over the function of the TX/RX FIFOs (TX/RX buffers) from the *Interrupt-driven API*.

As described in the *Interrupt-driven API*, the functions uart_irq_update(), uart_irq_is_pending(), uart_irq_rx_ready(), uart_irq_tx_ready() uart_fifo_read(), and uart_fifo_fill() should be called from the interrupt handler, see uart_irq_callback_user_data_set(). To prevent undefined behavior, the implementation of these functions checks in what context they are called and fails if it is not an interrupt handler.

Also, as described in the UART API, uart_irq_is_pending() uart_irq_rx_ready(), and uart_irq_tx_ready() can only be called after uart_irq_update().

Simplified, application interrupt handler should look something like:

```
static void interrupt_handler(const struct device *dev, void *user_data)
{
        while (true) {
                uart_irq_update(dev);

                if (uart_irq_is_pending(dev) <= 0) {
                        break;
                }

                if (uart_irq_rx_ready(dev)) {
                        int len;
                        int n;

                        /* ... */
                        n = uart_fifo_read(dev, buffer, len);
                        /* ... */
                }

                if (uart_irq_tx_ready(dev)) {
                        int len;
                        int n;

                        /* ... */
                        n = uart_fifo_fill(dev, buffer, len);
                  /* ... */
                }
        }
}
```

All these functions are not directly dependent on the status of the USB device. Filling the TX FIFO does not mean that data is being sent to the host. And successfully reading the RX FIFO does not mean that the device is still connected to the host. If there is space in the TX FIFO, and the TX interrupt is enabled, `uart_irq_tx_ready()` will succeed. If there is data in the RX FIFO, and the RX interrupt is enabled, `uart_irq_rx_ready()` will succeed. Function `uart_irq_tx_complete()` is not implemented yet.

Polling UART API The CDC ACM poll out implementation follows *Polling API* and blocks when the TX FIFO is full only if the hw-flow-control property is enabled and called from a non-ISR context.

USB device support APIs

USB device controller (UDC) driver API The USB device controller driver API is described in include/zephyr/drivers/usb/udc.h and referred to as the `UDC driver` API.

UDC driver API is unstable and is subject to change without notice. It is a replacement for *USB device controller driver API (deprecated)*. If you wish to port an existing driver to UDC driver API, or add a new driver, please use drivers/usb/udc/udc_skeleton.c as a starting point.

USB/IP protocol support

Overview New USB support includes initial support for the USB/IP protocol. It is still under development and is currently limited to supporting only one device connected to the host controller being exported.

USB/IP uses TCP/IP. Both of the underlying connectivity stacks, USB and networking, require significant memory resources, which must be considered when choosing a platform.

In the USB/IP protocol, a server exports the USB devices and a client imports them. USB/IP support in the Zephyr RTOS implements server functionality and exports a device connected to a host controller on a device running the Zephyr RTOS. A client, typically running the Linux kernel, imports this device. The USB/IP protocol is described in USB/IP protocol documentation.

To use USB/IP support, make sure the required modules are loaded on the client side.

```
modprobe vhci_hcd
modprobe usbip-core
modprobe usbip-host
```

On the client side, you will also need the **usbip** user tool. It can be installed using your Linux distribution's package management system or built from Linux kernel sources.

There are a few basic commands for everyday use. To list exported USB devices, run the following command:

```
$ usbip list -r 192.0.2.1
Exportable USB devices
======================
 - 192.0.2.1
        1-1: NordicSemiconductor : unknown product (2fe3:0001)
           : /sys/bus/usb/devices/usb1/1-1
           : Miscellaneous Device / ? / Interface Association (ef/02/01)
           :  0 - Communications / Abstract (modem) / None (02/02/00)
           :  1 - CDC Data / Unused / unknown protocol (0a/00/00)
```

To attach an exported device with busid 1-1:

```
$ sudo usbip attach -r 192.0.2.1 -b 1-1
```

To detach an exported device on port 0:

```
$ sudo usbip detach -p 0
```

USB/IP with native_sim The preferred method to develop with USB/IP support enabled is to use native_sim. Use on real hardware is not really tested yet. USB/IP requires a network connection, see *Networking with native_sim board* for how to set up the interface on the client side.

Building and running a sample with USB/IP requires extensive configuration, you can use usbip-native-sim snippet to configure host and USB/IP support.

```
# From the root of the zephyr repository
west build -b native_sim/native/64 samples/subsys/usb/cdc_acm -- -
↪DSNIPPET=usbip-native-sim -DEXTRA_DTC_OVERLAY_FILE=app.overlay
```

USB Power Delivery support

USB-C device stack

The USB-C device stack is a hardware independent interface between a Type-C Port Controller (TCPC) and customer applications. It is a port of the Google ChromeOS Type-C Port Manager (TCPM) stack. It provides the following functionalities:

- Uses the APIs provided by the Type-C Port Controller drivers to interact with the Type-C Port Controller.
- Provides a programming interface that's used by a customer applications. The APIs is described in include/zephyr/usb_c/usbc.h

Configuration options The USB-C device stack supports implementation of Sink only, Source only, and Dual Role Power (DRP) devices.

- `CONFIG_USBC_CSM_SINK_ONLY`: Sink USB-C Connection State Machine
- `CONFIG_USBC_CSM_SOURCE_ONLY`: Source USBC Connection State Machine

List of samples for different purposes.

Implementing a Sink Type-C and Power Delivery USB-C device The configuration of a USB-C Device is done in the stack layer and devicetree.

The following devicetree, structures and callbacks need to be defined:

- Devicetree usb-c-connector node referencing a TCPC
- Devicetree vbus node referencing a VBUS measurement device

- User defined structure that encapsulates application specific data
- Policy callbacks

For example, for the Sample USB-C Sink application:

Each Physical Type-C port is represented in the devicetree by a usb-c-connector compatible node:

```
                port1: usbc-port@1 {
                        compatible = "usb-c-connector";
                        reg = <1>;
                        tcpc = <&ucpd1>;
                        vbus = <&vbus1>;
                        power-role = "sink";
                        sink-pdos = <PDO_FIXED(5000, 100, 0)>;
                };
```

VBUS is measured by a device that's referenced in the devicetree by a usb-c-vbus-adc compatible node:

```
        vbus1: vbus {
                compatible = "zephyr,usb-c-vbus-adc";
                io-channels = <&adc2 8>;
                output-ohms = <49900>;
                full-ohms = <(330000 + 49900)>;
        };
```

A user defined structure is defined and later registered with the subsystem and can be accessed from callback through an API:

```
/**
 * @brief A structure that encapsulates Port data.
 */
static struct port0_data_t {
        /** Sink Capabilities */
        uint32_t snk_caps[DT_PROP_LEN(USBC_PORT0_NODE, sink_pdos)];
        /** Number of Sink Capabilities */
        int snk_cap_cnt;
        /** Source Capabilities */
        uint32_t src_caps[PDO_MAX_DATA_OBJECTS];
        /** Number of Source Capabilities */
        int src_cap_cnt;
        /* Power Supply Ready flag */
        atomic_t ps_ready;
} port0_data = {.snk_caps = DT_PROP(USBC_PORT0_NODE, sink_pdos),
                .snk_cap_cnt = DT_PROP_LEN(USBC_PORT0_NODE, sink_pdos),
                .src_caps = {0},
                .src_cap_cnt = 0,
                .ps_ready = 0};

```

These callbacks are used by the subsystem to set or get application specific data:

```
static int port0_policy_cb_get_snk_cap(const struct device *dev, uint32_t **pdos,␣
↪int *num_pdos)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        *pdos = dpm_data->snk_caps;
        *num_pdos = dpm_data->snk_cap_cnt;
```

(continues on next page)

(continued from previous page)

```

        return 0;
}

static void port0_policy_cb_set_src_cap(const struct device *dev, const uint32_t␣
↪*pdos,
                                        const int num_pdos)
{
        struct port0_data_t *dpm_data;
        int num;
        int i;

        dpm_data = usbc_get_dpm_data(dev);

        num = num_pdos;
        if (num > PDO_MAX_DATA_OBJECTS) {
                num = PDO_MAX_DATA_OBJECTS;
        }

        for (i = 0; i < num; i++) {
                dpm_data->src_caps[i] = *(pdos + i);
        }

        dpm_data->src_cap_cnt = num;
}

static uint32_t port0_policy_cb_get_rdo(const struct device *dev)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        return build_rdo(dpm_data);
}
```

This callback is used by the subsystem to query if a certain action can be taken:

```
bool port0_policy_check(const struct device *dev, const enum usbc_policy_check_t␣
↪policy_check)
{
        switch (policy_check) {
        case CHECK_POWER_ROLE_SWAP:
                /* Reject power role swaps */
                return false;
        case CHECK_DATA_ROLE_SWAP_TO_DFP:
                /* Reject data role swap to DFP */
                return false;
        case CHECK_DATA_ROLE_SWAP_TO_UFP:
                /* Accept data role swap to UFP */
                return true;
        case CHECK_SNK_AT_DEFAULT_LEVEL:
                /* This device is always at the default power level */
                return true;
        default:
                /* Reject all other policy checks */
                return false;
        }
}
```

This callback is used by the subsystem to notify the application of an event:

```
static void port0_notify(const struct device *dev, const enum usbc_policy_notify_t␣
↪policy_notify)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        switch (policy_notify) {
        case PROTOCOL_ERROR:
                break;
        case MSG_DISCARDED:
                break;
        case MSG_ACCEPT_RECEIVED:
                break;
        case MSG_REJECTED_RECEIVED:
                break;
        case MSG_NOT_SUPPORTED_RECEIVED:
                break;
        case TRANSITION_PS:
                atomic_set_bit(&dpm_data->ps_ready, 0);
                break;
        case PD_CONNECTED:
                break;
        case NOT_PD_CONNECTED:
                break;
        case POWER_CHANGE_0A0:
                LOG_INF("PWR 0A");
                break;
        case POWER_CHANGE_DEF:
                LOG_INF("PWR DEF");
                break;
        case POWER_CHANGE_1A5:
                LOG_INF("PWR 1A5");
                break;
        case POWER_CHANGE_3A0:
                LOG_INF("PWR 3A0");
                break;
        case DATA_ROLE_IS_UFP:
                break;
        case DATA_ROLE_IS_DFP:
                break;
        case PORT_PARTNER_NOT_RESPONSIVE:
                LOG_INF("Port Partner not PD Capable");
                break;
        case SNK_TRANSITION_TO_DEFAULT:
                break;
        case HARD_RESET_RECEIVED:
                break;
        case SENDER_RESPONSE_TIMEOUT:
                break;
        case SOURCE_CAPABILITIES_RECEIVED:
                break;
        default:
        }
}
```

Registering the callbacks:

```
        /* Register USB-C Callbacks */

        /* Register Policy Check callback */
        usbc_set_policy_cb_check(usbc_port0, port0_policy_check);
        /* Register Policy Notify callback */
        usbc_set_policy_cb_notify(usbc_port0, port0_notify);
        /* Register Policy Get Sink Capabilities callback */
        usbc_set_policy_cb_get_snk_cap(usbc_port0, port0_policy_cb_get_snk_cap);
        /* Register Policy Set Source Capabilities callback */
        usbc_set_policy_cb_set_src_cap(usbc_port0, port0_policy_cb_set_src_cap);
        /* Register Policy Get Request Data Object callback */
        usbc_set_policy_cb_get_rdo(usbc_port0, port0_policy_cb_get_rdo);
```

Register the user defined structure:

```
        /* Set Application port data object. This object is passed to the policy␣
↪callbacks */
        port0_data.ps_ready = ATOMIC_INIT(0);
        usbc_set_dpm_data(usbc_port0, &port0_data);
```

Start the USB-C subsystem:

```
        /* Start the USB-C Subsystem */
        usbc_start(usbc_port0);
```

Implementing a Source Type-C and Power Delivery USB-C device The configuration of a USB-C Device is done in the stack layer and devicetree.

Define the following devicetree, structures and callbacks:

- Devicetree `usb-c-connector` node referencing a TCPC
- Devicetree `vbus` node referencing a VBUS measurement device
- Devicetree `pwrctrl` node for VBUS and VCONN power control
- User defined structure that encapsulates application specific data
- Policy callbacks

For example, for the Sample USB-C Source application:

Each Physical Type-C port is represented in the devicetree by a `usb-c-connector` compatible node:

```
                port1: usbc-port@1 {
                        compatible = "usb-c-connector";
                        reg = <1>;
                        tcpc = <&ucpd1>;
                        vbus = <&vbus1>;
                        power-role = "source";
                        typec-power-opmode = "3.0A";
                        source-pdos = <PDO_FIXED(5000, 100, 0) PDO_FIXED(9000, 100,
↪ 0)
                                       PDO_FIXED(15000, 100, 0)>;
                };
```

VBUS is measured by a device that's referenced in the devicetree by a `usb-c-vbus-adc` compatible node:

```
        vbus1: vbus {
                compatible = "zephyr,usb-c-vbus-adc";
                io-channels = <&adc1 9>;
                output-ohms = <49900>;
                full-ohms = <(330000 + 49900)>;

                /* Pin B13 is used to control VBUS Discharge for Port1 */
                discharge-gpios = <&gpiob 13 GPIO_ACTIVE_HIGH>;
        };
```

Power control for VBUS and VCONN can be managed by a device referenced in the devicetree by a `zephyr,usb-c-pwrctrl` compatible node:

```
        pwrctrl1: pwrctrl {
                compatible = "zephyr,usb-c-pwrctrl";

                /* Pin D3 is used to enable VBUS Source */
                source-en-gpios = <&gpiod 3 GPIO_ACTIVE_HIGH>;

                /* Pin A1 is used for DCDC_EN */
                dcdc-en-gpios = <&gpioa 1 GPIO_ACTIVE_HIGH>;

                /* Pin D4 enables VCONN on CC1 */
                vconn1-en-gpios = <&gpiod 4 GPIO_ACTIVE_LOW>;

                /* Pin B9 enables VCONN on CC2 */
                vconn2-en-gpios = <&gpiob 9 GPIO_ACTIVE_LOW>;

                /* PWM for voltage selection */
                pwms = <&pwm15 1 PWM_USEC(50) PWM_POLARITY_INVERTED>;
        };
```

A user defined structure is defined and later registered with the subsystem and can be accessed from callback through an API:

```
/**
 * @brief A structure that encapsulates Port data.
 */
static struct port0_data_t {
        /** Power controller device */
        const struct device *pwrctrl;
        /** Source Capabilities */
        uint32_t src_caps[DT_PROP_LEN(USBC_PORT0_NODE, source_pdos)];
        /** Number of Source Capabilities */
        int src_cap_cnt;
        /** CC Rp value */
        int rp;
        /** Sink Request RDO */
        union pd_rdo sink_request;
        /** Requested Object Pos */
        int obj_pos;
        /** VCONN CC line*/
        enum tc_cc_polarity vconn_pol;
        /** True if power supply is ready */
        bool ps_ready;
        /** True if power supply should transition to a new level */
        bool ps_tran_start;
```

(continues on next page)

(continued from previous page)

```
        /** Log Sink Requested RDO to console */
        atomic_t show_sink_request;
} port0_data = {
        .rp = DT_ENUM_IDX(USBC_PORT0_NODE, typec_power_opmode),
        .src_caps = DT_PROP(USBC_PORT0_NODE, source_pdos),
        .src_cap_cnt = DT_PROP_LEN(USBC_PORT0_NODE, source_pdos),
};

```

These callbacks are used by the subsystem to set or get application specific data:

```
/**
 * @brief PE calls this function when it needs to set the Rp on CC
 */
int port0_policy_cb_get_src_rp(const struct device *dev, enum tc_rp_value *rp)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        *rp = dpm_data->rp;

        return 0;
}

/**
 * @brief PE calls this function to Enable (5V) or Disable (0V) the
 *          Power Supply
 */
int port0_policy_cb_src_en(const struct device *dev, bool en)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        source_ctrl_set(dpm_data->pwrctrl, en ? SOURCE_5V : SOURCE_0V);

        return 0;
}

/**
 * @brief PE calls this function to Enable or Disable VCONN
 */
int port0_policy_cb_vconn_en(const struct device *tcpc_dev, const struct device␣
↪*usbc_dev,
                             enum tc_cc_polarity pol, bool en)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(usbc_dev);

        dpm_data->vconn_pol = pol;

        if (en == false) {
                /* Disable VCONN on CC1 and CC2 */

                 */

                /* Power on VCONN */
                vconn_ctrl_set(dpm_data->pwrctrl, dpm_data->vconn_pol);

                /* PS should be at default level after receiving a Hard Reset */
                return true;
        default:
                /* Reject all other policy checks */
                return false;
        }
}
```

This callback is used by the subsystem to notify the application of an event:

```
static void port0_notify(const struct device *dev, const enum usbc_policy_notify_t␣
↪policy_notify)
{
        struct port0_data_t *dpm_data = usbc_get_dpm_data(dev);

        switch (policy_notify) {
        case PROTOCOL_ERROR:
                break;
        case MSG_DISCARDED:
                break;
        case MSG_ACCEPT_RECEIVED:
                break;
        case MSG_REJECTED_RECEIVED:
                break;
        case MSG_NOT_SUPPORTED_RECEIVED:
                break;
        case TRANSITION_PS:
                dpm_data->ps_tran_start = true;
                break;
        case PD_CONNECTED:
                break;
        case NOT_PD_CONNECTED:
                break;
```

```
        case DATA_ROLE_IS_UFP:
                break;
        case DATA_ROLE_IS_DFP:
                break;
        case PORT_PARTNER_NOT_RESPONSIVE:
                LOG_INF("Port Partner not PD Capable");
                break;
        case HARD_RESET_RECEIVED:
                /*
                 * This notification is sent from the PE_SRC_Transition_to_default
                 * state and requires the following:
                 *        1: Vconn should be turned OFF
                 *        2: Reset of the local hardware
                 */

                /* Power off VCONN */
                vconn_ctrl_set(dpm_data->pwrctrl, VCONN_OFF);
                /* Transition PS to Default level */
                source_ctrl_set(dpm_data->pwrctrl, SOURCE_5V);
                break;
        default:
        }
}
```

Registering the callbacks:

```
        /* Register USB-C Callbacks */

        /* Register Policy Check callback */
        usbc_set_policy_cb_check(usbc_port0, port0_policy_check);
        /* Register Policy Notify callback */
        usbc_set_policy_cb_notify(usbc_port0, port0_notify);
        /* Register Policy callback to set the Rp on CC lines */
        usbc_set_policy_cb_get_src_rp(usbc_port0, port0_policy_cb_get_src_rp);
        /* Register Policy callback to enable or disable power supply */
        usbc_set_policy_cb_src_en(usbc_port0, port0_policy_cb_src_en);
        /* Register Policy callback to enable or disable vconn */
        usbc_set_vconn_control_cb(usbc_port0, port0_policy_cb_vconn_en);
        /* Register Policy callback to send the source caps to the sink */
        usbc_set_policy_cb_get_src_caps(usbc_port0, port0_policy_cb_get_src_caps);
        /* Register Policy callback to check if the sink request is valid */
        usbc_set_policy_cb_check_sink_request(usbc_port0,␣
↪port0_policy_cb_check_sink_request);
        /* Register Policy callback to check if the power supply is ready */
        usbc_set_policy_cb_is_ps_ready(usbc_port0, port0_policy_cb_is_ps_ready);
        /* Register Policy callback to check if Present Contract is still valid */
        usbc_set_policy_cb_present_contract_is_valid(usbc_port0,
                                                     ␣
↪port0_policy_cb_present_contract_is_valid);

```

Register the user defined structure:

```
        /* Set Application port data object. This object is passed to the policy␣
↪callbacks */
        usbc_set_dpm_data(usbc_port0, &port0_data);
```

Start the USB-C subsystem:

```
        /* Start the USB-C Subsystem */
        usbc_start(usbc_port0);
```

Implementing a Dual Role Power (DRP) USB-C device DRP devices can operate as both Source and Sink, automatically negotiating the appropriate role with the port partner. When unattached, the device toggles between Source (Rp) and Sink (Rd) CC line advertisements to detect and connect with any partner type. Once an attach is detected, the device enters the appropriate attached state (Attached.SRC or Attached.SNK) and starts the corresponding Policy Engine state machine (PE_SRC or PE_SNK) to negotiate power delivery.

Configuration is similar to Source and Sink devices, with the following key differences:

- Set `power-role = "dual"` in the devicetree `usb-c-connector` node
- Implement callbacks for both Source and Sink operations

The DRP toggle behavior can be configured via Kconfig:

- `CONFIG_USBC_DRP_PERIOD_MS`: Toggle period (50-100ms, default 75ms)
- `CONFIG_USBC_DRP_DUTY_CYCLE`: Percentage of time as Source (30-70%, default 50%)

See usb-c-drp for a complete example.

4.1.4 Controller Area Network (CAN) Bus Protocols

ISO-TP Transport Protocol

- *Overview*
- *API Reference*

Overview ISO-TP is a transport protocol defined in the ISO-Standard ISO15765-2 Road vehicles - Diagnostic communication over Controller Area Network (DoCAN). Part2: Transport protocol and network layer services. As its name already implies, it is originally designed, and still used in road vehicle diagnostic over Controller Area Networks. Nevertheless, it's not limited to applications in road vehicles or the automotive domain.

This transport protocol extends the limited payload data size for classical CAN (8 bytes) and CAN FD (64 bytes) to theoretically four gigabytes. Additionally, it adds a flow control mechanism to influence the sender's behavior. ISO-TP segments packets into small fragments depending on the payload size of the CAN frame. The header of those segments is called Protocol Control Information (PCI).

Packets smaller or equal to seven bytes on Classical CAN are called single-frames (SF). They don't need to fragment and do not have any flow-control.

Packets larger than that are segmented into a first-frame (FF) and as many consecutive-frames (CF) as required. The FF contains information about the length of the entire payload data and additionally, the first few bytes of payload data. The receiving peer sends back a flow-control-frame (FC) to either deny, postpone, or accept the following consecutive frames. The FC also defines the conditions of sending, namely the block-size (BS) and the minimum separation time between frames (STmin). The block size defines how many CF the sender is allowed to send, before he has to wait for another FC.

4.1.5 LoRa and LoRaWAN

Overview

LoRa (abbrev. for Long Range) is a proprietary low-power wireless communication protocol developed by the Semtech Corporation.

LoRa acts as the physical layer (PHY) based on the chirp spread spectrum (CSS) modulation technique.

LoRaWAN (for Long Range Wide Area Network) defines a networking layer on top of the LoRa PHY.

Zephyr provides APIs for LoRa to send raw data packets directly over the wireless interface as well as APIs for LoRaWAN to connect the end device to the internet through a gateway.

Zephyr provides two LoRaWAN backend implementations:

- **LoRaMac-node** (default): Based on Semtech's LoRaMac-node library, included as a Zephyr module. Supports all regions defined by the LoRaWAN specification. Selected with `CONFIG_LORA_MODULE_BACKEND_LORAMAC_NODE`.
- **Native**: A Zephyr-idiomatic LoRaWAN 1.0.x Class A implementation that talks directly to the LoRa radio driver without external dependencies. Currently supports the EU868 region. Selected with `CONFIG_LORA_MODULE_BACKEND_NATIVE`.

Note

`LoRaMac-node` has been deprecated by Semtech in favor of LoRa Basics Modem. Porting the Zephyr API's to use `LoRa Basics Modem` as the backend is in progress.

Currently, only the base LoRa API is supported for the SX1261, SX1262, SX1272 and SX1276 chipsets through `CONFIG_LORA_MODULE_BACKEND_LORA_BASICS_MODEM`.

The LoRaWAN specification is published by the LoRa Alliance.

Configuration Options

LoRa PHY Related configuration options can be found under drivers/lora/Kconfig.

- `CONFIG_LORA`
- `CONFIG_LORA_SHELL`
- `CONFIG_LORA_INIT_PRIORITY`

LoRaWAN Related configuration options can be found under subsys/lorawan/Kconfig.

- `CONFIG_LORAWAN`
- `CONFIG_LORAWAN_SYSTEM_MAX_RX_ERROR`
- `CONFIG_LORAWAN_REGION_AS923`
- `CONFIG_LORAWAN_REGION_AU915`
- `CONFIG_LORAWAN_REGION_CN470`
- `CONFIG_LORAWAN_REGION_CN779`
- `CONFIG_LORAWAN_REGION_EU433`
- `CONFIG_LORAWAN_REGION_EU868`
- `CONFIG_LORAWAN_REGION_KR920`
- `CONFIG_LORAWAN_REGION_IN865`
- `CONFIG_LORAWAN_REGION_US915`

- CONFIG_LORAWAN_REGION_RU864

Native Backend The native backend is selected with CONFIG_LORA_MODULE_BACKEND_NATIVE and has additional options under subsys/lorawan/native/Kconfig:

- CONFIG_LORAWAN_NATIVE_ENGINE_STACK_SIZE
- CONFIG_LORAWAN_NATIVE_ENGINE_PRIORITY
- CONFIG_LORAWAN_NATIVE_PUBLIC_NETWORK
- CONFIG_LORAWAN_NATIVE_DUTY_CYCLE

4.1.6 Modbus

Modbus is an industrial messaging protocol. The protocol is specified for different types of networks or buses. Zephyr OS implementation supports communication over serial line and may be used with different physical interfaces, like RS485 or RS232. TCP support is not implemented directly, but there are helper functions to realize TCP support according to the application's needs.

Modbus communication is based on client/server model. Only one client may be present on the bus. Client can communicate with several server devices. Server devices themselves are passive and must not send requests or unsolicited responses. Services requested by the client are specified by function codes (FCxx), and can be found in the specification or documentation of the API below.

Zephyr RTOS implementation supports both client and server roles.

More information about Modbus and Modbus RTU can be found on the website MODBUS Protocol Specifications.

Samples

4.1.7 Modem modules

This service provides modules necessary to communicate with modems.

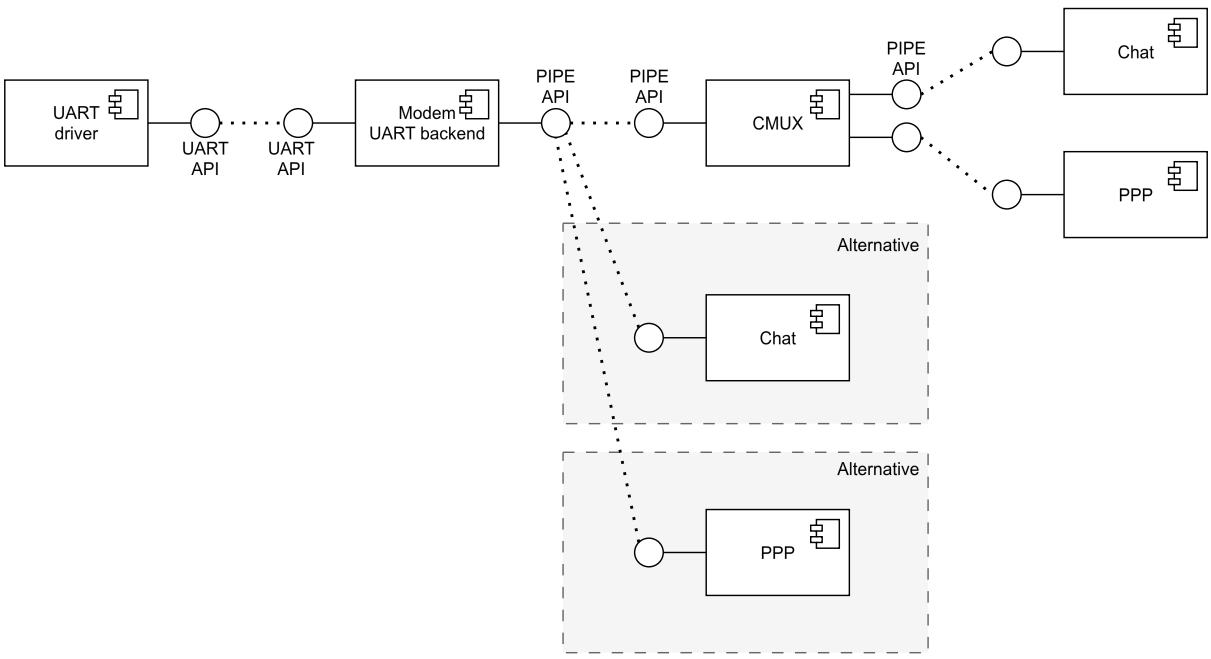
Modems are self-contained devices that implement the hardware and software necessary to perform RF (Radio-Frequency) communication, including GNSS, Cellular, WiFi etc.

The modem modules are inter-connected dynamically using data-in/data-out pipes making them independently testable and highly flexible, ensuring stability and scalability.

Modem pipe

This module is used to abstract data-in/data-out communication over a variety of mechanisms, like UART and CMUX DLCI channels, in a thread-safe manner.

A modem backend will internally contain an instance of a modem_pipe structure, alongside any buffers and additional structures required to abstract away its underlying mechanism.



The modem backend will return a pointer to its internal modem_pipe structure when initialized, which will be used to interact with the backend through the modem pipe API.

Modem Pipe

Related code samples

- AT Command ClientCreate a bidirectional UART bridge between console and modem for AT command communication.

Modem PPP

This module defines and binds a L2 PPP network interface, described in *L2 Layer Management*, to a modem backend. The L2 PPP interface sends and receives network packets. These network packets have to be wrapped in PPP frames before being transported via a modem backend. This module performs said wrapping.

Modem PPP

Modem CMUX

This module is an implementation of CMUX following the 3GPP 27.010 specification. CMUX is a multiplexing protocol, allowing for multiple bi-directional streams of data, called DLCI channels. The module attaches to a single modem backend, exposing multiple modem backends, each representing a DLCI channel.

Protocol defines simple framing for splitting each DLC into small chunks of data.

Flag	Address	Control	Length indicator	Information	FCS	Flag
1 octet	1 octet	1 octet	1 or 2 octet	Unspecified length	1 octet	1 octet

Zephyr implements the basic frame type, with build-time configurable MTU size.

The module also implements power-saving using CMUX Power Saving Command (PSC) for modems that support it. See the *CMUX Power Saving* section below for more details.

Modem CMUX

Modem pipelink

This module is used to share modem pipes globally. This module aims to decouple the creation and setup of modem pipes in device drivers from the users of said pipes. See drivers/modem/modem_at_shell.c and drivers/modem/modem_cellular.c for examples of how to use the modem pipelink between device driver and application.

Modem pipelink

Modem chat

This module implements scripted AT command communication with a modem. AT commands are organized into **scripts**, where each script is a sequence of command–response exchanges. The module sends a command string through a modem pipe and then waits for a response matching one of the expected patterns. When a match is found, an optional callback is invoked with parsed arguments.

Scripts are defined at build time using the `MODEM_CHAT_SCRIPT_DEFINE` and `MODEM_CHAT_SCRIPT_CMDS_DEFINE` macros. Each script entry pairs a request string with one or more `modem_chat_match` patterns. Match patterns support argument parsing by specifying a separator character (for example, `","`), making it easy to extract fields from responses such as `+CSQ: 20,99`.

In addition to scripted exchanges, the module continuously monitors the data stream for **unsolicited** responses — messages the modem sends without a preceding command (for example, `+CEREG:` network registration updates). These are handled by a separate set of match patterns registered when the chat instance is initialized.

The chat module attaches to any modem pipe, so it can communicate over a raw UART backend or over a CMUX DLCI channel interchangeably.

Modem Chat

Cellular Modem

The generic cellular modem driver, drivers/modem/modem_cellular.c, brings together all of the modules described above to implement a complete, hardware-agnostic cellular data connection. It exposes a standard Zephyr network interface so that applications can use the *BSD sockets API* without any modem-specific code.

Architecture overview The driver assembles the modem modules into a layered pipe architecture:

1. **UART backend** — A `modem_backend_uart` instance provides the lowest-level modem pipe. It abstracts the physical UART peripheral into the modem pipe API, performing thread-safe, interrupt-driven transfers.
2. **CMUX** — The `modem_cmux` instance attaches to the UART pipe and multiplexes it into two DLCI channels, following the 3GPP 27.010 specification.
3. **DLCI channel 1 (data)** — This pipe carries either AT command traffic during initialization, or PPP-framed IP data once the connection is established.
4. **DLCI channel 2 (commands)** — This pipe is dedicated to AT command traffic while the data connection is active, allowing the driver to query signal quality, registration status, and other parameters without interrupting the data flow.
5. **Modem chat** — A `modem_chat` instance executes AT command scripts. Before CMUX is started it attaches directly to the UART pipe; afterwards it moves to DLCI 1 for initialization scripts and then to DLCI 2 for periodic monitoring.
6. **Modem PPP** — A `modem_ppp` instance wraps Zephyr IP packets in PPP frames and sends them through DLCI 1. In the receive direction it strips the PPP framing and delivers packets to the network stack.

The simultaneous use of two DLCI channels is the key enabler: the modem can transfer IP data at full speed on DLCI 1 while the driver continues to exchange AT commands on DLCI 2 in the background.

Connection lifecycle The driver is built around an internal state machine that progresses through the following phases:

Power-on and hardware reset The driver pulses the modem reset and power GPIOs (if defined in the Device Tree) and waits for the modem to become responsive.

Initial AT configuration The modem chat module attaches directly to the UART pipe and runs the modem-specific `init_chat_script`. This script typically disables echo, queries the IMEI, model, firmware version, and configures unsolicited response reporting. All communication at this stage is plain AT over UART — CMUX is not yet active.

CMUX bring-up After the init script succeeds the driver sends the `AT+CMUX` command to switch the modem into multiplexed mode. The CMUX module attaches to the UART pipe and opens DLCI 1 and DLCI 2. From this point all communication is framed inside CMUX.

APN configuration and dialing The driver attaches the modem chat to DLCI 1 and runs a dynamically built APN script (`AT+CGDCONT`) followed by the dial script (`ATD*99#` or equivalent). On success the modem enters data mode on DLCI 1.

Data connection The modem PPP module attaches to the DLCI 1 pipe, and the modem chat moves to DLCI 2. The driver calls `net_if_carrier_on()` once a `+CEREG` (or `+CREG` / `+CGREG`) unsolicited response indicates that the modem has registered on the network.

At this point the Zephyr network stack negotiates a PPP session over DLCI 1 and the application can use sockets normally. Meanwhile, periodic chat scripts on DLCI 2 monitor signal quality and registration status.

Shutdown The driver runs a shutdown script and pulses the power-off GPIO to cleanly power down the modem. The state machine returns to the idle state.

Adding support for a new modem The generic cellular driver uses per-modem configuration supplied through Device Tree compatible bindings and associated chat scripts. Adding a new modem requires three artifacts:

1. A **Device Tree binding** that includes the common cellular modem base binding.
2. **Chat scripts** defining the AT command sequences for initialization, dialing, periodic monitoring, and (optionally) shutdown.
3. A **device instantiation macro** that ties the chat scripts and hardware configuration together.

The driver handles all pipe plumbing, CMUX management, PPP framing, and state machine logic automatically.

Supported modems The following modems are already supported in drivers/modem/modem_cellular.c:

- Fibocom LE250
- Quectel BG95, BG96
- Quectel EG25-G, EG800Q
- SIMCom SIM7080, A76xx
- u-blox SARA-R4, SARA-R5, LARA-R6
- Sierra Wireless HL7800
- Telit ME910G1, ME310G1, LE910C1 Thread-x, LEx10Q1
- Nordic Semiconductor nRF91 SLM
- Sequans GM02S

Each supported modem is defined using the same set of macros (`MODEM_CHAT_SCRIPT_CMDS_DEFINE`, `MODEM_CHAT_SCRIPT_DEFINE`, `MODEM_CELLULAR_DEFINE_INSTANCE`, etc.). Refer to drivers/modem/modem_cellular.c for complete examples of init, dial, periodic, and shutdown chat scripts. The common base Device Tree properties shared by all modems are documented in dts/bindings/modem/zephyr,cellular-modem-device.yaml.

Out-of-tree modem The driver macros and data structures are exported through include/zephyr/drivers/modem/modem_cellular.h, so a completely new modem can be defined **outside** the Zephyr tree — for example in application source — without modifying any upstream files. This is useful for fine-tuning AT command sequences for a specific use case, or for developing support for a new modem before submitting it upstream.

Start by creating a Device Tree binding that includes the common base binding, then write a driver source file using the macros from `modem_cellular.h`. The following three files are all that is needed.

Device Tree binding — `app/dts/bindings/my,modem.yaml`:

```
compatible: "my,modem"

include: zephyr,cellular-modem-device.yaml
```

Device Tree overlay — `app.overlay` (partial):

```
&uart30 {
    modem: modem {
        compatible = "my,modem";
        status = "okay";
        mdm-power-gpios = <&gpio1 13 GPIO_ACTIVE_HIGH>;
    };
};
```

Driver source — `app/src/my_modem.c`:

```
#include <zephyr/drivers/modem/modem_cellular.h>
#include <zephyr/device.h>

MODEM_CELLULAR_COMMON_CHAT_MATCHES();
MODEM_CHAT_MATCHES_DEFINE(my_modem_unsol,
    MODEM_CELLULAR_COMMON_UNSOL_MATCHES);

/* Init script - configure the modem, enable unsolicited LTE
 * registration notifications, then switch to CMUX.
 */
MODEM_CHAT_SCRIPT_CMDS_DEFINE(init_chat_script_cmds,
    MODEM_CHAT_SCRIPT_CMD_RESP("ATE0",              ok_match),
    MODEM_CHAT_SCRIPT_CMD_RESP("AT+CEREG=1",        ok_match),
    MODEM_CHAT_SCRIPT_CMD_RESP("AT+CMUX=0,0,5,127", ok_match));

MODEM_CHAT_SCRIPT_DEFINE(init_chat_script, init_chat_script_cmds,
    abort_matches, modem_cellular_chat_callback_handler, 1);

/* Dial script - enable the radio and open data mode */
MODEM_CHAT_SCRIPT_CMDS_DEFINE(dial_chat_script_cmds,
    MODEM_CHAT_SCRIPT_CMD_RESP("AT+CFUN=1", ok_match),
    MODEM_CHAT_SCRIPT_CMD_RESP("ATD*99#",   connect_match));

MODEM_CHAT_SCRIPT_DEFINE(dial_chat_script, dial_chat_script_cmds,
    dial_abort_matches, modem_cellular_chat_callback_handler, 60);

static const struct modem_cellular_vendor_config my_modem_vendor = {
    .scripts = {
        .init = &init_chat_script,
        .dial = &dial_chat_script,
    },
    .unsol_matches = {
        .matches = my_modem_unsol,

                                                                               \
    static struct modem_cellular_data                                          \
        MODEM_CELLULAR_INST_NAME(data, inst);                                  \
                                                                               \
    MODEM_CELLULAR_DEFINE_AND_INIT_USER_PIPES(inst,                            \
        (user_pipe_0, 3), (user_pipe_1, 4))                                    \
                                                                               \
    MODEM_CELLULAR_DEFINE_INSTANCE(inst, &my_modem_vendor, NULL)

#define DT_DRV_COMPAT my_modem
DT_INST_FOREACH_STATUS_OKAY(MY_MODEM_DEVICE)
#undef DT_DRV_COMPAT
```

The example above is minimal but enough to start a PPP connection on a generic cellular modem. Refer to drivers/modem/modem_cellular.c for more complete examples.

Board-specific init script The init, network and dial scripts are vendor-scoped (keyed to the devicetree compatible), so configuration that differs between boards using the same modem, for example RF tuner band routing, would otherwise require forking the vendor driver. A board may instead register its own chat script with `MODEM_CELLULAR_BOARD_INIT_DEFINE`. The script runs over the AT control channel after CMUX is established and before APN and network configuration. Boards that register no script add no ROM or RAM footprint.

The driver overrides the script's completion callback with the one that advances the connect sequence, so any callback set on the script is ignored.

```
MODEM_CHAT_MATCH_DEFINE(board_init_ok_match, "OK", "", NULL);
MODEM_CHAT_SCRIPT_CMDS_DEFINE(board_init_cmds,

CMUX Power Saving

The 3GPP TS 27.010 specifies a power saving mechanism for CMUX which can be used in Zephyr when the modem supports it.

The power saving mechanism is covered in the following sections on the specification:

- 5.2.5 Inter-frame Fill
- 5.4.6.3.2 Power Saving Control (PSC) message
- 5.4.7 Power Control and Wake-up Mechanisms

The power saving mechanism allows runtime power management for the UART device used by the CMUX module. When there is no data to be sent or received on any DLCI channel, the CMUX

module will enter the idle state after a configurable timeout. In the idle state, the CMUX module will send a Power Saving Control message to the modem, requesting it to enter a low power state. The CMUX module may then close the pipe device, allowing the UART device to be powered down if runtime power management is enabled.

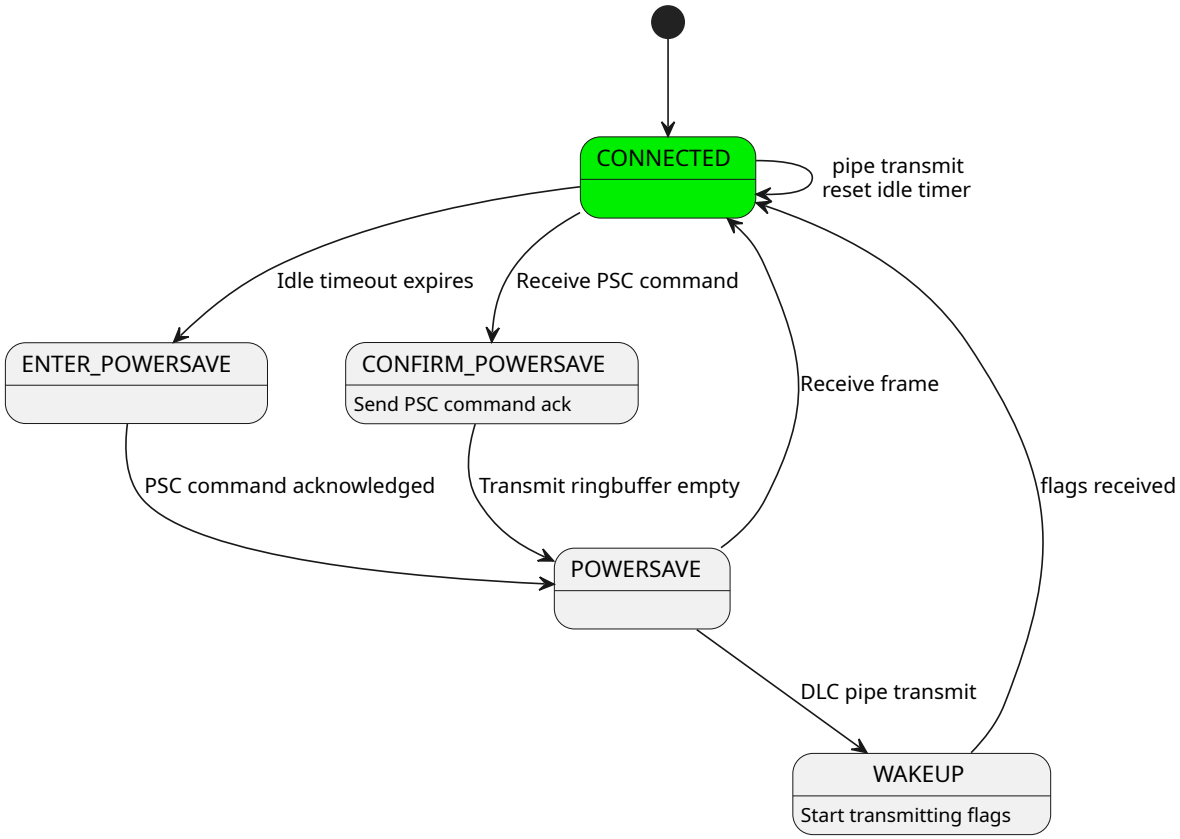
When data is to be sent or received on any DLCI channel, the CMUX module will exit the idle state and wakes the modem up by sending flag characters until it receives a flag character from the modem.

For modems that drive sleep and wake from a hardware line outside CMUX rather than via the in-band protocol, the `cmux-no-powersave-handshake` property opts out of the handshake on both halves. On entry CMUX skips the PSC frame exchange and transitions directly to power save. On exit CMUX skips the flag-character exchange and transitions directly to connected once the pipe is re-opened. The next outgoing frame re-synchronises framing on its own.

Some modems allow UART to be powered down only when the DTR (Data Terminal Ready) signal is de-asserted. In this case, a UART device with DTR support can be used with the CMUX module to control the DTR signal based on the power state of the UART.

Waking up on incoming data when UART is powered down requires a modem that supports RING signal to wake up the host. The RING signal is handled by the modem driver and it opens the pipe device when the RING signal is detected, allowing the CMUX module to wake up the modem and process incoming data.

The subsys/modem/modem_cmux.c module implements the power saving mechanism using the following state machine.



Within a connected state, `modem_cmux_process_received_byte()` is required to reply repeated flag characters as described in 5.2.5 Inter-frame Fill at the specification. Idle timer is kept running and cleared on every sent or received frame. Timer expiry will initiate transitioning to power saving modes.

Within the POWERSAVE state all DLC pipes remain open but the pipe towards UART is blocked or closed, so all data is buffered within CMUX ringbuffers to wait for waking up. Within this state,

repeated flag characters are also replied to allow remote end proceed with wake-up procedure as described in 5.4.7. If pipe is closed, it allows UART device to be powered down if runtime power management is enabled.

When idle timer expires on CONNECTED state, CMUX state machine blocks all DLC pipes and sends PSC command for remote end to initiate transitioning to POWERSAVE state. When PSC command is replied, CMUX transitions to POWERSAVE mode.

When within the CONNECTED state, the remote end may send a PSC command to initiate the transitioning to power saving mode. CMUX blocks all DLC pipes and sends a PSC response. When TX buffers are emptied, CMUX enters the POWERSAVE state.

When any of DLC pipes try to transmit data during POWERSAVE state, CMUX buffers it and moves to WAKEUP state that initiates wake-up procedure as specified in 5.4.7 by sending repeated stream of flag characters. Remote end replies the flag characters to indicate it is ready to receive data. CMUX then stops sending flag characters and moves back to CONNECTED state, resuming normal operation.

The CMUX power saving mechanism can be configured using the following Device Tree properties:

```
cmux-enable-runtime-power-save:
  type: boolean
  description: Enable runtime power saving using CMUX PSC commands.
               This requires modem to support CMUX and PSC commands while keeping␣
↪the data
               connection active.
cmux-close-pipe-on-power-save:
  type: boolean
  description: Close the modem pipe when entering power save mode.
              When runtime power management is enabled, this closes the UART.
              This requires modem to support waking up the UART using RING signal.
cmux-idle-timeout-ms:
  type: int
  description: Time in milliseconds after which CMUX will enter power save mode.
  default: 10000
```

Example Device Tree setup for CMUX with power saving:

```
&uart1 {
  status = "okay";
  zephyr,pm-device-runtime-auto;

  uart_dtr: uart-dtr {
    compatible = "zephyr,uart-dtr";
    dtr-gpios = <&interface_to_nrf9160 4 GPIO_ACTIVE_LOW>;
    status = "okay";
    zephyr,pm-device-runtime-auto;

    modem: modem {
      compatible = "nordic,nrf91-slm";
      status = "okay";
      mdm-ring-gpios = <&interface_to_nrf9160 5 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
      zephyr,pm-device-runtime-auto;
      cmux-enable-runtime-power-save;
      cmux-close-pipe-on-power-save;
      cmux-idle-timeout-ms = <5000>;
    };
  };
};
```

The above example shows a UART device with DTR support being used by a modem that supports CMUX and PSC commands. The DTR signal is used to control the power state of the UART. The RING signal from the modem is used to wake up the modem subsystem when it is powered down.

Input / Output

4.2 Input / Output

This section covers services for interacting with the outside world at runtime: reading from input devices, writing to the console, formatting output, and moving data efficiently between application code and hardware.

4.2.1 Console

Console API

Related code samples

- Console echoEcho an input character back to the output using the Console API.

4.2.2 Input

The input subsystem provides an API for dispatching input events from input devices to the application.

Input Events

The subsystem is built around the `input_event` structure. An input event represents a change in an individual event entity, for example the state of a single button, or a movement in a single axis.

The `input_event` structure describes the specific event, and includes a synchronization bit to indicate that the device reached a stable state, for example when the events corresponding to multiple axes of a multi-axis device have been reported.

Input Devices

An input device can report input events directly using `input_report()` or any related function; for example buttons or other on-off input entities would use `input_report_key()`.

Complex devices may use a combination of multiple events, and set the `sync` bit once the output is stable.

The `input_report*` functions take a `device` pointer, which is used to indicate which device reported the event and can be used by subscribers to only receive events from a specific device. If there's no actual device associated with the event, it can be set to `NULL`, in which case only subscribers with no device filter will receive the event.

Application API

An application can register a callback using the `INPUT_CALLBACK_DEFINE` macro. If a device node is specified, the callback is only invoked for events from the specific device, otherwise the callback will receive all the events in the system. This is the only type of filtering supported, any more complex filtering logic has to be implemented in the callback itself.

The subsystem can operate synchronously or by using an event queue, depending on the `CONFIG_INPUT_MODE` option. If the input thread is used, all the events are added to a queue and

executed in a common `input` thread. If the thread is not used, the callback are invoked directly in the input driver context.

The synchronous mode can be used in a simple application to keep a minimal footprint, or in a complex application with an existing event model, where the callback is just a wrapper to pipe back the event in a more complex application specific event system.

HID code mapping

A common use case for input devices is to use them to generate HID reports. For this purpose, the `input_to_hid_code()` and `input_to_hid_modifier()` functions can be used to map input codes to HID codes and modifiers.

General Purpose Drivers

- `adc-keys`: for buttons connected to a resistor ladder.
- `analog-axis`: for absolute position devices connected to an ADC input (thumbsticks, sliders...).
- `gpio-kbd-matrix`: for GPIO-connected keyboard matrices.
- `gpio-keys`: for switches directly connected to a GPIO, implements button debouncing.
- `gpio-qdec`: for GPIO-connected quadrature encoders.
- `input-keymap`: maps row/col/touch events from a keyboard matrix to key events.
- `zephyr,input-longpress`: listens for key events, emits events for short and long press.
- `zephyr,input-double-tap`: listens for key events, emits events for input double taps and, optionally, single taps
- `zephyr,lvgl-button-input` `zephyr,lvgl-encoder-input` `zephyr,lvgl-keypad-input` `zephyr,lvgl-pointer-input`: listens for input events and translates those to various types of LVGL input devices.

Detailed Driver Documentation

GPIO Keyboard Matrix The `gpio-kbd-matrix` driver supports a large variety of keyboard matrix hardware configurations and has numerous options to change its behavior. This is an overview of some common setups and how they can be supported by the driver.

The conventional configuration for all of these is that the driver reads on the row GPIOs (inputs) and selects on the columns GPIOs (output).

Base use case, no isolation diodes, interrupt capable GPIOs This is the common configuration found on consumer keyboards with membrane switches and flexible circuit boards, no isolation diodes, requires ghosting detection (which is enabled by default).

The system must support GPIO interrupts, and the interrupt can be enabled on all row GPIOs at the same time.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 1 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 2 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_LOW>,
                 <&gpio0 4 GPIO_ACTIVE_LOW>,
                 <&gpio0 5 GPIO_ACTIVE_LOW>;
};
```

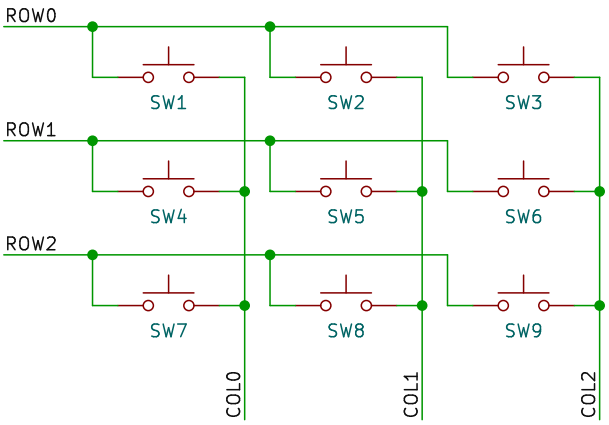


Fig. 23: A 3x3 matrix, no diodes

In this configuration the matrix scanning library enters idle mode once all keys are released, and the keyboard matrix thread only wakes up when a key has been pressed.

GPIOs for columns that are not currently selected are configured in high impedance mode. This means that the row state may need some time to settle to avoid misreading the key state from a column to the following one. The settle time can be tweaked by changing the `settle-time-us` property.

Isolation diodes If the matrix has isolation diodes for every key, then it's possible to:

- disable ghosting detection, allowing any key combination to be detected
- configuring the driver to drive unselected columns GPIO to inactive state rather than high impedance, this allows to reduce the settle time (potentially down to 0), and use the more efficient port wide GPIO read APIs (happens automatically if the GPIO pins are sequential)

Matrixes with diodes going from rows to columns must use pull-ups on rows and active low columns.

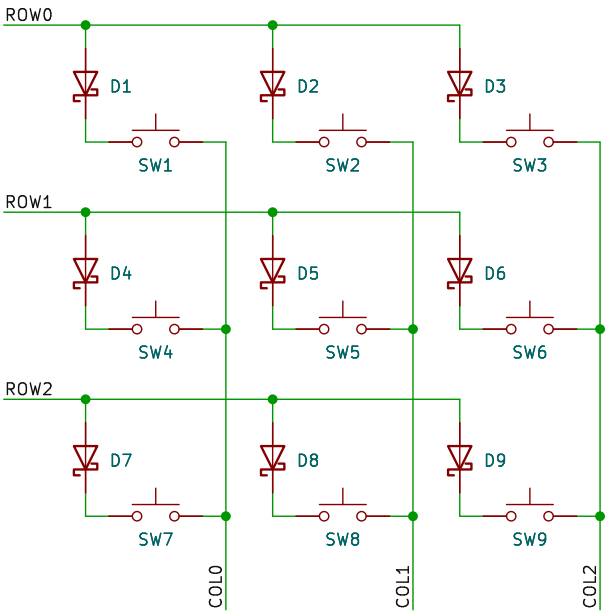

Fig. 24: A 3x3 matrix with row to column isolation diodes.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 1 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>,
                 <&gpio0 2 (GPIO_PULL_UP | GPIO_ACTIVE_LOW)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_LOW>,
                 <&gpio0 4 GPIO_ACTIVE_LOW>,
                 <&gpio0 5 GPIO_ACTIVE_LOW>;
     col-drive-inactive;
     settle-time-us = <0>;
     no-ghostkey-check;
};
```

Matrixes with diodes going from columns to rows must use pull-downs on rows and active high columns.

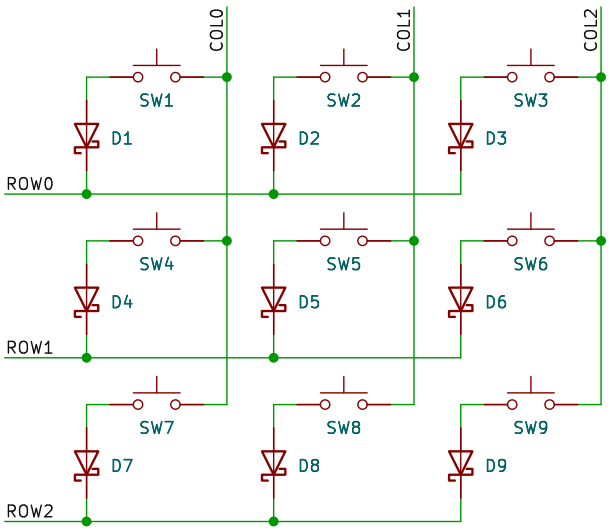

Fig. 25: A 3x3 matrix with column to row isolation diodes.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     row-gpios = <&gpio0 0 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>,
                 <&gpio0 1 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>,
                 <&gpio0 2 (GPIO_PULL_DOWN | GPIO_ACTIVE_HIGH)>;
     col-gpios = <&gpio0 3 GPIO_ACTIVE_HIGH>,
                 <&gpio0 4 GPIO_ACTIVE_HIGH>,
                 <&gpio0 5 GPIO_ACTIVE_HIGH>;
     col-drive-inactive;
     settle-time-us = <0>;
     no-ghostkey-check;
};
```

GPIO with no interrupt support Some GPIO controllers have limitations on GPIO interrupts, and may not support enabling interrupts on all row GPIOs at the same time.

In this case, the driver can be configured to not use interrupt at all, and instead idle by selecting all columns and keep polling on the row GPIOs, which is a single GPIO API operation if the pins are sequential.

This configuration can be enabled by setting the `idle-mode` property to `poll`:

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     idle-mode = "poll";
};
```

GPIO multiplexer In more extreme cases, such as if the columns are using a multiplexer and it's impossible to select all of them at the same time, the driver can be configured to scan continuously.

This can be done by setting `idle-mode` to `scan` and `poll-timeout-ms` to `0`.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     poll-timeout-ms = <0>;
     idle-mode = "scan";
};
```

Row and column GPIO selection If the row GPIOs are sequential and on the same gpio controller, the driver automatically switches API to read from the whole GPIO port rather than the individual pins. This is particularly useful if the GPIOs are not memory mapped, for example on an I2C or SPI port expander, as this significantly reduces the number of transactions on the corresponding bus.

The same is true for column GPIOs, but only if the matrix is configured for `col-drive-inactive`, so that is only usable for matrixes with isolation diodes.

16-bit row support The driver uses an 8-bit datatype to store the row state by default, which limits the matrix row size to 8. This can be increased to 16 by enabling the `CONFIG_INPUT_KBD_MATRIX_16_BIT_ROW` option.

Actual key mask configuration If the key matrix is not complete, a map of the keys that are actually populated can be specified using the `actual-key-mask` property. This allows the matrix state to be filtered to remove keys that are not present before ghosting detection, potentially allowing key combinations that would otherwise be blocked by it.

For example for a 3x3 matrix missing a key:

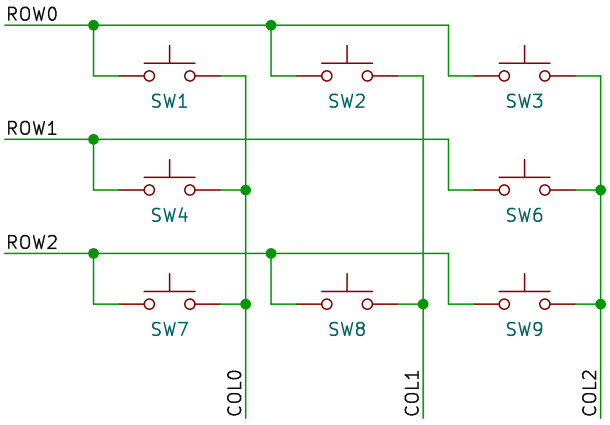

Fig. 26: A 3x3 matrix missing a key.

```
kbd-matrix {
     compatible = "gpio-kbd-matrix";
     ...
     actual-key-mask = <0x07 0x05 0x07>;
};
```

This would allow, for example, to detect pressing SW1, SW2 and SW4 at the same time without triggering anti ghosting.

The actual key mask can be changed at runtime by enabling CONFIG_INPUT_KBD_ACTUAL_KEY_MASK_DYNAMIC and the using the input_kbd_matrix_actual_key_mask_set() API.

Keymap configuration Keyboard matrix devices report a series of x/y/touch events. These can be mapped to normal key events using the input-keymap driver.

For example, the following would setup a keymap device that take the x/y/touch events as an input and generate corresponding key events as an output:

```
kbd {
    ...
    keymap {
        compatible = "input-keymap";
        keymap = <
            MATRIX_KEY(0, 0, INPUT_KEY_1)
            MATRIX_KEY(0, 1, INPUT_KEY_2)
            MATRIX_KEY(0, 2, INPUT_KEY_3)
            MATRIX_KEY(1, 0, INPUT_KEY_4)
            MATRIX_KEY(1, 1, INPUT_KEY_5)
            MATRIX_KEY(1, 2, INPUT_KEY_6)
            MATRIX_KEY(2, 0, INPUT_KEY_7)
            MATRIX_KEY(2, 1, INPUT_KEY_8)
            MATRIX_KEY(2, 2, INPUT_KEY_9)
        >;
        row-size = <3>;
        col-size = <3>;
    };
};
```

Keymap utilities

Keyboard matrix shell commands The shell command kbd_matrix_state_dump can be used to test the functionality of any keyboard matrix driver implemented using the keyboard matrix library. Once enabled it logs the state of the matrix every time it changes, and once disabled it prints an or-mask of any key that has been detected, which can be used to set the actual-key-mask property.

The command can be enabled using the CONFIG_INPUT_SHELL_KBD_MATRIX_STATE.

Example usage:

```
uart:~$ device list
devices:
- kbd-matrix (READY)
uart:~$ input kbd_matrix_state_dump kbd-matrix
Keyboard state logging enabled for kbd-matrix
[00:01:41.678,466] <inf> input: kbd-matrix state [01 -- -- --] (1)
[00:01:41.784,912] <inf> input: kbd-matrix state [-- -- -- --] (0)
```

(continues on next page)

(continued from previous page)

```
...
press more buttons
...
uart:~$ input kbd_matrix_state_dump off
Keyboard state logging disabled
[00:01:47.967,651] <inf> input: kbd-matrix key-mask [07 05 07 --] (8)
```

Keyboard matrix library The GPIO keyboard matrix driver is based on a generic keyboard matrix library, which implements the core functionalities such as scanning delays, debouncing, idle mode etc. This can be reused to implement other keyboard matrix drivers, potentially application specific.

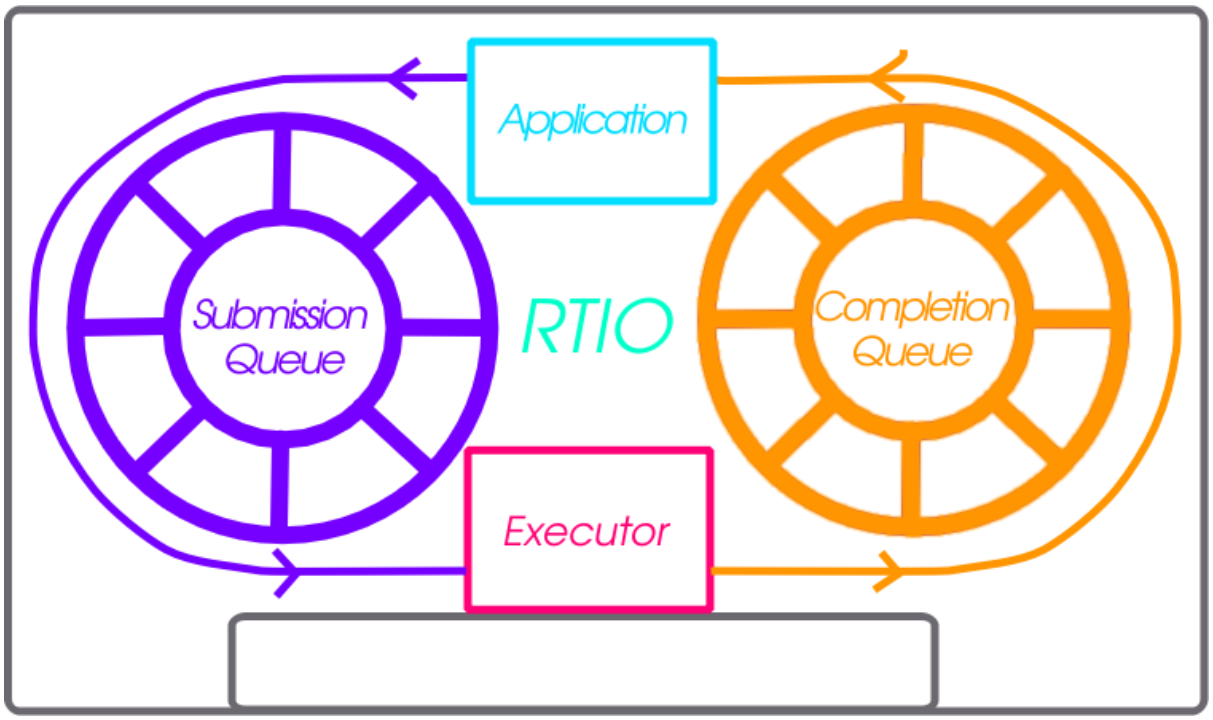
4.2.3 Real Time I/O (RTIO)

- *Problem*
- *Inspiration, introducing io_uring*
- *Submission Queue*
- *Completion Queue*
- *Executor*
- *IO Device*
- *Cancellation*
- *Memory pools*
- *When to Use*
- *Supported Buses*
- *API Reference*



RTIO provides a framework for doing asynchronous operation chains with event driven I/O. This section covers the RTIO API, queues, executor, iodev, and common usage patterns with peripheral devices.

RTIO takes a lot of inspiration from Linux's io_uring in its operations and API as that API matches up well with hardware transfer queues and descriptions such as DMA transfer lists.

Problem

An application wishing to do complex DMA or interrupt driven operations today in Zephyr requires direct knowledge of the hardware and how it works. There is no understanding in the DMA API of other Zephyr devices and how they relate.

This means doing complex audio, video, or sensor streaming requires direct hardware knowledge or leaky abstractions over DMA controllers. Neither is ideal.

To enable asynchronous operations, especially with DMA, a description of what to do rather than direct operations through C and callbacks is needed. Enabling DMA features such as channels with priority, and sequences of transfers requires more than a simple list of descriptions.

Using DMA and/or interrupt driven I/O shouldn't dictate whether or not the call is blocking or not.

Inspiration, introducing io_uring

It's better not to reinvent the wheel (or ring in this case) and io_uring as an API from the Linux kernel provides a winning model. In io_uring there are two lock-free ring buffers acting as queues shared between the kernel and a userland application. One queue for submission entries which may be chained and flushed to create concurrent sequential requests. A second queue for completion queue events. Only a single syscall is actually required to execute many operations, the io_uring_submit call. This call may block the caller when a number of operations to wait on is given.

This model maps well to DMA and interrupt driven transfers. A request to do a sequence of operations in an asynchronous way directly relates to the way hardware typically works with interrupt driven state machines potentially involving multiple peripheral IPs like bus and DMA controllers.

Submission Queue

The submission queue (sq), is the description of the operations to perform in concurrent chains.

For example imagine a typical SPI transfer where you wish to write a register address to then read from. So the sequence of operations might be...

1. Chip Select
2. Clock Enable
3. Write register address into SPI transmit register
4. Read from the SPI receive register into a buffer
5. Disable clock
6. Disable Chip Select

If anything in this chain of operations fails give up. Some of those operations can be embodied in a device abstraction that understands a read or write implicitly means setup the clock and chip select. The transactional nature of the request also needs to be embodied in some manner. Of the operations above perhaps the read could be done using DMA as its large enough make sense. That requires an understanding of how to setup the device's particular DMA to do so.

The above sequence of operations is embodied in RTIO as chain of submission queue entries (sqe). Chaining is done by setting a bitflag in an sqe to signify the next sqe must wait on the current one.

Because the chip select and clocking is common to a particular SPI controller and device on the bus it is embodied in what RTIO calls an iodev.

Multiple operations against the same iodev are done in the order provided as soon as possible. If two operation chains have varying points using the same device its possible one chain will have to wait for another to complete.

Completion Queue

In order to know when a sqe has completed there is a completion queue (cq) with completion queue events (cqe). A sqe once completed results in a cqe being pushed into the cq. The ordering of cqe may not be the same order of sqe. A chain of sqe will however ensure ordering and failure cascading.

Other potential schemes are possible but a completion queue is a well trod idea with io_uring and other similar operating system APIs.

Executor

The RTIO executor is a low overhead concurrent I/O task scheduler. It ensures certain request flags provide the expected behavior. It takes a list of submissions working through them in order. Various flags allow for changing the behavior of how submissions are worked through. Flags to form in order chains of submissions, transactional sets of submissions, or create multi-shot (continuously producing) requests are all possible!

IO Device

Turning submission queue entries (sqe) into completion queue events (cqe) is the job of objects implementing the iodev (IO device) API. This API accepts requests in the form of the iodev submit API call. It is the io devices job to work through its internal queue of submissions and convert them into completions. In effect every io device can be viewed as an independent, event driven actor like object, that accepts a never ending queue of I/O like requests. How the iodev does this work is up to the author of the iodev, perhaps the entire queue of operations can be converted to a set of DMA transfer descriptors, meaning the hardware does almost all of the real work.

Cancellation

Canceling an already queued operation is possible but not guaranteed. If the SQE has not yet started, it's likely that a call to `rtio_sqe_cancel()` will remove the SQE and never run it. If, however, the SQE already started running, the cancel request will be ignored.

Memory pools

In some cases requests to read may not know how much data will be produced. Alternatively, a reader might be handling data from multiple io devices where the frequency of the data is unpredictable. In these cases it may be wasteful to bind memory to in flight read requests. Instead with memory pools the memory to read into is left to the iodev to allocate from a memory pool associated with the RTIO context that the read was associated with. To create such an RTIO context the `RTIO_DEFINE_WITH_MEMPOOL` can be used. It allows creating an RTIO context with a dedicated pool of "memory blocks" which can be consumed by the iodev. Below is a snippet setting up the RTIO context with a memory pool. The memory pool has 128 blocks, each block has the size of 16 bytes, and the data is 4 byte aligned.

```
#include <zephyr/rtio/rtio.h>

#define SQ_SIZE       4
#define CQ_SIZE       4
#define MEM_BLK_COUNT 128
#define MEM_BLK_SIZE  16
#define MEM_BLK_ALIGN 4

RTIO_DEFINE_WITH_MEMPOOL(rtio_context,
    SQ_SIZE, CQ_SIZE, MEM_BLK_COUNT, MEM_BLK_SIZE, MEM_BLK_ALIGN);
```

When a read is needed, the caller simply needs to replace the call `rtio_sqe_prep_read()` (which takes a pointer to a buffer and a length) with a call to `rtio_sqe_prep_read_with_pool()`. The iodev requires only a small change which works with both pre-allocated data buffers as well as the mempool. When the read is ready, instead of getting the buffers directly from the `rtio_iodev_sqe`, the iodev should get the buffer and count by calling `rtio_sqe_rx_buf()` like so:

```
uint8_t *buf;
uint32_t buf_len;
int rc = rtio_sqe_rx_buff(iodev_sqe, MIN_BUF_LEN, DESIRED_BUF_LEN, &buf, &buf_len);

if (rc != 0) {
  LOG_ERR("Failed to get buffer of at least %u bytes", MIN_BUF_LEN);
  return;
}
```

Finally, the consumer will be able to access the allocated buffer via `rtio_cqe_get_mempool_buffer()`.

```
uint8_t *buf;
uint32_t buf_len;
int rc = rtio_cqe_get_mempool_buffer(&rtio_context, &cqe, &buf, &buf_len);

if (rc != 0) {
  LOG_ERR("Failed to get mempool buffer");
  return rc;
}

/* Release the cqe events (note that the buffer is not released yet */
rtio_cqe_release_all(&rtio_context);

/* Do something with the memory */

/* Release the mempool buffer */
rtio_release_buffer(&rtio_context, buf);
```

When to Use

RTIO is useful in cases where concurrent or batch like I/O flows are useful.

From the driver/hardware perspective the API enables batching of I/O requests, potentially in an optimal way. Many requests to the same SPI peripheral for example might be translated to hardware command queues or DMA transfer descriptors entirely. Meaning the hardware can potentially do more than ever.

There is a small cost to each RTIO context and iodev. This cost could be weighed against using a thread for each concurrent I/O operation or custom queues and threads per peripheral. RTIO is much lower cost than that.

Supported Buses

To check if your bus supports RTIO natively, you can check the driver API implementation, if the driver implements the `iodev_submit` function of the bus API, then RTIO is supported. If the driver doesn't support the RTIO APIs, it will set the submit function to `i2c_iodev_submit_fallback`.

I2C buses have a default implementation which allows apps to leverage the RTIO work queue while vendors implement the submit function. With this queue, any I2C bus driver that does not implement the `iodev_submit` function will defer to a work item which will perform a blocking I2C transaction. To change the pool size, set a different value to `CONFIG_RTIO_WORKQ_POOL_ITEMS`.

4.2.4 Formatted Output

Applications as well as Zephyr itself requires infrastructure to format values for user consumption. The standard C99 library `*printf()` functionality fulfills this need for streaming output devices or memory buffers, but in an embedded system devices may not accept streamed data and memory may not be available to store the formatted output.

Internal Zephyr API traditionally provided this both for `printk()` and for Zephyr's internal minimal libc, but with separate internal interfaces. Logging, tracing, shell, and other applications made use of either these APIs or standard libc routines based on build options.

The `cbprintf()` public APIs convert C99 format strings and arguments, providing output produced one character at a time through a callback mechanism, replacing the original internal functions and providing support for almost all C99 format specifications. Existing use of `s*printf()` C libraries in Zephyr can be converted to `snprintfcb()` to avoid pulling in libc implementations.

Several Kconfig options control the set of features that are enabled, allowing some control over features and memory usage:

- `CONFIG_CBPRINTF_FULL_INTEGRAL` or `CONFIG_CBPRINTF_REDUCED_INTEGRAL`
- `CONFIG_CBPRINTF_FP_SUPPORT`
- `CONFIG_CBPRINTF_FP_A_SUPPORT`
- `CONFIG_CBPRINTF_FP_ALWAYS_A`
- `CONFIG_CBPRINTF_N_SPECIFIER`

`CONFIG_CBPRINTF_LIBC_SUBSTS` can be used to provide functions that behave like standard libc functions but use the selected cbprintf formatter rather than pulling in another formatter from libc.

In addition `CONFIG_CBPRINTF_NANO` can be used to revert back to the very space-optimized but limited formatter used for `printk()` before this capability was added.

Cbprintf Packaging

Typically, strings are formatted synchronously when a function from `printf` family is called. However, there are cases when it is beneficial that formatting is deferred. In that case, a state (format string and arguments) must be captured. Such state forms a self-contained package which contains format string and arguments. Additionally, package may contain copies of strings which are part of a format string (format string or any %s argument). Package primary content resembles va_list stack frame thus standard formatting functions are used to process a package. Since package contains data which is processed as va_list frame, strict alignment must be maintained. Due to required padding, size of the package depends on alignment. When package is copied, it should be copied to a memory block with the same alignment as origin.

Package can have following variants:

- **Self-contained** - non read-only strings appended to the package. String can be formatted from such package as long as there is access to read-only string locations. Package may contain information where read-only strings are located within the package. That information can be used to convert packet to fully self-contained package.
- **Fully self-contained** - all strings are appended to the package. String can be formatted from such package without any external data.
- **Transient**- only arguments are stored. Package contain information where pointers to non read-only strings are located within the package. Optionally, it may contain read-only string location information. String can be formatted from such package as long as non read-only strings are still valid and read-only strings are accessible. Alternatively, package can be converted to **self-contained** package or **fully self-contained** if information about read-only string locations is present in the package.

Package can be created using two methods:

- runtime - using `cbprintf_package()` or `cbvprintf_package()`. This method scans format string and based on detected format specifiers builds the package.
- static - types of arguments are detected at compile time by the preprocessor and package is created as simple assignments to a provided memory. This method is significantly faster than runtime (more than 15 times) but has a significant limitation: it cannot distinguish between `%p` and `%s` if char pointer is used. It treats all (unsigned) char pointers as `%s` thus it will attempt to append string to a package. It can be handled correctly during conversion from **transient** package to **self-contained** package using `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag. However, it requires access to the format string and it is not always possible thus it is recommended to cast char pointers used for `%p` to `void *`. There is a logging warning generated by `cbprintf_package_convert()` called with `CBPRINTF_PACKAGE_CONVERT_PTR_CHECK` flag when char pointer is used with `%p`.

Several Kconfig options control behavior of the packaging:

- `CONFIG_CBPRINTF_PACKAGE_LONGDOUBLE`
- `CONFIG_CBPRINTF_STATIC_PACKAGE_CHECK_ALIGNMENT`

Cbprintf package conversion It is possible to convert package to a variant which contains more information, e.g **transient** package can be converted to **self-contained**. Conversion to **fully self-contained** package is possible if `CBPRINTF_PACKAGE_ADD_RO_STR_POS` flag was used when package was created.

`cbprintf_package_copy()` is used to calculate space needed for the new package and to copy and convert a package.

Cbprintf package format Format of the package contains paddings which are platform specific. Package consists of header which contains size of package (excluding appended strings) and number of appended strings. It is followed by the arguments which contains alignment paddings and resembles *va_list* stack frame. It is followed by data associated with character pointer arguments used by the string which are not appended to the string (but may be appended later by `cbprinf_package_convert()`). Finally, package, optionally, contains appended strings. Each string contains 1 byte header which contains index of the location where address argument is stored. During packaging address is set to null and before string formatting it is updated to point to the current string location within the package. Updating address argument must happen just before string formatting since address changes whenever package is copied.

Header sizeof(void *)	1 byte: Argument list size including header and *fmt* (in 32 bit words)
	1 byte: Number of strings appended to the package
	1 byte: Number of read-only string argument locations
	1 byte: Number of transient string argument locations
	platform specific padding to sizeof(void *)
Arguments	Pointer to *fmt* (or null if *fmt* is appended to the package)
	(optional padding for platform specific alignment)
	argument 0
	(optional padding for platform specific alignment)
	argument 1
	...
String location information (optional)	Indexes of words within the package where read-only strings are located
	Pairs of argument index and argument location index where transient strings are located
Appended strings (optional)	1 byte: Index within the package to the location of associated argument
	Null terminated string
	...

Warning

If `CONFIG_MINIMAL_LIBC` is selected in combination with `CONFIG_CBPRINTF_NANO` formatting with C standard library functions like `printf` or `snprintf` is limited. Among other things the `%n` specifier, most format flags, precision control, and floating point are not supported.

Limitations and recommendations

- It is recommended to cast any character pointer used with `%p` format specifier to other pointer type (e.g. `void *`). If format string is not accessible then only static packaging is possible and it will append all detected strings. Character pointer used for `%p` will be considered as string pointer. Copying from unexpected location can have serious consequences (e.g., memory fault or security violation).

Formatted Output APIs

Inter-Process Communication

4.3 Inter-Process Communication

This section covers mechanisms for exchanging data and events between threads, between cores, and between virtualized environments running on the same system.

4.3.1 Interprocessor Communication (IPC)

IPC service

- *Overview*
- *Simple data exchange*
- *Data exchange using the no-copy API*
- *Backends*
- *API Reference*
  - *IPC service API*
  - *IPC service backend API*

The IPC service API provides an interface to exchange data between two domains or CPUs.

Overview An IPC service communication channel consists of one instance and one or several endpoints associated with the instance.

An instance is the external representation of a physical communication channel between two domains or CPUs. The actual implementation and internal representation of the instance is peculiar to each backend.

An individual instance is not used to send data between domains/CPUs. To send and receive the data, the user must create (register) an endpoint in the instance. This allows for the connection of the two domains of interest.

It is possible to have zero or multiple endpoints for one single instance, possibly with different priorities, and to use each to exchange data. Endpoint prioritization and multi-instance ability highly depend on the backend used.

The endpoint is an entity the user must use to send and receive data between two domains (connected by the instance). An endpoint is always associated to an instance.

The creation of the instances is left to the backend, usually at init time. The registration of the endpoints is left to the user, usually at run time.

The API does not mandate a way for the backend to create instances but it is strongly recommended to use the devicetree to retrieve the configuration parameters for an instance. Currently, each backend defines its own DT-compatible configuration that is used to configure the interface at boot time.

The following usage scenarios are supported:

- Simple data exchange.
- Data exchange using the no-copy API.

Simple data exchange To send data between domains or CPUs, an endpoint must be registered onto an instance.

See the following example:

> **Note**
>
> Before registering an endpoint, the instance must be opened using the `ipc_service_open_instance()` function.

```
#include <zephyr/ipc/ipc_service.h>

static void bound_cb(void *priv)
```

(continues on next page)

(continued from previous page)

```
{
   /* Endpoint bounded */
}

static void recv_cb(const void *data, size_t len, void *priv)
{
   /* Data received */
}

static struct ipc_ept_cfg ept0_cfg = {
   .name = "ept0",
   .cb = {
      .bound    = bound_cb,
      .received = recv_cb,
   },
};

int main(void)
{
   const struct device *inst0;
   struct ipc_ept ept0;
   int ret;

   inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
   ret = ipc_service_open_instance(inst0);
   ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

   /* Wait for endpoint bound (bound_cb called) */

   unsigned char message[] = "hello world";
   ret = ipc_service_send(&ept0, &message, sizeof(message));
}
```

Data exchange using the no-copy API If the backend supports the no-copy API you can use it to directly write and read to and from shared memory regions.

See the following example:

```
#include <zephyr/ipc/ipc_service.h>
#include <stdint.h>
#include <string.h>

static struct ipc_ept ept0;

static void bound_cb(void *priv)
{
   /* Endpoint bounded */
}

static void recv_cb_nocopy(const void *data, size_t len, void *priv)
{
   int ret;

   ret = ipc_service_hold_rx_buffer(&ept0, (void *)data);
   /* Process directly or put the buffer somewhere else and release. */
   ret = ipc_service_release_rx_buffer(&ept0, (void *)data);
```

(continues on next page)

(continued from previous page)

```
}

static struct ipc_ept_cfg ept0_cfg = {
   .name = "ept0",
   .cb = {
      .bound    = bound_cb,
      .received = recv_cb,
   },
};

int main(void)
{
   const struct device *inst0;
   int ret;

   inst0 = DEVICE_DT_GET(DT_NODELABEL(ipc0));
   ret = ipc_service_open_instance(inst0);
   ret = ipc_service_register_endpoint(inst0, &ept0, &ept0_cfg);

   /* Wait for endpoint bound (bound_cb called) */
   void *data;
   unsigned char message[] = "hello world";
   uint32_t len = sizeof(message);

   ret = ipc_service_get_tx_buffer(&ept0, &data, &len, K_FOREVER);

   memcpy(data, message, len);

   ret = ipc_service_send_nocopy(&ept0, data, sizeof(message));
}
```

Backends The requirements needed for implementing backends give flexibility to the IPC service. These allow for the addition of dedicated backends having only a subsets of features for specific use cases.

The backend must support at least the following:

- The init-time creation of instances.
- The run-time registration of an endpoint in an instance.

Additionally, the backend can also support the following:

- The run-time deregistration of an endpoint from the instance.
- The run-time closing of an instance.
- The no-copy API.

Each backend can have its own limitations and features that make the backend unique and dedicated to a specific use case. The IPC service API can be used with multiple backends simultaneously, combining the pros and cons of each backend.

ICMsg backend The inter core messaging backend (ICMsg) is a lighter alternative to the heavier RPMsg static vrings backend. It offers a minimal feature set in a small memory footprint. The ICMsg backend is build on top of *Single Producer Single Consumer Packet Buffer*.

Overview The ICMsg backend uses shared memory and MBOX devices for exchanging data. Shared memory is used to store the data, MBOX devices are used to signal that the data has been

written.

The backend supports the registration of a single endpoint on a single instance. If the application requires more than one communication channel, you must define multiple instances, each having its own dedicated endpoint.

Configuration The backend is configured via Kconfig and devicetree. When configuring the backend, do the following:

- If at least one of the cores uses data cache on shared memory, set the `dcache-alignment` value. This must be the largest value of the invalidation or the write-back size for both sides of the communication. You can skip it if none of the communication sides is using data cache on shared memory.
- Define two memory regions and assign them to `tx-region` and `rx-region` of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define MBOX devices which are used to send the signal that informs the other domain (or CPU) that data has been written. Ensure that the other domain (or CPU) is able to receive the signal.

Caution

Make sure that you set correct value of the `dcache-alignment`. At first, wrong value may not show any signs, which may give a false impression that everything works. Unstable behavior will appear sooner or later.

See the following configuration example for one of the instances:

```
reserved-memory {
   tx: memory@20070000 {
      reg = <0x20070000 0x0800>;
   };

   rx: memory@20078000 {
      reg = <0x20078000 0x0800>;
   };
};

   ipc {
      ipc0: ipc0 {
         compatible = "zephyr,ipc-icmsg";
         dcache-alignment = <32>;
         tx-region = <&tx>;
         rx-region = <&rx>;
         mboxes = <&mbox 0>, <&mbox 1>;
         mbox-names = "tx", "rx";
         status = "okay";
      };
   };
};
```

You must provide a similar configuration for the other side of the communication (domain or CPU) but you must swap the MBOX channels and memory regions (`tx-region` and `rx-region`).

Bonding When the endpoint is registered, the following happens on each domain (or CPU) connected through the IPC instance:

1. The domain (or CPU) writes a magic number to its `tx-region` of the shared memory.
2. It then sends a signal to the other domain or CPU, informing that the data has been written. Sending the signal to the other domain or CPU is repeated with timeout.
3. When the signal from the other domain or CPU is received, the magic number is read from `rx-region`. If it is correct, the bonding process is finished and the backend informs the application by calling `ipc_service_cb.bound` callback.

Samples

- ipc-icmsg

Detailed Protocol Specification The ICMsg uses two shared memory regions and two MBOX channels. The region and channel pair are used to transfer messages in one direction. The other pair is symmetric and transfers messages in the opposite direction. For this reason, the specification below focuses on one such pair. The other pair is identical.

The ICMsg provides just one endpoint per instance.

Shared Memory Region Organization If data caching is enabled, the shared memory region provided to ICMsg must be aligned according to the cache requirement. If cache is not enabled, the required alignment is 4 bytes.

The shared memory region is entirely used by a single FIFO. It contains read and write indexes followed by the data buffer. The detailed structure is contained in the following table:

Field name	Size (bytes)	Byte order	Description
`rd_idx`	4	little-endian	Index of the first incoming byte in the `data` field.
`padding`	depends on cache alignment	n/a	Padding added to align `wr_idx` to the cache alignment.
`wr_idx`	4	little-endian	Index of the byte after the last incoming byte in the `data` field.
`data`	everything to the end of the region	n/a	Circular buffer containing actual bytes to transfer.

This is usual FIFO with a circular buffer:

- The Indexes (`rd_idx` and `wr_idx`) are wrapped around when they reach the end of the `data` buffer.
- The FIFO is empty if `rd_idx == wr_idx`.
- The FIFO has one byte less capacity than the `data` buffer length.

Packets Packets are sent over the FIFO described in the above section. One packet can be wrapped around if it occurs at the end of the FIFO buffer.

The following is the packet structure:

Field name	Size (bytes)	Byte order	Description
`len`	2	big-endian	Length of the `data` field.
`reserved`	2	n/a	Reserved for the future use. It must be 0 for the current protocol version.
`data`	`len`	n/a	Packet data.
`padding`	0-3	n/a	Padding is added to align the total packet size to 4 bytes.

The packet send procedure is the following:

1. Check if the packet fits into the buffer.
2. Write the packet to `data` FIFO buffer starting at `wr_idx`. Wrap it if needed.
3. Write a new value of the `wr_idx`.
4. Notify the receiver over the MBOX channel.

Initialization The initialization sequence is the following:

1. Set the `wr_idx` and `rd_idx` to zero.
2. Push a single packet to FIFO containing magic data: `45 6d 31 6c 31 4b 30 72 6e 33 6c 69 34`. The MBOX is not used yet.
3. Initialize the MBOX.
4. Repeat the notification over the MBOX channel using some interval, for example, 1 ms.
5. Wait for an incoming packet containing the magic data. It will arrive over the other pair (shared memory region and MBOX).
6. Stop repeating the MBOX notification.

After this, the ICMsg is bound, and it is ready to transfer packets.

ICMsg with dynamically allocated buffers backend Data transferred over this backend travels in dynamically allocated buffers on shared memory. Allocation is thread safe and can happen from any context. The backend supports:

- Multiple endpoints.
- No-copy sending.
- Holding RX buffers.
- Sending from an interrupt context.
- Two levels of endpoint priorities.
- Statistics and optional shell command with utilization report
- Up to 32 blocks are supported.
- Data cache support.
- Low memory footprint (around 2 kB of code).

Overview For each direction a shared memory region is reserved and each region is divided into two parts. One part forms a pool of fixed size buffers and the allocator builds a variable size buffer from adjacent buffers in the pool. The other part is used for control path consisting of two message queues (for each direction). There is a producer queue which is written by the sender and read by the receiver and a consumer queue which is written by the receiver and read by the sender. The producer queue has information about location (within the pool) of the next message. The consumer queue has information about location (within the pool) of the consumed message.

The data sending process is following:

- The sender allocates one or more blocks from the pool. If there are not enough sequential blocks, a thread context waits using the timeout provided in the parameter that also includes K_FOREVER and K_NO_WAIT.
- The allocated blocks are filled with data. At the beginning of the first block there is a 32 bit message header with length, endpoint ID and own block index. For the zero-copy case, this is done by the caller, otherwise, it is copied automatically. During this time other threads

are not blocked in any way as long as there are enough free blocks for them. They can allocate, send data and receive data.

- A block index with the beginning of the message is written to the producer queue. Information about the priority of the endpoint is appended to the block index. `CONFIG_IPC_SERVICE_BACKEND_ICBMSG_MAX_ACTIVE_COUNT` defines number of slots in the queue. Mailbox notification is send to the receiver.
- The receiver reads the producer queue. Higher prioriy messages are processed first. It can hold the data as long as desired. Again, other threads are not blocked as long as there are enough free blocks for them.
- When data is no longer needed, the receiver writes to the consumer queue the block index.
- The sender is performing a garbage collection by reading the consumer queue and freeing the buffers. Garbage collection is performed after sending any message or if there is no available buffers.

Configuration The backend is configured using Kconfig and devicetree.

There are following Kconfig options:

`CONFIG_IPC_SERVICE_BACKEND_ICBMSG_NUM_EP` - maximum number of registered endpoints.

`CONFIG_IPC_SERVICE_BACKEND_ICBMSG_MAX_ACTIVE_COUNT` - number of slots in the queues.

`CONFIG_IPC_SERVICE_BACKEND_ICBMSG_DEINIT` - support for deregistration and closing.

`CONFIG_IPC_SERVICE_BACKEND_ICBMSG_SHELL` - support for the shell command.

When configuring the backend, do the following:

- If at least one of the cores uses data cache on shared memory, set the `dcache-alignment` value. This must be the largest value of the invalidation or the write-back size for both sides of the communication. You can skip it if none of the communication sides is using data cache on shared memory.
- Define two memory regions and assign them to `tx-region` and `rx-region` of an instance. Ensure that the memory regions used for data exchange are unique (not overlapping any other region) and accessible by both domains (or CPUs).
- Define the number of allocable blocks for each region with `tx-blocks` and `rx-blocks`.
- Define MBOX devices for sending a signal that informs the other domain (or CPU) of the written data. Ensure that the other domain (or CPU) can receive the signal.

Caution

Make sure that you set correct value of the `dcache-alignment`. At first, wrong value may not show any signs, which may give a false impression that everything works. Unstable behavior will appear sooner or later.

If `dcache-alignment` is used then configuration for the number of blocks should be selected carefully to avoid inefficient usage of the memory. That is because the blocks are aligned to the cache alignment and if the number of blocks is not a multiple of the cache alignment then the last block will not be used efficiently. That is because the blocks and control data are aligned to the cache alignment. For example, if `dcache-alignment` is 32 and 1024 bytes of shared memory is used for one direction. Control data will take 64 bytes and 960 bytes are left for the buffers. Using 16 blocks will result in 32 bytes per block (due to the cache alignment). Using 15 blocks will result in 64 bytes per block (due to the cache alignment) with much better memory utilization.

See the following configuration example for one of the instances:

```
reserved-memory {
   tx: memory@20070000 {
      reg = <0x20070000 0x0800>;
   };

   rx: memory@20078000 {
      reg = <0x20078000 0x0800>;
   };
};

ipc {
   ipc0: ipc0 {
      compatible = "zephyr,ipc-icbmsg";
      dcache-alignment = <32>;
      tx-region = <&tx>;
      rx-region = <&rx>;
      tx-blocks = <16>;
      rx-blocks = <16>;
      mboxes = <&mbox 0>, <&mbox 1>;
      mbox-names = "tx", "rx";
      status = "okay";
   };
};
```

You must provide a similar configuration for the other side of the communication (domain or CPU). Swap the MBOX channels, memory regions (`tx-region` and `rx-region`), and block count (`tx-blocks` and `rx-blocks`).

Limitations

- Expected same endianness on both sides of the communication.
- No support for detection of unexpected remote reset.

Samples

- ipc_multi_endpoint

Detailed Protocol Specification The ICBMsg protocol transfers messages using dynamically allocated blocks of shared memory.

Shared Memory Organization The ICBMsg uses two shared memory regions, `rx-region` for message receiving, and `tx-region` for message transmission. The regions do not need to be next to each other, placed in any specific order, or be of the same size. Those regions are interchanged on each core.

Each shared memory region is divided into following two parts:

- **Control area** - An area reserved by producer and consumer queues.
- **Blocks area** - An area containing allocatable blocks carrying the content of the messages. This area is divided into even-sized blocks aligned to cache boundaries.

The location of each area is calculated to fulfill cache boundary requirements and allow optimal region usage. It is calculated using the following algorithm:

Inputs:

- `region_begin`, `region_end` - Boundaries of the region.
- `local_blocks` - Number of blocks in this region.

- `remote_blocks` - Number of blocks in the opposite region.
- `alignment` - Memory cache alignment.

The algorithm:

1. Align region boundaries to cache:
   - `region_begin_aligned = ROUND_UP(region_begin, alignment)`
   - `region_end_aligned = ROUND_DOWN(region_end, alignment)`
   - `region_size_aligned = region_end_aligned - region_begin_aligned`
2. Calculate the minimum size required for the control area:
   - for each queue there is `IPC_SERVICE_BACKEND_ICBMSG_MAX_ACTIVE_COUNT` bytes and 8 byte queue header.
   - Typically control data takes less than 64 bytes per direction.
3. Calculate available size for block area. Note that the actual size may be smaller because of block alignment:

   `blocks_area_available_size = region_size_aligned - control_area`
4. Calculate single block size:

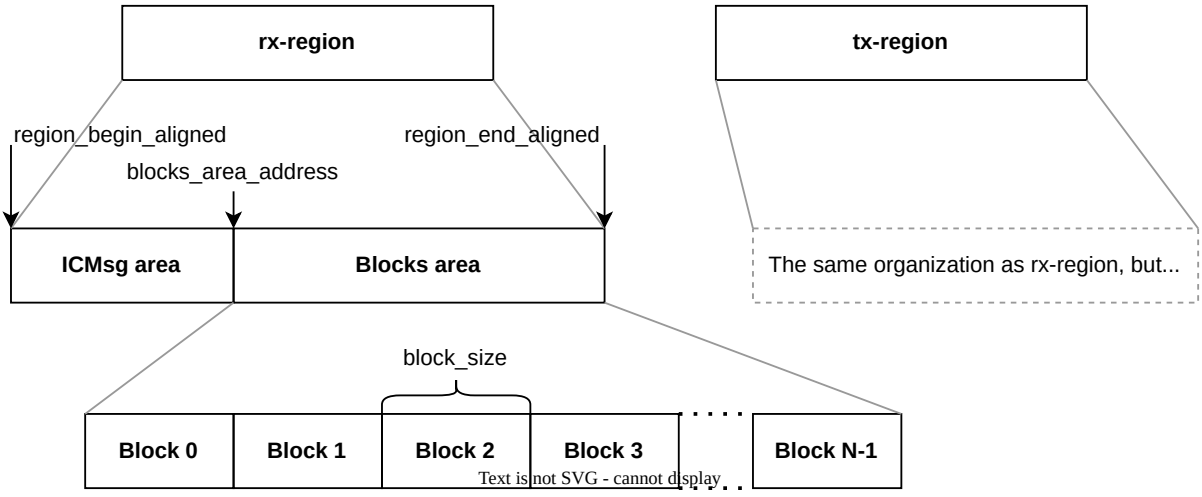
   `block_size = ROUND_DOWN(blocks_area_available_size / local_blocks, alignment)`
5. Calculate actual block area size:

   `blocks_area_size = block_size * local_blocks`
6. Calculate block area start address:

   `blocks_area_begin = region_end_aligned - blocks_area_size`

The result:

- `region_begin_aligned` - The start of ICMsg area.
- `blocks_area_begin` - End of ICMsg area and the start of block area.
- `block_size` - Single block size.
- `region_end_aligned` - End of blocks area.

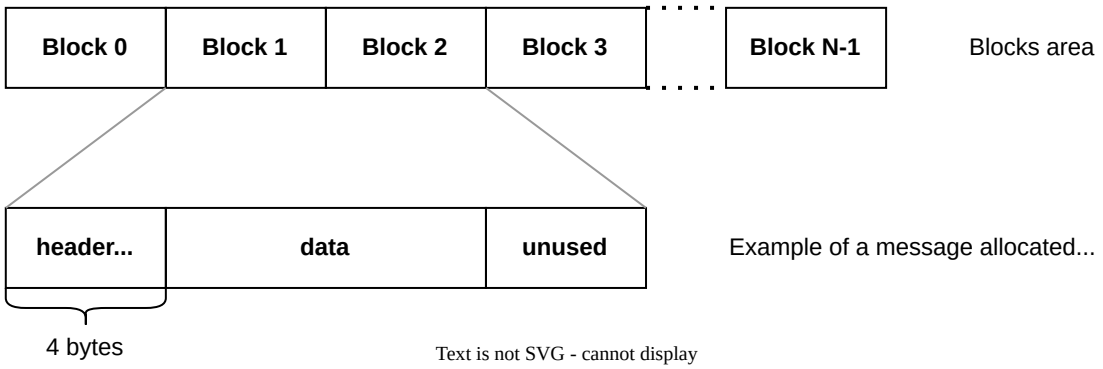


Message Transfer The ICBMsg uses following two types of messages:

- **Control message** - Messages like binding or unbinding.
- **Data message** - Message carrying actual user data.

They serve different purposes, but their lifetime and flow are the same. The following steps describe it:

1. The sender wants to send a message that contains `K` bytes.
2. The sender reserves blocks from his `tx-region` blocks area that can hold at least `K + 4` bytes. The additional `+ 4` bytes are reserved for the header. The blocks must be continuous (one after another). The sender is responsible for block allocation management. If blocks are not available then a thread context may block and an interrupt context will return error.
3. The sender fills the header.
4. The sender fills the remaining part of the blocks with his data. Unused space is ignored.
5. The sender writes the message to the producer queue and sends the mailbox signal.
6. The receiver excutes mailbox callback in the mailbox interrupt context and reads the producer queue.
7. The receiver reads the block index and locates the message within his `rx-region`.
8. The receiver reads the endpoint and message length and processes the message.
9. The receiver consumes the message by writing its block index to the consumer queue. The mailbox signal is not send.
10. The sender checks consume queue after each sending or if sending fails. Messages are read from the consumer queue and released to the pool.



Binding Instances When backend instance is opened it send bound message which contains a 64 bit magic number. Mailbox callback is enabled and instance is waiting for bound message. After receiving bound message, instance is bound to the remote instance and endpoints can be registered.

Binding Endpoint Endpoint binding message contains SHA of the endpoint name and endpoint ID which is the index in the local array with endpoint's data.

There are two possible scenarios:

- The remote instance sent binding message for the endpoint before it was registered.
- The endpoint is registered before receiving the binding message from the remote instance.

When the binding message is received then SHA is compared to the stored SHA in the array of endpoint's data. If match is found then it means that the endpoint is already registered by the local instance. Endpoint ID is stored in the endpoint's data and bound callback is called. If match is not found then empty slot is found and endpoint ID and SHA is stored in the available slot.

When endpoint is registered then SHA for the name is calculated and compared to the stored SHA in the array of endpoint's data. If match is found then it means that remote binding message for that endpoint is already received. In this case binding message is sent to the remote instance and bound callback is called. If match is not found then empty slot is found and endpoint ID and SHA is stored in the available slot. Binding message is sent to the remote instance but endpoints are not bound yet.

Later on, remote endpoint ID is used for data message to identify the endpoint.

Unbinding Endpoint When endpoint is unregistered then unbinding control message is sent. Endpoint is removed from the array of endpoint's data. When unbinding message is received then endpoint slot is marked as empty and unbinding callback is called.

  - *Proxy Agent Configuration Options*
- *API Reference*

Concepts

Threads can send messages to one or more observers using zbus. It makes the many-to-many communication possible. The bus implements message-passing and publish/subscribe communication paradigms that enable threads to communicate synchronously or asynchronously through shared memory.

The communication through zbus is channel-based. Threads (or callbacks) use channels to exchange messages. Additionally, besides other actions, threads can publish and observe channels. When a thread publishes a message on a channel, the bus will make the message available to all the published channel's observers. Based on the observer's type, it can access the message directly, receive a copy of it, or even receive only a reference of the published channel.

The figure below shows an example of a typical application using zbus in which the application logic (hardware independent) talks to other threads via software bus. Note that the threads are decoupled from each other because they only use zbus channels and do not need to know each other to talk.

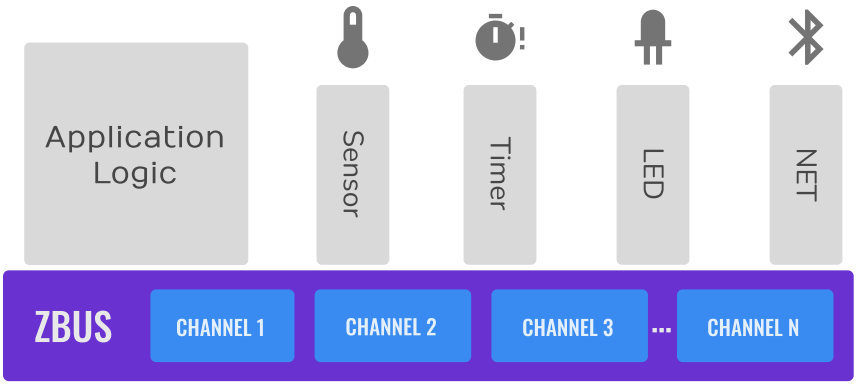

Fig. 27: A typical zbus application architecture.

The bus comprises:

- Set of channels that consists of the control metadata information, and the message itself;
- *Virtual Distributed Event Dispatcher* (VDED), the bus logic responsible for sending notifications/messages to the observers. The VDED logic runs inside the publishing action in the same thread context, giving the bus an idea of a distributed execution. When a thread publishes to a channel, it also propagates the notifications to the observers;
- Threads (subscribers and message subscribers), callbacks (listeners), and async listeners (callbacks deferred to a work queue) publishing, reading, and receiving notifications from the bus.

The bus makes the publish, read, claim, finish, notify, and subscribe actions available over channels. Publishing, reading, claiming, and finishing are available in all RTOS thread contexts and ISRs. The publish and read operations are simple and fast; the procedure is channel locking followed by a memory copy to and from a shared memory region and then a channel unlocking. Another essential aspect of zbus is the observers. There are four types of observers:

- Listeners, a callback that the event dispatcher executes every time an observed channel is published or notified;

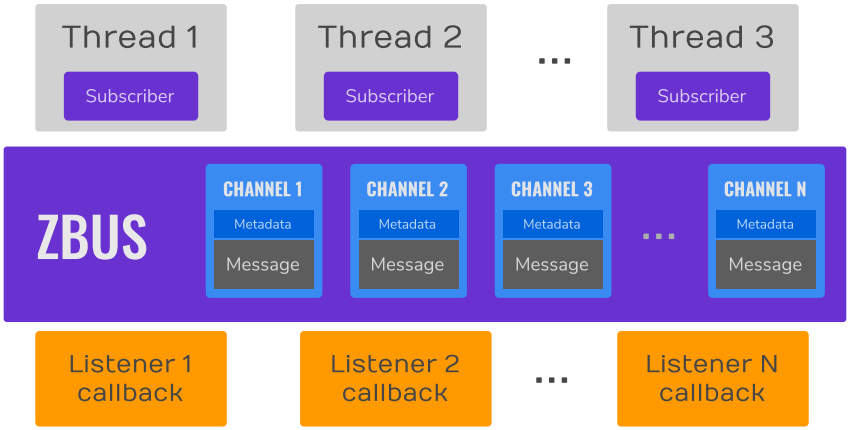

Fig. 28: ZBus anatomy.

Fig. 29: ZBus observers.

- Async Listeners, a callback that the event dispatcher schedules to execute in a work queue (system work queue by default) every time an observed channel is published or notified;
- Subscriber, a thread-based observer that relies internally on a message queue where the event dispatcher puts a changed channel's reference every time an observed channel is published or notified. Note this kind of observer does not receive the message itself. It should read the message from the channel after receiving the notification;
- Message subscribers, a thread-based observer that relies internally on a FIFO where the event dispatcher puts a copy of the message every time an observed channel is published or notified.

Channel observation structures define the relationship between a channel and its observers. For every observation, a channel/observer pair is created. Developers can statically allocate observations using the `ZBUS_CHAN_DEFINE` or `ZBUS_CHAN_ADD_OBS`. There are also runtime observers, enabling developers to create runtime observations. It is possible to disable an observer entirely or observations individually. The event dispatcher will ignore disabled observers and observations.

The above figure illustrates some states, from (a) to (d), for channels from `C1` to `C5`, `Subscriber 1`, and the observations. The last two are in orange to indicate they are dynamically allocated (runtime observation). (a) shows that the observer and all observations are enabled. (b) shows the observer is disabled, so the event dispatcher will ignore it. (c) shows the observer enabled. However, there is one static observation disabled. The event dispatcher will only stop sending notifications from channel `C3`. In (d), the event dispatcher will stop sending notifications from channels `C3` and `C5` to `Subscriber 1`.

Suppose a usual sensor-based solution is in the figure below for illustration purposes. When triggered, the timer publishes to the `Trigger` channel. As the sensor thread subscribed to the `Trigger` channel, it receives the sensor data. Notice the VDED executes the `Blink` because it also listens to the `Trigger` channel. When the sensor data is ready, the sensor thread publishes it to the `Sensor data` channel. The core thread receives the message as a `Sensor data` channel message subscriber, processes the sensor data, and stores it in an internal sample buffer. It repeats until the sample buffer is full; when it happens, the core thread aggregates the sample buffer information, prepares a package, and publishes that to the `Payload` channel. The LoRa thread receives that because it is a `Payload` channel message subscriber and sends the payload to the cloud. When it completes the transmission, the LoRa thread publishes to the `Transmission done` channel. The VDED executes the `Blink` again since it listens to the `Transmission done` channel.

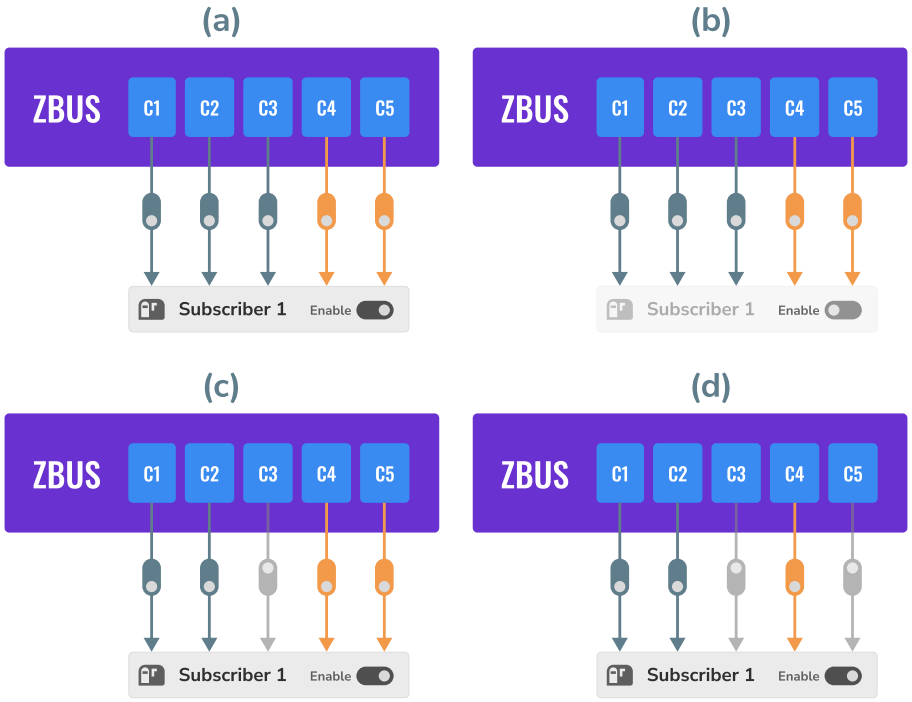

Fig. 30: ZBus observation mask.

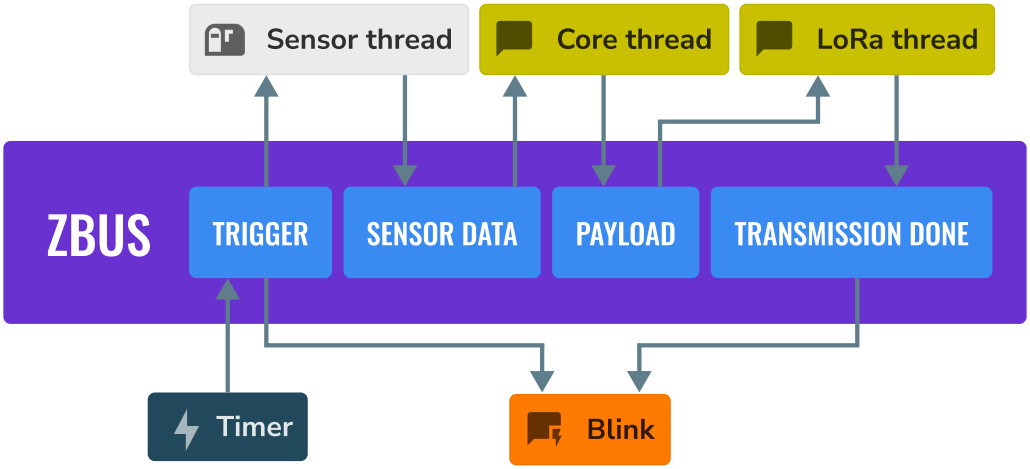

Fig. 31: ZBus sensor-based application.

This way of implementing the solution makes the application more flexible, enabling us to change things independently. For example, we want to change the trigger from a timer to a button press. We can do that, and the change does not affect other parts of the system. Likewise, we would like to change the communication interface from LoRa to Bluetooth; we only need to change the LoRa thread. No other change is required in order to make that work. Thus, the developer would do that for every block of the image. Based on that, this indicates that zbus promotes decoupling in the system architecture.

Another important aspect of using zbus is the reuse of system modules. If a code portion with well-defined behaviors (we call that module) only uses zbus channels and not hardware interfaces, it can easily be reused in other solutions. The new solution must implement the interfaces (set of channels) the module needs to work. That indicates zbus could improve the module reuse.

The last important note is the flexibility of zbus. Zbus provides many features that give developers freedom to create solutions that fit their specific needs. These features include:

- Messages can be dynamically or statically allocated
- Notifications can be synchronous or asynchronous
- Channels can be controlled in various ways by claiming them
- Custom metadata can be added to channels using the user-data field
- Optional validators can be used to enforce message format accuracy

These characteristics expand the range of solutions that can be built with zbus and make it well-suited as an open-source community tool.

Virtual Distributed Event Dispatcher The VDED execution always happens in the publisher's context. It can be a thread or an ISR. Be careful with publications inside ISR because the scheduler won't preempt the VDED. Use that wisely. The basic description of the execution is as follows:

- The channel lock is acquired;
- The channel receives the new message via direct copy (by a raw `memcpy()`);
- The event dispatcher logic executes the listeners, sends a copy of the message to the message subscribers, and pushes the channel's reference to the subscribers' notification message queue in the same sequence they appear on the channel observers' list. The listeners can perform non-copy quick access to the constant message reference directly (via the `zbus_chan_const_msg()` function) since the channel is still locked;
- At last, the publishing function unlocks the channel.

To illustrate the VDED execution, consider the example illustrated below. We have four threads in ascending priority `S1`, `MS2`, `MS1`, and `T1` (the highest priority); two listeners, `L1` and `L2`; and channel A. Supposing `L1`, `L2`, `MS1`, `MS2`, and `S1` observe channel A.

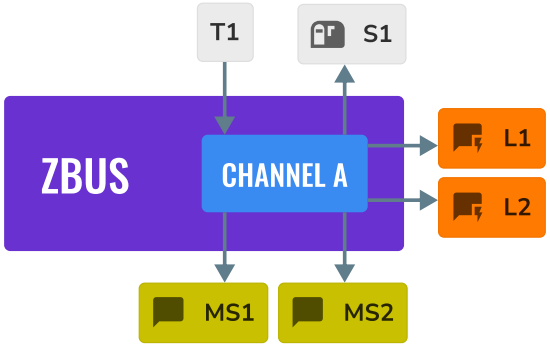

Fig. 32: ZBus VDED execution example scenario.

The following code implements channel A. Note the `struct a_msg` is illustrative only.

```
ZBUS_CHAN_DEFINE(a_chan,                          /* Name */
         struct a_msg,                            /* Message type */

         NULL,                                    /* Validator */
         NULL,                                    /* User Data */
         ZBUS_OBSERVERS(L1, L2, MS1, MS2, S1),    /* observers */
         ZBUS_MSG_INIT(0)                         /* Initial value {0} */
);
```

In the figure below, the letters indicate some action related to the VDED execution. The X-axis represents the time, and the Y-axis represents the priority of threads. Channel A's message, represented by a voice balloon, is only one memory portion (shared memory). It appears several times only as an illustration of the message at that point in time.

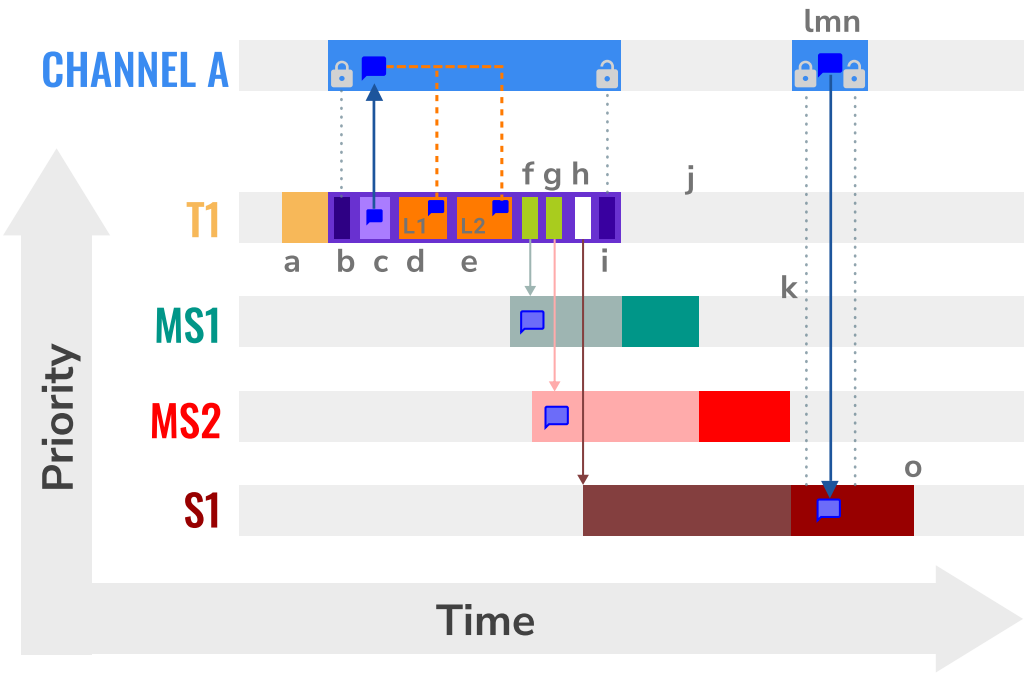

Fig. 33: ZBus VDED execution detail for priority T1 > MS1 > MS2 > S1.

The figure above illustrates the actions performed during the VDED execution when T1 publishes to channel A. Thus, the table below describes the activities (represented by a letter) of the VDED execution. The scenario considers the following priorities: T1 > MS1 > MS2 > S1. T1 has the highest priority.

Table 44: VDED execution steps in detail for priority T1 > MS1 > MS2 > S1.

Actions	Description
a	T1 starts and, at some point, publishes to channel A.
b	The publishing (VDED) process starts. The VDED locks the channel A.
c	The VDED copies the T1 message to the channel A message.
d, e	The VDED executes L1 and L2 in the respective sequence. Inside the listeners, usually, there is a call to the `zbus_chan_const_msg()` function, which provides a direct constant reference to channel A's message. It is quick, and no copy is needed here.
f, g	The VDED copies the message and sends that to MS1 and MS2 sequentially. Notice the threads get ready to execute right after receiving the notification. However, they go to a pending state because they have less priority than T1.
h	The VDED pushes the notification message to the queue of S1. Notice the thread gets ready to execute right after receiving the notification. However, it goes to a pending state because it cannot access the channel since it is still locked.
i	VDED finishes the publishing by unlocking channel A. The MS1 leaves the pending state and starts executing.
j	MS1 finishes execution. The MS2 leaves the pending state and starts executing.
k	MS2 finishes execution. The S1 leaves the pending state and starts executing.
l, m, n	The S1 leaves the pending state since channel A is not locked. It gets in the CPU again and starts executing. As it did receive a notification from channel A, it performed a channel read (as simple as lock, memory copy, unlock), continues its execution and goes out of the CPU.
o	S1 finishes its workload.

The figure below illustrates the actions performed during the VDED execution when T1 publishes to channel A. The scenario considers the following priorities: T1 < MS1 < MS2 < S1.

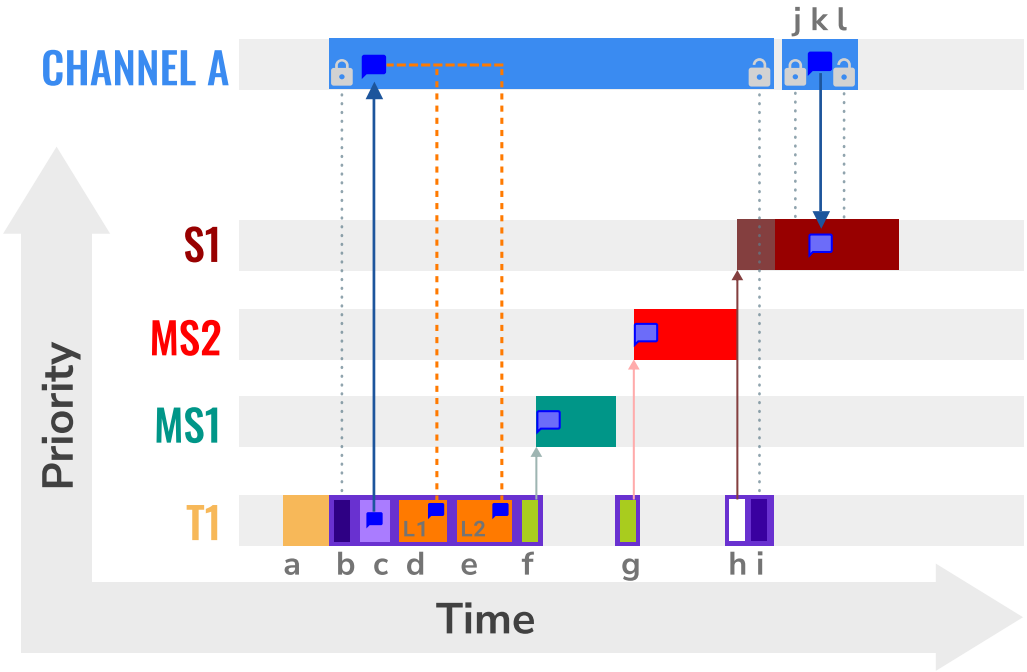

Fig. 34: ZBus VDED execution detail for priority T1 < MS1 < MS2 < S1.

Thus, the table below describes the activities (represented by a letter) of the VDED execution.

Table 45: VDED execution steps in detail for priority T1 < MS1 < MS2 < S1.

Actions	Description
a	T1 starts and, at some point, publishes to channel A.
b	The publishing (VDED) process starts. The VDED locks the channel A.
c	The VDED copies the T1 message to the channel A message.
d, e	The VDED executes L1 and L2 in the respective sequence. Inside the listeners, usually, there is a call to the `zbus_chan_const_msg()` function, which provides a direct constant reference to channel A's message. It is quick, and no copy is needed here.
f	The VDED copies the message and sends that to MS1. MS1 preempts T1 and starts working. After that, the T1 regains the CPU.
g	The VDED copies the message and sends that to MS2. MS2 preempts T1 and starts working. After that, the T1 regains the CPU.
h	The VDED pushes the notification message to the queue of S1.
i	VDED finishes the publishing by unlocking channel A.
j, k, l	The S1 leaves the pending state since channel A is not locked. It gets in the CPU again and starts executing. As it did receive a notification from channel A, it performs a channel read (as simple as lock, memory copy, unlock), continues its execution, and yields the CPU.

HLP priority boost ZBus implements the Highest Locker Protocol that relies on the observers' thread priority to determine a temporary publisher priority. The protocol considers the channel's Highest Observer Priority (HOP); even if the observer is not waiting for a message on the channel, it is considered in the calculation. The VDED will elevate the publisher's priority based on the HOP to ensure small latency and as few preemptions as possible.

Note

The priority boost is enabled by default. To deactivate it, disable the `CONFIG_ZBUS_PRIORITY_BOOST` configuration option.

Warning

ZBus priority boost does not consider runtime observers on the HOP calculations.

The figure below illustrates the actions performed during the VDED execution when T1 publishes to channel A. The scenario considers the priority boost feature and the following priorities: T1 < MS1 < MS2 < S1.

To properly use the priority boost, attaching the observer to a thread is necessary. When the subscriber is attached to a thread, it assumes its priority, and the priority boost algorithm will consider the observer's priority. The following code illustrates the thread-attaching function.

```
ZBUS_SUBSCRIBER_DEFINE(s1, 4);
void s1_thread(void *ptr1, void *ptr2, void *ptr3)
{
        ARG_UNUSED(ptr1);
        ARG_UNUSED(ptr2);
        ARG_UNUSED(ptr3);

        const struct zbus_channel *chan;
```

(continues on next page)

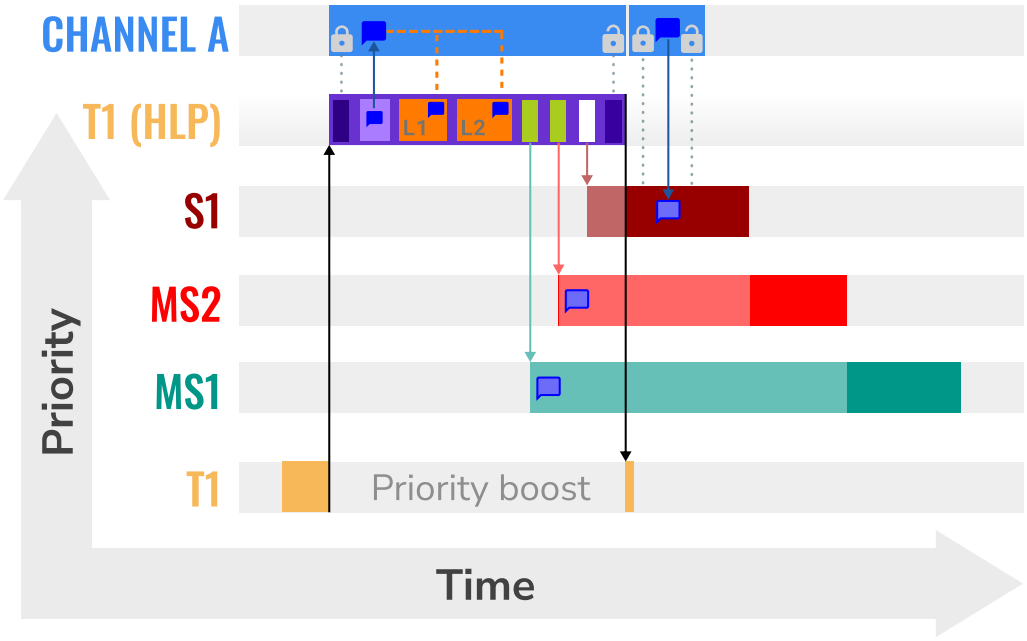

Fig. 35: ZBus VDED execution detail with priority boost enabled and for priority T1 < MS1 < MS2 < S1.

(continued from previous page)

```
        zbus_obs_attach_to_thread(&s1);

        while (1) {
                zbus_sub_wait(&s1, &chan, K_FOREVER);

                /* Subscriber implementation */

        }
}
K_THREAD_DEFINE(s1_id, CONFIG_MAIN_STACK_SIZE, s1_thread, NULL, NULL, NULL, 2, 0,␣
↪0);
```

On the above code, the `zbus_obs_attach_to_thread()` will set the s1 observer with priority two as the thread has that priority. It is possible to reverse that by detaching the observer using the `zbus_obs_detach_from_thread()`. Only enabled observers and observations will be considered on the channel HOP calculation. Masking a specific observation of a channel will affect the channel HOP.

In summary, the benefits of the feature are:

- The HLP is more effective for zbus than the mutexes priority inheritance;
- No bounded priority inversion will happen among the publisher and the observers;
- No other threads (that are not involved in the communication) with priority between T1 and S1 can preempt T1, avoiding unbounded priority inversion;
- Message subscribers will wait for the VDED to finish the message delivery process. So the VDED execution will be faster and more consistent;
- The HLP priority is dynamic and can change in execution;
- ZBus operations can be used inside ISRs;
- The priority boosting feature can be turned off, and plain semaphores can be used as the

channel lock mechanism;

- The Highest Locker Protocol's major disadvantage, the Inheritance-related Priority Inversion, is acceptable in the zbus scenario since it will ensure a small bus latency.

Limitations Based on the fact that developers can use zbus to solve many different problems, some challenges arise. ZBus will not solve every problem, so it is necessary to analyze the situation to be sure zbus is applicable. For instance, based on the zbus benchmark, it would not be well suited to a high-speed stream of bytes between threads. The *Pipe* kernel object solves this kind of need.

Delivery guarantees ZBus always delivers the messages to the listeners, message subscribers, and async listeners. However, there are no message delivery guarantees for subscribers because zbus only sends the notification, but the message reading depends on the subscriber's implementation. It is possible to increase the delivery rate by following design tips:

- Keep the listeners as quick as possible (deal with them as ISRs). If time-consuming processing is required, consider offloading some or all of it to a work queue using async listeners.
- Try to give consumers a high priority to avoid losses.
- Leave spare CPU for observers to consume data produced.
- Consider using message queues or pipes for intensive byte transfers.

Warning

ZBus uses include/zephyr/net_buf.h (network buffers) to exchange data with message subscribers. Thus, choose carefully the configurations `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_SIZE` and `CONFIG_HEAP_MEM_POOL_ADD_SIZE_ZBUS` are crucial to a proper VDED execution (delivery guarantee) considering message subscribers and async listeners. If you want to keep an isolated pool for a specific set of channels, you can use `CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_ISOLATION` with a dedicated pool. Look at the zbus-msg-subscriber and zbus-async-listeners to see the isolation in action.

Warning

Subscribers will receive only the reference of the changing channel. A data loss may be perceived if the channel is published twice before the subscriber reads it. The second publication overwrites the value from the first. Thus, the subscriber will receive two notifications, but only the last data is there.

Message delivery sequence The message delivery will follow the precedence:

1. Observers defined in a channel using the `ZBUS_CHAN_DEFINE` (following the definition sequence);
2. Observers defined using the `ZBUS_CHAN_ADD_OBS` based on the sequence priority (parameter of the macro);
3. The latest is the runtime observers in the addition sequence using the `zbus_chan_add_obs()`.

Note

The VDED will ignore all disabled observers or observations.

Usage

ZBus operation depends on channels and observers. Therefore, it is necessary to determine the channel's message during the channel definition and its list of observers, which can be either statically (in the channel definition), using the ZBUS_CHAN_ADD_OBS or at runtime (see *runtime observers*). A message is a regular C struct; the observer can be a listener (synchronous), an async listener (asynchronous), a subscriber (asynchronous), or a message subscriber (asynchronous).

The following code defines and initializes a regular channel and its dependencies. This channel exchanges accelerometer data, for example.

```
struct acc_msg {
        int x;
        int y;
        int z;
};

ZBUS_CHAN_DEFINE(acc_chan,                              /* Name */
         struct acc_msg,                                /* Message type */

         NULL,                                          /* Validator */
         NULL,                                          /* User Data */
         ZBUS_OBSERVERS(my_listener, my_subscriber,
                        my_msg_subscriber),             /* observers */
         ZBUS_MSG_INIT(.x = 0, .y = 0, .z = 0)          /* Initial value */
);

void listener_callback_example(const struct zbus_channel *chan)
{
        const struct acc_msg *acc;
        if (&acc_chan == chan) {
                acc = zbus_chan_const_msg(chan); // Direct message access
                LOG_DBG("From listener -> Acc x=%d, y=%d, z=%d", acc->x, acc->y,␣
↪acc->z);
        }
}

ZBUS_LISTENER_DEFINE(my_listener, listener_callback_example);

ZBUS_LISTENER_DEFINE(my_listener2, listener_callback_example);

ZBUS_CHAN_ADD_OBS(acc_chan, my_listener2, 3);

ZBUS_SUBSCRIBER_DEFINE(my_subscriber, 4);
void subscriber_task(void)
{
        const struct zbus_channel *chan;

        while (!zbus_sub_wait(&my_subscriber, &chan, K_FOREVER)) {
                struct acc_msg acc = {0};

                if (&acc_chan == chan) {
                        // Indirect message access
                        zbus_chan_read(&acc_chan, &acc, K_NO_WAIT);
                        LOG_DBG("From subscriber -> Acc x=%d, y=%d, z=%d", acc.x,␣
↪acc.y, acc.z);
                }
        }
```

(continues on next page)

(continued from previous page)

```
}
K_THREAD_DEFINE(subscriber_task_id, 512, subscriber_task, NULL, NULL, NULL, 3, 0,␣
↪0);

ZBUS_MSG_SUBSCRIBER_DEFINE(my_msg_subscriber);
static void msg_subscriber_task(void *ptr1, void *ptr2, void *ptr3)
{
        ARG_UNUSED(ptr1);
        ARG_UNUSED(ptr2);
        ARG_UNUSED(ptr3);
        const struct zbus_channel *chan;

        struct acc_msg acc = {0};

        while (!zbus_sub_wait_msg(&my_msg_subscriber, &chan, &acc, K_FOREVER)) {
                if (&acc_chan == chan) {
                        LOG_INF("From msg subscriber -> Acc x=%d, y=%d, z=%d",␣
↪acc.x, acc.y, acc.z);
                }
        }
}
K_THREAD_DEFINE(msg_subscriber_task_id, 1024, msg_subscriber_task, NULL, NULL,␣
↪NULL, 3, 0, 0);
```

It is possible to add static observers to a channel using the `ZBUS_CHAN_ADD_OBS`. We call that a post-definition static observer. The command enables us to indicate an initialization priority that affects the observers' initialization order. The sequence priority param only affects the post-definition static observers. There is no possibility to overwrite the message delivery sequence of the static observers.

Note

It is unnecessary to claim/lock a channel before accessing the message inside the listener since the event dispatcher calls listeners with the notifying channel already locked. Subscribers, however, must claim/lock that or use regular read operations to access the message after being notified.

Channels can have a *validator function* that enables a channel to accept only valid messages. Publish attempts invalidated by hard channels will return immediately with an error code. This allows original creators of a channel to exert some authority over other developers/publishers who may want to piggy-back on their channels. The following code defines and initializes a *hard channel* and its dependencies. Only valid messages can be published to a *hard channel*. It is possible because a *validator function* was passed to the channel's definition. In this example, only messages with `move` equal to 0, -1, and 1 are valid. Publish function will discard all other values to `move`.

```
struct control_msg {
        int move;
};

bool control_validator(const void* msg, size_t msg_size) {
        const struct control_msg* cm = msg;
        bool is_valid = (cm->move == -1) || (cm->move == 0) || (cm->move == 1);
        return is_valid;
}
```

(continues on next page)

(continued from previous page)

```
static int message_count = 0;

ZBUS_CHAN_DEFINE(control_chan,     /* Name */
         struct control_msg,       /* Message type */

         control_validator,        /* Validator */
         &message_count,           /* User data */
         ZBUS_OBSERVERS_EMPTY,     /* observers */
         ZBUS_MSG_INIT(.move = 0) /* Initial value */
);
```

The following sections describe in detail how to use zbus features.

Publishing to a channel Messages are published to a channel in zbus by calling `zbus_chan_pub()`. For example, the following code builds on the examples above and publishes to channel `acc_chan`. The code is trying to publish the message `acc1` to channel `acc_chan`, and it will wait up to one second for the message to be published. Otherwise, the operation fails. As can be inferred from the code sample, it's OK to use stack allocated messages since VDED copies the data internally.

```
struct acc_msg acc1 = {.x = 1, .y = 1, .z = 1};
zbus_chan_pub(&acc_chan, &acc1, K_SECONDS(1));
```

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

Reading from a channel Messages are read from a channel in zbus by calling `zbus_chan_read()`. So, for example, the following code tries to read the channel `acc_chan`, which will wait up to 500 milliseconds to read the message. Otherwise, the operation fails.

```
struct acc_msg acc = {0};
zbus_chan_read(&acc_chan, &acc, K_MSEC(500));
```

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

Warning

Choose the timeout of `zbus_chan_read()` after receiving a notification from `zbus_sub_wait()` carefully because the channel will always be unavailable during the VDED execution. Using `K_NO_WAIT` for reading is highly likely to return a timeout error if there are more than one subscriber. For example, consider the VDED illustration again and notice how `S1` read attempts would definitely fail with K_NO_WAIT. For more details, check the *Virtual Distributed Event Dispatcher* section.

Notifying a channel It is possible to force zbus to notify a channel's observers by calling `zbus_chan_notify()`. For example, the following code builds on the examples above and forces a notification for the channel `acc_chan`. Note this can send events with no message, which does

not require any data exchange. See the code example under *Claim and finish a channel* where this may become useful.

```
zbus_chan_notify(&acc_chan, K_NO_WAIT);
```

Warning

Only use this function inside an ISR with a K_NO_WAIT timeout.

Declaring channels and observers For accessing channels or observers from files other than its defining files, it is necessary to declare them by calling ZBUS_CHAN_DECLARE and ZBUS_OBS_DECLARE. In other words, zbus channel definitions and declarations with the same channel names in different files would point to the same (global) channel. Thus, developers should be careful about existing channels, and naming new channels or linking will fail. It is possible to declare more than one channel or observer on the same call. The following code builds on the examples above and displays the defined channels and observers.

```
ZBUS_OBS_DECLARE(my_listener, my_subscriber);
ZBUS_CHAN_DECLARE(acc_chan, version_chan);
```

Unique channel identifiers To simplify integrations with external entities, it is possible to assign a unique numeric identifier to a channel. Users can then retrieve the channel reference by using the identifier with zbus_chan_from_id(), rather than needing to obtain the reference at compile time with ZBUS_CHAN_DECLARE. Channels using this feature are declared with ZBUS_CHAN_DEFINE_WITH_ID.

```
ZBUS_CHAN_DEFINE_WITH_ID(control_chan,    /* Name */
    0x12345678,              /* Unique channel identifier */
    struct control_msg,      /* Message type */
    control_validator,       /* Validator */
    &message_count,          /* User data */
    ZBUS_OBSERVERS_EMPTY,    /* observers */
    ZBUS_MSG_INIT(.move = 0) /* Initial value */
);

static void channel_retrieve(void)
{
    const struct zbus_channel *chan = zbus_chan_from_id(0x12345678);

    ...
}
```

Runtime channel creation ZBus allows for the creation of channels at runtime when CONFIG_ZBUS_RUNTIME_CHANNEL_REGISTRATION is enabled. This is useful in scenarios where the number of channels or their configuration is not known at compile time. The following code demonstrates how to create a channel at runtime. Note that the zbus_runtime_channel, zbus_channel_data and message structures passed to zbus_runtime_channel_register() must remain valid in memory until zbus_runtime_channel_unregister() is called.

```
struct runtime_msg {
    int data;
};

void create_runtime_channel(void)
```

(continues on next page)

(continued from previous page)

```
{
    struct zbus_runtime_channel runtime_chan;
    struct zbus_channel_data data;
    struct runtime_msg msg = {0};
    int ret;

    /* Initialise and register the runtime channel */
    zbus_runtime_channel_init(&runtime_chan, &data, "chan", 0x12345678, NULL, &msg,
                              sizeof(msg), NULL);
    ret = zbus_runtime_channel_register(&runtime_chan);
    if (ret < 0) {
        LOG_ERR("Failed to register runtime channel (%d)", ret);
        return;
    }

    /* Use the runtime channel here */
    struct runtime_msg pub_data = {42};

    zbus_chan_pub(&runtime_chan.channel, &pub_data, K_MSEC(100));
    ...

    /* Unregister the runtime channel when done */
    zbus_runtime_channel_unregister(&runtime_chan);
}
```

Iterating over channels and observers ZBus subsystem also implements *Iterable Sections* for channels and observers, for which there are supporting APIs like `zbus_iterate_over_channels()`, `zbus_iterate_over_channels_with_user_data()`, `zbus_iterate_over_observers()` and `zbus_iterate_over_observers_with_user_data()`. This feature enables developers to call a procedure over all declared channels, where the procedure parameter is a `zbus_channel`. The execution sequence is in the alphabetical name order of the channels (see *Iterable Sections* documentation for details). ZBus also implements this feature for `zbus_observer`.

```
static bool print_channel_data_iterator(const struct zbus_channel *chan, void␣
↪*user_data)
{
      int *count = user_data;

      LOG_INF("%d - Channel %s:", *count, zbus_chan_name(chan));
      LOG_INF("      Message size: %d", zbus_chan_msg_size(chan));
      LOG_INF("      Observers:");

      ++(*count);

      struct zbus_channel_observation *observation;

      for (int16_t i = *chan->observers_start_idx, limit = *chan->
↪observers_end_idx; i < limit;
           ++i) {
           STRUCT_SECTION_GET(zbus_channel_observation, i, &observation);

           LOG_INF("      - %s", observation->obs->name);
      }
```

(continues on next page)

(continued from previous page)

```
	struct zbus_observer_node *obs_nd, *tmp;

	SYS_SLIST_FOR_EACH_CONTAINER_SAFE(chan->observers, obs_nd, tmp, node) {
		LOG_INF("	- %s", obs_nd->obs->name);
	}

	return true;
}

static bool print_observer_data_iterator(const struct zbus_observer *obs, void␣
↪*user_data)
{
	int *count = user_data;

	LOG_INF("%d - %s %s", *count, obs->queue ? "Subscriber" : "Listener",␣
↪zbus_obs_name(obs));

	++(*count);

	return true;
}

int main(void)
{
	int count = 0;

	LOG_INF("Channel list:");

	zbus_iterate_over_channels_with_user_data(print_channel_data_iterator, &
↪count);

	count = 0;

	LOG_INF("Observers list:");

	zbus_iterate_over_observers_with_user_data(print_observer_data_iterator, &
↪count);

	return 0;
}
```

The code will log the following output:

```
D: Channel list:
D: 0 - Channel acc_chan:
D:       Message size: 12
D:       Observers:
D:       - my_listener
D:       - my_subscriber
D: 1 - Channel version_chan:
D:       Message size: 4
D:       Observers:
D: Observers list:
D: 0 - Listener my_listener
D: 1 - Subscriber my_subscriber
```

Advanced channel control ZBus was designed to be as flexible and extensible as possible. Thus, there are some features designed to provide some control and extensibility to the bus.

Listeners message access For performance purposes, listeners can access the receiving channel message directly since they already have the channel locked for it. To access the channel's message, the listener should use the `zbus_chan_const_msg()` because the channel passed as an argument to the listener function is a constant pointer to the channel. The const pointer return type tells developers not to modify the message.

```
void listener_callback_example(const struct zbus_channel *chan)
{
        const struct acc_msg *acc;
        if (&acc_chan == chan) {
                acc = zbus_chan_const_msg(chan); // Use this
                // instead of zbus_chan_read(chan, &acc, K_MSEC(200))
                // or zbus_chan_msg(chan)

                LOG_DBG("From listener -> Acc x=%d, y=%d, z=%d", acc->x, acc->y,␣
↪acc->z);
        }
}
```

Async listeners message access Async listeners are implemented by utilizing the established message subscriber infrastructure. They are executed in a work queue context rather than in the publisher's context. When using the system work queue, the user will experience similar behavior to the regular listeners. Since the system work queue is, by default, a cooperative thread with a priority of -1, async listeners would run before all other application threads (usually preemptive) after the VDED execution.

Async listeners can access the receiving channel's message directly via the message copy reference passed to the callback. Be aware that the message copy is freed just after the async listener execution. To access the channel's message, the async listener should only cast to the proper constant message format. The following example demonstrates how to access the message from an async listener.

```
static void async_listener_callback(const struct zbus_channel *chan, const void␣
↪*message)
{
        if (chan != &chan_event) {
                LOG_ERR("Unexpected channel");
                return;
        }

        const struct msg_event *msg = message;

        LOG_INF("From async listener -> Evt=%d | %s", msg->type,
                k_thread_name_get(k_current_get()));
}
```

User Data It is possible to pass custom data into the channel's `user_data` for various purposes, such as writing channel metadata. That can be achieved by passing a pointer to the channel definition macro's `user_data` field, which will then be accessible by others. Note that `user_data` is individual for each channel. Also, note that `user_data` access is not thread-safe. For thread-safe access to `user_data`, see the next section.

Claim and finish a channel To take more control over channels, two functions were added `zbus_chan_claim()` and `zbus_chan_finish()`. With these functions, it is possible to access the

channel's metadata safely. When a channel is claimed, no actions are available to that channel. After finishing the channel, all the actions are available again.

Warning

Never change the fields of the channel struct directly. It may cause zbus behavior inconsistencies and scheduling issues.

Warning

Only use this function inside an ISR with a `K_NO_WAIT` timeout.

The following code builds on the examples above and claims the `acc_chan` to set the `user_data` to the channel. Suppose we would like to count how many times the channels exchange messages. We defined the `user_data` to have the 32 bits integer. This code could be added to the listener code described above.

```
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
        int *message_counting = (int *) zbus_chan_user_data(&acc_chan);
        *message_counting += 1;
        zbus_chan_finish(&acc_chan);
}
```

The following code has the exact behavior of the code in *Publishing to a channel*.

```
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
        struct acc_msg *acc1 = (struct acc_msg *) zbus_chan_msg(&acc_chan);
        acc1->x = 1;
        acc1->y = 1;
        acc1->z = 1;
        zbus_chan_finish(&acc_chan);
        zbus_chan_notify(&acc_chan, K_SECONDS(1));
}
```

The following code has the exact behavior of the code in *Reading from a channel*.

```
if (!zbus_chan_claim(&acc_chan, K_MSEC(200))) {
        const struct acc_msg *acc1 = (const struct acc_msg *) zbus_chan_const_msg(&
↪acc_chan);
        // access the acc_msg fields directly.
        zbus_chan_finish(&acc_chan);
}
```

Runtime observer registration It is possible to add observers to channels in runtime. Set the `CONFIG_ZBUS_RUNTIME_OBSERVERS` to enable the feature. This feature uses the heap to allocate the nodes dynamically, a memory slab to allocate the nodes statically, or user-provided nodes. It depends on the `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC`, which can be `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_DYNAMIC`, `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_STATIC`, and `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_NONE`. The dynamic is the default. When `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_STATIC` is enabled, you need to set the number of runtime observers you are going to use by setting the `CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_POOL_SIZE` configuration. The following example illustrates the runtime registration usage.

```
ZBUS_LISTENER_DEFINE(my_listener, callback);
// ...

void thread_entry(void) {
        // ...
        /* Adding the observer to channel chan1 */
        zbus_chan_add_obs(&chan1, &my_listener, K_NO_WAIT);
        /* Removing the observer from channel chan1 */
        zbus_chan_rm_obs(&chan1, &my_listener, K_NO_WAIT);
}
```

Warning

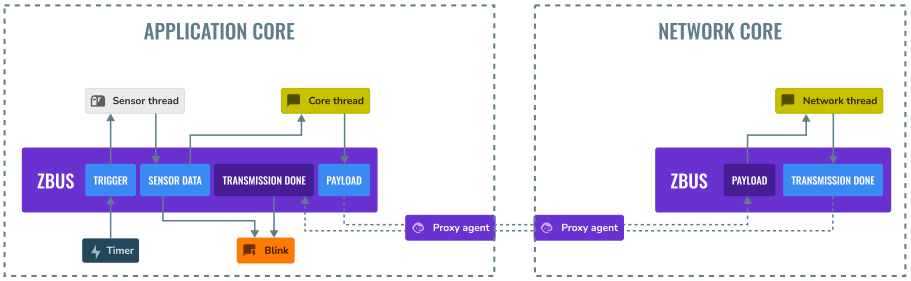
The `zbus_observer_node` can only be reused in `zbus_chan_add_obs_with_node()` after removing the channel observer it was first associated with through `zbus_chan_rm_obs()`.

Proxy Agent Communication (Experimental)

Warning

Proxy agent communication is experimental and may change without deprecation.

ZBus supports proxy agent forwarding, enabling message passing between different execution domains such as CPU cores or separate devices.



Concepts Proxy agent communication introduces several key concepts:

- **Shadow channels**: Read-only channels that mirror channels from other domains
- **Proxy agents**: Background services that synchronize channel data between domains
- **Transport backends**: Communication mechanisms used by proxy agents

Proxy agents are set up in code using `ZBUS_PROXY_AGENT_DEFINE`, specifying the transport backend and configuration parameters. Channels are defined using standard zbus macros (`ZBUS_CHAN_DEFINE` or `ZBUS_CHAN_DEFINE_WITH_ID`) and shadow channels use `ZBUS_SHADOW_CHAN_DEFINE` to create read-only mirrors linked to specific proxy agents.

Transport Backends ZBus proxy agent communication relies on transport backends to forward messages between different execution domains.

IPC Backend The IPC backend forwards messages between CPU cores within the same system using Inter-Process Communication mechanisms.

See the zbus-proxy-agent-ipc sample for a complete implementation.

Usage

1. Enable CONFIG_ZBUS_PROXY_AGENT and the desired backend option.
2. Provide the backend device in devicetree.
3. Instantiate the proxy agent:

```
#include <zephyr/zbus/proxy_agent/zbus_proxy_agent.h>
#include <zephyr/zbus/proxy_agent/zbus_proxy_agent_ipc.h>

#define IPC_DEV_NODE DT_NODELABEL(ipc0)

ZBUS_PROXY_AGENT_DEFINE(proxy_agent,                    /* Proxy agent name */
                        ZBUS_PROXY_AGENT_BACKEND_IPC,   /* Proxy agent type */
                        IPC_DEV_NODE                    /* Backend node */
);
```

Where:

- "proxy_agent": Name of the proxy agent instance
- "ZBUS_PROXY_AGENT_BACKEND_IPC": Transport backend type (IPC in this case)
- "IPC_DEV_NODE": Device tree node for the backend device

4. Forward local channels through the agent:

```
ZBUS_CHAN_DEFINE(my_channel, struct my_msg, NULL, NULL,
                 ZBUS_OBSERVERS_EMPTY, ZBUS_MSG_INIT(0));
ZBUS_PROXY_ADD_CHAN(proxy_agent, my_channel);

zbus_chan_pub(&my_channel, &msg, K_MSEC(100));
```

Any message published to "my_channel" will be forwarded by "proxy_agent" to remote domains.

5. Mirror remote channels with shadows:

```
ZBUS_SHADOW_CHAN_DEFINE(my_channel_shadow, struct my_msg,
                        proxy_agent, NULL, ZBUS_OBSERVERS_EMPTY,
                        ZBUS_MSG_INIT(0));
```

Where the shadow channel can be used like any regular channel, but is read-only. For example, adding a listener:

```
void my_listener_cb(const struct zbus_channel *chan)
{
    const struct my_msg *data = zbus_chan_const_msg(chan);
    printk("Received: %d\n", data->data);
}

ZBUS_LISTENER_DEFINE(my_listener, my_listener_cb);
ZBUS_CHAN_ADD_OBS(my_channel_shadow, my_listener, 0);
```

Samples

For a complete overview of zbus usage, take a look at the samples. There are the following samples available:

- zbus-hello-world illustrates the code used above in action;

- zbus-work-queue shows how to define and use different kinds of observers. Note there is an example of using a work queue instead of executing the listener as an execution option;
- zbus-msg-subscriber illustrates how to use message subscribers;
- zbus-async-listeners illustrates how to use async listeners;
- zbus-dyn-channel demonstrates how to use dynamically allocated exchanging data in zbus;
- zbus-uart-bridge shows an example of sending the operation of the channel to a host via serial;
- zbus-remote-mock illustrates how to implement an external mock (on the host) to send and receive messages to and from the bus;
- zbus-priority-boost illustrates zbus priority boost feature with a priority inversion scenario;
- zbus-runtime-obs-registration illustrates a way of using the runtime observer registration feature;
- zbus-confirmed-channel implements a way to implement a confirmed channel using only subscribers;
- zbus-benchmark implements a benchmark with different combinations of inputs.
- zbus-proxy-agent-ipc demonstrates multi-core communication using IPC proxy agents;

Suggested Uses

Use zbus to transfer data (messages) between threads in one-to-one, one-to-many, and many-to-many synchronously or asynchronously. Choosing the proper observer type is crucial. Use subscribers for scenarios that can tolerate message losses and duplications; when they cannot, use message subscribers (if you need a thread) or listeners (if you need to be lean and fast). In addition to the listener, another asynchronous message processing mechanism (like *message queues*) may be necessary to retain the pending message until it gets processed.

For proxy agent scenarios, use zbus to enable communication across execution boundaries:

- **Multi-core systems**: Use IPC backend proxy agents to coordinate between application and network processors, or distribute workloads across multiple CPU cores.

Note

ZBus can be used to transfer streams from the producer to the consumer. However, this can increase zbus' communication latency. So maybe consider a Pipe a good alternative for this communication topology.

Configuration Options

For enabling zbus, it is necessary to enable the `CONFIG_ZBUS` option.

Related configuration options:

- `CONFIG_ZBUS_PRIORITY_BOOST` zbus Highest Locker Protocol implementation;
- `CONFIG_ZBUS_CHANNELS_SYS_INIT_PRIORITY` determine the `SYS_INIT` priority used by zbus to organize the channels observations by channel;
- `CONFIG_ZBUS_CHANNEL_NAME` enables the name of channels to be available inside the channels metadata. The log uses this information to show the channels' names;
- `CONFIG_ZBUS_OBSERVER_NAME` enables the name of observers to be available inside the channels metadata;
- `CONFIG_ZBUS_PREFER_DYNAMIC_ALLOCATION` instructs zbus to use dynamic allocation for its internals. That can be disabled by the user and tuned later;

- CONFIG_ZBUS_MSG_SUBSCRIBER enables the message subscriber observer type;
- CONFIG_ZBUS_MSG_SUBSCRIBER_BUF_ALLOC_DYNAMIC uses the heap to allocate message buffers;
- CONFIG_ZBUS_MSG_SUBSCRIBER_BUF_ALLOC_STATIC uses the stack to allocate message buffers;
- CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_SIZE the available number of message buffers to be used simultaneously;
- CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_POOL_ISOLATION enables the developer to isolate a pool for the message subscriber for a set of channels; a channel only switches to a dedicated pool once zbus_chan_set_msg_sub_pool() has been called for it;
- CONFIG_ZBUS_MSG_SUBSCRIBER_NET_BUF_STATIC_DATA_SIZE the biggest message of zbus channels to be transported into a message buffer;
- CONFIG_HEAP_MEM_POOL_ADD_SIZE_ZBUS the reserved heap size for ZBus in a whole including message buffer allocation;
- CONFIG_ZBUS_ASYNC_LISTENER enables the async listener observer type;
- CONFIG_ZBUS_RUNTIME_OBSERVERS enables the runtime observer registration;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_DYNAMIC allocate the runtime observers dynamically using the heap;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_STATIC allocate the runtime observers statically using a memory slab;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_POOL_SIZE the amount of enabled runtime observers to statically allocate;
- CONFIG_ZBUS_RUNTIME_OBSERVERS_NODE_ALLOC_NONE use user-provided runtime observers nodes;
- CONFIG_ZBUS_PROXY_AGENT enable proxy agent communication support.

Proxy Agent Configuration Options

- CONFIG_ZBUS_PROXY_AGENT_LOG_LEVEL log level for proxy agent communication;
- CONFIG_ZBUS_PROXY_AGENT_IPC enable IPC backend for proxy agent communication;
- CONFIG_ZBUS_PROXY_AGENT_IPC_LOG_LEVEL log level for IPC backend proxy agent communication;
- CONFIG_ZBUS_PROXY_AGENT_MAX_MESSAGE_SIZE maximum message size for proxy agent channels;
- CONFIG_ZBUS_PROXY_AGENT_MAX_CHANNEL_NAME_SIZE maximum size of channel names in proxy agent communication;
- CONFIG_ZBUS_PROXY_AGENT_INIT_PRIORITY initialization priority for proxy agent setup.
- CONFIG_ZBUS_PROXY_AGENT_WORK_QUEUE_STACK_SIZE stack size for the proxy agent receive work queue thread;
- CONFIG_ZBUS_PROXY_AGENT_WORK_QUEUE_PRIORITY priority for the proxy agent receive work queue thread.
- CONFIG_ZBUS_PROXY_AGENT_RX_QUEUE_DEPTH depth of the proxy agent receive queue for incoming messages from remote domains.

4.3.3 Asynchronous Notifications

Zephyr APIs often include *async* functions where an operation is initiated and the application needs to be informed when it completes, and whether it succeeded. Using `k_poll()` is often a good method, but some application architectures may be more suited to a callback notification, and operations like enabling clocks and power rails may need to be invoked before kernel functions are available so a busy-wait for completion may be needed.

This API is intended to be embedded within specific subsystems such as *On-Off Manager* and other APIs that support async transactions. The subsystem wrappers are responsible for extracting operation-specific data from requests that include a notification element, and for invoking callbacks with the parameters required by the API.

A limitation is that this API is not suitable for *System Calls* because:

- `sys_notify` is not a kernel object;
- copying the notification content from userspace will break use of `CONTAINER_OF` in the implementing function;
- neither the spin-wait nor callback notification methods can be accepted from userspace callers.

Where a notification is required for an asynchronous operation invoked from a user mode thread the subsystem or driver should provide a syscall API that uses `k_poll_signal` for notification.

API Reference

Asynchronous Notification APIs

4.3.4 Virtualization

Inter-VM Shared Memory

- *Overview*
- *Support*
- *ivshmem-v2*
- *API Reference*

Overview As Zephyr is enabled to run as a guest OS on Qemu and ACRN it might be necessary to make VMs aware of each other, or aware of the host. This is made possible by exposing a shared memory among parties via a feature called ivshmem, which stands for inter-VM Shared Memory.

The two types are supported: a plain shared memory (ivshmem-plain) or a shared memory with the ability for a VM to generate an interruption on another, and thus to be interrupted as well itself (ivshmem-doorbell).

Please refer to the official Qemu ivshmem documentation for more information.

Support Zephyr supports both versions: plain and doorbell. Ivshmem driver can be built by enabling `CONFIG_IVSHMEM`. By default, this will expose the plain version. `CONFIG_IVSHMEM_DOORBELL` needs to be enabled to get the doorbell version.

Because the doorbell version uses MSI-X vectors to support notification vectors, the `CONFIG_IVSHMEM_MSI_X_VECTORS` has to be tweaked to the number of vectors that will be needed.

Note that a tiny shell module can be exposed to test the ivshmem feature by enabling `CONFIG_IVSHMEM_SHELL`.

ivshmem-v2 Zephyr also supports ivshmem-v2:

https://github.com/siemens/jailhouse/blob/master/Documentation/ivshmem-v2-specification.md

This is primarily used for IPC in the Jailhouse hypervisor (e.g. eth-ivshmem). It is also possible to use ivshmem-v2 without Jailhouse by building the Siemens fork of QEMU, and modifying the QEMU launch flags:

https://github.com/siemens/qemu/tree/wip/ivshmem2

Logging, Tracing & Debugging

4.4 Logging, Tracing & Debugging

This section covers services that help you observe, diagnose, and debug a running system: emitting log messages, tracing execution, inspecting the system through a shell, and monitoring runtime health.

4.4.1 Logging

- *Global Kconfig Options*
- *Usage*
  - *Logging in a module*
  - *Logging in a module instance*
  - *Controlling the logging*
- *Rate-limited logging*
  - *Configuration*
- *Logging panic*
- *Printk*
- *Architecture*
  - *Default Frontend*
  - *Custom Frontend*
  - *Logging strings*
  - *Multi-domain support*
  - *Logging backends*
  - *Dictionary-based Logging*
- *Recommendations and limitations*
- *Benchmark*
- *Stack usage*
- *Logging using ARM Coresight STM*
- *API Reference*

The logging API provides a common interface to process messages issued by developers. Messages are passed through a frontend and then processed by active backends. The frontend is responsible for immediate filtering and queueing of log messages, so it needs to be fast. Backends may run later and take more time. They format the log message and send it to a destination, for example UART, RTT or BLE. A custom frontend and custom backends can be used if needed.

Summary of the logging features:

- Deferred logging reduces the time needed to log a message by shifting time consuming operations to a known context, instead of processing and sending the log message when called.
- Multiple backends supported (up to 9 backends).
- Custom frontend support, which can work together with standard backends.
- Compile time filtering on module level.

- Independent runtime filtering for each backend.
- Additional runtime filtering on module instance level.
- Timestamping with a user provided function. Timestamps can be 32 or 64 bits large.
- Dedicated API for dumping data.
- Dedicated API for handling transient strings.
- Panic support - in panic mode, logging switches to blocking, synchronous processing.
- Printk support - printk messages can be redirected to the logging system.
- Design ready for multi-domain/multi-processor systems.
- Support for logging floating point and `long long` values.
- Built-in copying of transient strings used as arguments.
- Support for multi-domain logging.
- Rate-limited logging macros to prevent log flooding when messages are generated frequently.

The logging API is highly configurable at compile time as well as at runtime. Using Kconfig options (see *Global Kconfig Options*), logs can be gradually removed from compilation to reduce image size and execution time when logs are not needed. During compilation, logs can be filtered out by module and severity level.

Logs can also be compiled in but filtered at runtime using a dedicate API. Runtime filtering is independent for each backend and each source of log messages. The source of a log message can be a module or specific instance of a module.

There are four severity levels available in the system: error, warning, info and debug. For each severity level, the logging API (include/zephyr/logging/log.h) has a set of dedicated macros. There are also macros for logging data.

For each severity level, the following set of macros is available:

- `LOG_X` for standard printf-like messages, e.g. `LOG_ERR`.
- `LOG_HEXDUMP_X` for dumping data, e.g. `LOG_HEXDUMP_WRN`.
- `LOG_INST_X` for standard printf-like messages associated with a particular instance, e.g. `LOG_INST_INF`.
- `LOG_INST_HEXDUMP_X` for dumping data associated with a particular instance, e.g. `LOG_INST_HEXDUMP_DBG`

The warning level also exposes the following additional macro:

- `LOG_WRN_ONCE` for warnings where only the first occurrence is of interest.

Rate-limited logging macros are also available for all severity levels to prevent log flooding:

- `LOG_X_RATELIMIT` for rate-limited standard printf-like messages using the default rate, e.g. `LOG_ERR_RATELIMIT`.
- `LOG_X_RATELIMIT_RATE` for rate-limited standard printf-like messages with a custom rate, e.g. `LOG_ERR_RATELIMIT_RATE`.
- `LOG_HEXDUMP_X_RATELIMIT` for rate-limited data dumping using the default rate, e.g. `LOG_HEXDUMP_WRN_RATELIMIT`.
- `LOG_HEXDUMP_X_RATELIMIT_RATE` for rate-limited data dumping with a custom rate, e.g. `LOG_HEXDUMP_WRN_RATELIMIT_RATE`.

The convenience macros use the default rate specified by `CONFIG_LOG_RATELIMIT_INTERVAL_MS`, while the explicit rate macros take a rate parameter (in milliseconds) that specifies the minimum interval between log messages.

There are two configuration categories: configurations per module and global configuration. When logging is enabled globally, it is enabled for all modules by default. However, modules can disable logging locally. Every module can specify its own logging level. The module must define the LOG_LEVEL macro before using the API. Unless a global override is set, the module logging level will be honored. The global override can only increase the logging level. It cannot be used to lower module logging levels that were previously set higher. It is also possible to globally limit logs by providing a maximal severity level present in the system, where maximal means lowest severity (e.g. if maximal level in the system is set to info, it means that errors, warnings and info levels are present, but debug messages are excluded).

Each module which is using the logging must specify its unique name and register itself to the logging. If a module consists of more than one file, then registration is performed in only one file, but each file must specify the module name.

The logger's default frontend is designed to be thread safe and minimizes the time needed to log the message. Time consuming operations like string formatting or access to the transport are not performed by default when the logging API is called. When the logging API is called, a message is created and added to the list. A dedicated, configurable buffer for a pool of log messages is used. There are 2 types of messages: standard and hexdump. Each message contains a source ID (module or instance ID and domain ID, which might be used for multiprocessor systems), timestamp and severity level. A standard message contains pointers to the string and arguments. A hexdump message contains the copied data and string.

Global Kconfig Options

These options can be found in the following file: subsys/logging/Kconfig.

CONFIG_LOG: Global switch, turns on/off the logging.

Mode of operations:

CONFIG_LOG_MODE_DEFERRED: Deferred mode.

CONFIG_LOG_MODE_IMMEDIATE: Immediate (synchronous) mode.

CONFIG_LOG_MODE_MINIMAL: Minimal footprint mode.

Filtering options:

CONFIG_LOG_RUNTIME_FILTERING: Enables runtime reconfiguration of the filtering.

CONFIG_LOG_DEFAULT_LEVEL: Default level, sets the logging level used by modules that are not setting their own logging level.

CONFIG_LOG_OVERRIDE_LEVEL: It overrides module logging level when it is not set or set lower than the override value.

CONFIG_LOG_MAX_LEVEL: Maximal (lowest severity) level which is compiled in.

Processing options:

CONFIG_LOG_MODE_OVERFLOW: When new message cannot be allocated, oldest one are discarded.

CONFIG_LOG_BLOCK_IN_THREAD: If enabled and new log message cannot be allocated thread context will block for up to CONFIG_LOG_BLOCK_IN_THREAD_TIMEOUT_MS or until log message is allocated.

CONFIG_LOG_PRINTK: Redirect printk calls to the logging.

CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD: When the number of buffered log messages reaches the threshold, the dedicated thread (see log_thread_set()) is woken up. If CONFIG_LOG_PROCESS_THREAD is enabled then this threshold is used by the internal thread.

CONFIG_LOG_PROCESS_THREAD: When enabled, logging thread is created which handles log processing.

CONFIG_LOG_PROCESS_THREAD_STARTUP_DELAY_MS: Delay in milliseconds after which logging thread is started.

CONFIG_LOG_BUFFER_SIZE: Number of bytes dedicated for the circular packet buffer.

CONFIG_LOG_FRONTEND: Direct logs to a custom frontend.

CONFIG_LOG_FRONTEND_ONLY: No backends are used when messages goes to frontend.

CONFIG_LOG_FRONTEND_OPT_API: Optional API optimized for the most common simple messages.

CONFIG_LOG_CUSTOM_HEADER: Injects an application provided header into log.h

CONFIG_LOG_TIMESTAMP_64BIT: 64 bit timestamp.

CONFIG_LOG_SIMPLE_MSG_OPTIMIZE: Optimizes simple log messages for size and performance. Option available only for 32 bit architectures.

Formatting options:

CONFIG_LOG_FUNC_NAME_PREFIX_ERR: Prepend standard ERROR log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_WRN: Prepend standard WARNING log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_INF: Prepend standard INFO log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_FUNC_NAME_PREFIX_DBG: Prepend standard DEBUG log messages with function name. Hexdump messages are not prepended.

CONFIG_LOG_BACKEND_SHOW_TIMESTAMP: Enables backend to print timestamps with log.

CONFIG_LOG_BACKEND_SHOW_LEVEL: Enables backend to print levels with log.

CONFIG_LOG_BACKEND_SHOW_COLOR: Enables coloring of errors (red) and warnings (yellow).

CONFIG_LOG_BACKEND_FORMAT_TIMESTAMP: If enabled timestamp is formatted to *hh:mm:ss:mmm,uuu*. Otherwise is printed in raw format.

Backend options:

CONFIG_LOG_BACKEND_UART: Enable built-in UART backend.

CONFIG_LOG_BACKEND_NET: Enable built-in Networking backend to send syslog messages to a network server.

Usage

Logging in a module In order to use logging in the module, a unique name for the module must be specified and the module must be registered using LOG_MODULE_REGISTER. Optionally, a compile time log level for the module can be specified as the second parameter. The default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if a custom log level is not provided.

```
#include <zephyr/logging/log.h>
LOG_MODULE_REGISTER(foo, CONFIG_FOO_LOG_LEVEL);
```

If the module consists of multiple files, then LOG_MODULE_REGISTER() should appear in exactly one of them. Each other file should use LOG_MODULE_DECLARE to declare its membership in the module. Optionally, a compile time log level for the module can be specified as the second parameter. The default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if a custom log level is not provided.

```
#include <zephyr/logging/log.h>
/* In all files comprising the module but one */
LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);
```

In order to use the logging API in a function implemented in a header file, LOG_MODULE_DECLARE macro must be used in the function body before the logging API is called. Optionally, a compile time log level for the module can be specified as the second parameter. The default log level (CONFIG_LOG_DEFAULT_LEVEL) is used if a custom log level is not provided.

```
#include <zephyr/logging/log.h>

static inline void foo(void)
{
	LOG_MODULE_DECLARE(foo, CONFIG_FOO_LOG_LEVEL);

	LOG_INF("foo");
}
```

The dedicated Kconfig template (subsys/logging/Kconfig.template.log_config) can be used to create a local log level configuration.

The example below shows the template being used. As a result, CONFIG_FOO_LOG_LEVEL will be generated:

```
module = FOO
module-str = foo
source "subsys/logging/Kconfig.template.log_config"
```

Logging in a module instance In case there are modules which are multi-instance and instances are widely used across the system, enabling logs will lead to flooding. The logging API provides tools which can be used to filter logs on the instance level rather than the module level. For example, logging can be enabled for a particular instance only.

In order to use instance level filtering, the following steps must be performed:

- A pointer to a specific logging structure is declared in the instance structure. LOG_INSTANCE_PTR_DECLARE is used for that.

```
#include <zephyr/logging/log_instance.h>

struct foo_object {
	LOG_INSTANCE_PTR_DECLARE(log);
	uint32_t id;
}
```

- The module must provide a macro for its instantiation. In that macro, the logging instance is registered and the log instance pointer is initialized in the object structure.

```
#define FOO_OBJECT_DEFINE(_name)                                \
	LOG_INSTANCE_REGISTER(foo, _name, CONFIG_FOO_LOG_LEVEL) \
	struct foo_object _name = {                             \
		LOG_INSTANCE_PTR_INIT(log, foo, _name)          \
	}
```

Note that when logging is disabled, the logging instance and pointer to that instance are not created.

In order to use the instance logging API in a source file, a compile-time log level must be set using LOG_LEVEL_SET.

```
LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

void foo_init(foo_object *f)
{
```

(continues on next page)

(continued from previous page)

```
	LOG_INST_INF(f->log, "Initialized.");
}
```

In order to use the instance logging API in a header file, a compile-time log level must be set using `LOG_LEVEL_SET`.

```
static inline void foo_init(foo_object *f)
{
	LOG_LEVEL_SET(CONFIG_FOO_LOG_LEVEL);

	LOG_INST_INF(f->log, "Initialized.");
}
```

Controlling the logging By default, log processing in deferred mode is handled internally by a dedicated task which starts automatically. However, it might not be available if multithreading is disabled. It can also be disabled by unsetting `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`. In that case, logging can be controlled using the API defined in include/zephyr/logging/log_ctrl.h. Logging must be initialized before it can be used. Optionally, the user can provide a function which returns a timestamp value. If not provided, `k_cycle_get` or `k_cycle_get_32` is used for timestamping. The `log_process()` function is used to process one log message (if pending), and returns true if there are more messages pending. However, it is recommended to use macro wrappers (`LOG_INIT` and `LOG_PROCESS`), which handle the case where logging is disabled.

The following snippet shows how logs can be processed in a simple infinite loop.

```
#include <zephyr/logging/log_ctrl.h>

int main(void)
{
	LOG_INIT();
	/* If multithreading is enabled provide thread id to the logging. */
	log_thread_set(k_current_get());

	while (1) {
		if (LOG_PROCESS() == false) {
			/* sleep */
		}
	}
}
```

If logs are processed from a thread (user or internal), then it is possible to enable a feature which will wake up the processing thread when a certain number of log messages is buffered (see `CONFIG_LOG_PROCESS_TRIGGER_THRESHOLD`).

Rate-limited logging

Rate-limited logging macros provide a way to prevent log flooding when messages are generated frequently. These macros ensure that log messages are not output more frequently than a specified interval, similar to Linux's `printk_ratelimited` functionality.

The rate-limited logging system provides two types of macros:

Convenience macros (using default rate): - `LOG_ERR_RATELIMIT` - Rate-limited error messages - `LOG_WRN_RATELIMIT` - Rate-limited warning messages - `LOG_INF_RATELIMIT` - Rate-limited info messages - `LOG_DBG_RATELIMIT` - Rate-limited debug messages - `LOG_HEXDUMP_ERR_RATELIMIT` - Rate-limited error hexdump - `LOG_HEXDUMP_WRN_RATELIMIT` - Rate-limited warning hexdump - `LOG_HEXDUMP_INF_RATELIMIT` - Rate-limited info hexdump - `LOG_HEXDUMP_DBG_RATELIMIT` - Rate-limited debug hexdump

Explicit rate macros (with custom rate): - `LOG_ERR_RATELIMIT_RATE` - Rate-limited error messages with custom rate - `LOG_WRN_RATELIMIT_RATE` - Rate-limited warning messages with custom rate - `LOG_INF_RATELIMIT_RATE` - Rate-limited info messages with custom rate - `LOG_DBG_RATELIMIT_RATE` - Rate-limited debug messages with custom rate - `LOG_HEXDUMP_ERR_RATELIMIT_RATE` - Rate-limited error hexdump with custom rate - `LOG_HEXDUMP_WRN_RATELIMIT_RATE` - Rate-limited warning hexdump with custom rate - `LOG_HEXDUMP_INF_RATELIMIT_RATE` - Rate-limited info hexdump with custom rate - `LOG_HEXDUMP_DBG_RATELIMIT_RATE` - Rate-limited debug hexdump with custom rate

The convenience macros use the default rate specified by `CONFIG_LOG_RATELIMIT_INTERVAL_MS` (5000ms by default). The explicit rate macros take a rate parameter (in milliseconds) that specifies the minimum interval between log messages. The rate limiting is per-macro-call-site, meaning that each unique call to a rate-limited macro has its own independent rate limit.

Example usage:

```
#include <zephyr/logging/log.h>
#include <zephyr/kernel.h>

LOG_MODULE_REGISTER(my_module, CONFIG_LOG_DEFAULT_LEVEL);

void process_data(void)
{
    /* Convenience macros using default rate (CONFIG_LOG_RATELIMIT_INTERVAL_MS) */
    LOG_WRN_RATELIMIT("Data processing warning: %d", error_code);
    LOG_ERR_RATELIMIT("Critical error occurred: %s", error_msg);
    LOG_INF_RATELIMIT("Processing status: %d items", item_count);
    LOG_HEXDUMP_WRN_RATELIMIT(data_buffer, data_len, "Data buffer:");

    /* Explicit rate macros with custom intervals */
    LOG_WRN_RATELIMIT_RATE(1000, "Fast rate warning: %d", error_code);
    LOG_ERR_RATELIMIT_RATE(30000, "Slow rate error: %s", error_msg);
    LOG_INF_RATELIMIT_RATE(2000, "Custom rate status: %d items", item_count);
    LOG_HEXDUMP_ERR_RATELIMIT_RATE(5000, data_buffer, data_len, "Error data:");
}
```

Rate-limited logging is particularly useful for:

- Error conditions that might occur frequently but don't need to flood the logs
- Status updates in tight loops or high-frequency callbacks
- Debug information that could overwhelm the logging system
- Network or I/O operations that might fail repeatedly

Configuration Rate-limited logging can be configured using the following Kconfig options:

- `CONFIG_LOG_RATELIMIT` - Master switch to enable/disable rate-limited logging
- `CONFIG_LOG_RATELIMIT_INTERVAL_MS` - Default interval for convenience macros (5000ms)

When `CONFIG_LOG_RATELIMIT` is disabled, the behavior of rate-limited macros is controlled by the `CONFIG_LOG_RATELIMIT_FALLBACK` choice:

- `CONFIG_LOG_RATELIMIT_FALLBACK_LOG` - All rate-limited macros behave as regular logging macros
- `CONFIG_LOG_RATELIMIT_FALLBACK_DROP` - All rate-limited macros expand to no-ops (default)

This allows you to control whether rate-limited log macros should always print or be completely suppressed when rate limiting is not available.

The rate limiting is implemented using static variables and `k_uptime_get_32()` to track the last log time for each call site.

Logging panic

In case of an error condition, the system usually can no longer rely on the scheduler or interrupts. In that situation, deferred log message processing is not an option. The logger controlling API provides a function for entering into panic mode (`log_panic()`), which should be called in such a situation.

When `log_panic()` is called, a *panic* notification is sent to all active backends. Once all backends are notified, all buffered messages are flushed. From that moment forward, all logs are processed in a blocking way.

Printk

Typically, logging and `printk()` use the same output, which they compete for. This can lead to issues if the output does not support preemption, but it may also result in corrupted output because logging data is interleaved with printk data. However, it is possible to redirect printk messages to the logging subsystem by enabling `CONFIG_LOG_PRINTK`. In that case, printk entries are treated as log messages with level 0 (they cannot be disabled). When enabled, logging manages the output, so there is no interleaving. However, in deferred mode, the printk behaviour is changed since the output is delayed until the logging thread processes the data. `CONFIG_LOG_PRINTK` is enabled by default.

Architecture

Logging consists of 3 main parts:

- Frontend
- Core
- Backends

A log message is generated by a source of logging, which can be a module or an instance of a module.

Default Frontend The default frontend is engaged when the logging API is called by a source of logging (e.g. `LOG_INF`) and is responsible for filtering a message (compile and runtime), allocating a buffer for the message, creating the message and committing that message. Since the logging API can be called in an interrupt, the frontend is optimized to log the message as fast as possible.

Log message A log message contains a message descriptor (source, domain and level), timestamp, formatted string details (see *Cbprintf Packaging*) and optional data. Log messages are stored in a continuous block of memory. Memory is allocated from a circular packet buffer (*Multi Producer Single Consumer Packet Buffer*), which has a few consequences:

- Each message is a self-contained, continuous block of memory. Thus, it is suited for copying the message (e.g. for offline processing).
- Messages must be freed sequentially. Backend processing is synchronous. Backends can make a copy for deferred processing.

A log message has the following format:

Message Header	2 bits: MPSC packet buffer header
	1 bit: Trace/Log message flag
	3 bits: Domain ID
	3 bits: Level
	10 bits: Cbprintf Package Length
	12 bits: Data length
	1 bit: Reserved
	pointer: Pointer to the source descriptor[1]
	32 or 64 bits: Timestamp[1]
	pointer: Pointer to thread ID (optional)[2]
	8 bits: core ID (optional)[3]
	Optional padding[4]
Cbprintf package (optional)	Header
	Arguments
	Appended strings
Hexdump data (optional)	
Alignment padding (optional)	

Log message allocation It may happen that the frontend cannot allocate a message. This happens if the system is generating more log messages than it can process in a certain time frame. There are two strategies to handle that case:

- No overflow - the new log is dropped if space for a message cannot be allocated.
- Overflow - the oldest pending messages are freed, until the new message can be allocated. Enabled by `CONFIG_LOG_MODE_OVERFLOW`. Note that it degrades performance thus it is recommended to adjust buffer size and amount of enabled logs to limit dropping.

Runtime filtering If runtime filtering is enabled, then for each source of logging a filter structure in RAM is declared. Such a filter is using 32 bits divided into ten 3 bit slots. Except for *slot 0*, each slot stores the current filter for one backend in the system. *Slot 0* (bits 0-2) is used to aggregate the maximal filter setting for a given source of logging. The aggregate slot determines if a log message is created for a given entry, since it indicates if there is at least one backend expecting that log entry. Backend slots are examined when a message is processed by the core to determine if the message is accepted by the given backend. Compared to compile time filtering, the binary footprint is increased, because discarded logs are still compiled in.

In the example below, backend 1 is set to receive errors (*slot 1*) and backend 2 up to info level (*slot 2*). Slots 3-9 are not used. The aggregated filter (*slot 0*) is set to info level, meaning that up to this level, message from that particular source will be buffered.

slot 0	slot 1	slot 2	slot 3	...	slot 9
INF	ERR	INF	OFF	...	OFF

Custom Frontend Custom frontend is enabled using `CONFIG_LOG_FRONTEND`. Logs are directed to functions declared in include/zephyr/logging/log_frontend.h. If option `CONFIG_LOG_FRONTEND_ONLY` is enabled then log message is not created and no backend is handled. Otherwise, custom frontend can coexist with backends.

[1] Depending on their size, the source descriptor and timestamp fields may be swapped, in order to reduce the amount of padding.
[2] Only present if CONFIG_LOG_THREAD_ID_PREFIX is enabled.
[3] Only present if CONFIG_LOG_CORE_ID_PREFIX is enabled.
[4] It may be required for cbprintf package alignment.

In some cases, logs need to be redirected at the macro level. For these cases, `CONFIG_LOG_CUSTOM_HEADER` can be used to inject an application provided header named `zephyr_custom_log.h` at the end of include/zephyr/logging/log.h.

Frontend using ARM Coresight STM (System Trace Macrocell) For more details about logging using ARM Coresight STM see *Multi-domain logging using ARM Coresight STM*.

Logging strings String arguments are handled by *Cbprintf Packaging*. See *Limitations and recommendations* for limitations and recommendations.

Multi-domain support More complex systems can consist of multiple domains where each domain is an independent binary. Examples of domains are a core in a multicore SoC or one of the binaries (Secure or Nonsecure) on an ARM TrustZone core.

Tracing and debugging on a multi-domain system is more complex and requires an efficient logging system. Two approaches can be used to structure this logging system:

- Log inside each domain independently. This option is not always possible as it requires that each domain has an available backend (for example, UART). This approach can also be troublesome to use and not scalable, as logs are presented on independent outputs.
- Use a multi-domain logging system where log messages from each domain end up in one root domain, where they are processed exactly as in a single domain case. In this approach, log messages are passed between domains using a connection between domains created from the backend on one side and linked to the other.

  The Log link is an interface introduced in this multi-domain approach. The Log link is responsible for receiving any log message from another domain, creating a copy, and putting that local log message copy (including remote data) into the message queue. This specific log link implementation matches the complementary backend implementation to allow log messages exchange and logger control like configuring filtering, getting log source names, and so on.

There are three types of domains in a multi-domain system:

- The *end domain* has the logging core implementation and a cross-domain backend. It can also have other backends in parallel.
- The *relay domain* has one or more links to other domains but does not have backends that output logs to the user. It has a cross-domain backend either to another relay or to the root domain.
- The *root domain* has one or multiple links and a backend that outputs logs to the user.

See the following image for an example of a multi-domain setup:

In this architecture, a link can handle multiple domains. For example, let's consider an SoC with two ARM Cortex-M33 cores with TrustZone: cores A and B (see the example illustrated above). There are four domains in the system, as each core has both a Secure and a Nonsecure domain. If *core A nonsecure* (A_NS) is the root domain, it has two links: one to *core A secure* (A_NS-A_S) and one to *core B nonsecure* (A_NS-B_NS). *B_NS* domain has one link, to *core B secure B_NS-B_S*), and a backend to *A_NS*.

Since in all instances there is a standard logging subsystem, it is always possible to have multiple backends and simultaneously output messages to them. An example of this is shown in the illustration above as a dotted UART backend on the *B_NS* domain.

Domain ID The source of each log message can be identified by the following fields in the header: `source_id` and `domain_id`.

The value assigned to the `domain_id` is relative. Whenever a domain creates a log message, it sets its `domain_id` to `0`. When a message crosses the domain, `domain_id` changes as it is increased

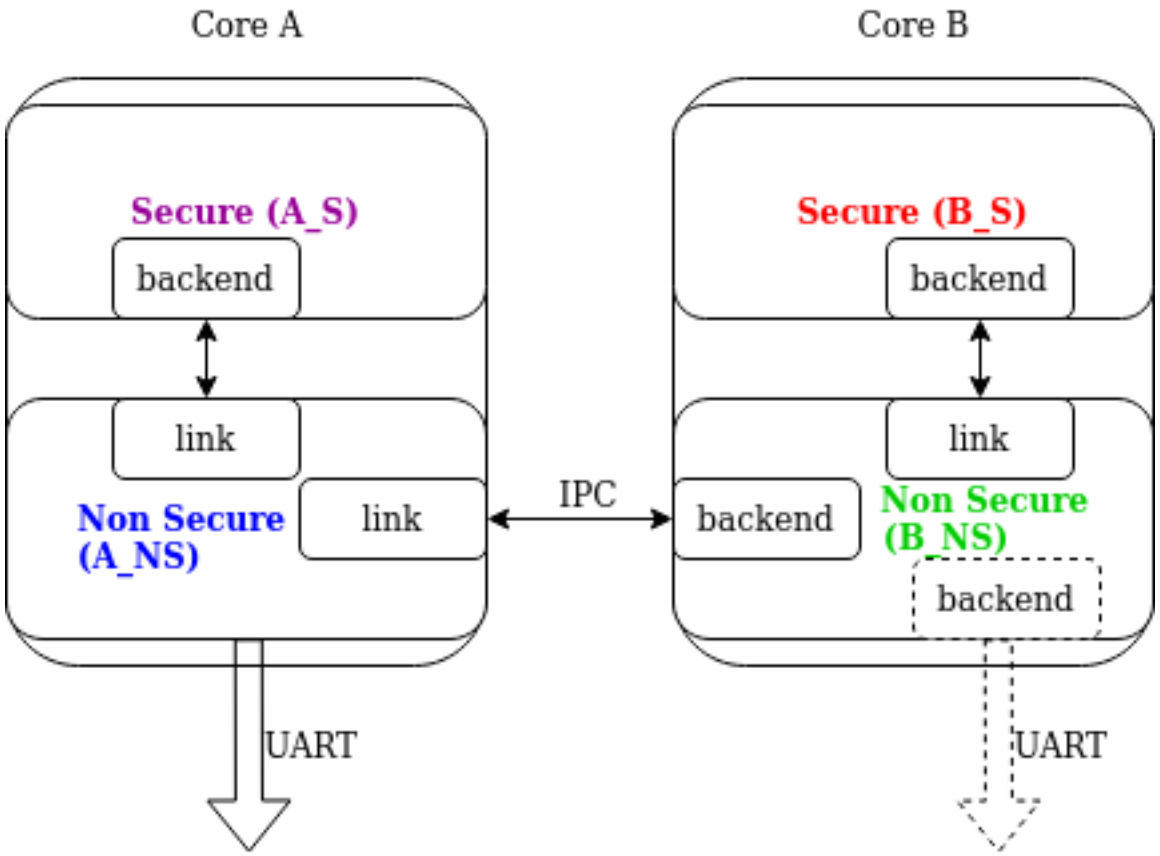

Fig. 36: Multi-domain example

by the link offset. The link offset is assigned during the initialization, where the logger core is iterating over all the registered links and assigned offsets.

The first link has the offset set to 1. The following offset equals the previous link offset plus the number of domains in the previous link.

The following example is shown below, where the assigned `domain_ids` are shown for each domain:

Let's consider a log message created on the *B_S* domain:

1. Initially, it has its `domain_id` set to `0`.
2. When the *B_NS*-*B_S* link receives the message, it increases the `domain_id` to `1` by adding the *B_NS*-*B_S* offset.
3. The message is passed to *A_NS*.
4. When the *A_NS*-*B_NS* link receives the message, it adds the offset (`2`) to the `domain_id`. The message ends up with the `domain_id` set to `3`, which uniquely identifies the message originator.

Cross-domain log message In most cases, the address space of each domain is unique, and one domain cannot access directly the data in another domain. For this reason, the backend can partially process the message before it is passed to another domain. Partial processing can include converting a string package to a *fully self-contained* version (copying read-only strings to the package body).

Each domain can have a different timestamp source in terms of frequency and offset. Logging does not perform any timestamp conversion.

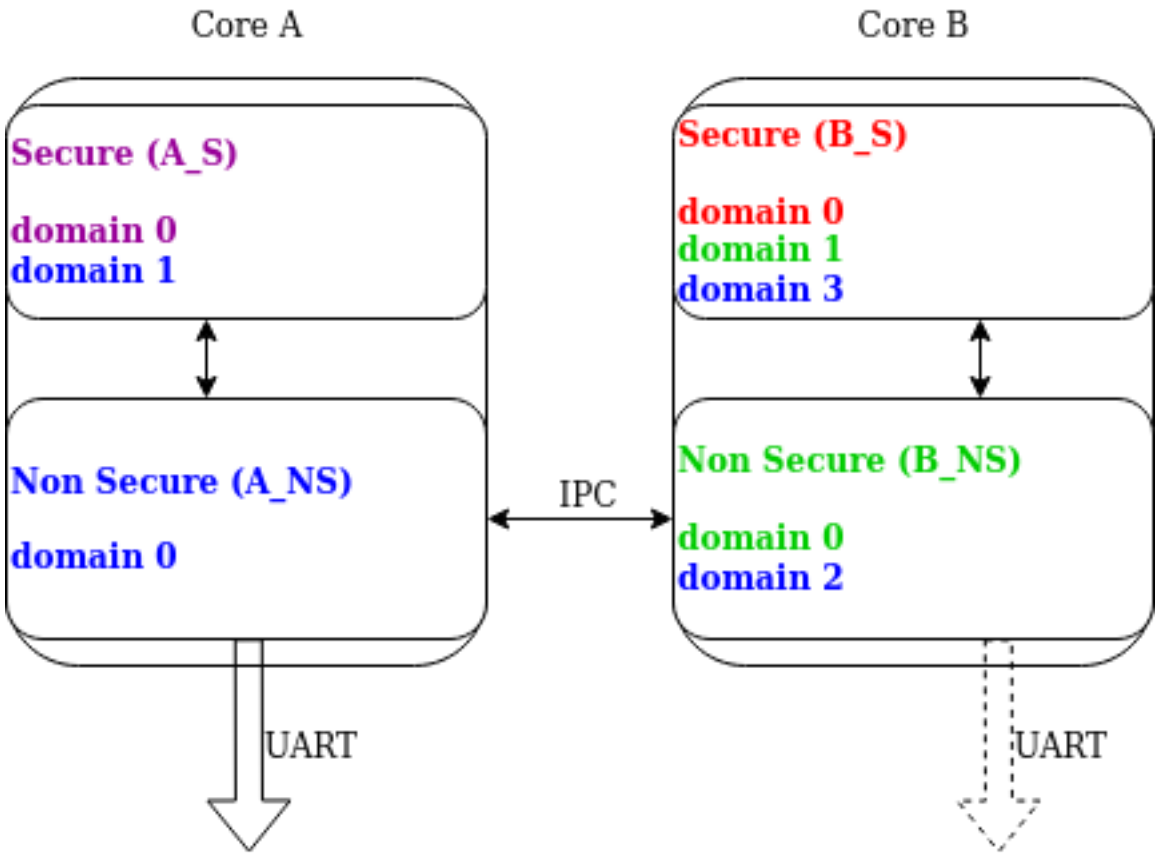

Fig. 37: Domain IDs assigning example

Runtime filtering In the single-domain case, each log source has a dedicated variable with runtime filtering for each backend in the system. In the multi-domain case, the originator of the log message is not aware of the number of backends in the root domain.

As such, to filter logs in multiple domains, each source requires a runtime filtering setting in each domain on the way to the root domain. As the number of sources in other domains is not known during the compilation, the runtime filtering of remote sources must use dynamically allocated memory (one word per source). When a backend in the root domain changes the filtering of the module from a remote domain, the local filter is updated. After the update, the aggregated filter (the maximum from all the local backends) is checked and, if changed, the remote domain is informed about this change. With this approach, the runtime filtering works identically in both multi-domain and single-domain scenarios.

Message ordering Logging does not provide any mechanism for synchronizing timestamps across multiple domains:

- If domains have different timestamp sources, messages will be processed in the order of arrival to the buffer in the root domain.
- If domains have the same timestamp source or if there is an out-of-bound mechanism that recalculates timestamps, there are 2 options:
  - Messages are processed as they arrive in the buffer in the root domain. Messages are unordered but they can be sorted by the host as the timestamp indicates the time of the message generation.
  - Links have dedicated buffers. During processing, the head of each buffer is checked and the oldest message is processed first.

    With this approach, it is possible to maintain the order of the messages at the cost of a

suboptimal memory utilization (since the buffer is not shared) and increased processing latency (see CONFIG_LOG_PROCESSING_LATENCY_US).

Logging backends Logging backends are registered using LOG_BACKEND_DEFINE. The macro creates an instance in the dedicated memory section. Backends can be dynamically enabled (log_backend_enable()) and disabled. When *Runtime filtering* is enabled, log_filter_set() can be used to dynamically change filtering of a module's logs for a given backend. A module is identified by source ID and domain ID. The source ID can be retrieved if the source name is known by iterating through all registered sources.

Logging supports up to 9 concurrent backends. A log message is passed to each backend in the processing phase. Additionally, a backend is notified when logging enters panic mode with log_backend_panic(). When that happens, the backend should switch to synchronous, interrupt-less operation or shut itself down if that is not supported. Occasionally, logging may inform the backend about the number of dropped messages with log_backend_dropped(). The message processing API is version specific.

log_backend_msg_process() is used for processing a message. It is common for standard and hexdump messages, because a standard message holds its formatting arguments in the same place where a hexdump message holds its data. It is also common for deferred and immediate logging.

Message formatting Logging provides a set of functions that can be used by the backend to format a message. Helper functions are available in include/zephyr/logging/log_output.h.

Example message formatted using log_output_msg_process():

```
[00:00:00.000,274] <info> sample_instance.inst1: logging message
```

Dictionary-based Logging Dictionary-based logging, instead of human readable text, outputs the log messages in binary format. This binary format encodes arguments to formatted strings in their native storage formats which can be more compact than their text equivalents. For statically defined strings (including the format strings and any string arguments), references to the ELF file are encoded instead of the whole strings. A dictionary created at build time contains the mappings between these references and the actual strings. This allows the offline parser to obtain the strings from the dictionary to parse the log messages. This binary format allows a more compact representation of log messages in certain scenarios. However, this requires the use of an offline parser and is not as intuitive to use as text-based log messages.

Note that `long double` is not supported by Python's `struct` module. Therefore, log messages with `long double` will not display the correct values.

Configuration Here are kconfig options related to dictionary-based logging:

- CONFIG_LOG_DICTIONARY_SUPPORT enables dictionary-based logging support. This should be selected by the backends which require it.
- The UART backend can be used for dictionary-based logging. These are additional config for the UART backend:
  - CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX tells the UART backend to output hexadecimal characters for dictionary based logging. This is useful when the log data needs to be captured manually via terminals and consoles.
  - CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_BIN tells the UART backend to output binary data.
- The RTT backend can also be used for dictionary-based logging:
  - CONFIG_LOG_BACKEND_RTT enables the RTT backend.

- `CONFIG_LOG_BACKEND_RTT_OUTPUT_DICTIONARY` enables dictionary-based output for the RTT backend. Use together with `CONFIG_USE_SEGGER_RTT`.
- `CONFIG_LOG_BACKEND_RTT_OUTPUT_DICTIONARY_HEX` tells the RTT backend to output hexadecimal characters for dictionary based logging.

Usage When dictionary-based logging is enabled via enabling related logging backends, a JSON database file, named `log_dictionary.json`, will be created in the build directory. This database file contains information for the parser to correctly parse the log data. Note that this database file only works with the same build, and cannot be used for any other builds.

Offline Parsing To parse a previously captured log file:

```
./scripts/logging/dictionary/log_parser.py <build dir>/log_dictionary.json <log␣
↪data file>
```

The parser takes two required arguments, where the first one is the full path to the JSON database file, and the second part is the file containing log data. Add an optional argument `--hex` to the end if the log data file contains hexadecimal characters (e.g. when `CONFIG_LOG_BACKEND_UART_OUTPUT_DICTIONARY_HEX=y`). This tells the parser to convert the hexadecimal characters to binary before parsing.

Live Parsing For real-time decoding of dictionary-based log output, use the live log parser. It connects to a running device and continuously decodes binary log data as it arrives. Note that the live parser only supports binary dictionary output (not hex-encoded). The live parser supports three input modes:

Serial (UART):

```
./scripts/logging/dictionary/live_log_parser.py <build dir>/log_dictionary.json␣
↪serial <port> <baudrate>
```

For example, to read from `/dev/ttyACM0` at 115200 baud:

```
./scripts/logging/dictionary/live_log_parser.py build/zephyr/log_dictionary.json␣
↪serial /dev/ttyACM0 115200
```

JLink RTT:

```
./scripts/logging/dictionary/live_log_parser.py <build dir>/log_dictionary.json␣
↪jlink-rtt <device_name>
```

For example, to read RTT output from an nRF5340:

```
./scripts/logging/dictionary/live_log_parser.py build/zephyr/log_dictionary.json␣
↪jlink-rtt nrf5340_xxaa_app
```

The JLink RTT mode requires the `pylink-square` Python package (`pip install pylink-square`). Optional arguments include `--channel` to select the RTT channel (default: 0), `--speed` to set the connection speed, and `--block-address` to specify the RTT control block address in hex.

File / stdin:

```
./scripts/logging/dictionary/live_log_parser.py <build dir>/log_dictionary.json␣
↪file <filepath>
```

When `<filepath>` is omitted, the parser reads from stdin, which allows piping binary data directly into it.

Please refer to the logging-dictionary sample for more examples on using the log parsers.

Recommendations and limitations

Consider the following recommendations:

- Enable CONFIG_LOG_SPEED to slightly speed up deferred logging at the cost of a slight increase in memory footprint.
- It is recommended to cast a pointer to const char * when it is used with a %s format specifier and it points to a constant string.
- It is recommended to cast a pointer to char * when it is used with a %s format specifier and it points to a transient string.
- It is required to cast a character pointer to non character pointer (e.g., void *) when it is used with a %p format specifier.

```
LOG_WRN("%s", str);
LOG_WRN("%p", (void *)str);
```

Consider the following limitations:

- Logging does not support string format specifiers with width (e.g., %.*s or %8s). That is because format string content is not used to build a log message, only argument types.
- If deferred logging is used and log messages are prefixed with the thread name (Kconfig option CONFIG_LOG_THREAD_ID_PREFIX=y and CONFIG_THREAD_NAME=y), it is assumed that the corresponding k_thread structure is still valid when the log message is formatted. This can be an issue when that structure is allocated dynamically, using k_malloc() or malloc() for instance. In this case, if the thread logs some messages and then gets stopped and its struct k_thread is freed, the log system will still try to access that structure when handling the message later. This creates a use-after-free scenario. To avoid this, a solution consists in calling log_flush() before freeing the structure.

```
struct k_thread *thread = k_malloc(sizeof(*thread)); /* struct allocated␣
↪dynamically */
k_thread_create(thread, ...);
k_thread_name_set(thread, "foobar");

/* Thread calls LOG_*(...) */

k_thread_join(thread, K_FOREVER);
log_flush();  /* flush log buffer before freeing the struct k_thread */
k_free(thread); /* avoid a potential use-after-free scenario if deferred logging␣
↪is used */
```

Benchmark

Benchmark numbers from tests/subsys/logging/log_benchmark performed on qemu_x86. It is a rough comparison to give a general overview.

Feature	
Kernel logging	7us[5]/11us
User logging	13us
kernel logging with overwrite	10us[Page 1221, 5]/15us
Logging transient string	42us
Logging transient string from user	50us
Memory utilization[6]	518
Memory footprint (test)[7]	2k
Memory footprint (application)[8]	3.5k
Message footprint[9]	47[Page 1221, 5]/32 bytes

Benchmark details

Stack usage

When logging is enabled, it impacts the stack usage of the context that uses the logging API. If the stack is optimized, it may lead to stack overflow. Stack usage depends on mode and optimization. It also significantly varies between platforms. In general, when `CONFIG_LOG_MODE_DEFERRED` is used, stack usage is smaller, since logging is limited to creating and storing log messages. If `CONFIG_LOG_MODE_IMMEDIATE` is used, the log message is processed by the backends, which includes string formatting, directly in the context that uses the logging API. In case of that mode, the stack usage will depend on which backends are used.

Some of the platforms characterization for log message with two `integer` arguments listed below:

Platform	Deferred	Deferred (no optimization)	Immediate	Immediate (no optimization)
ARM Cortex-M3	40	152	412	783

Log output

Multi-domain logging using ARM Coresight STM The Arm CoreSight SoC-400 is a comprehensive library of components for the creation of debug and trace functionality within a system. The STM (System Trace Macrocell) is a trace source that is integrated into a CoreSight system, designed primarily for high-bandwidth trace of instrumentation embedded into software. This instrumentation is made up of memory-mapped writes to the STMESP (STM Extended Stimulus Port) peripheral registers. Multiple cores can share and directly access the STM without being aware of each other. Each core has 65536 stimulus ports (identical register sets) which can be independently accessed thus there is no need for locking when various contexts want to log the data.

STM Extended Stimulus Port (STMESP) Local domain (each core) has access to its own set of STMESP peripherals. Each set has registers for writing data (with or without timestamp and with or without marking) and writing a flag. Each write to STMESP register results in the user data being encoded into MIPI System Trace Protocol v2 (STPv2). Hardware manages multiplexing of data from different STMESP register sets and from different cores by adding Major and Channel opcodes into the stream when necessary. Timestamp (from common source for all cores) and synchronization opcodes are autonomously added by the STM.

Data stream generated by STM can end up in various sinks. For example it can be directly send to TPIU (Trace Port Interface Unit) or saved in the RAM Circular Buffer which is called ETR (Embedded Trace Router). TPIU is a 5 pin interface (4 data pins and clock) and external tool is required to capture the data (e.g. J-Trace PRO). When ETR is used then one core in the system is responsible for processing that data, for example dumping it over UART to the host.

ARM Coresight Embedded Trace Router (ETR) ETR is a circular RAM buffer to which tracing data is saved. Since it may contain data from various sources additional wrapping protocol is used to multiplex them. `Coresight Trace Formatter` is used for that. Data is encoded into 16 bytes frames which holds up to 15 byte of data. Circular RAM buffer size is limited to 4k thus there is a risk of data overflow. If overflow occurs then data is lost but due to presence of synchronization opcodes in the STPv2 data stream synchronization can be restored.

Data from ETR is handled on the device. It can be forwarded as-is to the host (e.g. using UART), where a host tool is decoding the data or data can be decoded on-chip to output the data in human readable format.

Nordic Semiconductor NRF54H20 implementation instead of using ETR peripheral for getting buffer busyness is using own wrapper: Trace Buffer Monitor (TBM).

STMESP Logging frontend *Custom Frontend* API is implemented. Custom frontend assumes that all required operations are executed in the context of the logging macro call. It is also assumed that frontend provides the timestamp. Frontend utilizes a fact that there are multiple STMESP register sets and use multiple sets to avoid locking context. The atomically incremented channel counter is used to pick unique STMESP set and whole message is written to that STMESP. Limited pool of sets is used leaving most of channels for other purposes.

Early logging STMESP cannot be used before STM or ETR/TPIU is setup. In order to support early logging, before infrastructure is ready a dedicated RAM buffer is used to which data is written. When STM infrastructure readiness is notified (`log_frontend_stmesp_etr_ready()`) then RAM buffer content is written to STMESP. Early logging is applicable only to the core which owns and configures Coresight infrastructure (e.g. in case of NRF54H20 it is the Secure core).

Trace points There may be cases when logging is too slow (even though it is very fast). For cases like that a dedicated `trace point` API is added. It is extremely fast because it is just a single write to one STMESP register. There are 2 functions in the API:

- `log_frontend_stmesp_tp()` - It accepts single argument - index. Index is between 0 and 65280.
- `log_frontend_stmesp_tp_d32()` - It accepts two arguments - index and user data. Index is between 0 and 65280. User data is 32 bit word.

It takes less than 100 ns to log a single trace point on NRF54H20 and it is approx. 7 times faster than the fastest log message.

Logging using STM STM logging has 2 modes of operations:

- Dictionary-based - assisted mode which is using dictionary-based logging. In this mode logging strings can be removed from the binary because they are only needed for decoding and decoding is performed by the host tool. This mode takes less memory and is faster (2-3 times faster). There is less data written so there is less chance of data overflow in ETR buffer.
- Standalone - data is decoded on chip and human-readable strings are printed. This mode requires more device resources and processing power.

Following figure presents multi-domain logging using ARM Coresight STM.

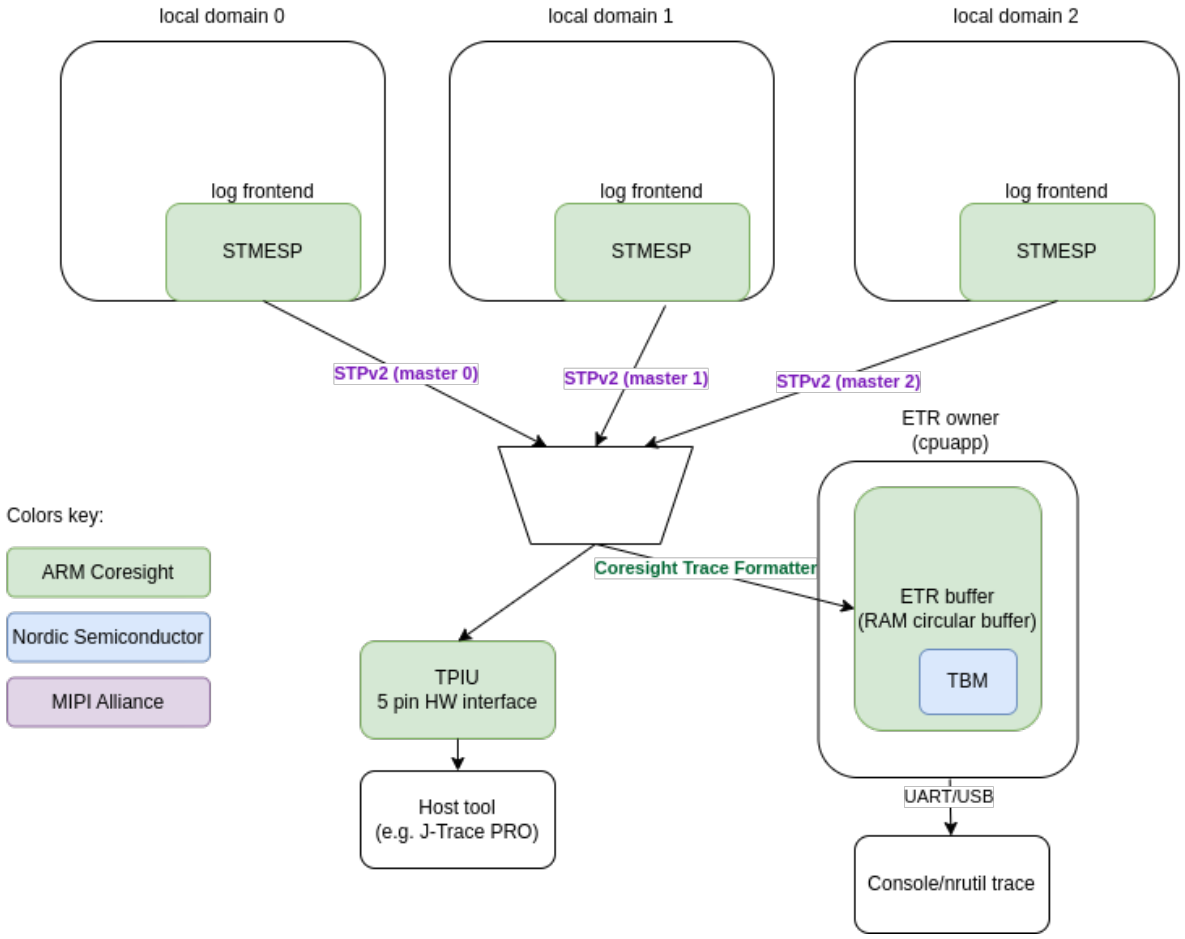
Each core (local domain) is using logging frontend which writes logging data to STMESP registers.

If TPIU is used as the output then there is no more software components needed. STPv2 stream of data is composed by STM and send over TPIU.

If ETR RAM buffer is used then buffer owner core (`proxy`) is responsible for handling that data. If dictionary-based logging is used then proxy just sends data as-is over UART. If standalone logging is used then proxy is using *ARM Coresight Trace Deformatter* and *MIPI STP Decoder* to decode data and demultiplex messages. Messages are formatted to human readable strings using logging *Message formatting*.

Dictionary-based logging Assisted multicore logging uses dictionary-based logging to send messages without redundant strings to STM, and is based on the *Dictionary-based Logging* feature of the logging API provided by Zephyr. Instead of including the format strings in the log messages, it logs the addresses (message IDs) where the strings are stored, which reduces the size of the logging subsystem. If the data goes to the ETR buffer, the proxy core's responsibility is to dump this data. The host PC, equipped with a decoder tool, translates these addresses back into human-readable text using a JSON database generated during the build process.

When using logs, this method has the following advantages:



local domain 0
local domain 1
local domain 2
log frontend
STMESP
log frontend
STMESP
log frontend
STMESP
STPv2 (master 0)
STPv2 (master 1)
STPv2 (master 2)
ETR owner
(cpuapp)
Colors key:
ARM Coresight
Nordic Semiconductor
MIPI Alliance
Coresight Trace Formatter
ETR buffer
(RAM circular buffer)
TBM
TPIU
5 pin HW interface
Host tool
(e.g. J-Trace PRO)
UART/USB
Console/nrutil trace

- It reduces the size of the binary, as the strings used in the log messages are not stored in the binary itself. Logging infrastructure is also very limited. On local domains it is just the frontend. There is even no need to have string formatting function.
- It reduces the amount of data that needs to be sent to and processed by the application core, as the string formatting is offloaded to the host side.
- Logging is fast. It takes less than 1 us to log a simple message (up to 2 arguments) on NRF54H20.

Proxy core is using Nordic specific peripheral (TBM) to get ETR buffer busyness and send data over UART. Nordic specific driver for ETR buffer is located in drivers/debug/debug_nrf_etr.c.

Configuration For Nordic SoC a dedicated snippet (*Nordic Dictionary-based STM logging snippet (nordic-log-stm-dict)*) shall be used to enable logging. Each core shall be build with that snippet. If any core wants to use it then application core is required to have it enabled too since it acts as the proxy (ETR buffer processing). All cores must use the same configuration of the logging.

Reading the logs To read the dictionary-based STM log output, do the following:

1. Set up the log capture.

   Use the `nrfutil trace stm` command to start capturing logs from the device, specifying the database configuration for each domain ID, as well as the serial port, the baud rate, and the output file name:

   ```
   nrfutil trace stm --database-config␣
   ↪34:build/zephyr/log_dictionary.json,35:build_rad/zephyr/log_dictionary.json␣
   ↪--input-serialport /dev/ttyACM1 --baudrate 115200 --output-ascii out.txt
   ```

2. Capture and decode the logs.

   nrfutil will capture the log data from the specified UART port and use the provided dictionary databases to decode the logs into a human-readable format. The decoded logs will be saved in the specified output file (the `out.txt` file in the previous example).

3. Open the output file to review the decoded log messages.

   The file will contain timestamps and the log messages in a format that is human-readable.

If the log capture fails to find a sync, rerun the capture process.

Note

Decoding artifacts or incorrect timestamps might occur when rerunning the process.

Each log line contains a domain-related or core-related prefix between the log level and the module name, indicating the core that generated the log entry. The following are the prefixes used to indicate the cores:

Table 46: nRF54H20 log prefixes

Core	Prefix	ID
Secure Domain	`sec`	0x21
Application core	`app`	0x22
Radio core	`rad`	0x23
System Controller (SysCtrl)	`sys`	0x2c
Fast Lightweight Processor (FLPR)	`flpr`	0x2d
Peripheral Processor (PPR)	`ppr`	0x2e
	`mod`	0x24

Stand-alone logging Frontend is writing to STMESP registers. Message format is aligned with the on chip decoder in subsys/logging/frontends/log_frontend_stmesp_demux.c.

`Proxy` is using Nordic specific peripheral (TBM) to get ETR buffer busyness and read and decode data and send human-readable data over UART. Nordic specific driver for ETR buffer is located in drivers/debug/debug_nrf_etr.c. It is using *ARM Coresight Trace Deformatter* and *MIPI STP Decoder* and above-mentioned demultiplexer to decode messages.

Logging messages contains read-only format string used in the logging macros thus they cannot be removed from the binary. This mode uses more read-only memory and has lower throughput because messages are longer and processing is time consuming. Compared to the dictionary-based mode logging is 2-3 slower.

Configuration For Nordic SoC a dedicated snippet (*Nordic Standalone STM logging snippet (nordic-log-stm)*) shall be used to enable logging. Each core shall be build with that snippet. If any core wants to use it then application core is required to have it enabled too since it acts as the proxy (ETR buffer processing). All cores must use the same configuration of the logging.

Reading the logs Logs are printed using Console UART.

> **Note**
>
> To use UART in your application, the UART's node must be described in devicetree. For more details, see *Introduction to devicetree*.

The following is an example log output:

```
[00:00:00.154,790] <inf> app/spsc_pbuf: alloc in 0x2f0df800
[00:00:00.163,319] <inf> app/spsc_pbuf: alloc 0x2f0df800 wr_idx:20

[00:00:00.202,577] <inf> rad/icmsg: mbox_callback
[00:00:00.214,750] <inf> rad/spsc_pbuf: claim 0x2f0df800 rd_idx:20
[00:00:00.235,823] <inf> rad/spsc_pbuf: free 0x2f0df800 len:20 rd_idx: 44
[00:00:00.244,507] <inf> rad/spsc_pbuf: read done 0x2f0df800 len:20
[00:00:00.272,444] <inf> rad/host: ep recv 0x330021f0, len:20
[00:00:00.283,939] <inf> rad/host: rx:00 exp:00
[00:00:00.292,200] <inf> rad/icmsg: read 0
[00:00:05.077,026] <inf> rad/spsc_pbuf: alloc in 0x2f0df000
[00:00:05.077,068] <inf> rad/spsc_pbuf: alloc 0x2f0df000 wr_idx:44
[00:00:05.077,098] <inf> rad/spsc_pbuf: commit in 0x2f0df000
[00:00:05.077,134] <inf> rad/spsc_pbuf: commit 0x2f0df000, len:20 wr_idx
```

Each log line contains a domain-related or core-related prefix between the log level and the module name, indicating the core that generated the log entry. The following are the prefixes used to indicate the cores:

Table 47: nRF54H20 log prefixes

Core	Prefix
Secure Domain	`sec`
Application core	`app`
Radio core	`rad`
System Controller (SysCtrl)	`sys`
Fast Lightweight Processor (FLPR)	`flpr`
Peripheral Processor (PPR)	`ppr`

Additional considerations When using STM logging, consider the following:

- Use optimized log macros (having up to 2 word size numeric arguments, like `LOG_INF("%d %c", (int)x, (char)y)`) to improve the size and speed of logging.
- For memory constrained applications (for example, when running on the PPR core), disable the `printk()` function by setting both the `CONFIG_PRINTK` and `CONFIG_BOOT_BANNER` Kconfig options to `n` in your project configuration.
- When working with multiple domains, such as the Radio core and Application core, ensure that each database is prefixed with the correct domain ID.
- Some log messages might be dropped due to the limited size of the RAM buffer that stores STM logs.

4.4.2 Tracing

Overview

The tracing feature provides hooks that permits you to collect data from your application and allows *Tracing Tools* running on a host to visualize the inner-working of the kernel and various subsystems.

Every system has application-specific events to trace out. Historically, that has implied:

1. Determining the application-specific payload,
2. Choosing suitable serialization-format,
3. Writing the on-target serialization code,
4. Deciding on and writing the I/O transport mechanics,
5. Writing the PC-side deserializer/parser,
6. Writing custom ad-hoc tools for filtering and presentation.

An application can use one of the existing formats or define a custom format by overriding the macros declared in include/zephyr/tracing/tracing.h.

Different formats, transports and host tools are available and supported in Zephyr.

In fact, I/O varies greatly from system to system. Therefore, it is instructive to create a taxonomy for I/O types when we must ensure the interface between payload/format (Top Layer) and the transport mechanics (bottom Layer) is generic and efficient enough to model these. See the *I/O taxonomy* section below.

Named Trace Events

Although the user can extend any of the supported serialization formats to enable additional tracing functions (or provide their own backend), zephyr also provides one generic named tracing function for convenience purposes, as well as to demonstrate how tracing frameworks could be extended.

Users can generate a custom trace event by calling `sys_trace_named_event()`, which takes an event name as well as two arbitrary 4 byte arguments. Tracing backends may truncate the provided event name if it is too long for the serialization format they support.

Serialization Formats

Common Trace Format (CTF) Support Common Trace Format, CTF, is an open format and language to describe trace formats. This enables tool reuse, of which line-textual (babeltrace) and graphical (TraceCompass) variants already exist.

CTF should look familiar to C programmers but adds stronger typing. See CTF - A Flexible, High-performance Binary Trace Format.

CTF allows us to formally describe application specific payload and the serialization format, which enables common infrastructure for host tools and parsers and tools for filtering and presentation.

A Generic Interface In CTF, an event is serialized to a packet containing one or more fields. As seen from *I/O taxonomy* section below, a bottom layer may:

- perform actions at transaction-start (e.g. mutex-lock),
- process each field in some way (e.g. sync-push emit, concat, enqueue to thread-bound FIFO),
- perform actions at transaction-stop (e.g. mutex-release, emit of concat buffer).

CTF Top-Layer Example The CTF_EVENT macro will serialize each argument to a field:

```
/* Example for illustration */
static inline void ctf_top_foo(uint32_t thread_id, ctf_bounded_string_t name)
{
  CTF_EVENT(
    CTF_LITERAL(uint8_t, 42),
    thread_id,
    name,
    "hello, I was emitted from function: ",
    __func__  /* __func__ is standard since C99 */
  );
}
```

How to serialize and emit fields as well as handling alignment, can be done internally and statically at compile-time in the bottom-layer.

The CTF top layer is enabled using the configuration option `CONFIG_TRACING_CTF` and can be used with the different transport backends both in synchronous and asynchronous modes.

Tracing Tools

Zephyr includes support for several popular tracing tools, presented below in alphabetical order.

Percepio Tracealyzer Support Zephyr includes support for Percepio Tracealyzer that offers trace visualization for simplified analysis, report generation and other analysis features. Tracealyzer allows for trace streaming over various interfaces and also snapshot tracing, where the events are kept in a RAM buffer.

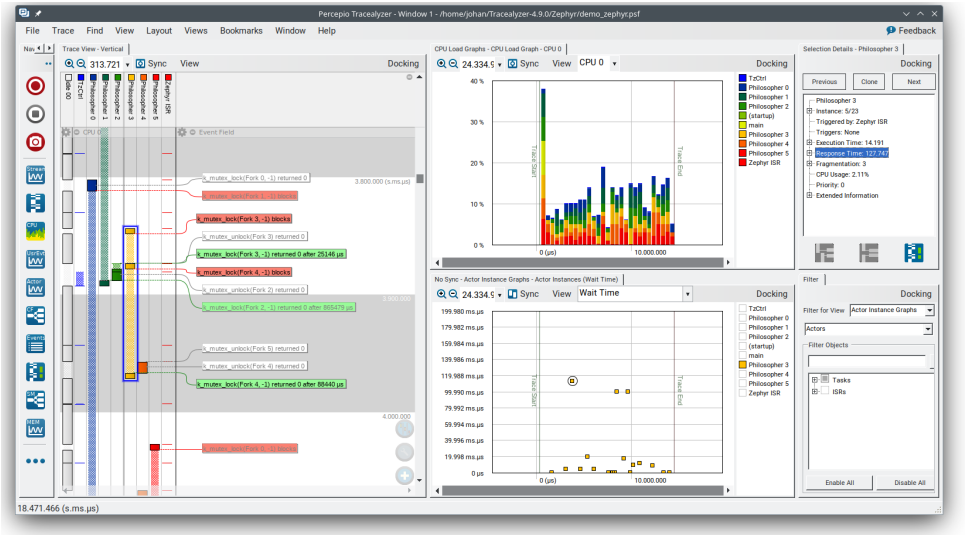
Zephyr kernel events are captured automatically when Tracealyzer tracing is enabled. Tracealyzer also provides extensive support for application logging, where you call the tracing library from your application code. This lets you visualize kernel events and application events together, for example as data plots or state diagrams on logged variables. Learn more in the Tracealyzer User Manual provided with the application.

Percepio TraceRecorder and Stream Ports The tracing library for Tracealyzer (TraceRecorder) is included in the Zephyr manifest and provided under the same license (Apache 2.0). This is enabled by adding the following configuration options in your prj.conf:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
```

Or using menuconfig:

- Enable *Subsystems and OS Services* ▸ *Tracing Support*



- Under *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Format*, select *Percepio Tracealyzer*

Some additional settings are needed to configure TraceRecorder. The most important configuration is to select the right "stream port". This specifies how to output the trace data. As of July 2024, the following stream ports are available in the Zephyr configuration system:

- **Ring Buffer**: The trace data is kept in a circular RAM buffer.
- **RTT**: Trace streaming via Segger RTT on J-Link debug probes.
- **ITM**: Trace streaming via the ITM function on Arm Cortex-M devices.
- **Semihost**: For tracing on QEMU. Streams the trace data to a host file.

Select the stream port in menuconfig under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Stream Port*.

Or simply add one of the following options in your prj.conf:

```
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RINGBUFFER=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RTT=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ITM=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ZEPHYR_SEMIHOST=y
```

Make sure to only include ONE of these configuration options.

The stream port modules have individual configuration options. In menuconfig these are found under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *(Stream Port) Config*. The most important options for each stream port are described below.

Tracealyzer Snapshot Tracing (Ring Buffer) The "Ring Buffer" stream port keeps the trace data in a RAM buffer on the device. By default, this is a circular buffer, meaning that it always contains the most recent data. This is used to dump "snapshots" of the trace data, e.g. by using the debugger. This usually only allows for short traces, unless you have megabytes of RAM to spare, so it is not suitable for profiling. However, it can be quite useful for debugging in combination with breakpoints. For example, if you set a breakpoint in an error handler, a snapshot trace can show the sequence of events leading up to the error. Snapshot tracing is also easy to begin with, since it doesn't depend on any particular debug probe or other development tool.

To use the Ring Buffer option, make sure to have the following configuration options in your prj.cnf:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RINGBUFFER=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RINGBUFFER_SIZE=<size in bytes>
```

Or if using menuconfig:

- Enable *Subsystems and OS Services* ▸ *Tracing Support*
- Under *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Recorder Start Mode*, select *Start*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Stream Port*, select *Ring Buffer*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Ring Buffer Config* ▸ *Buffer Size*, set the buffer size in bytes.

The default buffer size can be reduced if you are tight on RAM, or increased if you have RAM to spare and want longer traces. You may also optimize the Tracing Configuration settings to get longer traces by filtering out less important events. In menuconfig, see *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Configuration*.

To view the trace data, the easiest way is to start your debugger (west debug) and run the following GDB command:

```
dump binary value trace.bin *RecorderDataPtr
```

The resulting file is typically found in the root of the build folder, unless a different path is specified. Open this file in Tracealyzer by selecting *File* ▸ *Open* ▸ *Open File*.

Tracealyzer Streaming with SEGGER RTT Tracealyzer has built-in support for SEGGER RTT to receive trace data using a J-Link probe. This allows for recording very long traces. To configure Zephyr for RTT streaming to Tracealyzer, add the following configuration options in your prj.cnf:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START_FROM_HOST=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RTT=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_RTT_UP_BUFFER_SIZE=<size in bytes>
```

Or if using menuconfig:

- Enable *Subsystems and OS Services* ▸ *Tracing Support*
- Under *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Recorder Start Mode*, select *Start From Host*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Stream Port*, select *RTT*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *RTT Config*, set the size of the RTT “up” buffer in bytes.

The setting *RTT buffer size up* sets the size of the RTT transmission buffer. This is important for throughput. By default this buffer is quite large, 5000 bytes, to give decent performance also on onboard J-Link debuggers (they are not as fast as the stand-alone probes). If you are tight on RAM, you may consider reducing this setting. If using a regular J-Link probe it is often sufficient with a much smaller buffer, e.g. 1 KB or less.

Learn more about RTT streaming in the Tracealyzer User Manual. See Creating and Loading Traces -> Percepio TraceRecorder -> Using TraceRecorder v4.6 or later -> Stream ports (or search for RTT).

Tracealyzer Streaming with Arm ITM This stream port is for Arm Cortex-M devices featuring the ITM unit. It is recommended to use a fast debug probe that allows for SWO speeds of 10 MHz or higher. To use this stream port, apply the following configuration options:

```
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ITM=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ITM_PORT=1
```

Or if using menuconfig:

- Enable *Subsystems and OS Services* ▸ *Tracing Support*
- Under *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Recorder Start Mode*, select *Start*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Stream Port*, select *ITM*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *ITM Config*, set the ITM port to 1.

The main setting for the ITM stream port is the ITM port (0-31). A dedicated channel is needed for Tracealyzer. Port 0 is usually reserved for printf logging, so channel 1 is used by default.

The option *Use internal buffer* should typically remain disabled. It buffers the data in RAM before transmission and defers the data transmission to the periodic TzCtrl thread.

The host-side setup depends on what debug probe you are using. Learn more in the Tracealyzer User Manual. See *Creating and Loading Traces* ▸ *Percepio TraceRecorder* ▸ *Using TraceRecorder v4.6 or later* ▸ *Stream ports (or search for ITM)*.

Tracealyzer Streaming from QEMU (Semihost) This stream port is designed for Zephyr tracing in QEMU. This can be an easy way to get started with tracing and try out streaming trace without needing a fast debug probe. The data is streamed to a host file using semihosting. To use this option, apply the following configuration options:

```
CONFIG_SEMIHOST=y
CONFIG_TRACING=y
CONFIG_PERCEPIO_TRACERECORDER=y
CONFIG_PERCEPIO_TRC_START_MODE_START=y
CONFIG_PERCEPIO_TRC_CFG_STREAM_PORT_ZEPHYR_SEMIHOST=y
```

Using menuconfig

- Enable *General Architecture Options* ▸ *Semihosting support for Arm and RISC-V targets*
- Enable *Subsystems and OS Services* ▸ *Tracing Support*
- Under *Subsystems and OS Services* ▸ *Tracing Support* ▸ *Tracing Format*, select *Percepio Tracealyzer*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Recorder Start Mode*, select *Start*
- Under *Modules* ▸ *percepio* ▸ *TraceRecorder* ▸ *Stream Port*, select *Semihost*

By default, the resulting trace file is found in `./trace.psf` in the root of the build folder, unless a different path is specified. Open this file in Percepio Tracealyzer by selecting *File* ▸ *Open* ▸ *Open File*.

Recorder Start Mode You may have noticed the *Recorder Start Mode* option in the Tracealyzer examples above. This decides when the tracing starts. With the option *Start*, the tracing begins directly at startup, once the TraceRecorder library has been initialized. This is recommended when using the Ring Buffer and Semihost stream ports.

For streaming via RTT or ITM you may also use *Start From Host* or *Start Await Host*. Both listens for start commands from the Tracealyzer application. The latter option, *Start Await Host*, causes the TraceRecorder initialization to block until the start command is received from the Tracealyzer application.

Custom Stream Ports for Tracealyzer The stream ports are small modules within TraceRecorder that define what functions to call to output the trace data and (optionally) how to read start/stop commands from Tracealyzer. It is fairly easy to make custom stream ports to implement your own data transport and Tracealyzer can receive trace streams over various interfaces, including files, sockets, COM ports, named pipes and more. Note that additional stream port modules are available in the TraceRecorder repo (e.g. lwIP), although they might require modifications to work with Zephyr.

Learning More Learn more about how to get started in the Tracealyzer Getting Started Guides.

Percepio View for Zephyr Percepio View is a free-of-charge tracing tool based on Percepio Tracealyzer, intended for debugging and verification of Zephyr applications.

Percepio View can be used side-by-side with a traditional debugger and complements your debugger by visualising the real-time execution of threads, ISRs, syscalls and your own "User Events".

To learn more about Percepio View, how to get started and upgrade options, check out Percepio's product page.

Percepio View provides snapshot tracing, meaning the data is stored to a ring-buffer in target RAM and is saved to host using the regular debugger connection. For trace streaming support, Percepio offers (paid-for) upgrades to Percepio Profile or Percepio Tracealyzer. No modifications of the Zephyr source code are needed, only enabling the TraceRecorder library in Kconfig. Percepio View runs on Windows and Linux hosts.

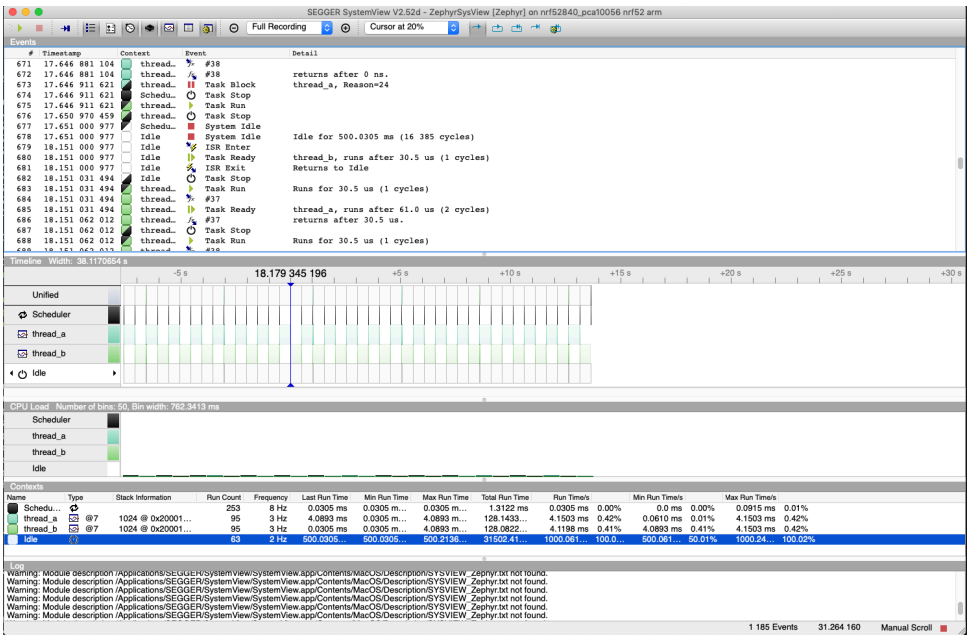
SEGGER SystemView Support Zephyr provides built-in support for SEGGER SystemView that can be enabled in any application for platforms that have the required hardware support.

The payload and format used with SystemView is custom to the application and relies on RTT as a transport. Newer versions of SystemView support other transports, for example UART or using snapshot mode (both still not supported in Zephyr).

To enable tracing support with SEGGER SystemView add the *SystemView RTT Tracing Snippet (rtt-tracing)* to your build command:

```
west build -b <board> -S rtt-tracing samples/synchronization
```

SystemView can also be used for post-mortem tracing, which can be enabled with `CONFIG_SEGGER_SYSVIEW_POST_MORTEM_MODE`. In this mode, a debugger can be attached after the system has crashed using `west attach` after which the latest data from the internal RAM buffer can be loaded into SystemView.



Recent versions of SEGGER SystemView come with an API translation table for Zephyr which is incomplete and does not match the current level of support available in Zephyr. To use the latest Zephyr API description table, copy the file available in the tree to your local configuration directory to override the builtin table:

```
# On Linux and MacOS
cp $ZEPHYR_BASE/subsys/tracing/sysview/SYSVIEW_Zephyr.txt ~/.config/SEGGER/
```

TraceCompass TraceCompass is an open source tool that visualizes CTF events such as thread scheduling and interrupts, and is helpful to find unintended interactions and resource conflicts on complex systems.

See also the presentation by Ericsson, Advanced Trouble-shooting Of Real-time Systems.

Perfetto Perfetto is a web trace viewer for the Chrome Trace Event Format. It shows the same scheduling and interrupt activity as TraceCompass without installing any tool: scripts/tracing/ctf2perfetto.py converts a CTF trace to that format with Python 3 alone:

```
$ZEPHYR_BASE/scripts/tracing/ctf2perfetto.py <trace file> -o trace.json
```

Loading `trace.json` at https://ui.perfetto.dev gives a timeline with one lane per thread, plus lanes for ISRs and for kernel objects such as semaphores, mutexes and timers.

The *Instrumentation* subsystem writes the same format from function call traces, so a build can be looked at either way in the same viewer.

The TSDL `metadata` is read from next to the trace, as babeltrace2 expects, unless `--metadata` points elsewhere. Use the metadata generated by the build that produced the trace: CTF records carry no length, so a record the metadata does not describe cannot be skipped, and the converter stops and names its event id rather than writing a partial trace.

User-Defined Tracing This tracing format lets the application define plain C functions that run on each hook, with no need to author or fork a tracing header. Each `sys_port_trace_*` hook is routed to a `__weak` callback named `sys_trace_<event>_user()`; the application overrides only the callbacks it cares about, and any callback it leaves undefined is a no-op.

Examples include:

- simple toggling of GPIO for external scope tracing while minimizing extra cpu load
- generating/outputting trace data in a non-standard or proprietary format that can not be supported by the other tracing systems

The callbacks cover thread/scheduler, ISR, idle, system init and sleep events, GPIO, timers, RTIO, and the kernel objects (semaphores, mutexes, condition variables, message queues, mailboxes, events, polling, memory slabs and work queues). The authoritative list, with exact signatures, is the set of `sys_trace_*_user` declarations in subsys/tracing/user/tracing_user.h. A representative subset:

```
void sys_trace_thread_create_user(struct k_thread *thread);
void sys_trace_thread_switched_in_user(void);
void sys_trace_thread_switched_out_user(void);
void sys_trace_isr_enter_user(void);
void sys_trace_isr_exit_user(void);
void sys_trace_idle_user(void);
void sys_trace_k_sem_give_enter_user(struct k_sem *sem);
void sys_trace_k_mutex_lock_enter_user(struct k_mutex *mutex, k_timeout_t timeout);
```

Enable this format with the `CONFIG_TRACING_USER` option. tests/subsys/tracing/tracing_user_callbacks shows an application overriding object callbacks.

Out-of-tree Tracing Formats A downstream module can supply its own tracing format without editing the Zephyr tree. Set `CONFIG_TRACING_FORMAT_HEADER` (a promptless Kconfig string, assigned from the module's `Kconfig` with a `default`) to the name of a header on the include path;

include/zephyr/tracing/tracing.h pulls it in with a computed `#include` when no in-tree format is selected.

The format header defines the `sys_port_trace_*` hooks it records and ends with:

```
/* default no-ops for the scheduler/idle/init/named function layer */
#include <zephyr/tracing/tracing_default_hooks.h>
/* no-op for every sys_port_trace_* hook this header does not define */
#include <zephyr/tracing/tracing_hooks.h>
```

so a format only has to implement the hooks it cares about. A tracing transport is added independently with `TRACING_BACKEND_DEFINE()` (see subsys/tracing/include/tracing_backend.h), so neither a custom format nor a custom backend requires changes to the core tree. tests/subsys/tracing/tracing_format_module is a complete worked example.

Transport Backends

The following backends are currently supported:

- UART
- USB
- File (Using the native port with POSIX architecture based targets)
- RTT (With SystemView)
- RAM (buffer to be retrieved by a debugger)

Using Tracing

The sample samples/subsys/tracing demonstrates tracing with different formats and backends.

To get started, the simplest way is to use the CTF format with the native_sim port, build the sample as follows:

Using west:

```
# From the root of the zephyr repository
west build -b native_sim samples/subsys/tracing -- -DCONF_FILE=prj_native_ctf.conf
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=native_sim -DCONF_FILE=prj_native_ctf.conf␣
↪samples/subsys/tracing

# Now run the build tool on the generated build system:
ninja -Cbuild
```

You can then run the resulting binary with the option `-trace-file` to generate the tracing data:

```
mkdir data
cp $ZEPHYR_BASE/subsys/tracing/ctf/tsdl/metadata data/
./build/zephyr/zephyr.exe -trace-file=data/channel0_0
```

The resulting CTF output can be visualized using babeltrace or TraceCompass by pointing the tool to the `data` directory with the metadata and trace files.

Using RAM backend For devices that do not have available I/O for tracing such as USB or UART but have enough RAM to collect trace data, the ram backend can be enabled with configuration `CONFIG_TRACING_BACKEND_RAM`. Adjust `CONFIG_RAM_TRACING_BUFFER_SIZE` to be able to record enough traces for your needs. Then thanks to a runtime debugger such as gdb this buffer can be fetched from the target to an host computer:

```
(gdb) dump binary memory data/channel0_0 <ram_tracing_start> <ram_tracing_end>
```

The resulting channel0_0 file have to be placed in a directory with the `metadata` file like the other backend.

Future LTTng Inspiration

Currently, the top-layer provided here is quite simple and bare-bones, and needlessly copied from Zephyr's Segger SystemView debug module.

For an OS like Zephyr, it would make sense to draw inspiration from Linux's LTTng and change the top-layer to serialize to the same format. Doing this would enable direct reuse of TraceCompass' canned analyses for Linux. Alternatively, LTTng-analyses in TraceCompass could be customized to Zephyr. It is ongoing work to enable TraceCompass visibility of Zephyr in a target-agnostic and open source way.

I/O Taxonomy

- Atomic Push/Produce/Write/Enqueue:
  - **synchronous:**
    means data-transmission has completed with the return of the call.
  - **asynchronous:**
    means data-transmission is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.
  - **buffered:**
    means data-transmissions are copied and grouped together to form a larger ones. Usually for amortizing overhead (burst dequeue) or jitter-mitigation (steady dequeue).

  Examples:

  - **sync unbuffered**
    E.g. PIO via GPIOs having steady stream, no extra FIFO memory needed. Low jitter but may be less efficient (can't amortize the overhead of writing).
  - **sync buffered**
    E.g. `fwrite()` or enqueuing into FIFO. Blockingly burst the FIFO when its buffer-waterlevel exceeds threshold. Jitter due to bursts may lead to missed deadlines.
  - **async unbuffered**
    E.g. DMA, or zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
  - **async buffered**
    E.g. enqueuing into FIFO.
- Atomic Pull/Consume/Read/Dequeue:
  - **synchronous:**
    means data-reception has completed with the return of the call.
  - **asynchronous:**
    means data-reception is pending or ongoing with the return of the call. Usually, interrupts/callbacks/signals or polling is used to determine completion.

- **buffered:**
  means data is copied-in in larger chunks than request-size. Usually for amortizing wait-time.

Examples:

- **sync unbuffered**
  E.g. Blocking read-call, `fread()` or SPI-read, zero-copying in shared memory.
- **sync buffered**
  E.g. Blocking read-call with caching applied. Makes sense if read pattern exhibits spatial locality.
- **async unbuffered**
  E.g. zero-copying in shared memory. Be careful of data hazards, race conditions, etc!
- **async buffered**
  E.g. `aio_read()` or DMA.

Unfortunately, I/O may not be atomic and may, therefore, require locking. Locking may not be needed if multiple independent channels are available.

- **The system has non-atomic write and one shared channel**
  E.g. UART. Locking required.

  ```
  lock(); emit(a); emit(b); emit(c); release();
  ```

- **The system has non-atomic write but many channels**
  E.g. Multi-UART. Lock-free if the bottom-layer maps each Zephyr thread+ISR to its own channel, thus alleviating races as each thread is sequentially consistent with itself.

  ```
  emit(a,thread_id); emit(b,thread_id); emit(c,thread_id);
  ```

- **The system has atomic write but one shared channel**
  E.g. `native_sim` or board with DMA. May or may not need locking.

  ```
  emit(a ## b ## c); /* Concat to buffer */

  lock(); emit(a); emit(b); emit(c); release(); /* No extra mem */
  ```

- **The system has atomic write and many channels**
  E.g. native_sim or board with multi-channel DMA. Lock-free.

  ```
  emit(a ## b ## c, thread_id);
  ```

Object tracking

The kernel can also keep track of the kernel objects in the system. Enabling `CONFIG_TRACING_OBJECT_TRACKING` enables the *object core framework*, which enumerates the objects of each kernel object type. For instance, to visit every mutex, one can write:

```
static int visit_mutex(struct k_obj_core *obj_core, void *data)
{
    struct k_mutex *mutex = CONTAINER_OF(obj_core, struct k_mutex, obj_core);

    /* Do something */

    return 0;
}

k_obj_type_walk_locked(k_obj_type_find(K_OBJ_TYPE_MUTEX_ID), visit_mutex, NULL);
```

Each object type can be excluded through its `CONFIG_OBJ_CORE_*` option. The object_cores sample can be built with object tracking enabled.

4.4.3 Debugging

Thread analyzer

The thread analyzer module enables all the Zephyr options required to track the thread information, e.g. thread stack size usage and other runtime thread runtime statistics.

The analysis is performed on demand when the application calls `thread_analyzer_run()` or `thread_analyzer_print()`.

For example, to build the synchronization sample with Thread Analyser enabled, do the following:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/synchronization/ -- -
↪DCONFIG_QEMU_ICOUNT=n -DCONFIG_THREAD_ANALYZER=y \
-DCONFIG_THREAD_ANALYZER_USE_PRINTK=y -DCONFIG_THREAD_ANALYZER_AUTO=y \
-DCONFIG_THREAD_ANALYZER_AUTO_INTERVAL=5
```

When you run the generated application in Qemu, you will get the additional information from Thread Analyzer:

```
thread_a: Hello World from cpu 0 on qemu_x86!
Thread analyze:
 thread_b            : STACK: unused 740 usage 284 / 1024 (27 %); CPU: 0 %

```

Configuration Configure this module using the following options.

`CONFIG_THREAD_ANALYZER`
: Enable the module.

`CONFIG_THREAD_ANALYZER_USE_PRINTK`
: Use printk for thread statistics.

`CONFIG_THREAD_ANALYZER_USE_LOG`
: Use the logger for thread statistics.

`CONFIG_THREAD_ANALYZER_AUTO`
: Run the thread analyzer automatically. You do not need to add any code to the application when using this option.

`CONFIG_THREAD_ANALYZER_AUTO_INTERVAL`
: The time for which the module sleeps between consecutive printing of thread analysis in automatic mode.

`CONFIG_THREAD_ANALYZER_AUTO_STACK_SIZE`
: The stack for thread analyzer automatic thread.

`CONFIG_THREAD_NAME`
: Print the name of the thread instead of its ID.

`CONFIG_THREAD_RUNTIME_STATS`
: Print thread runtime data such as utilization. This options is automatically selected by `CONFIG_THREAD_ANALYZER`.

`CONFIG_THREAD_ANALYZER_LONG_FRAME_PER_INTERVAL`
: Reset Longest Frame value statistics after printing. When using `SCHED_THREAD_USAGE_ANALYSIS` to get average and longest frame thread statistics, reset the Longest Frame value to zero after each time printing the thread statistics. This enables observation of the longest frame during the most recent interval rather than longest frame since startup.

`CONFIG_THREAD_ANALYZER_PRINT_THREAD_PRIORITY`
: Print each thread's priority.

API documentation
Thread analyzer

Core Dump

The core dump module enables dumping the CPU registers and memory content for offline debugging. This module is called when a fatal error is encountered and prints or stores data according to which backends are enabled.

Configuration Configure this module using the following options.

- DEBUG_COREDUMP: enable the module.

Here are the options to enable output backends for core dump:

- DEBUG_COREDUMP_BACKEND_LOGGING: use log module for core dump output.
- DEBUG_COREDUMP_BACKEND_LOGGING_UDP: same as logging backend with optional raw UDP transfer; the peer is DEBUG_COREDUMP_LOGGING_UDP_HOST, a string parsed by net_ipaddr_parse() (IPv4 or IPv6, optional :port with default UDP port 17777 when omitted). Use scripts/coredump/coredump_udp_receiver.py to build the binary for scripts/coredump/coredump_gdbserver.py.
- DEBUG_COREDUMP_BACKEND_FLASH_PARTITION: use flash partition for core dump output.
- DEBUG_COREDUMP_BACKEND_NULL: fallback core dump backend if other backends cannot be enabled. All output is sent to null.

Here are the choices regarding memory dump:

- DEBUG_COREDUMP_MEMORY_DUMP_MIN: only dumps the stack of the exception thread, its thread struct, and some other bare minimal data to support walking the stack in the debugger. Use this only if absolute minimum of data dump is desired.
- DEBUG_COREDUMP_MEMORY_DUMP_THREADS: Dumps the thread struct and stack of all threads and all data required to debug threads.
- DEBUG_COREDUMP_MEMORY_DUMP_LINKER_RAM: Dumps the memory region between _image_ram_start[] and _image_ram_end[]. This includes at least data, noinit, and BSS sections. This is the default.

Additional memory can be included in a dump (even with the "DEBUG_COREDUMP_MEMORY_DUMP_MIN" config selected) through one or more *coredump devices*

Usage When the core dump module is enabled, during a fatal error, CPU registers and memory content are printed or stored according to which backends are enabled. This core dump data can be fed into a custom-made GDB server as a remote target for GDB (and other GDB compatible debuggers). CPU registers, memory content and stack can be examined in the debugger.

This usually involves the following steps:

1. Get the core dump log from the device depending on enabled backends. For example, if the log module backend is used, get the log output from the log module backend.
2. Convert the core dump log into a binary format that can be parsed by the GDB server. For example, scripts/coredump/coredump_serial_log_parser.py can be used to convert the serial console log into a binary file. If the UDP coredump backend is enabled (DEBUG_COREDUMP_BACKEND_LOGGING_UDP), run scripts/coredump/coredump_udp_receiver.py on the collector host to reassemble UDP datagrams into the **same** raw binary format.
3. Start the custom GDB server using the script scripts/coredump/coredump_gdbserver.py with the core dump binary log file, and the Zephyr ELF file as parameters. The GDB server can also be started from within GDB, see below.
4. Start the debugger corresponding to the target architecture.

Note

Developers for Intel ADSP CAVS 15-25 platforms using ZEPHYR_TOOLCHAIN_VARIANT=zephyr should use the debugger in the xtensa-intel_apl_adsp toolchain of the SDK.

5. When DEBUG_COREDUMP_BACKEND_FLASH_PARTITION is enabled the core dump data is stored in the flash partition. The flash partition must be defined in the device tree:

```
&flash0 {
   partitions {
      coredump_partition: partition@255000 {
         label = "coredump-partition";
         reg = <0x255000 DT_SIZE_K(4)>;
      };
   };
};
```

Example This example uses the log module backend tied to serial console. This was done on qemu_x86 where a null pointer was dereferenced.

This is the core dump log from the serial console, and is stored in coredump.log:

```

```

1. Run the core dump serial log converter:

   ```
   ./scripts/coredump/coredump_serial_log_parser.py coredump.log coredump.bin
   ```

2. Start the custom GDB server:

   ```
   ./scripts/coredump/coredump_gdbserver.py build/zephyr/zephyr.elf coredump.bin
   ```

3. Start GDB:

   ```
   <path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb␣
   ↪build/zephyr/zephyr.elf
   ```

4. Inside GDB, connect to the GDB server via port 1234:

   ```
   (gdb) target remote localhost:1234
   ```

5. Examine the CPU registers:

   ```
   (gdb) info registers
   ```

   Output from GDB:

   ```
   eax            0x0                 0
   ecx            0x119d74            1154420
   edx            0x3f8               1016
   ebx            0x0                 0
   esp            0x119d00            0x119d00 <z_main_stack+844>
   ebp            0x119d10            0x119d10 <z_main_stack+860>
   esi            0x0                 0
   edi            0x101aa7            1055399
   eip            0x100459            0x100459 <func_3+16>
   eflags         0x206               [ PF IF ]
   cs             0x8                 8
   ss             <unavailable>
   ```

(continues on next page)

(continued from previous page)

```
ds             <unavailable>
es             <unavailable>
fs             <unavailable>
gs             <unavailable>
```

6. Examine the backtrace:

```
(gdb) bt
```

Output from GDB:

```
#0  0x00100459 in func_3 (addr=0x0) at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:14
#1  0x00100477 in func_2 (addr=0x0) at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:21
#2  0x00100492 in func_1 (addr=0x0) at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:28
#3  0x001004c8 in main () at␣
↪zephyr/rtos/zephyr/samples/hello_world/src/main.c:42
```

Starting the GDB server from within GDB You can use `target remote |` to start the custom GDB server from inside GDB, instead of in a separate shell.

1. Start GDB:

```
<path to SDK>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb␣
↪build/zephyr/zephyr.elf
```

2. Inside GDB, start the GDB server using the `--pipe` option:

```
(gdb) target remote | ./scripts/coredump/coredump_gdbserver.py --pipe␣
↪build/zephyr/zephyr.elf coredump.bin
```

File Format The core dump binary file consists of one file header, one architecture-specific block, zero or one threads metadata block(s), and multiple memory blocks. All numbers in the headers below are little endian.

File Header The file header consists of the following fields:

Table 48: Core dump binary file header

Field	Data Type	Description
ID	`char[2]`	`Z`, `E` as identifier of file.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Target code	`uint16_`	Indicate which target (e.g. architecture or SoC) so the parser can instantiate the correct register block parser.
Pointer size	'uint8_t'	Size of `uintptr_t` in power of 2. (e.g. 5 for 32-bit, 6 for 64-bit). This is needed to accommodate 32-bit and 64-bit target in parsing the memory block addresses.
Flags	`uint8_t`	
Fatal error reason	`unsigned int`	Reason for the fatal error, as the same in `enum k_fatal_error_reason` defined in include/zephyr/fatal.h

Architecture-specific Block The architecture-specific block contains the byte stream of data specific to the target architecture (e.g. CPU registers)

Table 49: Architecture-specific Block

Field	Data Type	Description
ID	`char`	`A` to indicate this is a architecture-specific block.
Header version	`uint16_`	Identify the version of this block. To be interpreted by the target architecture specific block parser.
Number of bytes	`uint16_`	Number of bytes following the header which contains the byte stream for target data. The format of the byte stream is specific to the target and is only being parsed by the target parser.
Register byte stream	`uint8_t`	Contains target architecture specific data.

Threads Metadata Block The threads metadata block contains the byte stream of data necessary for debugging threads.

Table 50: Threads Metadata Block

Field	Data Type	Description
ID	`char`	`T` to indicate this is a threads metadata block.
Header version	`uint16_`	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Number of bytes	`uint16_`	Number of bytes following the header which contains the byte stream for target data.
Byte stream	`uint8_t`	Contains data necessary for debugging threads.

Memory Block The memory block contains the start and end addresses and the data within the memory region.

Table 51: Memory Block

Field	Data Type	Description
ID	char	`M` to indicate this is a memory block.
Header version	uint16_	Identify the version of the header. This needs to be incremented whenever the header struct is modified. This allows parser to reject older header versions so it will not incorrectly parse the header.
Start address	uintptr_	The start address of the memory region.
End address	uintptr_	The end address of the memory region.
Memory byte stream	uint8_t	Contains the memory content between the start and end addresses.

Adding New Target The architecture-specific block is target specific and requires new dumping routine and parser for new targets. To add a new target, the following needs to be done:

1. Add a new target code to the `enum coredump_tgt_code` in include/zephyr/debug/coredump.h.
2. Implement `arch_coredump_tgt_code_get()` simply to return the newly introduced target code.
3. Implement `arch_coredump_info_dump()` to construct a target architecture block and call `coredump_buffer_output()` to output the block to core dump backend.
4. Add a parser to the core dump GDB stub scripts under `scripts/coredump/gdbstubs/`
    1. Extends the `gdbstubs.gdbstub.GdbStub` class.
    2. During `__init__`, store the GDB signal corresponding to the exception reason in `self.gdb_signal`.
    3. Parse the architecture-specific block from `self.logfile.get_arch_data()`. This needs to match the format as implemented in step 3 (inside `arch_coredump_info_dump()`).
    4. Implement the abstract method `handle_register_group_read_packet` where it returns the register group as GDB expected. Refer to GDB's code and documentation on what it is expecting for the new target.
    5. Optionally implement `handle_register_single_read_packet` for registers not covered in the `g` packet.
5. Extend `get_gdbstub()` in scripts/coredump/gdbstubs/__init__.py to return the newly implemented GDB stub.

UDP logging backend sample Sample README pages that exercise the UDP coredump path are linked into this chapter so Sphinx includes them in the documentation tree:

UDP coredump via shell

Overview Zephyr shell stays running on the serial console. Run **"coredump_crash"** to fault the board; with **"CONFIG_DEBUG_COREDUMP_BACKEND_LOGGING_UDP"** the coredump byte stream is mirrored as `#CD:` hex on the UART and sent as framed UDP to **"CONFIG_DEBUG_COREDUMP_LOGGING_UDP_HOST"** (syntax is whatever `net_ipaddr_parse()` accepts, e.g. `192.0.2.2`, `192.0.2.2:17777`, `[2001:db8::1]:17777`; port defaults to **17777** when omitted).

Board overlay **"boards/versalnet_apu.conf"** sets lab-style static IPv4; adjust for your bench. Networking and UDP coredump options live in **"prj.conf"** (defaults use `192.0.2.x` before the overlay applies).

See *Core Dump* and subsys/debug/coredump/coredump_backend_logging_udp.c.

Build

```
west build -b versalnet_apu samples/subsys/debug/coredump_udp_demos/demo_shell
```

GDB stub

- *Overview*
- *Features*
- *Enabling GDB Stub*
  - *Using Serial Backend*
- *Debugging*
  - *Using Serial Backend*
- *Example*

Overview The gdbstub feature provides an implementation of the GDB Remote Serial Protocol (RSP) that allows you to remotely debug Zephyr using GDB.

The protocol supports different connection types: serial, UDP/IP and TCP/IP. Zephyr currently supports only serial device communication.

The GDB program acts as a client while the Zephyr gdbstub acts as a server. When this feature is enabled, Zephyr stops its execution after `gdb_init()` starts gdbstub service and waits for a GDB connection. Once a connection is established it is possible to synchronously interact with Zephyr. Note that currently it is not possible to asynchronously send commands to the target.

Features The following features are supported:

- Add and remove breakpoints
- Continue and step the target
- Print backtrace
- Read or write general registers
- Read or write the memory

Enabling GDB Stub GDB stub can be enabled with the `CONFIG_GDBSTUB` option.

Using Serial Backend The serial backend for GDB stub can be enabled with the `CONFIG_GDBSTUB_SERIAL_BACKEND` option.

Since serial backend utilizes UART devices to send and receive GDB commands,

- If there are spare UART devices on the board, set `zephyr,gdbstub-uart` property of the chosen node to the spare UART device so that `printk()` and log messages are not being printed to the same UART device used for GDB.

- For boards with only one UART device, `printk()` and logging must be disabled if they are also using the same UART device for output. GDB related messages may interleave with log messages which may have unintended consequences. Usually this can be done by disabling `CONFIG_PRINTK` and `CONFIG_LOG`.

Debugging

Using Serial Backend

1. Build with GDB stub and serial backend enabled.
2. Flash built image onto board and reset the board.
   - Execution should now be paused at `gdb_init()`.
3. Execute GDB on development machine and connect to the GDB stub.

   ```
   target remote <serial device>
   ```

   For example,

   ```
   target remote /dev/ttyUSB1
   ```

4. GDB commands can be used to start debugging.

Example There is a test application tests/subsys/debug/gdbstub with one of its test cases `debug.gdbstub.breakpoints` demonstrating how the Zephyr GDB stub can be used. The test also has a case to connect to the QEMU's GDB stub implementation (at a custom port `tcp:1235`) as a reference to validate the test script itself.

Run the test with the following command from your *ZEPHYR_BASE* directory:

```
west twister -p qemu_x86 -T tests/subsys/debug/gdbstub
```

The test should run successfully, and now let's do something similar step-by-step to demonstrate how the Zephyr GDB stub works from the GDB user's perspective.

In the snippets below use and expect your appropriate directories instead of `<SDK install directory>`, `<build_directory>`, `<ZEPHYR_BASE>`.

1. Open two terminal windows.
2. On the first terminal, build and run the test application:

   ```
   # From the root of the zephyr repository
   west build -b qemu_x86 tests/subsys/debug/gdbstub -- '-
   ↪DCONFIG_QEMU_EXTRA_FLAGS="-serial tcp:localhost:5678,server"'
   west build -t run
   ```

   Note how we set `CONFIG_QEMU_EXTRA_FLAGS` to direct QEMU serial console port to the `localhost` TCP port `5678` to wait for a connection from the GDB `remote` command we are going to do on the next steps.

3. On the second terminal, start GDB:

   ```
   <SDK install directory>/x86_64-zephyr-elf/bin/x86_64-zephyr-elf-gdb
   ```

   1. Tell GDB where to look for the built ELF file:

      ```
      (gdb) symbol-file <build directory>/zephyr/zephyr.elf
      ```

      Response from GDB:

```
Reading symbols from <build directory>/zephyr/zephyr.elf...
```

2. Tell GDB to connect to the Zephyr gdbstub serial backend which is exposed earlier as a server through the TCP port `-serial` redirection at QEMU.

```
(gdb) target remote localhost:5678
```

Response from GDB:

```
Remote debugging using localhost:5678
arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:252
252     }
```

GDB also shows where the code execution is stopped. In this case, it is at arch/x86/core/ia32/gdbstub.c, line 252.

3. Use command `bt` or `backtrace` to show the backtrace of stack frames.

```
(gdb) bt
#0  arch_gdb_init () at <ZEPHYR_BASE>/arch/x86/core/ia32/gdbstub.c:252
#1  0x00104140 in gdb_init () at
↪<ZEPHYR_BASE>/zephyr/subsys/debug/gdbstub.c:852
#2  0x00109c13 in z_sys_init_run_level (level=INIT_LEVEL_PRE_KERNEL_2) at
↪<ZEPHYR_BASE>/kernel/init.c:360
#3  0x00109e73 in z_cstart () at <ZEPHYR_BASE>/kernel/init.c:630
#4  0x00104422 in z_prep_c (arg=0x1245bc <x86_cpu_boot_arg>) at
↪<ZEPHYR_BASE>/arch/x86/core/prep_c.c:80
#5  0x001000c9 in __csSet () at
↪<ZEPHYR_BASE>/arch/x86/core/ia32/crt0.S:290
#6  0x001245bc in uart_dev ()
#7  0x00134988 in z_interrupt_stacks ()
#8  0x00000000 in ?? ()
```

4. Use command `list` to show the source code and surroundings where code execution is stopped.

```
(gdb) list
247             __asm__ volatile ("int3");
248
249     #ifdef CONFIG_GDBSTUB_TRACE
250             printk("gdbstub:%s GDB is connected\n", __func__);
251     #endif
252     }
253
254     /* Hook current IDT. */
255     _EXCEPTION_CONNECT_NOCODE(z_gdb_debug_isr, IV_DEBUG, 3);
256     _EXCEPTION_CONNECT_NOCODE(z_gdb_break_isr, IV_BREAKPOINT, 3);
```

5. Use command `s` or `step` to step through program until it reaches a different source line. Now that it finished executing `arch_gdb_init()` and is continuing in `gdb_init()`.

```
(gdb) s
gdb_init () at <ZEPHYR_BASE>/subsys/debug/gdbstub.c:857
857     return 0;
```

```
(gdb) list
852             arch_gdb_init();
853
```

(continues on next page)

(continued from previous page)

```
854     #ifdef CONFIG_GDBSTUB_TRACE
855             printk("gdbstub:%s exit\n", __func__);
856     #endif
857             return 0;
858     }
859
860     #ifdef CONFIG_XTENSA
861     /*
```

6. Use command `br` or `break` to setup a breakpoint. For this example set up a breakpoint at `main()`, and let code execution continue without any intervention using command `c` (or `continue`).

```
(gdb) break main
Breakpoint 1 at 0x10064d: file
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c, line 27.
```

```
(gdb) continue
Continuing.
```

Once code execution reaches `main()`, execution will be stopped and GDB prompt returns.

```
Breakpoint 1, main () at
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:27
27              printk("%s():enter\n", __func__);
```

Now GDB is waiting at the beginning of `main()`:

```
(gdb) list
22
23      int main(void)
24      {
25              int ret;
26
27              printk("%s():enter\n", __func__);
28              ret = test();
29              printk("ret=%d\n", ret);
30              return 0;
31      }
```

7. To examine the value of `ret`, the command `p` or `print` can be used.

```
(gdb) p ret
$1 = 1273788
```

Since `ret` has not been initialized, it contains some random value.

8. If step (`s` or `step`) is used here, it will continue execution skipping the interior of `test()`. To examine code execution inside `test()`, a breakpoint can be set for `test()`, or simply using `si` (or `stepi`) to execute one machine instruction, where it has the side effect of going into the function. The GDB command `finish` can be used to continue execution without intervention until the function returns.

```
(gdb) finish
Run till exit from #0  test () at
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:17
0x00100667 in main () at
```

(continues on next page)

(continued from previous page)

```
↪<ZEPHYR_BASE>/tests/subsys/debug/gdbstub/src/main.c:28
28              ret = test();
Value returned is $2 = 30
```

9. Examine `ret` again which should have the return value from `test()`. Sometimes, the assignment is not done until another `step` is issued, as in this case. This is due to the assignment code is done after returning from function. The assignment code is generated by the toolchain as machine instructions which are not visible when viewing the corresponding C source file.

```
(gdb) p ret
$3 = 1273788
(gdb) step
29              printk("ret=%d\n", ret);
(gdb) p ret
$4 = 30
```

10. If `continue` is issued here, code execution will continue indefinitely as there are no breakpoints to further stop execution. Breaking execution in GDB via `Ctrl-C` does not currently work as the Zephyr gdbstub does not support this functionality yet. Switch to the first console with QEMU running the Zephyr image and stop it manually with `Ctrl+a x`. When the same test is executed by Twister, it automatically takes care of stopping the QEMU instance.

Cortex-M Debug Monitor

Monitor mode debugging is a Cortex-M feature, that provides a non-halting approach to debugging. With this it's possible to continue the execution of high-priority interrupts, even when waiting on a breakpoint. This strategy makes it possible to debug time-sensitive software, that would otherwise crash when the core halts (e.g. applications that need to keep communication links alive).

Zephyr provides support for enabling and configuring the Debug Monitor exception. It also contains a ready implementation of the interrupt, which can be used with SEGGER J-Link debuggers.

Configuration Configure this module using the following options.

- `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK`: enable the module. This option, by itself, requires an implementation of debug monitor interrupt that will be executed every time the program enters a breakpoint.

With a SEGGER debug probe, it's possible to use a ready, SEGGER-provided implementation of the interrupt.

- `CONFIG_SEGGER_DEBUGMON`: enables SEGGER debug monitor interrupt. Can be used with SEGGER JLinkGDBServer and a SEGGER debug probe.

Usage When monitor mode debugging is enabled, entering a breakpoint will not halt the processor, but rather generate an interrupt with ISR implemented under `z_arm_debug_monitor` symbol. `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK` config configures this interrupt to be the lowest available priority, which will allow other interrupts to execute while processor spins on a breakpoint.

Using SEGGER-provided ISR The ready implementation provided with `CONFIG_SEGGER_DEBUGMON` provides functionality required to debug in the monitor mode using regular GDB commands. Steps to configure SEGGER debug monitor:

1. Build a sample with `CONFIG_CORTEX_M_DEBUG_MONITOR_HOOK`` and `CONFIG_SEGGER_DEBUGMON` configs enabled.
2. Attach JLink GDB server to the target. Example linux command: `JLinkGDBServerCLExe -device <device> -if swd`.
3. Connect to the server with your GDB installation. Example linux command: `arm-none-eabi-gdb --ex="file build/zephyr.elf" --ex="target remote localhost:2331"`.
4. Enable monitor mode debugging in GDB using command: `monitor exec SetMonModeDebug=1`.

After these steps use regular gdb commands to debug your program.

Using other custom ISR In order to provide a custom debug monitor interrupt, override `z_arm_debug_monitor` symbol. Additionally, manual configuration of some registers is required (see debugmon sample).

MIPI STP Decoder

The MIPI System Trace Protocol (MIPI STP) was developed as a generic base protocol that can be shared by multiple application-specific trace protocols. It serves as a wrapper protocol that merges disparate streams that typically contain different trace protocols from different trace sources. Stream consists of opcode (shortest is 4 bit long) followed by optional data and optional timestamp. There are opcodes for data (8, 16, 32, 64 bit data marked/not marked, with or without timestamp), stream recognition (master and channel), synchronization (ASYNC opcode) and others.

One example where protocol is used is ARM Coresight STM (System Trace Macrocell) where data written to Stimulus Port registers maps directly to STP stream.

This module can be used to perform on-chip decoding of the data stream. STP v2 is used.

Usage Decoder is initialized with a callback. A callback is called on each decoded opcode. Decoder has internal state since there are dependency between opcodes (e.g. timestamp can be relative). Decoder can be in synchronization or not. Initial state is configurable. If decoder is not synchronized to the stream then it decodes each nibble in search for ASYNC opcode. Loss of synchronization can be indicated to the decoder by calling `mipi_stp_decoder_sync_loss()`. `mipi_stp_decoder_decode()` is used to decode the data.

Limitations There are following limitations:

- Decoder supports only little endian architectures.
- When decoding nibbles, it is more efficient when core supports unaligned memory access. Implementation supports optimized version with unaligned memory access and generic one. Optimized version is used for ARM Cortex-M (expect for M0).
- Limited set of the most common opcodes is implemented.

API documentation

STP Decoder API

Symbol Table (Symtab)

The Symtab module, when enabled, will generate full symbol table during the Zephyr linking stage that keep tracks of the information about the functions' name and address, for advanced application with a lot of functions, this is expected to consume a sizable amount of ROM.

Currently, this is being used to look up the function names during a stack trace in supported architectures.

Usage Application can gain access to the symbol table data structure by including the `symtab.h` header file and call `symtab_get()`. For now, we only provide `symtab_find_symbol_name()` function to look-up the symbol name and offset of an address. More advanced functionalities and be achieved by directly accessing the members of the data structure.

Configuration Configure this module using the following options.

- `CONFIG_SYMTAB`: enable the generation of the symbol table.

API documentation
Symbol Table API

ARM Coresight Trace Deformatter

Formatter is a method of wrapping multiple trace streams (specified by 7 bit ID) into a single output stream. Formatter is using 16 byte frames which wraps up to 15 bytes of data. It is used, for example, by ETR (Embedded Trace Router) which is a circular RAM buffer where data from various trace streams can be saved. Typically tracing data is decoded offline by the host but deformatter can be used on-chip to decode the data during application runtime.

Usage Deformatter is initialized with a user callback. Data is decoded using `cs_trace_defmt_process()` in 16 bytes chunks. Callback is called whenever stream changes or end of chunk is reached. Callback contains stream ID and the data.

API documentation
Coresight Trace Deformatter

Zyclictest

The zyclictest module enables estimation of worst case latencies of realtime threads. It can measure the time from the hardware interrupt to the service routine and further to the Zephyr thread.

This module and its name is inspired from the cyclictest program on Linux. That's why it's a Zephyr cyclictest.

The idea is to use the timer interrupt as interrupt source as we know exactly the point of time when it occurred. In the interrupt service routine we take the time and calculate the difference to the programmed time of the timer interrupt.

Further a thread is also synchronizing itself on the timer and also measures the difference to the programmed timer.

Both times are put into an array which serves as data source of the histogram printed out at the end of the measurement.

This measurement is done in a cyclic manner with a certain interval time.

If someone wants to know the worst case latency of a task with priority <p> then the application needs to be running. While it is running we can start zyclictest with a priority at least one digit less than the application thread probed. For example if our application with the thread of interest has the priority -10 than we need to start zyclictest with a priority of -11 or less.

Another important argument is the interval time. It's not meant to have an interval less than the measured worst case latency. Therefore it's recommended to set up an interval with at least double the time of the expected or measured worst case latency.

If there are overflows indicated at the end of the measurement than this means that there is no deterministic worst case latency inside the range of the histogram.

For a meaningful output it's recommended to set up `CONFIG_SYS_CLOCK_TICKS_PER_SEC` to at least 1000000 as this means a minimum resolution of 1 microsecond. A tickless kernel is also needed (`CONFIG_TICKLESS_KERNEL`:).

Mode of operation Zyclictest can be started free running without a fixed number of cycles. This is the default. When stopped the result so far is printed out.

In the loop mode (option start with -l <loops>) zyclictest is running for a predefined number of cycles. When the number of cycles is reached there is a message on the shell indicating the end of the test. But the test can be canceled prematurely with zyclictest stop -c.

Configuration Configure this module using the following options.

- `CONFIG_ZYCLICTEST_SHELL`: enable the shell command.

Usage

zyclictest start [options]

-i <interval>	Interval in microseconds
-l <loops>	Use loop mode with predefined number of cycles
-p <prio>	Setup priority of Thread

zyclictest stop [options]

-c	Cancel loop mode prematurely
-q	Quiet mode, print summary, but no histogram data

Example In this example we want to know the worst case latency of a thread which is woken up by an interrupt and running as cooperative task with priority -10. We expect a latency of less then 200 us. We are using the free running mode.

1. Start the zyclictest thread with an interval of 400 us (double of expected worst case latency) and a priority of -11 (one digit higher than the application thread):

```
zyclictest start -i 400 -p -11
```

2. Do whatever should be tested....
3. Stop the measurement:

```
zyclictest stop
```

Output from zyclictest:

```
Count: 547329
                    IRQ  Thread
Max-Latency:         21      27
Errors:               0       0
Overflow:             0       0
Histogram:
[...]
 23                   0  547306
 24                   0       2
 25                   0       5
 26                   0       5
```

(continues on next page)

(continued from previous page)

```
 27                  0       2
 28                  0       0
[...]
```

4. Interpret the result:

   Where are no errors and no overflows which means the measurement can be used. There were 547329 cycles in the test. Worst case interrupt latency is 21 us and for threads it's 27 us.

4.4.4 Profiling

Required Kconfig: `CONFIG_PROFILING`

Perf

Perf is a profiler tool based on stack tracing. It can be used for lightweight profiling with minimal code overhead.

Work Principle The `perf record` shell command starts a timer with the perf tracer function. Timers are driven by interrupts, so the perf tracer function is called during an interruption. The Zephyr core saves the return address and frame pointer in the interrupt stack, `callee_saved` structure, or architecture-specific exception frame before calling the interrupt handler. Thus, the perf trace function makes stack traces by using the return address and frame pointer.

On Cortex-M, perf wraps the SysTick handler so it can sample the interrupted Thread-mode Process Stack Pointer (PSP) frame before the normal timer ISR uses the handler stack. The backend validates that frame before passing it to the Arm stack walker.

The Cortex-M backend is unavailable for Non-secure Trusted Execution images because Secure exception frames are inaccessible to Non-secure firmware.

The scripts/profiling/stackcollapse.py script can be used to convert return addresses in the stack trace to function names using symbols from the ELF file, and to prints them in the format expected by FlameGraph.

Configuration You can configure this module using the following options:

- `CONFIG_PROFILING_PERF`: Enables the module. This option adds the `perf` command to the shell.
- `CONFIG_PROFILING_PERF_BUFFER_SIZE`: Sets the size of the perf buffer where samples are saved before printing.

Architecture backends may require additional stack-unwind support. The Cortex-M backend requires SysTick, thread stack information, extra exception information, Arm stack walking support, and a uniprocessor configuration.

Usage Refer to the profiling-perf sample for an example of how to use the perf tool.

4.4.5 Instrumentation

Overview

The instrumentation subsystem provides compiler-managed runtime system instrumentation capabilities for Zephyr applications. It enables developers to trace function calls, observe context switches, and profile application performance with minimal manual instrumentation effort.

Unlike the *tracing* subsystem, which provides RTOS-aware tracing with structured event APIs, the instrumentation subsystem works at a lower level by leveraging compiler instrumentation hooks. This approach makes it possible to capture virtually any function entry and exit events without requiring manual tracing calls in the code.

Tracing vs. Instrumentation

When to use Tracing: Choose the tracing subsystem when you need RTOS-aware event tracing (e.g. thread switches, semaphore operations, etc.) and want to minimize overhead.

When to use Instrumentation: Choose instrumentation when you need a detailed view of function-level execution to better understand code flow, or to identify performance bottlenecks without adding manual trace points.

The instrumentation subsystem relies on compiler support for automatic function instrumentation. When enabled, the compiler automatically inserts calls to special instrumentation handler functions at the entry and exit of every function in your application (excluding those explicitly marked with `__no_instrumentation__`). Currently, only GCC is supported with the `-finstrument-functions` compiler flag.

The subsystem initializes automatically after RAM initialization and uses trigger/stopper functions to control when recording is active. The default trigger and stopper functions are both set to `main()` (configurable via Kconfig), meaning instrumentation captures the entire execution from when `main()` starts until it returns.

The recorded data is stored in RAM and can be accessed from a host computer thanks to a UART backend that exposes a set of simple commands. scripts/instrumentation/zaru.py script allows to execute these commands through a high-level command-line interface and makes it easy to obtain data in a format suitable for further analysis (e.g. using Perfetto).

Operational Modes

The instrumentation subsystem supports two modes that can be enabled independently or together:

Callgraph Mode (Tracing) In callgraph mode (enabled with `CONFIG_INSTRUMENTATION_MODE_CALLGRAPH`), the subsystem records function entry and exit events along with timestamps and context information in a memory buffer. This enables:

- Reconstruction of the complete function call graph
- Observation of thread context switches
- Analysis of execution flow and timing relationships

The trace buffer can operate in ring buffer mode (default, overwrites old entries) or fixed buffer mode (stops when full). Buffer size is configurable via `CONFIG_INSTRUMENTATION_MODE_CALLGRAPH_TRACE_BUFFER_SIZE`.

Listing 11: Example of callgraph mode output. See *zaru.py Usage* for more details.

```
$ ./scripts/instrumentation/zaru.py trace

       ... (truncated) ...
```

Statistical Mode (Profiling) In statistical mode (enabled with `CONFIG_INSTRUMENTATION_MODE_STATISTICAL`), the subsystem accumulates timing statistics for each unique function executed between the trigger and stopper points. This provides total execution time per function and helps identify performance bottlenecks. The subsystem tracks up to `CONFIG_INSTRUMENTATION_MODE_STATISTICAL_MAX_NUM_FUNC` unique functions.

Listing 12: Example of statistical mode output (top 10 most expensive functions). See *zaru.py Usage* for more details.

```
$ ./scripts/instrumentation/zaru.py profile -n 10

9.45% 0000061d main
6.00% 0000049d k_msleep
5.98% 00000469 k_sleep
5.95% 0000aea1 k_sleep_ticks
5.93% 0000ad6d z_impl_k_sleep_ticks
5.66% 00000431 k_sem_take
5.65% 00007e65 z_impl_k_sem_take
5.51% 0000ac29 z_pend_curr
2.83% 000063ed sys_clock_isr
2.67% 0000d361 sys_clock_announce
```

Configuration

Enable instrumentation with:

```
CONFIG_INSTRUMENTATION=y
CONFIG_INSTRUMENTATION_MODE_CALLGRAPH=y    # For tracing
CONFIG_INSTRUMENTATION_MODE_STATISTICAL=y  # For profiling
```

The instrumentation subsystem communicates with the target device via a UART console. Ensure that the `zephyr_console` chosen node points to the desired UART controller.

Retained memory allows trigger/stopper function addresses to persist across reboots. This feature is optional and enabled with the `CONFIG_INSTRUMENTATION_DYNAMIC_TRIGGER` Kconfig option. Once enabled, devicetree must specify a retained memory region:

```
/ {
    sram@2003FC00 {
        compatible = "zephyr,memory-region", "mmio-sram";
        reg = <0x2003FC00 DT_SIZE_K(1)>;
        zephyr,memory-region = "RetainedMem";

        retainedmem {
            compatible = "zephyr,retained-ram";
            status = "okay";

            instrumentation_triggers: retention@0 {
                compatible = "zephyr,retention";
                status = "okay";
```

(continues on next page)

(continued from previous page)

```
                reg = <0x0 0x10>;
            };
        };
    };
};

/* Adjust main SRAM to exclude retained region */
&sram0 {
    reg = <0x20000000 DT_SIZE_K(255)>;
};
```

See the instrumentation sample for complete configuration examples. Additional options include buffer sizes, trigger functions, and function/file exclusion lists (see Kconfig options starting with `CONFIG_INSTRUMENTATION_*`).

`zaru.py` Usage

The `zaru.py` command-line tool (located in scripts/instrumentation/zaru.py) provides an interface for controlling instrumentation and extracting data from the target over UART.

The tool offers several commands:

- `status`: Check if the target device supports
  - callgraph (tracing) mode
  - statistical (profiling) mode
  - dynamic trigger/stopper functions configuration
- `trace`: Capture and display function call traces.
- `profile`: Capture and display function profiling data.
- `reboot`: Reboot the target device.

You can get help for each command by running `zaru.py <command> --help`.

By default, `zaru.py` attempts to connect to the target device using `/dev/ttyACM0`. You can specify a different serial port using the `--serial` option:

```
$ ./scripts/instrumentation/zaru.py --serial /dev/ttyACM1 status
```

The `--build-dir` option can be used to specify the Zephyr build directory, which is needed to locate the ELF file for symbol resolution. If not provided, `zaru.py` will attempt to find it automatically.

See the instrumentation sample documentation for detailed usage instructions.

Limitations and Considerations

Compiler support
: The instrumentation subsystem requires GCC with `-finstrument-functions` support. Other compilers are not supported.

Stack size requirements
: Instrumentation adds overhead to every function call, which increases stack usage. You will likely need to increase thread stack sizes to accommodate the additional space required by instrumentation handlers and nested function calls.

Execution overhead
: All function calls incur instrumentation overhead. Code size will increase due to added instrumentation calls, and performance will be impacted.

Initialization constraints
: Code that runs before RAM initialization (e.g., early boot functions) is not captured as it runs before the instrumentation subsystem is initialized.

To reduce overhead, use trigger/stopper functions to instrument only code regions of interest, and exclude performance-critical functions via `CONFIG_INSTRUMENTATION_EXCLUDE_FUNCTION_LIST` and `CONFIG_INSTRUMENTATION_EXCLUDE_FILE_LIST`.

4.4.6 CPU load

The CPU load module tracks the fraction of time the CPU spends outside of the idle state. Two measurement backends are available, selected with the `CPU_LOAD_BACKEND` Kconfig choice:

Scheduler runtime statistics
: `CONFIG_CPU_LOAD_BACKEND_RUNTIME_STATS` derives the load from the scheduler per-CPU runtime statistics. It is portable across architectures and supports multiple CPUs.

Architecture idle hooks
: `CONFIG_CPU_LOAD_BACKEND_IDLE_HOOK` measures the load using the architecture idle hooks, which are called before and after the CPU goes to idle. It has lower overhead than the runtime-statistics backend and can use a *Counter* device for higher precision (the counter path is single-CPU only). It is available on any architecture that emits the idle hooks (`CONFIG_ARCH_HAS_CPU_IDLE_HOOKS`). Compared to *Thread analyzer* it is more accurate since it takes into account time spent in the interrupt context as well. This backend does not depend on the tracing subsystem.

The load is retrieved with `cpu_load_get()` for the current CPU or `cpu_load_get_cpu()` for a specific CPU. Both return the load in per mille (0...1000) and can reset the measurement window. Use `CPU_LOAD_PERMILLE_TO_PERCENT` to convert the value to whole percent.

The load can also be reported periodically using a logging message. The period is configured using `CONFIG_CPU_LOAD_LOG_PERIODICALLY`.

For an example refer to the cpu_freq_on_demand sample.

Using a counter device

The idle-hook backend uses `k_cycle_get_32()` by default. When higher precision is needed a *Counter* device can be used by enabling `CONFIG_CPU_LOAD_USE_COUNTER` and setting the chosen node in devicetree.

```
chosen {
  zephyr,cpu-load-counter = &counter_device;
};
```

Overview

This module allows you to create and handle a shell with a user-defined command set. You can use it in examples where more than simple button or LED user interaction is required. This module is a Unix-like shell with these features:

- Support for multiple instances.
- Advanced cooperation with the *Logging*.
- Support for static and dynamic commands.
- Support for dictionary commands.
- Smart command completion with the Tab key.
- Built-in commands: `aliases`, `clear`, `shell`, `colors`, `echo`, `history` and `resize`.

- Viewing recently executed commands using keys: ↑ ↓ or meta keys.
- Text edition using keys: ←, →, `Backspace`, `Delete`, `End`, `Home`, `Insert`.
- Support for ANSI escape codes: `VT100` and `ESC[n~` for cursor control and color printing.
- Support for editing multiline commands.
- Built-in handler to display help for the commands.
- Support for wildcards: `*` and `?`.
- Support for meta keys.
- Support for getopt and getopt_long.
- Kconfig configuration to optimize memory usage.

Note

Some of these features have a significant impact on RAM and flash usage, but many can be disabled when not needed. To default to options which favor reduced RAM and flash requirements instead of features, you should enable `CONFIG_SHELL_MINIMAL` and selectively enable just the features you want.

Backends

The module can be connected to any transport for command input and output. At this point, the following transport layers are implemented:

- MQTT
- Segger RTT
- SMP
- Telnet
- UART
- USB
- Bluetooth LE (NUS)
- RPMSG
- DUMMY - not a physical transport layer.

Telnet Enabling `CONFIG_SHELL_BACKEND_TELNET` will allow users to use telnet as a shell backend. Connecting to it can be done using PuTTY or any `telnet` client. For example:

```
telnet <ip address> <port>
```

By default the telnet client won't handle telnet commands and configuration. Although command support can be enabled with `CONFIG_SHELL_TELNET_SUPPORT_COMMAND`. This will give the telnet client access to a very limited set of supported commands but still can be turned on if needed. One of the command options it supports is the `ECHO` option. This will allow the client to be in character mode (character at a time), similar to a UART backend in that regard. This will make the client send a character as soon as it is typed having the effect of increasing the network traffic considerably. For that cost, it will enable the line editing, *tab completion*, and *history* features of the shell.

USB CDC ACM To configure Shell USB CDC ACM backend, simply add the snippet `cdc-acm-console` to your build:

```
west build -S cdc-acm-console [...]
```

Details on the configuration settings are captured in the following files:

- snippets/cdc-acm-console/cdc-acm-console.conf.
- snippets/cdc-acm-console/cdc-acm-console.overlay.

Bluetooth LE (NUS) To configure Bluetooth LE (NUS) backend, simply add the snippet `nus-console` to your build:

```
west build -S nus-console [...]
```

Details on the configuration settings are captured in the following files:

- snippets/nus-console/nus-console.conf.
- snippets/nus-console/nus-console.overlay.

Segger RTT To configure Segger RTT backend, add the following configurations to your build:

- `CONFIG_USE_SEGGER_RTT`
- `CONFIG_SHELL_BACKEND_RTT`
- `CONFIG_SHELL_BACKEND_SERIAL`

Details on additional configuration settings are captured in: samples/subsys/shell/shell_module/prj_minimal_rtt.conf.

Using west Attach to and configure RTT with:

```
$ west rtt
```

Note

If your default runner does not have support for RTT, check your board's documentation page for any other runners that support RTT. You may then use the `--runner` option to specify a different runner.

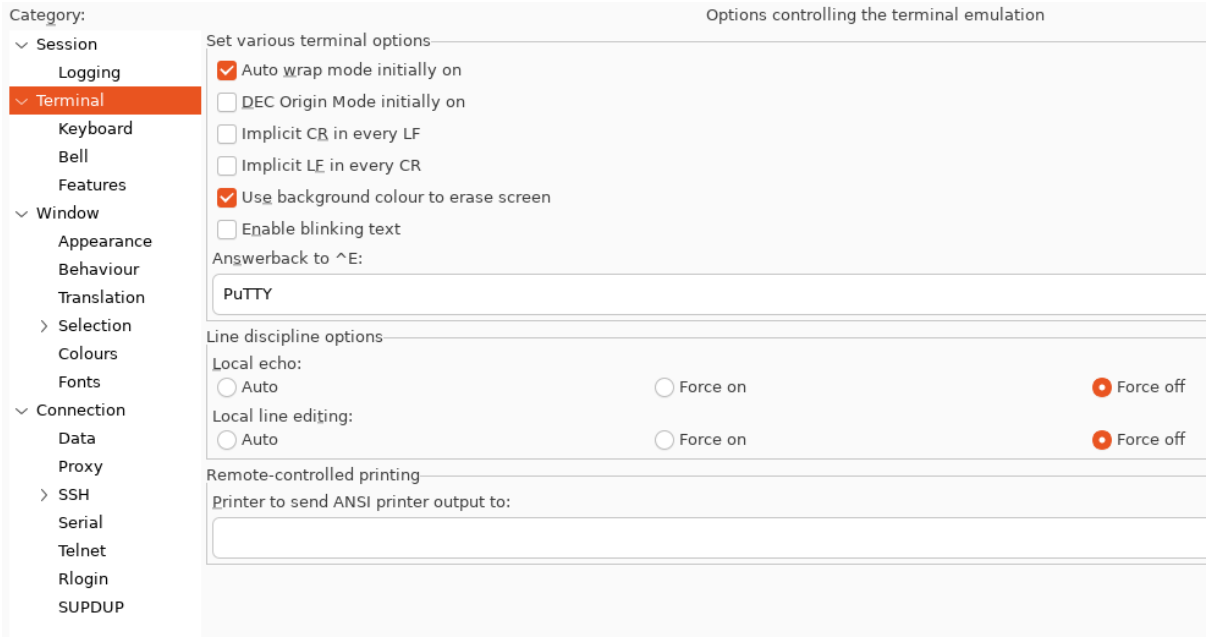
```
$ west rtt --runner <runner>
```

Using PuTTY Use following procedure:

- Open debug session and continue running the application.

  ```
  west attach
  ```

- Open `PuTTY`. Use telnet port 19021 and specific Terminal configuration. Set `Local echo` to `Force off` and `Local line editing` to `Force off` (see image below).



- Now you should have a network connection to RTT that will let you enter input to the shell.

Connecting to Segger RTT via TCP (on macOS, for example) On macOS JLinkRTTClient won't let you enter input. Instead, please use following procedure:

- Open up a first Terminal window and enter:

```
JLinkRTTLogger -Device NRF52840_XXAA -RTTChannel 1 -if SWD -Speed 4000 ~/
↪rtt.log
```

  (change device if required)

- Open up a second Terminal window and enter:

```
nc localhost 19021
```

- Now you should have a network connection to RTT that will let you enter input to the shell. However, contrary to *PuTTY* some features like `Tab` completion do not work.

Commands

Shell commands are organized in a tree structure and grouped into the following types:

- Root command (level 0): Gathered and alphabetically sorted in a dedicated memory section.
- Static subcommand (level > 0): Number and syntax must be known during compile time. Created in the software module.
- Dynamic subcommand (level > 0): Number and syntax does not need to be known during compile time. Created in the software module.

Commonly-used command groups The following list is a set of useful command groups and how to enable them:

GPIO

- `CONFIG_GPIO`
- `CONFIG_GPIO_SHELL`

I2C

- CONFIG_I2C
- CONFIG_I2C_SHELL

Sensor

- CONFIG_SENSOR
- CONFIG_SENSOR_SHELL

Flash

- CONFIG_FLASH
- CONFIG_FLASH_SHELL

File-System

- CONFIG_FILE_SYSTEM
- CONFIG_FILE_SYSTEM_SHELL

ADC

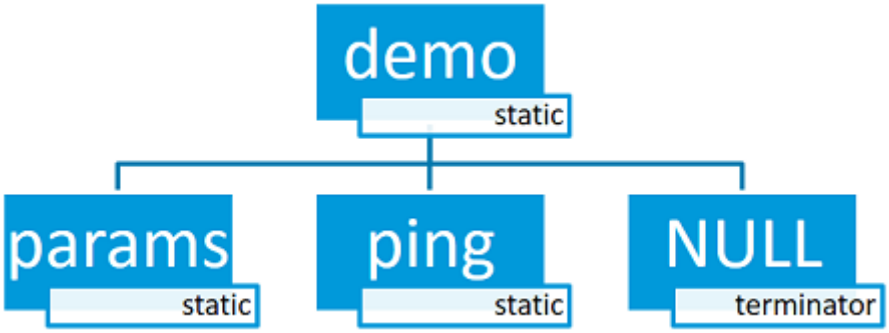
- CONFIG_ADC
- CONFIG_ADC_SHELL
- CONFIG_ADC_EMUL_SHELL (requires CONFIG_ADC_EMUL)

Creating commands Use the following macros for adding shell commands:

- SHELL_CMD_REGISTER - Create root command. All root commands must have different name.
- SHELL_COND_CMD_REGISTER - Conditionally (if compile time flag is set) create root command. All root commands must have different name.
- SHELL_CMD_ARG_REGISTER - Create root command with arguments. All root commands must have different name.
- SHELL_COND_CMD_ARG_REGISTER - Conditionally (if compile time flag is set) create root command with arguments. All root commands must have different name.
- SHELL_CMD - Initialize a command.
- SHELL_COND_CMD - Initialize a command if compile time flag is set.
- SHELL_EXPR_CMD - Initialize a command if compile time expression is non-zero.
- SHELL_CMD_ARG - Initialize a command with arguments.
- SHELL_COND_CMD_ARG - Initialize a command with arguments if compile time flag is set.
- SHELL_EXPR_CMD_ARG - Initialize a command with arguments if compile time expression is non-zero.
- SHELL_STATIC_SUBCMD_SET_CREATE - Create a static subcommands array.
- SHELL_SUBCMD_DICT_SET_CREATE - Create a dictionary subcommands array.
- SHELL_DYNAMIC_CMD_CREATE - Create a dynamic subcommands array.

Commands can be created in any file in the system that includes include/zephyr/shell/shell.h. All created commands are available for all shell instances.

Static commands Example code demonstrating how to create a root command with static subcommands.



```
/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
        SHELL_CMD(params, NULL, "Print params command.",
                                                cmd_demo_params),
        SHELL_CMD(ping,   NULL, "Ping command.", cmd_demo_ping),
        SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);
```

Example implementation can be found under following location: samples/subsys/shell/shell_module/src/main.c.

Dictionary commands This is a special kind of static commands. Dictionary commands can be used every time you want to use a pair: (string <-> corresponding data) in a command handler. The string is usually a verbal description of a given data. The idea is to use the string as a command syntax that can be prompted by the shell and corresponding data can be used to process the command.

Let's use an example. Suppose you created a command to set an ADC gain. It is a perfect place where a dictionary can be used. The dictionary would be a set of pairs: (string: gain_value, int: value) where int value could be used with the ADC driver API.

Abstract code for this task would look like this:

```
static int gain_cmd_handler(const struct shell *sh,
                            size_t argc, char **argv, void *data)
{
        int gain;

        /* data is a value corresponding to called command syntax */
        gain = (int)data;
        adc_set_gain(gain);

        shell_print(sh, "ADC gain set to: %s\n"
                        "Value send to ADC driver: %d",
                        argv[0],
                        gain);

        return 0;
}

SHELL_SUBCMD_DICT_SET_CREATE(sub_gain, gain_cmd_handler,
```

(continues on next page)

(continued from previous page)

```
        (gain_1, 1, "gain 1"), (gain_2, 2, "gain 2"),
        (gain_1_2, 3, "gain 1/2"), (gain_1_4, 4, "gain 1/4")
);
SHELL_CMD_REGISTER(gain, &sub_gain, "Set ADC gain", NULL);
```

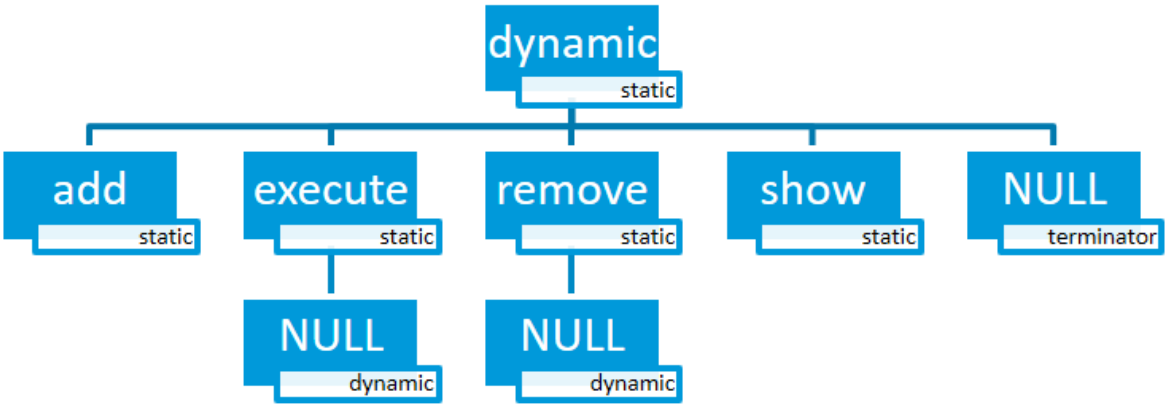
This is how it would look like in the shell:

```
uart:~$ gain ga
  gain_1    gain_2    gain_1_2  gain_1_4
uart:~$ gain gain_1
ADC gain set to: gain_1
Value send to ADC driver: 1
uart:~$ gain gain_2
ADC gain set to: gain_2
Value send to ADC driver: 2
uart:~$ gain gain_1_2
ADC gain set to: gain_1_2
Value send to ADC driver: 3
uart:~$ gain gain_1_4
ADC gain set to: gain_1_4
Value send to ADC driver: 4
uart:~$
```

Dynamic commands Example code demonstrating how to create a root command with static and dynamic subcommands. At the beginning dynamic command list is empty. New commands can be added by typing:

```
dynamic add <new_dynamic_command>
```

Newly added commands can be prompted or autocompleted with the `Tab` key.



```
/* Buffer for 10 dynamic commands */
static char dynamic_cmd_buffer[10][50];
```

(continues on next page)

(continued from previous page)

```
/* commands counter */
static uint8_t dynamic_cmd_cnt;

/* Function returning command dynamically created
 * in  dynamic_cmd_buffer.
 */
static void dynamic_cmd_get(size_t idx,
                            struct shell_static_entry *entry)
{
        if (idx < dynamic_cmd_cnt) {
                entry->syntax = dynamic_cmd_buffer[idx];
                entry->handler  = NULL;
                entry->subcmd = NULL;
                entry->help = "Show dynamic command name.";
        } else {
                /* if there are no more dynamic commands available
                 * syntax must be set to NULL.
                 */
                entry->syntax = NULL;
        }
}

SHELL_DYNAMIC_CMD_CREATE(m_sub_dynamic_set, dynamic_cmd_get);
SHELL_STATIC_SUBCMD_SET_CREATE(m_sub_dynamic,
        SHELL_CMD(add, NULL,"Add new command to dynamic_cmd_buffer and"
                  " sort them alphabetically.",
                  cmd_dynamic_add),
        SHELL_CMD(execute, &m_sub_dynamic_set,
                  "Execute a command.", cmd_dynamic_execute),
        SHELL_CMD(remove, &m_sub_dynamic_set,
                  "Remove a command from dynamic_cmd_buffer.",
                  cmd_dynamic_remove),
        SHELL_CMD(show, NULL,
                  "Show all commands in dynamic_cmd_buffer.",
                  cmd_dynamic_show),
        SHELL_SUBCMD_SET_END
);
SHELL_CMD_REGISTER(dynamic, &m_sub_dynamic,
           "Demonstrate dynamic command usage.", cmd_dynamic);
```

Example implementation can be found under following location: samples/subsys/shell/shell_module/src/dynamic_cmd.c.

Commands execution Each command or subcommand may have a handler. The shell executes the handler that is found deepest in the command tree and further subcommands (without a handler) are passed as arguments. Characters within parentheses are treated as one argument. If shell won't find a handler it will display an error message.

Commands can be also executed from a user application using any active backend and a function `shell_execute_cmd()`, as shown in this example:

```
int main(void)
{
        /* Below code will execute "clear" command on a DUMMY backend */
        shell_execute_cmd(NULL, "clear");
```

(continues on next page)

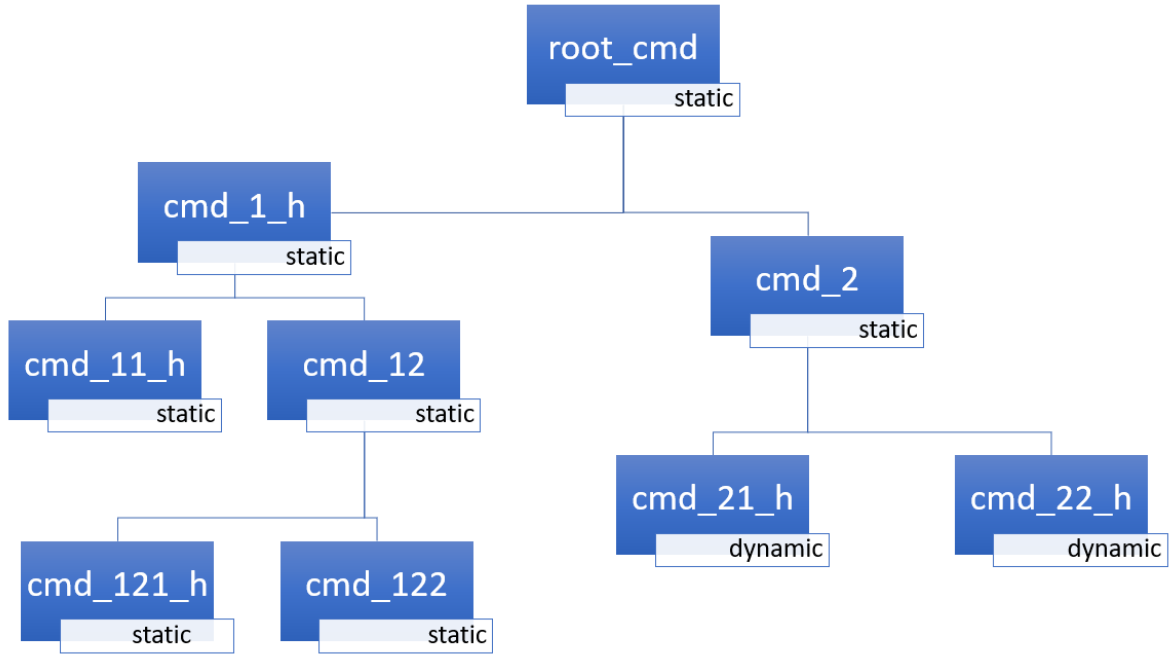
(continued from previous page)

```
        /* Below code will execute "shell colors off" command on
         * an UART backend
         */
        shell_execute_cmd(shell_backend_uart_get_ptr(),
                          "shell colors off");
}
```

Enable the DUMMY backend by setting the Kconfig `CONFIG_SHELL_BACKEND_DUMMY` option.

Commands execution example Let's assume a command structure as in the following figure, where:

- `root_cmd` - root command without a handler
- `cmd_xxx_h` - command has a handler
- `cmd_xxx` - command does not have a handler



Example 1 Sequence: `root_cmd cmd_1_h cmd_12_h cmd_121_h parameter` will execute command `cmd_121_h` and `parameter` will be passed as an argument.

Example 2 Sequence: `root_cmd cmd_2 cmd_22_h parameter1 parameter2` will execute command `cmd_22_h` and `parameter1 parameter2` will be passed as an arguments.

Example 3 Sequence: `root_cmd cmd_1_h parameter1 cmd_121_h parameter2` will execute command `cmd_1_h` and `parameter1`, `cmd_121_h` and `parameter2` will be passed as an arguments.

Example 4 Sequence: `root_cmd parameter cmd_121_h parameter2` will not execute any command.

Command handler Simple command handler implementation:

```
static int cmd_handler(const struct shell *sh, size_t argc,
                       char **argv)
{
        ARG_UNUSED(argc);
        ARG_UNUSED(argv);

        shell_fprintf(sh, SHELL_INFO, "Print info message\n");

        shell_print(sh, "Print simple text.");

        shell_warn(sh, "Print warning text.");

        shell_error(sh, "Print error text.");

        return 0;
}
```

Function `shell_fprintf()` or the shell print macros: `shell_print`, `shell_info`, `shell_warn` and `shell_error` can be used from the command handler or from threads, but not from an interrupt context. Instead, interrupt handlers should use *Logging* for printing.

Command help Every user-defined command or subcommand can have its own help description. The help for commands and subcommands can be created with respective macros: `SHELL_CMD_REGISTER`, `SHELL_CMD_ARG_REGISTER`, `SHELL_CMD`, and `SHELL_CMD_ARG`.

Shell prints this help message when you call a command or subcommand with `-h` or `--help` parameter.

Parent commands In the subcommand handler, you can access both the parameters passed to commands or the parent commands, depending on how you index `argv`.

- When indexing `argv` with positive numbers, you can access the parameters.
- When indexing `argv` with negative numbers, you can access the parent commands.
- The subcommand to which the handler belongs has the `argv` index of 0.

```
static int cmd_handler(const struct shell *sh, size_t argc,
                       char **argv)
{
        ARG_UNUSED(argc);

        /* If it is a subcommand handler parent command syntax
         * can be found using argv[-1].
         */
        shell_print(sh, "This command has a parent command: %s",
                    argv[-1]);

        /* Print this command syntax */
        shell_print(sh, "This command syntax is: %s", argv[0]);

        /* Print first argument */
        shell_print(sh, "%s", argv[1]);

        return 0;
}
```

Built-in commands These commands are activated by CONFIG_SHELL_CMDS set to y.

- **aliases** - Shows currently configured aliases. This command needs extra activation: CONFIG_SHELL_CMDS_ALIASES set to y.
- **clear** - Clears the screen.
- **history** - Shows the recently entered commands.
- **resize** - Must be executed when terminal width is different than 80 characters or after each change of terminal width. It ensures proper multiline text display and ←, →, End, Home keys handling. Currently this command works only with UART flow control switched on. It can be also called with a subcommand:
  - **default** - Shell will send terminal width = 80 to the terminal and assume successful delivery.

  These command needs extra activation: CONFIG_SHELL_CMDS_RESIZE set to y.
- **select** - It can be used to set new root command. Exit to main command tree is with alt+r. This command needs extra activation: CONFIG_SHELL_CMDS_SELECT set to y.
- **shell** - Root command with useful shell-related subcommands like:
  - **echo** - Toggles shell echo.
  - **colors** - Toggles colored syntax. This might be helpful in case of Bluetooth shell to limit the amount of transferred bytes.
  - **stats** - Shows shell statistics.

Alias support

The shell can expand aliases before executing a command when CONFIG_SHELL_ALIASES is enabled. Zephyr always provides the built-in alias **?**, which expands to **help**.

To load additional aliases from a host file, set CONFIG_SHELL_ALIASES_FILE and generate the corresponding include file from the application CMakeLists.txt file. When CONFIG_SHELL_ALIASES_FILE is non-empty, CONFIG_SHELL_ALIASES_HAS_FILE is enabled automatically.

```
if(CONFIG_SHELL_ALIASES_HAS_FILE)
  set(gen_dir ${ZEPHYR_BINARY_DIR}/include/generated/)
  set(aliases_src ${CONFIG_SHELL_ALIASES_FILE})

  generate_shell_aliases_inc_file_for_target(
    app
    ${aliases_src}
    ${gen_dir}/generated-shell-aliases.inc
  )
endif()
```

The aliases file uses one alias=command entry per line. Lines beginning with # are comments, and command strings containing spaces must be quoted. The sample at samples/net/sockets/echo_service/shell_aliases.txt uses the following format:

```
# Example shell aliases file
stacks="kernel thread stacks"
scan="wifi scan"
connect="wifi connect"
```

Use the **aliases** command to inspect the aliases available in the running shell.

Tab Feature

The Tab button can be used to suggest commands or subcommands. This feature is enabled by `CONFIG_SHELL_TAB` set to `y`. It can also be used for partial or complete auto-completion of commands. This feature is activated by `CONFIG_SHELL_TAB_AUTOCOMPLETION` set to `y`. When user starts writing a command and presses the `Tab` button then the shell will do one of 3 possible things:

- Autocomplete the command.
- Prompts available commands and if possible partly completes the command.
- Will not do anything if there are no available or matching commands.

```
uart:~$ log
  backend        disable        enable         go             halt
  list_backends  status
uart:~$ log enable
  dbg   err   inf   none  wrn
uart:~$ log enable err
  app               app_test          log               os
  shell.shell_uart  shell_uart
uart:~$ log enable err shell
  shell.shell_uart  shell_uart
uart:~$ log enable err shell
```

History Feature

This feature enables commands history in the shell. It is activated by: `CONFIG_SHELL_HISTORY` set to `y`. History can be accessed using keys: ↑↓ or `Ctrl+n` and `Ctrl+p` if meta keys are active. Number of commands that can be stored depends on size of `CONFIG_SHELL_HISTORY_BUFFER` parameter.

Wildcards Feature

The shell module can handle wildcards. Wildcards are interpreted correctly when expanded command and its subcommands do not have a handler. For example, if you want to set logging level to `err` for the `app` and `app_test` modules you can execute the following command:

```
log enable err a*
```

```
uart:~$ log status
module_name                                     | current | built-in
------------------------------------------------------------------
app                                             | inf     | inf
app_test                                        | inf     | inf
shell.uart_shell                                | inf     | inf
uart:~$ log enable err a*
uart:~$ log status
module_name                                     | current | built-in
------------------------------------------------------------------
app                                             | err     | inf
app_test                                        | err     | inf
shell.uart_shell                                | inf     | inf
uart:~$
```

This feature is activated by CONFIG_SHELL_WILDCARD set to y.

Note

When the wildcard feature is enabled, the characters * and ? cannot be used as normal characters in commands or arguments.

Meta Keys Feature

The shell module supports the following meta keys:

Table 52: Implemented meta keys

Meta keys	Action
Ctrl+a	Moves the cursor to the beginning of the line.
Ctrl+b	Moves the cursor backward one character.
Ctrl+c	Preserves the last command on the screen and starts a new command in a new line.
Ctrl+d	Deletes the character under the cursor.
Ctrl+e	Moves the cursor to the end of the line.
Ctrl+f	Moves the cursor forward one character.
Ctrl+k	Deletes from the cursor to the end of the line.
Ctrl+l	Clears the screen and leaves the currently typed command at the top of the screen.
Ctrl+n	Moves in history to next entry.
Ctrl+p	Moves in history to previous entry.
Ctrl+t	Toggles logs output on the shell when CONFIG_SHELL_LOG_BACKEND is set.
Ctrl+u	Clears the currently typed command.
Ctrl+w	Removes the word or part of the word to the left of the cursor. Words separated by period instead of space are treated as one word.
Alt+b	Moves the cursor backward one word.
Alt+f	Moves the cursor forward one word.

This feature is activated by CONFIG_SHELL_METAKEYS set to y.

sys_getopt Feature

Some shell users apart from subcommands might need to use options as well. the arguments string, looking for supported options. Typically, this task is accomplished by the getopt family functions.

For this purpose shell supports a variant of the getopt and getopt_long libraries from the FreeBSD project called sys_getopt and sys_getopt_long. This feature is activated by: CONFIG_GETOPT set to y and CONFIG_GETOPT_LONG set to y.

This feature can be used in thread safe as well as non thread safe manner. The former is full compatible with regular getopt usage while the latter a bit differs.

An example non-thread safe usage:

```
char *cvalue = NULL;
while ((char c = sys_getopt(argc, argv, "abhc:")) != -1) {
      switch (c) {
      case 'c':
              cvalue = sys_getopt_optarg;
              break;
      default:
```

(continues on next page)

(continued from previous page)

```
                break;
        }
}
```

An example thread safe usage:

```
char *cvalue = NULL;
struct sys_getopt_state *state;
while ((char c = sys_getopt(argc, argv, "abhc:")) != -1) {
        state = sys_getopt_state_get();
        switch (c) {
        case 'c':
                cvalue = state->optarg;
                break;
        default:
                break;
        }
}
```

Thread safe sys_getopt functionality is activated by `CONFIG_SHELL_GETOPT` set to `y`.

Obscured Input Feature

With the obscured input feature, the shell can be used for implementing a login prompt or other user interaction whereby the characters the user types should not be revealed on screen, such as when entering a password.

Once the obscured input has been accepted, it is normally desired to return the shell to normal operation. Such runtime control is possible with the `shell_obscure_set` function.

An example of login and logout commands using this feature is located in samples/subsys/shell/shell_module/src/main.c and the config file samples/subsys/shell/shell_module/prj_login.conf.

This feature is activated upon startup by `CONFIG_SHELL_START_OBSCURED` set to `y`. With this set either way, the option can still be controlled later at runtime. `CONFIG_SHELL_CMDS_SELECT` is useful to prevent entry of any other command besides a login command, by means of the `shell_set_root_cmd` function. Likewise, `CONFIG_SHELL_PROMPT_UART` allows you to set the prompt upon startup, but it can be changed later with the `shell_prompt_change` function.

Reading User Input

The shell provides a `shell_readline()` function that allows command handlers to interactively read a line of input from the user. This is useful for implementing commands that need to prompt the user for additional information, such as confirmation dialogs, multi-step wizards, or interactive data entry.

The function reads from the shell transport until a newline character is received, storing the data in a provided buffer. The newline character itself is not included in the buffer. The buffer is automatically null-terminated on success.

Use `shell_readline_prompt_set()` before calling `shell_readline()` to display a prompt string (e.g. `"Proceed? [y/N]: "`). The prompt is printed automatically at the start of readline and restored after any log messages that interrupt the input line. It is cleared when `shell_readline()` returns.

Note

The `shell_readline()` function should be called from the shell thread in a shell command handler and blocks the thread until a result is returned.

Example usage:

```
static int cmd_read_secret(const struct shell *sh, size_t argc, char **argv)
{
        uint8_t input_buf[256];
        int ret;

        shell_obscure_set(sh, true);
        shell_readline_prompt_set(sh, "Enter your secret: ");
        ret = shell_readline(sh, input_buf, sizeof(input_buf), K_SECONDS(10));
        shell_obscure_set(sh, false);

        if (ret < 0) {
                if (ret == -ETIMEDOUT) {
                        shell_error(sh, "Timeout waiting for input");
                } else if (ret == -ECANCELED) {
                        shell_error(sh, "Input canceled");
                } else if (ret == -ENOBUFS) {
                        shell_error(sh, "Input too long");
                }
                return ret;
        }

        shell_print(sh, "Secret input received (%d bytes)", ret);
        return 0;
}
```

Shell Logger Backend Feature

Shell instance can act as the *Logging* backend. Shell ensures that log messages are correctly multiplexed with shell output. Log messages from logger thread are enqueued and processed in the shell thread. Logger thread will block for configurable amount of time if queue is full, blocking logger thread context for that time. Oldest log message is removed from the queue after timeout and new message is enqueued. Use the `shell stats show` command to retrieve number of log messages dropped by the shell instance. Log queue size and timeout are `SHELL_DEFINE` arguments.

This feature is activated by: `CONFIG_SHELL_LOG_BACKEND` set to `y`.

Warning

Enqueuing timeout must be set carefully when multiple backends are used in the system. The shell instance could have a slow transport or could block, for example, by a UART with hardware flow control. If timeout is set too high, the logger thread could be blocked and impact other logger backends.

Warning

As the shell is a complex logger backend, it can not output logs if the application crashes before the shell thread is running. In this situation, you can enable one of the simple logging backends instead, such as UART (`CONFIG_LOG_BACKEND_UART`) or RTT (`CONFIG_LOG_BACKEND_RTT`), which are available earlier during system initialization.

Note

The shell log backend is enabled by `shell_start()`. With `CONFIG_SHELL_AUTOSTART` set to `y` this happens in the shell thread, when it is scheduled for the first time. The shell thread runs at a low priority by default, so this moment depends on when higher priority threads, including the main thread executing system initialization, block or finish. Log messages and `printk()` output routed through the logger (`CONFIG_LOG_PRINTK`) issued before that point are handled by the logging core, not by the shell:

- In deferred mode (`CONFIG_LOG_MODE_DEFERRED`) they are buffered and printed once the shell starts, as long as they fit in `CONFIG_LOG_BUFFER_SIZE`.
- In immediate mode (`CONFIG_LOG_MODE_IMMEDIATE`) they are lost, because there is no active backend to output them.

If the application needs early output on the shell, set `CONFIG_SHELL_AUTOSTART` to `n` and call `shell_start()` explicitly, for example from a `SYS_INIT` hook with a priority higher than the shell backend initialization priority (e.g. `CONFIG_SHELL_BACKEND_SERIAL_INIT_PRIORITY`). Alternatively, do not route `printk()` through the logger.

RTT Backend Channel Selection

Instead of using the shell as a logger backend, RTT shell backend and RTT log backend can also be used simultaneously, but over different channels. By separating them, the log can be captured or monitored without shell output or the shell may be scripted without log interference. Enabling both the Shell RTT backend and the Log RTT backend does not work by default, because both default to channel `0`. There are two options:

1. The Shell buffer can use an alternate channel, for example using `CONFIG_SHELL_BACKEND_RTT_BUFFER` set to `1`. This allows monitoring the log using JLinkRTTViewer while a script interfaces over channel 1.

2. The Log buffer can use an alternate channel, for example using `CONFIG_LOG_BACKEND_RTT_BUFFER` set to `1`. This allows interactive use of the shell through JLinkRTTViewer, while the log is written to file.

See *shell backends* for details on how to enable RTT as a Shell backend.

Remote Shell

The shell module supports remote shell. Remote shell allows to execute commands on the remote core using the main core shell interface. User interface features like `Tab` autocompletion or history navigation are supported on the remote shell client. There can be multiple remote clients connected to the main core shell. Each remote client has its own tree of commands. Remote client commands are executed in the context of the remote client core. Remote shell is using *IPC service* to communicate with the remote core.

If only a single remote client is enabled then `remote_shell` command is registered as a root command for the remote core tree of commands. If multiple remote clients are enabled then `remote_shell <core_name>` is used as a root for the given remote client.

Remote client implementation supports case where threads are disabled (`CONFIG_MULTITHREADING` set to `n`).

This approach has two main benefits:

1. It allows to use the same shell interface for both the main and the remote cores.
2. Full shell implementation is present only on the host core, significantly reducing the memory footprint of the remote cores. Implementation uses less than 3 kB per remote client. Half of the memory is used for string formatting and can be shared with other modules that use string formatting (for example, logging).

See shell-module for details on how to enable remote shell.

Configuration Following Kconfig options are available for remote shell host configuration:

`CONFIG_SHELL_REMOTE`: Enables remote shell on the host core.

`CONFIG_SHELL_REMOTE_MULTI_CLI`: Enables multiple remote clients.

`CONFIG_SHELL_REMOTE_TMP_BUF_SIZE`: Size of the temporary buffer for remote shell command data. Need to be large enough to hold the command and its arguments.

Following Kconfig options are available for remote shell client configuration:

`CONFIG_SHELL_REMOTE_CLI`: Enables remote shell client on the remote core.

`CONFIG_SHELL_REMOTE_CLI_BUF_SIZE`: Size of the internal buffer used for remote messages. Need to be large enough to hold the command syntax and help text. Help text is truncated if the buffer is too small. It is also used to hold data for shell print messages. If it is too small then the print message is replaced with the error message.

`CONFIG_SHELL_REMOTE_CLI_KWORK`: Use kwork context for command execution.

`CONFIG_SHELL_REMOTE_CLI_STACK_SIZE`: Thread stack size for remote shell client.

If a single client is used then IPC service device is automatically chosen based on the devicetree configuration. User can specify the IPC device tree node using chosen node. If not specified then if there is only a single IPC device available that one is used.

IPC service device tree node configuration example:

```
chosen {
        zephyr,ipc_shell = &ipc0;
};
```

Limitations Some shell features are not supported on the remote shell client:

- Bypass mode is not supported on the remote shell client.
- Select mode is not supported on the remote shell client.

IPC communication assumes same endianness and alignment of the data on both sides. It has been tested on the following core pairs:

- Cortex-M33 (host) and Cortex-M33 (client)
- Cortex-M33 (host) and RISC-V 32 (client)

Usage

The following code shows a simple use case of this library:

```
int main(void)
{

}

static int cmd_demo_ping(const struct shell *sh, size_t argc,
                         char **argv)
{
        ARG_UNUSED(argc);
        ARG_UNUSED(argv);

        shell_print(sh, "pong");
        return 0;
```

(continues on next page)

(continued from previous page)

```
}

static int cmd_demo_params(const struct shell *sh, size_t argc,
                           char **argv)
{
        int cnt;

        shell_print(sh, "argc = %d", argc);
        for (cnt = 0; cnt < argc; cnt++) {
                shell_print(sh, "  argv[%d] = %s", cnt, argv[cnt]);
        }
        return 0;
}

/* Creating subcommands (level 1 command) array for command "demo". */
SHELL_STATIC_SUBCMD_SET_CREATE(sub_demo,
        SHELL_CMD(params, NULL, "Print params command.",
                                                cmd_demo_params),
        SHELL_CMD(ping,   NULL, "Ping command.", cmd_demo_ping),
        SHELL_SUBCMD_SET_END
);
/* Creating root (level 0) command "demo" without a handler */
SHELL_CMD_REGISTER(demo, &sub_demo, "Demo commands", NULL);

/* Creating root (level 0) command "version" */
SHELL_CMD_REGISTER(version, NULL, "Show kernel version", cmd_version);
```

Users may use the Tab key to complete a command/subcommand or to see the available subcommands for the currently entered command level. For example, when the cursor is positioned at the beginning of the command line and the Tab key is pressed, the user will see all root (level 0) commands:

```
clear  demo  shell  history  log  resize  version
```

Note

To view the subcommands that are available for a specific command, you must first type a space after this command and then hit Tab.

These commands are registered by various modules, for example:

- **clear**, **shell**, **history**, and **resize** are built-in commands which have been registered by subsys/shell/shell.c
- **demo** and **version** have been registered in example code above by main.c
- **log** has been registered by subsys/logging/log_cmds.c

Then, if a user types a **demo** command and presses the Tab key, the shell will only print the subcommands registered for this command:

```
params  ping
```

4.4.8 Task Watchdog

Overview

Many microcontrollers feature a hardware watchdog timer peripheral. Its purpose is to trigger an action (usually a system reset) in case of severe software malfunctions. Once initialized, the watchdog timer has to be restarted ("fed") in regular intervals to prevent it from timing out. If the software got stuck and does not manage to feed the watchdog anymore, the corrective action is triggered to bring the system back to normal operation.

In real-time operating systems with multiple tasks running in parallel, a single watchdog instance may not be sufficient anymore, as it can be used for only one task. This software watchdog based on kernel timers provides a method to supervise multiple threads or tasks (called watchdog channels).

An existing hardware watchdog can be used as an optional fallback if the task watchdog itself or the scheduler has a malfunction.

The task watchdog uses a kernel timer as its backend. If configured properly, the timer ISR is never actually called during normal operation, as the timer is continuously updated in the feed calls.

It's currently not possible to have multiple instances of task watchdogs. Instead, the task watchdog API can be accessed globally to add or delete new channels without passing around a context or device pointer in the firmware.

The maximum number of channels is predefined via Kconfig and should be adjusted to match exactly the number of channels required by the application.

Configuration Options

Related configuration options can be found under subsys/task_wdt/Kconfig.

Storage & Configuration

4.5 Storage & Configuration

4.5.1 Disk Access

Overview

The disk access API provides access to storage devices.

Initializing Disks

Since many disk devices (such as SD cards) are hotpluggable, the disk access API provides IOCTLs to initialize and de-initialize the disk. They are as follows:

- `DISK_IOCTL_CTRL_INIT`: Initialize the disk. Must be called before additional I/O operations can be run on the disk device. Equivalent to calling the legacy function `disk_access_init()`.
- `DISK_IOCTL_CTRL_DEINIT`: De-initialize the disk. Once this IOCTL is issued, the `DISK_IOCTL_CTRL_INIT` must be issued before the disk can be used for addition I/O operations.

Init/deinit IOCTL calls are balanced, so a disk will not de-initialize until an equal number of deinit IOCTLs have been issued as init IOCTLs.

It is also possible to force a disk de-initialization by passing a pointer to a boolean set to `true` as a parameter to the `DISK_IOCTL_CTRL_DEINIT` IOCTL. This is an unsafe operation which each disk driver may handle differently, but it will always return a value indicating success.

Note that de-initializing a disk is a low level operation- typically the de-initialization and initialization calls should be left to the filesystem implementation, and the user application should not need to manually de-initialize the disk and can instead call `fs_unmount()`

SD Card support

Zephyr has support for some SD card controllers and support for interfacing SD cards via SPI. These drivers use disk driver interface and a file system can access the SD cards via disk access API. Both standard and high-capacity SD cards are supported.

> **Note**
>
> FAT filesystems are not power safe so the filesystem may become corrupted if power is lost or if the card is removed without unmounting the filesystem

SD Memory Card subsystem Zephyr supports SD memory cards via the disk driver API, or via the SDMMC subsystem. This subsystem can be used transparently via the disk driver API, but also supports direct block level access to cards. The SDMMC subsystem interacts with the *sd host controller api* to communicate with attached SD cards.

SD Card support via SPI Example devicetree fragment below shows how to add SD card node to `spi1` interface. Example uses pin `PA27` for chip select, and runs the SPI bus at 24 MHz once the SD card has been initialized:

```
&spi1 {
        status = "okay";
        cs-gpios = <&porta 27 GPIO_ACTIVE_LOW>;

        sdhc0: sdhc@0 {
                compatible = "zephyr,sdhc-spi-slot";
```

(continues on next page)

(continued from previous page)

```
                reg = <0>;
                status = "okay";
                mmc {
                    compatible = "zephyr,sdmmc-disk";
                    disk-name = "SD";
                    status = "okay";
                };
                spi-max-frequency = <24000000>;
        };
};
```

The SD card will be automatically detected and initialized by the filesystem driver when the board boots.

To read and write files and directories, see the *File Systems* in include/zephyr/fs/fs.h such as `fs_open()`, `fs_read()`, and `fs_write()`.

eMMC Device Support

Zephyr also has support for eMMC devices using the Disk Access API. MMC in zephyr is implemented using the SD subsystem because the MMC bus shares a lot of similarity with the SD bus. MMC controllers also use the SDHC device driver API.

Emulated block device on flash partition support

Zephyr flashdisk driver makes it possible to use flash memory partition as a block device. The flashdisk instances are defined in devicetree:

```
/ {
    msc_disk0 {
        compatible = "zephyr,flash-disk";
        partition = <&storage_partition>;
        disk-name = "NAND";
        cache-size = <4096>;
    };
};
```

The cache size specified in `zephyr,flash-disk` node should be equal to backing partition minimum erasable block size.

NVMe disk support NVMe disks are also supported

NVMe NVMe is a standardized logical device interface on PCIe bus exposing storage devices.

NVMe controllers and disks are supported. Disks can be accessed via the *Disk Access API* they expose and thus be used through the *File System API*.

Driver design The driver is sliced up in 3 main parts:

- NVMe controller: drivers/disk/nvme/nvme_controller.c
- NVMe commands: drivers/disk/nvme/nvme_cmd.c
- NVMe namespace: drivers/disk/nvme/nvme_namespace.c

Where the NVMe controller is the root of the device driver. This is the one that will get device driver instances. Note that this is only what DTS describes: the NVMe controller, and none of its namespaces (disks). The NVMe command is the generic logic used to communicate with the controller and the namespaces it exposes. Finally the NVMe namespace is the dedicated part to

deal with an actual namespace which, in turn, enables applications accessing each ones through the Disk Access API drivers/disk/nvme/nvme_disk.c.

If a controller exposes more than 1 namespace (disk), it will be possible to raise the amount of built-in namespace support by tweaking the configuration option CONFIG_NVME_MAX_NAMESPACES (see below).

Each exposed disk, via it's related disk_info structure, will be distinguished by its name which is inherited from it's related namespace. As such, the disk name follows NVMe naming which is nvme<k>n<n> where k is the controller number and n the namespame number. Most of the time, if only one NVMe disk is plugged into the system, one will see 'nvme0n0' as an exposed disk.

NVMe configuration

DTS Any board exposing an NVMe disk should provide a DTS overlay to enable its use within Zephyr

```
#include <zephyr/dt-bindings/pcie/pcie.h>
/ {
    pcie0 {
        nvme0: nvme0 {
            compatible = "nvme-controller";
            vendor-id = <VENDOR_ID>;
            device-id = <DEVICE_ID>;
            status = "okay";
        };
    };
};
```

Where VENDOR_ID and DEVICE_ID are the ones from the exposed NVMe controller.

Options

- CONFIG_NVME

Note that NVME requires the target to support PCIe multi-vector MSI-X in order to function.

- CONFIG_NVME_MAX_NAMESPACES

Important note for users NVMe specifications mandate the data buffer to be placed in a dword (4 bytes) aligned address. While this is not a problem for advanced OS managing virtual memory and dynamic allocations below the user processes, this can become an issue in Zephyr as soon as buffer addresses map directly to physical memory.

At this stage then, it is up to the user to make sure the buffer address being provided to `disk_access_read()` and `disk_access_write()` are dword aligned.

VirtIO block device support

VirtIO block devices are also supported

VirtIO Block VirtIO is a standardized interface for exposing virtual devices to a guest, typically under a hypervisor such as QEMU. The `virtio,blk` driver presents a VirtIO block device as a Zephyr disk: it is reachable through the *Disk Access API* and, through it, the *File System API*.

The driver is transport-agnostic and runs unchanged over both VirtIO transports Zephyr supports, PCI and MMIO (see *VirtIO*). An instance is created for every enabled `virtio,blk` devicetree node.

Driver design The driver lives in drivers/disk/virtio_blk.c and is layered on top of the generic VirtIO API. A `virtio,blk` node is a child of a VirtIO transport device (`DT_INST_PARENT`), so the same code serves a PCI or an MMIO device without change.

Single in-flight request The `disk_access` read/write API is synchronous and blocking. The driver also serializes callers with a mutex, so each device keeps exactly one request in flight: it adds a single descriptor chain to the request virtqueue, notifies the device, and blocks on a semaphore that the completion callback signals from interrupt context.

Because there is no request pipelining, the whole virtqueue is spent on a single request's scatter-gather chain. The user-facing knob is the maximum number of data segments per request (`CONFIG_DISK_VIRTIO_BLK_MAX_SEGMENTS`); the driver sizes the virtqueue by rounding `MAX_SEGMENTS + 2` up to a power of two, leaving room for the request header and the status byte.

Block size The VirtIO block protocol always addresses the device in fixed 512-byte sectors and reports device capacity in those units. The logical block size exposed to `disk_access` may differ:

- When the device offers `VIRTIO_BLK_F_BLK_SIZE`, the driver negotiates it and exposes the device-advertised `blk_size`.
- Otherwise it falls back to `CONFIG_DISK_VIRTIO_BLK_SECTOR_SIZE`.

All addressing is converted to 512-byte VirtIO sectors internally. The block size must be a multiple of 512 and, under `CONFIG_MMU`, must not exceed the MMU page size; an unsupported value is rejected at initialization.

Zero-copy transfers Caller buffers are handed to the device directly, without a bounce buffer. Under `CONFIG_MMU` a buffer may lie outside the kernel's linear RAM mapping (for example the thread-stack work area `f_mkfs()` passes down) and need not be physically contiguous. The driver walks such a buffer page by page with `arch_page_phys_get()`, coalesces physically adjacent runs into scatter-gather segments, and, when a transfer is more fragmented than the segment budget allows, splits it across several device requests.

Feature negotiation Besides `VIRTIO_BLK_F_BLK_SIZE` the driver negotiates:

- `VIRTIO_BLK_F_RO` — a read-only device is reported as `DISK_STATUS_WR_PROTECT` and write requests are rejected with `-EROFS`.
- `VIRTIO_BLK_F_FLUSH` — `DISK_IOCTL_CTRL_SYNC` issues a flush to the device. When the device did not offer `FLUSH` there is no writeback cache to flush, so the ioctl is a successful no-op rather than an error.

A completed request whose status byte is not `OK` is logged and mapped to an errno: an unsupported request becomes `-ENOTSUP` and an I/O error `-EIO`.

VirtIO block configuration

DTS A `virtio,blk` node is placed under its VirtIO transport parent and requires a `disk-name` used by the `disk_access` APIs. Over the PCI transport:

```
#include <zephyr/dt-bindings/pcie/pcie.h>

/ {
    pcie0 {
        virtio-blk-pci {
            compatible = "virtio,pci";
            vendor-id = <0x1af4>;
            device-id = <0x1001>;
```

(continues on next page)

(continued from previous page)

```
            interrupts = <0xb 0x0 0x0>;
            interrupt-parent = <&intc>;
            status = "okay";

            virtio_blk: virtio-blk {
                compatible = "virtio,blk";
                disk-name = "VIRTIOBLK0";
                status = "okay";
            };
        };
    };
};
```

Over the MMIO transport the node is a child of an existing `virtio,mmio` bus:

```
&virtio_mmio4 {
    status = "okay";

    virtio_blk: virtio-blk {
        compatible = "virtio,blk";
        disk-name = "VIRTIOBLK0";
        status = "okay";
    };
};
```

Options

- `CONFIG_DISK_DRIVER_VIRTIO_BLK`
- `CONFIG_DISK_VIRTIO_BLK_MAX_SEGMENTS`
- `CONFIG_DISK_VIRTIO_BLK_SECTOR_SIZE`

QEMU options When `CONFIG_DISK_DRIVER_VIRTIO_BLK` is enabled on a QEMU board, the emulation layer creates a raw backing image and attaches it to the emulated virtio-blk device. PCI transports are attached from the common QEMU emulation code; the `qemu_cortex_a53` board attaches an MMIO `virtio-blk-device` to `virtio-mmio-bus.4`.

- `CONFIG_QEMU_VIRTIO_BLK_LOGICAL_BLOCK_SIZE`
- `CONFIG_QEMU_VIRTIO_BLK_DISK_SIZE`

Limitations

- Exactly one request is in flight at a time. This matches the synchronous `disk_access` contract, so it costs that consumer no throughput, but the driver provides no request pipelining.
- Like the rest of Zephyr's VirtIO subsystem, the driver assumes coherent DMA and performs no cache maintenance on descriptors, rings, or data buffers.
- Under an MMU the logical block size cannot exceed the MMU page size.

4.5.2 Flash Circular Buffer (FCB)

Flash circular buffer provides an abstraction through which you can treat flash like a FIFO. You append entries to the end, and read data from the beginning.

Description

Entries in the flash contain the length of the entry, the data within the entry, and checksum over the entry contents.

Storage of entries in flash is done in a FIFO fashion. When you request space for the next entry, space is located at the end of the used area. When you start reading, the first entry served is the oldest entry in flash.

Entries can be appended to the end of the area until storage space is exhausted. You have control over what happens next; either erase oldest block of data, thereby freeing up some space, or stop writing new data until existing data has been collected. FCB treats underlying storage as an array of flash sectors; when it erases old data, it does this a sector at a time.

Entries in the flash are checksummed. That is how FCB detects whether writing entry to flash completed ok. It will skip over entries which don't have a valid checksum.

Usage

To add an entry to circular buffer:

- Call `fcb_append()` to get the location where data can be written. If this fails due to lack of space, you can call `fcb_rotate()` to erase the oldest sector which will make the space. And then call `fcb_append()` again.
- Use `flash_area_write()` to write entry contents.
- Call `fcb_append_finish()` when done. This completes the writing of the entry by calculating the checksum.

To read contents of the circular buffer:

- Call `fcb_walk()` with a pointer to your callback function.
- Within callback function copy in data from the entry using `flash_area_read()`. You can tell when all data from within a sector has been read by monitoring the returned entry's area pointer. Then you can call `fcb_rotate()`, if you're done with that data.

Alternatively:

- Call `fcb_getnext()` with 0 in entry offset to get the pointer to the oldest entry.
- Use `flash_area_read()` to read entry contents.
- Call `fcb_getnext()` with pointer to current entry to get the next one. And so on.

API Reference

The FCB subsystem APIs are provided by `fcb.h`:

Data structures
Flash Circular Buffer Data Structures

API functions
fcb API

4.5.3 File Systems

Zephyr RTOS Virtual Filesystem Switch (VFS) allows applications to mount multiple file systems at different mount points (e.g., `/fatfs` and `/lfs`). The mount point data structure contains all the necessary information required to instantiate, mount, and operate on a file system. The File system Switch decouples the applications from directly accessing an individual file system's specific API or internal functions by introducing file system registration mechanisms.

In Zephyr, any file system implementation or library can be plugged into or pulled out through a file system registration API. Each file system implementation must have a globally unique integer identifier; use `FS_TYPE_EXTERNAL_BASE` to avoid clashes with in-tree identifiers.

```
int fs_register(int type, const struct fs_file_system_t *fs);

int fs_unregister(int type, const struct fs_file_system_t *fs);
```

Zephyr RTOS supports multiple instances of a file system by making use of the mount point as the disk volume name, which is used by the file system library while formatting or mounting a disk.

A file system is declared as:

```
static struct fs_mount_t mp = {
.type = FS_FATFS,
.mnt_point = FATFS_MNTP,
.fs_data = &fat_fs,
};
```

where

- `FS_FATFS` is the file system type like FATFS or LittleFS.
- `FATFS_MNTP` is the mount point where the file system will be mounted.
- `fat_fs` is the file system data which will be used by fs_mount() API.

Samples

Samples for the VFS are mainly supplied in `samples/subsys/fs`, although various examples of the VFS usage are provided as important functionalities in samples for different subsystems. Here is the list of samples worth looking at:

- fs is an example of FAT file system usage with SDHC media;

- shell-fs is an example of Shell fs subsystem, using internal flash partition formatted to LittleFS;
- usb-mass example of USB Mass Storage device that uses FAT FS driver with RAM or SPI connected FLASH, or LittleFS in flash, depending on the sample configuration.

4.5.4 Flash map

The <zephyr/storage/flash_map.h> API allows accessing information about device flash partitions via `flash_area` structures.

Each `flash_area` describes a flash partition. The API provides access to a "flash map", which contains predefined flash areas accessible via globally unique ID numbers. The map is created from "fixed-partitions" and "zephyr,mapped-partition" compatible entries in DTS file. Users may also create `flash_area` objects at runtime for application-specific purposes.

This documentation uses "flash area" when referencing single "fixed-partitions" or "zephyr,mapped-partition" entities.

The `flash_area` contains a pointer to a `device`, which can be used to access the flash device an area is placed on directly with the *flash API*. Each flash area is characterized by a device it is placed on, offset from the beginning of the device and size on the device. An additional identifier parameter is used by the `flash_area_open()` function to find flash area in flash map.

The flash_map.h API provides functions for operating on a `flash_area`. The main examples are `flash_area_read()` and `flash_area_write()`. These functions are basically wrappers around the flash API with additional offset and size checks, to limit flash operations to a predefined area.

Most <zephyr/storage/flash_map.h> API functions require a `flash_area` object pointer characterizing the flash area they will be working on. There are two possible methods to obtain such a pointer:

- obtain it using `flash_area_open()`;
- defining a `flash_area` type object, which requires providing a valid `device` object pointer with offset and size of the area within the flash device.

`flash_area_open()` uses numeric identifiers to search flash map for `flash_area` objects and returns, if found, a pointer to an object representing area with given ID. The ID number for a flash

area can be obtained from a “fixed-partitions” or a “zephyr,mapped-partition” DTS node label using `PARTITION_ID()`; these labels are obtained from the devicetree as described below.

Relationship with Devicetree

The flash_map.h API uses data generated from the *Devicetree API*, in particular its *Fixed and mapped flash partitions*. Zephyr additionally has some partitioning conventions used for *Device Firmware Upgrade* via the MCUboot bootloader, as well as defining partitions usable by *file systems* or other non-volatile *storage*.

Here is an example devicetree fragment which uses fixed flash partitions for both MCUboot and a storage partition. Some details were left out for clarity.

```
/ {
        soc {
                flashctrl: flash-controller@deadbeef {
                        flash0: flash@0 {
                                compatible = "soc-nv-flash";
                                reg = <0x0 0x100000>;

                                partitions {
                                        compatible = "fixed-partitions";
                                        #address-cells = <0x1>;
                                        #size-cells = <0x1>;

                                        boot_partition: partition@0 {
                                                reg = <0x0 0x10000>;
                                                read-only;
                                        };

                                        storage_partition: partition@1e000 {
                                                reg = <0x1e000 0x2000>;
                                        };

                                        slot0_partition: partition@20000 {
                                                reg = <0x20000 0x60000>;
                                        };

                                        slot1_partition: partition@80000 {
                                                reg = <0x80000 0x60000>;
                                        };

                                        scratch_partition: partition@e0000 {
                                                reg = <0xe0000 0x20000>;
                                        };
                                };
                        };
                };
        };
};
```

Partition offset shall be expressed in relation to the flash memory beginning address, to which the partition belongs to.

The `boot_partition`, `slot0_partition`, `slot1_partition`, and `scratch_partition` node labels are defined for MCUboot, though not all MCUboot configurations require all of them to be defined. See the MCUboot documentation for more details.

The `storage_partition` node is defined for use by a file system or other nonvolatile storage API.

Numeric flash area ID is obtained by passing DTS node label to `PARTITION_ID()`; for example to obtain ID number for `slot0_partition`, user would invoke `PARTITION_ID(slot0_partition)`.

All `PARTITION_*` macros take DTS node labels as partition identifiers.

Users do not have to obtain a `flash_area` object pointer using `flash_map_open()` to get information on flash area size, offset or device, if such area is defined in DTS file. Knowing the DTS node label of an area, users may use `PARTITION_OFFSET()`, `PARTITION_SIZE()` or `PARTITION_DEVICE()` respectively to obtain such information directly from DTS node definition. For example to obtain offset of `storage_partition` it is enough to invoke `PARTITION_OFFSET(storage_partition)`.

Below example shows how to obtain a `flash_area` object pointer using `flash_area_open()` and DTS node label:

```
const struct flash_area *my_area;
int err = flash_area_open(PARTITION_ID(slot0_partition), &my_area);

if (err != 0) {
     handle_the_error(err);
} else {
     flash_area_read(my_area, ...);
}
```

4.5.5 Non-Volatile Memory (NVMEM)

The NVMEM subsystem provides a generic interface for accessing non-volatile memory devices. It abstracts the underlying hardware and provides a unified API for reading and writing data.

Key Concepts

NVMEM Provider An NVMEM provider is a driver that exposes NVMEM cells. For example, an EEPROM driver can be an NVMEM provider. The NVMEM provider is responsible for reading and writing data to the underlying hardware.

NVMEM Cell An NVMEM cell is a region of non-volatile memory. It is defined in the devicetree and has properties like offset, size, and read-only status.

NVMEM Consumer An NVMEM consumer is a driver or application that uses NVMEM cells to store or retrieve data.

Configuration

- `CONFIG_NVMEM`: Enables the NVMEM subsystem.
- `CONFIG_NVMEM_BBRAM`: Enables NVMEM support for Battery Backed RAM.
- `CONFIG_NVMEM_EEPROM`: Enables NVMEM support for EEPROM devices.
- `CONFIG_NVMEM_FLASH.*`: Configure NVMEM support for flash devices.

- `CONFIG_NVMEM_OTP.*`: Configure NVMEM support for OTP devices.

Devicetree Bindings

The NVMEM subsystem relies on devicetree bindings to define NVMEM cells. The following is an example of how to define an NVMEM provider and cells in the devicetree:

```
&eeprom0 {
        nvmem-layout {
                compatible = "fixed-layout";
                #address-cells = <1>;
                #size-cells = <1>;

                mac_address: mac_address@0 {
                        reg = <0x0 6>;
                        #nvmem-cell-cells = <0>;
                        read-only;
                };

                calibration_data: calibration_data@6 {
                        reg = <0x6 100>;
                        #nvmem-cell-cells = <0>;
                };
        };
};
```

The reg property is an array containing:

- The offset in the memory in which we are creating the cell,
- The size of the cell, in bytes.

`#nvmem-cell-cells` describes the number of property items in the phandle, see *Specifier cell names (*-cells)*, typically set to zero.

A consumer can then reference the NVMEM cells like this:

```
my_consumer: my-consumer {
        compatible = "my,consumer";
        nvmem-cells = <&mac_address>, <&calibration_data>;
        nvmem-cell-names = "mac-address", "calibration-data";
};
```

Usage Example

The following is an example of how to use the NVMEM API to read data from an NVMEM cell:

```
#include <zephyr/nvmem.h>

static const struct nvmem_cell mac_address =
        NVMEM_CELL_GET_BY_NAME(DT_NODELABEL(my_consumer), mac_address);

int main(void)
{
        uint8_t mac[6];
        int ret;

        if (!nvmem_cell_is_ready(&mac_address)) {
                printk("NVMEM cell is not ready\n");
```

(continues on next page)

(continued from previous page)

```
                return -ENODEV;
        }

        ret = nvmem_cell_read(&mac_address, mac, 0, sizeof(mac));
        if (ret < 0) {
                printk("Failed to read MAC address: %d\n", ret);
                return ret;
        }

        /* ... */
}
```

NVMEM

4.5.6 Non-Volatile Storage (NVS)

Elements, represented as id-data pairs, are stored in flash using a FIFO-managed circular buffer. The flash area is divided into sectors. Elements are appended to a sector until storage space in the sector is exhausted. Then a new sector in the flash area is prepared for use (erased). Before erasing the sector it is checked that identifier - data pairs exist in the sectors in use, if not the id-data pair is copied.

The id is a 16-bit unsigned number. NVS ensures that for each used id there is at least one id-data pair stored in flash at all time.

NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Each element is stored in flash as metadata (8 byte) and data. The metadata is written in a table starting from the end of a nvs sector, the data is written one after the other from the start of the sector. The metadata consists of: id, data offset in sector, data length, part (unused), and a CRC. This CRC is only calculated over the metadata and only ensures that a write has been completed. The actual data of the element can be protected by a different (and optional) CRC-32. Use the `CONFIG_NVS_DATA_CRC` configuration item to enable the data part CRC.

Note

The data CRC is checked only when the whole data of the element is read. The data CRC is not checked for a partial read, as it is stored at the end of the element data area.

Note

Enabling the data CRC feature on a previously existing NVS content without data CRC will make all existing data invalid.

A write of data to nvs always starts with writing the data, followed by a write of the metadata. Data that is written in flash without metadata is ignored during initialization.

During initialization NVS will verify the data stored in flash, if it encounters an error it will ignore any data with missing/incorrect metadata.

NVS checks the id-data pair before writing data to flash. If the id-data pair is unchanged no write to flash is performed.

To protect the flash area against frequent erases it is important that there is sufficient free space. NVS has a protection mechanism to avoid getting in a endless loop of flash page erases when there is limited free space. When such a loop is detected NVS returns that there is no more space available.

For NVS the file system is declared as:

```
static struct nvs_fs fs = {
.flash_device = NVS_FLASH_DEVICE,
.sector_size = NVS_SECTOR_SIZE,
.sector_count = NVS_SECTOR_COUNT,
.offset = NVS_STORAGE_OFFSET,
};
```

where

- NVS_FLASH_DEVICE is a reference to the flash device that will be used. The device needs to be operational.
- NVS_SECTOR_SIZE is the sector size, it has to be a multiple of the flash erase page size and a power of 2.
- NVS_SECTOR_COUNT is the number of sectors, it is at least 2, one sector is always kept empty to allow copying of existing data.
- NVS_STORAGE_OFFSET is the offset of the storage area in flash.

Flash wear

When writing data to flash a study of the flash wear is important. Flash has a limited life which is determined by the number of times flash can be erased. Flash is erased one page at a time and the pagesize is determined by the hardware. As an example a nRF51822 device has a pagesize of 1024 bytes and each page can be erased about 20,000 times.

Calculating expected device lifetime Suppose we use a 4 bytes state variable that is changed every minute and needs to be restored after reboot. NVS has been defined with a sector_size equal to the pagesize (1024 bytes) and 2 sectors have been defined.

Each write of the state variable requires 12 bytes of flash storage: 8 bytes for the metadata and 4 bytes for the data. When storing the data the first sector will be full after 1024/12 = 85.33 minutes. After another 85.33 minutes, the second sector is full. When this happens, because we're using only two sectors, the first sector will be used for storage and will be erased after 171 minutes of system time. With the expected device life of 20,000 writes, with two sectors writing every 171 minutes, the device should last about 171 * 20,000 minutes, or about 6.5 years.

More generally then, with

- NS as the number of storage requests per minute,
- DS as the data size in bytes,
- SECTOR_SIZE in bytes, and
- PAGE_ERASES as the number of times the page can be erased,

the expected device life (in minutes) can be calculated as:

```
SECTOR_COUNT * SECTOR_SIZE * PAGE_ERASES / (NS * (DS+8)) minutes
```

From this formula it is also clear what to do in case the expected life is too short: increase SECTOR_COUNT or SECTOR_SIZE.

Flash write block size migration

It is possible that during a DFU process, the flash driver used by the NVS changes the supported minimal write block size. The NVS in-flash image will stay compatible unless the physical ATE size changes. Especially, migration between 1,2,4,8-bytes write block sizes is allowed.

Sample

A sample of how NVS can be used is supplied in `samples/subsys/kvss/nvs`.

Troubleshooting

MPU fault while using NVS, or `-ETIMEDOUT` error returned
NVS can use the internal flash of the SoC. While the MPU is enabled, the flash driver requires MPU RWX access to flash memory, configured using `CONFIG_MPU_ALLOW_FLASH_WRITE`. If this option is disabled, the NVS application will get an MPU fault if it references the internal SoC flash and it's the only thread running. In a multi-threaded application, another thread might intercept the fault and the NVS API will return an `-ETIMEDOUT` error.

4.5.7 Retention System

The retention system provides an API which allows applications to read and write data from and to memory areas or devices that retain the data while the device is powered. This allows for sharing information between different applications or within a single application without losing state information when a device reboots. The stored data should not persist in the event of a power failure (or during some low-power modes on some devices) nor should it be stored to a non-volatile storage like *Flash*, *EEPROM API*, or battery-backed RAM.

The retention system builds on top of the retained data driver, and adds additional software-level features to it for ensuring the validity of data. Optionally, a magic header can be used to check if the front of the retained data memory section contains this specific value, and an optional checksum (1, 2, or 4-bytes in size) of the stored data can be appended to the end of the data. Additionally, the retention system API allows partitioning of the retained data sections into multiple distinct areas. For example, a 64-byte retained data area could be split up into 4 bytes for a boot mode, 16 bytes for a timestamp, 44 bytes for a last log message. All of these sections can be accessed or updated independently. The prefix and checksum can be set per-instance using devicetree.

Devicetree setup

To use the retention system, a retained data driver must be setup for the board you are using, there is a zephyr driver which can be used which will use some RAM as non-init for this purpose. The retention system is then initialised as a child node of this device 1 or more times - note that the memory region will need to be decremented to account for this reserved portion of RAM. See the following example (examples in this guide are based on the nrf52840dk board and memory layout):

```
/ {
        sram@2003FC00 {
                compatible = "zephyr,memory-region", "mmio-sram";
                reg = <0x2003FC00 DT_SIZE_K(1)>;
                zephyr,memory-region = "RetainedMem";
                status = "okay";

                retainedmem {
                        compatible = "zephyr,retained-ram";
                        status = "okay";
                        #address-cells = <1>;
                        #size-cells = <1>;

                        /* This creates a 256-byte partition */
                        retention0: retention@0 {
                                compatible = "zephyr,retention";
                                status = "okay";

                                /* The total size of this area is 256
                                 * bytes which includes the prefix and
                                 * checksum, this means that the usable
                                 * data storage area is 256 - 3 = 253
                                 * bytes
                                 */
                                reg = <0x0 0x100>;

                                /* This is the prefix which must appear
                                 * at the front of the data
                                 */
                                prefix = [08 04];

                                /* This uses a 1-byte checksum */
                                checksum = <1>;
                        };

                        /* This creates a 768-byte partition */
                        retention1: retention@100 {
                                compatible = "zephyr,retention";
                                status = "okay";

                                /* Start position must be after the end
                                 * of the previous partition. The total
                                 * size of this area is 768 bytes which
                                 * includes the prefix and checksum,
                                 * this means that the usable data
                                 * storage area is 768 - 6 = 762 bytes
                                 */
                                reg = <0x100 0x300>;

                                /* This is the prefix which must appear
                                 * at the front of the data
                                 */
                                prefix = [00 11 55 88 fa bc];

                                /* If omitted, there will be no
                                 * checksum
                                 */
```

(continues on next page)

(continued from previous page)

```
                        };
                };
        };
};

/* Reduce SRAM0 usage by 1KB to account for non-init area */
&sram0 {
        reg = <0x20000000 DT_SIZE_K(255)>;
};
```

The retention areas can then be accessed using the data retention API (once enabled with CONFIG_RETENTION, which requires that CONFIG_RETAINED_MEM be enabled) by getting the device by using:

```
#include <zephyr/device.h>
#include <zephyr/retention/retention.h>

const struct device *retention0 = DEVICE_DT_GET(DT_NODELABEL(retention0));
const struct device *retention1 = DEVICE_DT_GET(DT_NODELABEL(retention1));
```

When the write function is called, the magic header and checksum (if enabled) will be set on the area, and it will be marked as valid from that point onwards.

Mutex protection

Mutex protection of retention areas is enabled by default when applications are compiled with multithreading support. This means that different threads can safely call the retention functions without clashing with other concurrent thread function usage, but means that retention functions cannot be used from ISRs. It is possible to disable mutex protection globally on all retention areas by enabling CONFIG_RETENTION_MUTEX_FORCE_DISABLE - users are then responsible for ensuring that the function calls do not conflict with each other. Note that to use this, retention driver mutex support must also be disabled by enabling CONFIG_RETAINED_MEM_MUTEX_FORCE_DISABLE.

Boot mode

An addition to the retention subsystem is a boot mode interface, this can be used to dynamically change the state of an application or run a different application with a minimal set of functions when a device is rebooted (an example is to have a buttonless way of entering mcuboot's serial recovery feature from the main application).

To use the boot mode feature, a data retention entry must exist in the device tree, which is dedicated for use as the boot mode selection (the user area data size only needs to be a single byte), and this area be assigned to the chosen node of zephyr,boot-mode. See the following example:

```
/ {
        sram@2003FFFF {
                compatible = "zephyr,memory-region", "mmio-sram";
                reg = <0x2003FFFF 0x1>;
                zephyr,memory-region = "RetainedMem";
                status = "okay";

                retainedmem {
                        compatible = "zephyr,retained-ram";
                        status = "okay";
                        #address-cells = <1>;
                        #size-cells = <1>;
```

(continues on next page)

(continued from previous page)

```
                        retention0: retention@0 {
                                compatible = "zephyr,retention";
                                status = "okay";
                                reg = <0x0 0x1>;
                        };
                };
        };

        chosen {
                zephyr,boot-mode = &retention0;
        };
};

/* Reduce SRAM0 usage by 1 byte to account for non-init area */
&sram0 {
        reg = <0x20000000 0x3FFFF>;
};
```

The boot mode interface can be enabled with `CONFIG_RETENTION_BOOT_MODE` and then accessed by using the boot mode functions. If using mcuboot with serial recovery, it can be built with `CONFIG_MCUBOOT_SERIAL` and `CONFIG_BOOT_SERIAL_BOOT_MODE` enabled which will allow rebooting directly into the serial recovery mode by using:

```
#include <zephyr/retention/bootmode.h>
#include <zephyr/sys/reboot.h>

bootmode_set(BOOT_MODE_TYPE_BOOTLOADER);
sys_reboot(0);
```

Retention system modules

Modules can expand the functionality of the retention system by using it as a transport (e.g. between a bootloader and application).

Bootloader Information The bootloader information (abbreviated to blinfo) subsystem is an extension of the *Retention System* which allows for reading shared data from a bootloader and allowing applications to query it. It has an optional feature of organising the information retrieved from the bootloader and storing it in the *Settings* with the `blinfo/` prefix.

Devicetree setup To use the bootloader information subsystem, a retention area needs to be created which has a retained data section as its parent, generally non-init RAM is used for this purpose. See the following example (examples in this guide are based on the nrf52840dk board and memory layout):

```
/ {
        sram@2003FC00 {
                compatible = "zephyr,memory-region", "mmio-sram";
                reg = <0x2003FC00 DT_SIZE_K(1)>;
                zephyr,memory-region = "RetainedMem";
                status = "okay";

                retainedmem {
                        compatible = "zephyr,retained-ram";
                        status = "okay";
```

(continues on next page)

(continued from previous page)

```
                        #address-cells = <1>;
                        #size-cells = <1>;

                        boot_info0: boot_info@0 {
                                compatible = "zephyr,retention";
                                status = "okay";
                                reg = <0x0 0x100>;
                        };
                };
        };

        chosen {
                zephyr,bootloader-info = &boot_info0;
        };
};

/* Reduce SRAM0 usage by 1KB to account for non-init area */
&sram0 {
        reg = <0x20000000 DT_SIZE_K(255)>;
};
```

Note that this configuration needs to be applied on both the bootloader (MCUboot) and application to be usable. It can be combined with other retention system APIs such as the *Boot mode*

MCUboot setup Once the above devicetree configuration is applied, MCUboot needs to be configured to store the shared data in this area, the following Kconfigs need to be set for this:

- `CONFIG_RETAINED_MEM` - Enables retained memory driver
- `CONFIG_RETENTION` - Enables retention system
- `CONFIG_BOOT_SHARE_DATA` - Enables shared data
- `CONFIG_BOOT_SHARE_DATA_BOOTINFO` - Enables boot information shared data type
- `CONFIG_BOOT_SHARE_BACKEND_RETENTION` - Stores shared data using retention/blinfo subsystem

Application setup The application must enable the following base Kconfig options for the bootloader information subsystem to function:

- `CONFIG_RETAINED_MEM`
- `CONFIG_RETENTION`
- `CONFIG_RETENTION_BOOTLOADER_INFO`
- `CONFIG_RETENTION_BOOTLOADER_INFO_TYPE_MCUBOOT`

The following include is needed to use the bootloader information subsystem:

```
#include <zephyr/retention/blinfo.h>
```

By default, only the lookup function is provided: `blinfo_lookup()`, the application can call this to query the information from the bootloader. This function is enabled by default with `CONFIG_RETENTION_BOOTLOADER_INFO_OUTPUT_FUNCTION`, however, applications can optionally choose to use the settings storage feature instead. In this mode, the bootloader information can be queries by using settings keys, the following Kconfig options need to be enabled for this mode:

- `CONFIG_SETTINGS`

- CONFIG_SETTINGS_RUNTIME
- CONFIG_RETENTION_BOOTLOADER_INFO_OUTPUT_SETTINGS

This allows the information to be queried via the settings_runtime_get() function with the following keys:

- blinfo/mode The mode that MCUboot is configured for (enum mcuboot_mode value)
- blinfo/signature_type The signature type MCUboot is configured for (enum mcuboot_signature_type value)
- blinfo/recovery The recovery type enabled in MCUboot (enum mcuboot_recovery_mode value)
- blinfo/running_slot The running slot, useful for direct-XIP mode to know which slot to use for an update
- blinfo/bootloader_version Version of the bootloader (struct image_version object)
- blinfo/max_application_size Maximum size of an application (in bytes) that can be loaded

In addition to the previous include, the following includes are required for this mode:

```
#include <bootutil/boot_status.h>
#include <bootutil/image.h>
#include <zephyr/mcuboot_version.h>
#include <zephyr/settings/settings.h>
```

4.5.8 Secure Storage

The secure storage subsystem provides an implementation of the functions defined in the Platform Security Architecture (PSA) Secure Storage API.
It can be enabled on *board targets* that don't already have an implementation of the API.

Overview

The secure storage subsystem makes the PSA Secure Storage API available on all board targets with non-volatile memory support. As such, it provides an implementation of the API on those that don't already have one, ensuring functional support for the API. Board targets with *Trusted Firmware-M (TF-M)* enabled (ending in /ns), for instance, cannot enable the subsystem because TF-M already provides an implementation of the API.

In addition to providing functional support for the API, depending on device-specific security features and the configuration, the subsystem may secure the data stored via the PSA Secure Storage API at rest.
Keep in mind, however, that it's preferable to use a secure processing environment like TF-M when possible because it's able to provide more security due to isolation guarantees.

Limitations

The secure storage subsystem's implementation of the PSA Secure Storage API:

- does not aim at full compliance with the specification.

  Its foremost goal is functional support for the API on all board targets.
  See below for important ways the implementation deviates from the specification.

- does not guarantee that the data it stores will be secure at rest in all cases.

  This depends on device-specific security features and the configuration.

- does not yet provide an implementation of the Protected Storage (PS) API as of this writing.

  Instead, the PS API directly calls into the Internal Trusted Storage (ITS) API (unless a *custom implementation* of the PS API is provided).

Below are some ways the implementation purposefully deviates from the specification and an explanation why. This is not an exhaustive list.

- The UID type is only 30 bits by default. (Against 2.5 UIDs.)

  This is an optimization done to make it more convenient to directly use the UIDs as storage entry IDs (e.g., with *ZMS* when `CONFIG_SECURE_STORAGE_ITS_STORE_IMPLEMENTATION_ZMS` is enabled).
  Zephyr defines numerical ranges to be used by different users of the API which guarantees that there are no collisions and that they all fit within 30 bits. See the header files in include/zephyr/psa for more information.

- The data stored in the ITS is by default encrypted and authenticated (Against `1.` in 3.2. Internal Trusted Storage requirements.)

  The specification considers the storage underlying the ITS to be `implicitly confidential and protected from replay` (2.4. The Internal Trusted Storage API) because `most embedded microprocessors (MCU) have on-chip flash storage that can be made inaccessible except to software running on the MCU` (2.2. Technical Background).
  This is not the case on all MCUs. Thus, additional protection is provided to the stored data.

  However, this does not guarantee that the data stored will be secure at rest in all cases, because this depends on device-specific security features and the configuration. It requires a random entropy source and especially a secure encryption key provider (`CONFIG_SECURE_STORAGE_ITS_TRANSFORM_AEAD_KEY_PROVIDER`).

  In addition, the data stored in the ITS is not protected against replay attacks, because this requires storage that is protected by hardware.

- The data stored via the PSA Secure Storage API is not protected from direct read/write by software or debugging. (Against `2.` and `10.` in 3.2. Internal Trusted Storage requirements.)

  It is only secured at rest. Protecting it at runtime as well requires specific hardware mechanisms to support this.

- The `PSA_STORAGE_FLAG_WRITE_ONCE` flag only protects an entry against modification through the API, not against modification of the storage medium itself.

  Upholding the flag requires knowing that an entry was created in the first place, which is state that has to survive the storage medium being rewritten. Like replay protection, that requires storage that is protected by hardware.
  An attacker who can write to the storage medium can therefore have a write-once entry overwritten or removed: either by tampering with it, after which the subsystem treats it as corrupted and allows it to be replaced, or simply by erasing it, after which it appears never to have existed. Neither can be prevented by encrypting and authenticating the entry.

- The `psa_its_get*()` functions can return `PSA_ERROR_INVALID_SIGNATURE` and `PSA_ERROR_DATA_CORRUPT`.

  The specification doesn't define these for the ITS API because it assumes that the storage underlying it is protected by hardware, and thus that data read back from it is always intact. As it's not the case here, these error codes are passed on to let callers tell an entry that has been tampered with apart from an internal failure.

Configuration

To configure the implementation of the PSA Secure Storage API provided by Zephyr, have a look at the available Kconfig options. They are defined in the various Kconfig files found under subsys/secure_storage/.

Customization

Custom implementations can also replace those of Zephyr at different levels if the functionality provided by the existing implementations isn't enough.

Whole API If you already have an implementation of the whole ITS or PS API and want to make use of it, you can do so by enabling the following Kconfig option and implementing the relevant functions:

- `CONFIG_SECURE_STORAGE_ITS_IMPLEMENTATION_CUSTOM`, for the ITS API.
- `CONFIG_SECURE_STORAGE_PS_IMPLEMENTATION_CUSTOM`, for the PS API.

ITS API Zephyr's implementation of the ITS API (`CONFIG_SECURE_STORAGE_ITS_IMPLEMENTATION_ZEPHYR`) makes use of the ITS transform and store modules, which can be configured and customized separately. Have a look at the ITS transform and store Kconfig options to see the different configuration possibilities.

It's especially recommended to use or implement a secure encryption key provider.

4.5.9 Settings

The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. A variety of storage implementations are provided behind a common API using FCB, NVS, ZMS or a file system. These different implementations give the application developer flexibility to select an appropriate storage medium, and even change it later as needs change. This subsystem is used by various Zephyr components and can be used simultaneously by user applications.

Settings items are stored as key-value pair strings. By convention, the keys can be organized by the package and subtree defining the key, for example the key `id/serial` would define the `serial` configuration element for the package `id`.

Convenience routines are provided for converting a key value to and from a string type.

For an example of the settings subsystem refer to settings sample.

Note

As of Zephyr release 4.1 the recommended backends for non-filesystem storage are *NVS* and *ZMS*.

Handlers

Settings handlers for subtree implement a set of handler functions. These are registered using a call to `settings_register()` for dynamic handlers or defined using a call to `SETTINGS_STATIC_HANDLER_DEFINE()` for static handlers.

h_get
: This gets called when asking for a settings element value by its name using `settings_runtime_get()` from the runtime backend.

h_set
: This gets called when the value is loaded from persistent storage with `settings_load()`, or when using `settings_runtime_set()` from the runtime backend.

h_commit
: This gets called after the settings have been loaded in full. Sometimes you don't want an individual setting value to take effect right away, for example if there are multiple settings which are interdependent.

h_export
: This gets called to write all current settings. This happens when `settings_save()` tries to save the settings or transfer to any user-implemented back-end.

Settings handlers also have a commit priority `cprio` that allows to prioritize the `h_commit` calls. This can be advantageous when e.g. a subsystem initializes a service that other `h_commit` calls depend on.

Settings handlers `h_commit` routines are by default initialized with `cprio = 0`, initializing a settings handler with a different priority is done using a call to `settings_register_with_cprio()` for dynamic handlers or using a call to `SETTINGS_STATIC_HANDLER_DEFINE_WITH_CPRIO()` for

static handlers. The specified `cprio` value is an integer where lower values mean higher priority.

Backends

Backends are meant to load and save data to/from setting handlers, and implement a set of handler functions. These are registered using a call to `settings_src_register()` for backends that can load data, and/or `settings_dst_register()` for backends that can save data. The current implementation allows for multiple source backends but only a single destination backend.

csi_load
: This gets called when loading values from persistent storage using `settings_load()`.

csi_load_one
: This gets called when loading only one item from persistent storage using `settings_load_one()`.

csi_get_val_len
: This gets called when getting a value's length from persistent storage using `settings_get_val_len()`.

csi_save
: This gets called when saving a single setting to persistent storage using `settings_save_one()`.

csi_save_start
: This gets called when starting a save of all current settings using `settings_save()` or `settings_save_subtree()`.

csi_save_end
: This gets called after having saved of all current settings using `settings_save()` or `settings_save_subtree()`.

Zephyr Storage Backends

Zephyr offers the following storage backends:

- Flash Circular Buffer (`CONFIG_SETTINGS_FCB`).
- A file in the filesystem (`CONFIG_SETTINGS_FILE`).
- Non-Volatile Storage (`CONFIG_SETTINGS_NVS`).
- Zephyr Memory Storage (`CONFIG_SETTINGS_ZMS`).

You can declare multiple sources for settings; settings from all of these are restored when `settings_load()` is called.

There can be only one target for writing settings; this is where data is stored when you call `settings_save()`, or `settings_save_one()`.

FCB read target is registered using `settings_fcb_src()`, and write target using `settings_fcb_dst()`. As a side-effect, `settings_fcb_src()` initializes the FCB area, so it must be called before calling `settings_fcb_dst()`. File read target is registered using `settings_file_src()`, and write target by using `settings_file_dst()`.

Non-volatile storage read target is registered using `settings_nvs_src()`, and write target by using `settings_nvs_dst()`.

Zephyr Memory Storage (ZMS) read target is registered using `settings_zms_src()`, and write target is registered using `settings_zms_dst()`.

ZMS backend has the particularity of using hash functions to hash the settings key before storing it to the persistent storage. This implementation implies that some collisions between key's hashes could occur if a big number of different keys are stored. This number depends on the selected hash function.

ZMS backend can handle 2^n maximum collisions where n is defined by (CONFIG_SETTINGS_ZMS_MAX_COLLISIONS_BITS).

Storage Location

The FCB, non-volatile storage (NVS) and ZMS backends look for a fixed partition with label "storage" by default. A different partition can be selected by setting the `zephyr,settings-partition` property of the chosen node in the devicetree.

The file path used by the file backend to store settings is selected via the option CONFIG_SETTINGS_FILE_PATH.

Loading data from persistent storage

A call to `settings_load()` uses an `h_set` implementation to load settings data from storage to volatile memory. After all data is loaded, the `h_commit` handler is issued, signalling the application that the settings were successfully retrieved.

Alternatively, a call to `settings_load_one()` will load only one Settings entry and store it in the provided buffer.

Optionally, to get only the value's length associated with the Settings entry, a call to `settings_get_val_len()` can be performed. This is used for example by applications that allocates dynamically the data buffer and needs to get the data size before reading it by settings_load_one().

Technically FCB and file backends may store some history of the entities. This means that the newest data entity is stored after any older existing data entities. Starting with Zephyr 2.1, the back-end must filter out all old entities and call the callback with only the newest entity.

Storing data to persistent storage

A call to `settings_save_one()` uses a backend implementation to store settings data to the storage medium. A call to `settings_save()` uses an `h_export` implementation to store different data in one operation using `settings_save_one()`. A key needs to be covered by a `h_export` only if it is supposed to be stored by `settings_save()` call.

For both FCB and file back-end only storage requests with data which changes most actual key's value are stored, therefore there is no need to check whether a value changed by the application. Such a storage mechanism implies that storage can contain multiple value assignments for a key , while only the last is the current value for the key.

Garbage collection When storage becomes full (FCB) or consumes too much space (file), the backend removes non-recent key-value pairs records and unnecessary key-delete records.

Secure domain settings

Currently settings doesn't provide scheme of being secure, and non-secure configuration storage simultaneously for the same instance. It is recommended that secure domain uses its own settings instance and it might provide data for non-secure domain using dedicated interface if needed (case dependent).

Example: Device Configuration

This is a simple example, where the settings handler only implements `h_set` and `h_export`. `h_set` is called when the value is restored from storage (or when set initially), and `h_export` is used to write the value to storage thanks to `storage_func()`. The user can also implement some other export functionality, for example, writing to the shell console).

```
#define DEFAULT_FOO_VAL_VALUE 1

static int8 foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                            settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            /* key-value pair was properly read.
             * rc contains value length.
             */
            return 0;
        }
        /* read-out error */
        return rc;
    }

    return -ENOENT;
}

static int foo_settings_export(int (*storage_func)(const char *name,
                                                   const void *value,
                                                   size_t val_len))
{
    return storage_func("foo/bar", &foo_val, sizeof(foo_val));
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set,
    .h_export = foo_settings_export
};
```

Example: Persist Runtime State

This is a simple example showing how to persist runtime state. In this example, only `h_set` is defined, which is used when restoring value from persistent storage.

In this example, the `main` function increments `foo_val`, and then persists the latest number. When the system restarts, the application calls `settings_load()` while initializing, and `foo_val` will continue counting up from where it was before restart.

```
#include <zephyr/kernel.h>
#include <zephyr/sys/reboot.h>
#include <zephyr/settings/settings.h>
#include <zephyr/sys/printk.h>
#include <inttypes.h>
```

(continues on next page)

(continued from previous page)

```
#define DEFAULT_FOO_VAL_VALUE 0

static uint8_t foo_val = DEFAULT_FOO_VAL_VALUE;

static int foo_settings_set(const char *name, size_t len,
                            settings_read_cb read_cb, void *cb_arg)
{
    const char *next;
    int rc;

    if (settings_name_steq(name, "bar", &next) && !next) {
        if (len != sizeof(foo_val)) {
            return -EINVAL;
        }

        rc = read_cb(cb_arg, &foo_val, sizeof(foo_val));
        if (rc >= 0) {
            return 0;
        }

        return rc;
    }

    return -ENOENT;
}

struct settings_handler my_conf = {
    .name = "foo",
    .h_set = foo_settings_set
};

int main(void)
{
    settings_subsys_init();
    settings_register(&my_conf);
    settings_load();

    foo_val++;
    settings_save_one("foo/bar", &foo_val, sizeof(foo_val));

    printk("foo: %d\n", foo_val);

    k_msleep(1000);
    sys_reboot(SYS_REBOOT_COLD);
}
```

Example: Custom Backend Implementation

This is a simple example showing how to register a simple custom backend handler (`CONFIG_SETTINGS_CUSTOM`).

```
static int settings_custom_load(struct settings_store *cs,
                                const struct settings_load_arg *arg)
{
    //...
```

(continues on next page)

(continued from previous page)

```
}

static int settings_custom_save(struct settings_store *cs, const char *name,
                                const char *value, size_t val_len)
{
    //...
}

/* custom backend interface */
static struct settings_store_itf settings_custom_itf = {
    .csi_load = settings_custom_load,
    .csi_save = settings_custom_save,
};

/* custom backend node */
static struct settings_store settings_custom_store = {
    .cs_itf = &settings_custom_itf
};

int settings_backend_init(void)
{
    /* register custom backend */
    settings_dst_register(&settings_custom_store);
    settings_src_register(&settings_custom_store);
    return 0;
}
```

4.5.10 Stream Flash

The Stream Flash module takes contiguous fragments of a stream of data (e.g. from radio packets), aggregates them into a user-provided buffer, then when the buffer fills (or stream ends) writes it to a raw flash partition. It supports providing the read-back buffer to the client to use in validating the persisted stream content.

One typical use of a stream write operation is when receiving a new firmware image to be used in a DFU operation.

There are several reasons why one might want to use buffered writes instead of writing the data directly as it is made available. Some devices have hardware limitations which does not allow flash writes to be performed in parallel with other operations, such as radio RX and TX. Also, fewer write operations result in faster response times seen from the application.

Persistent stream write progress

Some stream write operations, such as DFU operations, may run for a long time. When performing such long running operations it can be useful to be able to save the stream write progress to persistent storage so that the operation can resume at the same point after an unexpected interruption.

The Stream Flash module offers an API for loading, saving and clearing stream write progress to persistent storage using the *Settings* module. The API can be enabled using `CONFIG_STREAM_FLASH_PROGRESS`.

API Reference

Stream to flash interface

4.5.11 Zephyr Memory Storage (ZMS)

Zephyr Memory Storage is a new key-value storage system that is designed to work with all types of non-volatile storage technologies. It supports classical on-chip NOR flash as well as new technologies like RRAM and MRAM that do not require a separate erase operation at all, that is, data on these types of devices can be overwritten directly at any time.

General behavior

ZMS divides the memory space into sectors (minimum 2), and each sector is filled with key-value pairs until it is full.

The key-value pair is divided into two parts:

- The key part is written in an ATE (Allocation Table Entry) called “ID-ATE” which is stored starting from the bottom of the sector.
- The value part is defined as “data” and is stored raw starting from the top of the sector.

Additionally, for each sector we store at the last positions header ATEs which are ATEs that are needed for the sector to describe its status (closed, open) and the current version of ZMS.

When the current sector is full we verify first that the following sector is empty, we garbage collect the sector N+2 (where N is the current sector number) by moving the valid ATEs to the N+1 empty sector, we erase the garbage-collected sector and then we close the current sector by writing a garbage_collect_done ATE and the close ATE (one of the header entries). Afterwards we move forward to the next sector and start writing entries again.

This behavior is repeated until it reaches the end of the partition. Then it starts again from the first sector after garbage collecting it and erasing its content.

Composition of a sector A sector is organized in this form (example with 3 sectors):

Sector 0 (closed)	Sector 1 (open)	Sector 2 (empty)
Data_a0	Data_b0	Data_c0
Data_a1	Data_b1	Data_c1
Data_a2	Data_b2	Data_c2
GC_done	.	.
.	.	.
.	.	.
.	ID ATE_b2	ID ATE_c2
ID ATE_a2	ID ATE_b1	ID ATE_c1
ID ATE_a1	ID ATE_b0	ID ATE_c0
ID ATE_a0	GC_done ATE	GC_done ATE
Close ATE (cyc=1)	Close ATE (cyc=1)	Close ATE (cyc=1)
Empty ATE (cyc=1)	Empty ATE (cyc=2)	Empty ATE (cyc=2)

Definition of each element in the sector `Empty ATE` is written when erasing a sector (last position of the sector).

`Close ATE` is written when closing a sector (second to last position of the sector).

`GC_done ATE` is written to indicate that the next sector has already been garbage-collected. This ATE could be at any position of the sector.

`ID ATE` contains a key of type `zms_id_t` and describes where the data is stored, its size and its CRC32.

`Data` is the actual value associated to the ID-ATE.

How does ZMS work?

Mounting the storage system Mounting the storage system starts by getting the flash parameters, checking that the file system properties are correct (sector_size, sector_count ...) then calling the zms_init function to make the storage ready.

By default, `zms_mount()` returns an error if the partition cannot be mounted. For recovery-oriented use cases, `zms_mount_force()` can be used to automatically wipe and reinitialize the partition when the first mount attempt fails.

Mount flags ZMS mount behavior can be controlled with optional flags in `zms_fs.mount_flags`.

- Default behavior (no optional flags set, `mount_flags = 0`): if the partition is erased and no valid ZMS header is found, `zms_mount()` formats the partition by creating the initial ZMS header.
- `ZMS_MOUNT_FLAG_NO_FORMAT`: if the partition is erased and no valid ZMS header is found, `zms_mount()` does not format the partition and returns `-ENOTSUP`.

To mount the filesystem the following elements in the `zms_fs` structure must be initialized:

```
struct zms_fs {
        /** File system offset in flash **/
        off_t offset;

        /** Storage system is split into sectors, each sector size must be␣
↪multiple of
```

(continues on next page)

(continued from previous page)

```
         * erase-blocks if the device has erase capabilities
         */
        uint32_t sector_size;
        /** Number of sectors in the file system */
        uint32_t sector_count;

        /** Optional mount behavior flags (enum zms_mount_flags) */
        uint32_t mount_flags;

        /** Flash device runtime structure */
        const struct device *flash_device;
};
```

Initialization As ZMS has a fast-forward write mechanism, it must find the last sector and the last pointer of the entry where it stopped the last time. It must look for a closed sector followed by an open one, then within the open sector, it finds (recovers) the last written ATE. After that, it checks that the sector after this one is empty, or it will erase it.

ZMS ID/data write To avoid rewriting the same data with the same ID again, ZMS must look in all the sectors if the same ID exists and then compares its data. If the data is identical, no write is performed. If it must perform a write, then an ATE and the data (if the operation is not a delete) are written in the sector. If the sector is full (cannot hold the current data + ATE), ZMS has to move to the next sector, garbage collect the sector after the newly opened one then erase it.

ZMS ID/data read (with history) By default ZMS looks for the last data with the same ID by browsing through all stored ATEs from the most recent ones to the oldest ones. If it finds a valid ATE with a matching ID it retrieves its data and returns the number of bytes that were read. If a history count is provided and different than 0, older data with same ID is retrieved.

ZMS entry enumeration (iterator API) Applications can enumerate stored entries without supplying a predefined list of IDs. This is useful when IDs are derived from payload data (for example packed addresses) and the application does not keep a separate index in flash.

This API family is generally used at boot, when the application rebuilds its in-memory state from the ID/length metadata persisted in ZMS.

The iterator API consists of:

- `zms_iter_init()` to initialize iterator state.
- `zms_iter_init_with_config()` to initialize iterator state with optional ID mask and inclusive ID range and predicate filters.
- `zms_iter_next()` to retrieve one live entry (unique ID) at a time.
- `zms_iter_next_all()` to retrieve all matching entries (full history, including delete markers).

Choosing between `zms_iter_next()` and `zms_iter_next_all()`

- `zms_iter_next()` returns unique live `(id, len)` pairs:
  - Sector/header entries are skipped.
  - Delete markers (entries with `len == 0`) are skipped.
  - If the same ID appears multiple times in storage history, only the newest valid occurrence is returned.

  - To guarantee uniqueness, ZMS checks for newer entries of each candidate ID, which can require additional scanning.
- `zms_iter_next_all()` is faster and returns all matching `(id, len)` pairs as encountered:
  - Historical entries for the same ID are returned.
  - Delete markers (entries with `len == 0`) are returned.
  - No uniqueness filtering is performed.
  - The application is responsible for filtering/compacting the returned pairs according to its own policy.

  Use `zms_iter_init_with_config()` when you want to enumerate only IDs matching a bitmask, a specific inclusive ID range, a predicate callback, or any combination of those filters.

Iterator return values Calling either `zms_iter_next()` or `zms_iter_next_all()` returns:

- `1` when an entry is found; output arguments contain ID and data length.
- `0` when there are no more entries to enumerate.
- Negative errno on error (for example `-EINVAL`, `-EIO`, `-ENXIO`).

The iterator always reports metadata (ID and length). In addition, when the caller provides a non-NULL `data` buffer, the iterator also copies the entry's content directly into it, but only for entries small enough to be stored inside the ATE. For larger entries, or when no buffer is provided, the data must be read explicitly using `zms_read()` for the latest value, or `zms_read_hist()` for older revisions.

Concurrency and snapshot behavior The iterator captures a traversal boundary when `zms_iter_init()` is called. Entries written after initialization are not part of that traversal.

Do not call `zms_write()` (including delete operations) on the same `zms_fs` between two iterator-step calls (`zms_iter_next()` or `zms_iter_next_all()`). If a write triggers garbage collection while iterating, iterator behavior is undefined. This rule applies to the thread doing the iteration regardless of locking: taking the lock described below only keeps *other* threads from writing during the traversal.

Locking out concurrent writers `zms_fs` exposes its internal write lock as a plain `struct k_mutex zms_lock` field. `zms_write()` and `zms_delete()` take this mutex internally for the duration of the write. An application with multiple threads sharing the same `zms_fs` can hold this same mutex across an entire iteration to block writes from *other* threads for as long as the traversal boundary must stay valid:

```
k_mutex_lock(&fs.zms_lock, K_FOREVER);

rc = zms_iter_init(&fs, &iter);
/* ... */

while ((rc = zms_iter_next(&fs, &iter, &id, &len, NULL, 0)) == 1) {
  /* ... */
}

k_mutex_unlock(&fs.zms_lock);
```

Usage example

```
struct zms_iter iter;
bool predicate_id_not_2(zms_id_t id)
```

(continues on next page)

(continued from previous page)

```
{
  return id != (zms_id_t)2;
}

struct zms_iter_config iter_config = {
  .mask_id = (zms_id_t)0x03,
  .min_id = (zms_id_t)0x01,
  .max_id = (zms_id_t)0x03,
  .use_mask = true,
  .use_range = true,
  .use_predicate = true,
  .predicate_func = predicate_id_not_2,
};
zms_id_t id;
size_t len;
uint8_t data[ZMS_DATA_IN_ATE_SIZE];
int rc;

/* Block writes from other threads for the duration of the traversal. */
k_mutex_lock(&fs.zms_lock, K_FOREVER);

rc = zms_iter_init_with_config(&fs, &iter, &iter_config);
if (rc) {
  /* handle error */
}

while ((rc = zms_iter_next(&fs, &iter, &id, &len, data, sizeof(data))) == 1) {
  /* id: entry ID matching configured mask/range/predicate, len: current stored␣
↪size */
  /* data: filled with the entry's content when it is small enough to be
   * stored directly inside the ATE; otherwise left untouched, in which case
   * zms_read() must be used to fetch it.
   */
  printk("id=0x%llx len=%zu\n", (unsigned long long)id, len);
}

k_mutex_unlock(&fs.zms_lock);

if (rc < 0) {
  /* handle iterator error */
}
```

The optional `data`/`data_len` arguments can be set to `NULL`/`0` when only the `(id, len)` pairs are needed. When a buffer is provided, only the data that ZMS stores directly inside the ATE is copied; larger entries must still be retrieved with `zms_read()`.

Zero-initialize `zms_iter_config` or leave `use_mask`, `use_range`, and `use_predicate` disabled to keep the default behavior: accept all IDs and the full `zms_id_t` range.

To determine how many revisions exist for an ID returned by the iterator, call `zms_read_hist()` with increasing `cnt` until `-ENOENT` is returned.

ZMS free space calculation ZMS can also return the free space remaining in the partition. However, this operation is very time-consuming as it needs to browse through all valid ATEs in all sectors of the partition and for each valid ATE try to find if an older one exists. It is not recommended for applications to use this function often, as it is time-consuming and could slow down the calling thread.

The cycle counter Each sector has a lead cycle counter which is a `uint8_t` that is used to validate all the other ATEs. The lead cycle counter is stored in the empty ATE. To become valid, an ATE must have the same cycle counter as the one stored in the empty ATE. Each time an ATE is moved from a sector to another it must get the cycle counter of the destination sector. To erase a sector, the cycle counter of the empty ATE is incremented and a single write of the empty ATE is done. All the ATEs in that sector become invalid.

Closing sectors To close a sector a close ATE is added at the end of the sector and it must have the same cycle counter as the empty ATE. When closing a sector, all the remaining space that has not been used is filled with garbage data to avoid having old ATEs with a valid cycle counter.

Triggering garbage collection Some applications need to make sure that storage writes have a maximum defined latency. When calling ZMS to make a write, the current sector could be almost full such that ZMS needs to trigger the GC to switch to the next sector. This operation is time-consuming and will cause some applications to not meet their real time constraints. ZMS adds an API for the application to get the current remaining free space in a sector. The application could then decide when to switch to the next sector if the current one is almost full. This will of course trigger the garbage collection operation on the next sector. This will guarantee the application that the next write won't trigger the garbage collection.

ATE (Allocation Table Entry) structure An entry uses 16 bytes to encode its information. The exact structure is determined by ATE format which can be selected for a given application.

ZMS defines multiple ATE formats tailored for different feature sets. At runtime, it recognizes the format using the metadata field in empty ATEs, which has the same byte position in all formats.

Table 53: Entry format for 32-bit IDs

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
crc8	cycle_cnt	len		id				data (if len <= 8)							
								offset				data_crc			
												metadata			

This is the default format which is captured in the API documentation for `zms_ate`. The `data_crc` is optionally included to integrity-check data stored at the top of the sector.

Note

The CRC of the data is checked only when a full read of the data is made. The CRC of the data is not checked for a partial read, as it is computed for the whole element.

Warning

Enabling the CRC feature on previously existing ZMS content that did not have it enabled will make all existing data invalid.

Table 54: Entry format for 64-bit IDs

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
crc8	cycle_cnt	len		id								data (if len <= 4)			
												offset			
												metadata			

This format is selected when `CONFIG_ZMS_ID_64BIT` is enabled.

Warning

Selecting a different ATE format than the one used by previously existing ZMS content will make all existing data invalid.

Note

The ZMS backend for *Settings* does not support this format.

Available space for user data (key-value pairs)

ZMS always needs an empty sector to be able to perform the garbage collection (GC). So, if we suppose that 4 sectors exist in a partition, ZMS will only use 3 sectors to store key-value pairs and keep one sector empty to be able to perform GC. The empty sector will rotate between the 4 sectors in the partition.

Note

The maximum single data length that can be written at once in a sector is 64K (this could change in future versions of ZMS).

Small data values Values which are sufficiently small will be stored within the entry (ATE) itself, without writing data at the top of the sector. The amount of data that can fit inside the entry depends on its selected format. See the *ATE structure* section.

ZMS has an entry size of 16 bytes which means that the maximum available space in a partition to store data is computed in this scenario as:

$$\frac{(NUM_SECTORS - 1) \times (SECTOR_SIZE - (5 \times ATE_SIZE)) \times (DATA_SIZE)}{ATE_SIZE}$$

Where:

`NUM_SECTOR`: Total number of sectors

`SECTOR_SIZE`: Size of the sector

`ATE_SIZE`: 16 bytes

`(5 * ATE_SIZE)`: Reserved ATEs for header and delete items

`DATA_SIZE`: 8 bytes or 4 bytes depending on the ATE format

For example for 4 sectors of 1024 bytes, with the default ATE format, free space for 8-byte length data is $\frac{3 \times 944 \times 8}{16} = 1416$ bytes.

Large data values Values exceeding `DATA_SIZE` are stored outside of the ATE at the top of the sector. In this case, it is hard to estimate the free available space, as this depends on the size of the data. But we can take into account that for N bytes of data added at the top of the sector, an additional 16 bytes of ATE must be added at the bottom of the sector, which adds up to $N + 16$ bytes for the key-value pair.

Let's take an example:

For a partition that has 4 sectors of 1024 bytes and for data size of 64 bytes. Only 3 sectors are available for writes with a capacity of 944 bytes each, which makes it possible to store 11 key-value pairs in each sector ($\frac{944}{64+16}$). Total data that could be stored in this partition for this case is $11 \times 3 \times 64 = 2112$ bytes.

Available space calculator

Wear leveling

This storage system is optimized for devices that do not require an erase. Storage systems that rely on an erase value (NVS as an example) need to emulate the erase with write operations. This causes a significant decrease in the life expectancy of these devices as well as more delays for write operations and initialization of the device when it is empty. ZMS uses a cycle count mechanism that avoids emulating erase operations for these devices. It also guarantees that every memory location is written only once for each cycle of sector write.

As an example, to erase a 4096-byte sector on devices that do not require an erase operation using NVS, 256 flash writes must be performed (supposing that `write-block-size` = 16 bytes), while using ZMS, only 1 write of 16 bytes is needed. This operation is 256 times faster in this case.

The garbage collection operation also reduces the memory cell life expectancy as it performs write operations when moving blocks from one sector to another. To make the garbage collector not affect the life expectancy of the device it is recommended to dimension the partition appropriately. Its size should be the double of the maximum size of data (including headers) that could be written in the storage.

See *Available space for user data*.

Device lifetime calculation Storage devices, whether they are classical flash or new technologies like RRAM/MRAM, have a limited life expectancy which is determined by the number of times memory cells can be erased/written. Flash devices are erased one page at a time as part of their functional behavior (otherwise memory cells cannot be overwritten), and for storage devices that do not require an erase operation, memory cells can be overwritten directly.

A typical scenario is shown here to calculate the life expectancy of a device: Let's suppose that we store a 4-byte variable using the same ID but its content changes every minute. The partition has 4 sectors with 1024 bytes each. Each write of the variable requires 16 bytes of storage. As we have 944 bytes available for ATEs for each sector, and because ZMS is a fast-forward storage system, we are going to rewrite the first location of the first sector after $\frac{(944 \times 4)}{16} = 236$ minutes.

In addition to the normal writes, the garbage collector will move the data that is still valid from old sectors to new ones. As we are using the same ID and a big partition size, no data will be moved by the garbage collector in this case. For storage devices that can be written 20 000 times, the storage will last about 4 720 000 minutes (~9 years).

To make a more general formula we must first compute the effective used size in ZMS by our typical set of data. For ID/data pairs with *small data*, `effective_size` is `16` bytes, while for *large data*, `effective_size` is `16 + sizeof(data)` bytes. Let's suppose that `total_effective_size` is the total size of the data that is written in the storage and that the partition is sized appropriately (double of the effective size) to avoid having the garbage collector moving blocks all the time.

The expected lifetime of the device in minutes is computed as:

$$\frac{(SECTOR_EFFECTIVE_SIZE \times SECTOR_NUMBER \times MAX_NUM_WRITES)}{(TOTAL_EFFECTIVE_SIZE \times WR_MIN)}$$

Where:

`SECTOR_EFFECTIVE_SIZE`: The sector size - header size (80 bytes)

`SECTOR_NUMBER`: The number of sectors

`MAX_NUM_WRITES`: The life expectancy of the storage device in number of writes

`TOTAL_EFFECTIVE_SIZE`: Total effective size of the set of written data

`WR_MIN`: Number of writes of the set of data per minute

Device lifetime calculator

Features

ZMS has introduced many features compared to existing storage system like NVS and will evolve from its initial version to include more features that satisfies new technologies requirements such as low latency and bigger storage space.

Existing features

Version 1

- Supports storage devices that do not require an erase operation (only one write operation to invalidate a sector)
- Supports large partition and sector sizes (64-bit address space)
- Supports 32-bit IDs and 64-bit IDs
- Small data values are stored in the ATE itself
- Built-in data CRC32 (included in the ATE)
- Versioning of ZMS (to handle future evolutions)
- Supports large `write-block-size` (only for platforms that need it)
- Supports multiple ATE formats to satisfy the requirements of different applications
- Supports forced mount recovery via `zms_mount_force()` (automatic partition wipe and reinitialization on mount failure)
- Supports a lookup cache to speed up repeated ID lookups with optional per-instance cache configuration to customize the cache size on a per-partition basis
- Supports live-entry enumeration without predeclared ID lists via `zms_iter_init()` and `zms_iter_next()`

Future features

- Add the possibility to mount multiple filesystems with different ATE formats (currently, all filesystems in the same application must use the same format)
- Add the possibility to skip garbage collector for some application usage where ID/value pairs are written periodically and do not exceed half of the partition size (there is always an old entry with the same ID).
- Divide IDs into namespaces and allocate IDs on demand from application to handle collisions between IDs used by different subsystems or samples.
- Add the possibility to retrieve the wear out value of the device based on the cycle count value
- Add a recovery function that can recover a storage partition if something went wrong
- Add a library/application to allow migration from NVS entries to ZMS entries

ZMS and other storage systems in Zephyr This section describes ZMS in the wider context of storage systems in Zephyr (not full filesystems, but simpler, non-hierarchical ones). Today Zephyr includes at least two other systems that are somewhat comparable in scope and functionality: *NVS* and *FCB*. Which one to use in your application will depend on your needs and the hardware you are using, and this section provides information to help make a choice.

- If you are using devices that do not require an erase operation like RRAM or MRAM, *ZMS* is definitely the best fit for your storage subsystem as it is designed to avoid emulating erase operation using large block writes for these devices and replaces it with a single write call.
- For devices that have a large `write_block_size` and/or need a sector size that is different than the classical flash page size (equal to erase_block_size), *ZMS* is also the best fit as there is the possibility to customize these parameters and add the support of these devices in ZMS.
- For classical flash technology devices, *NVS* is recommended as it has low footprint (smaller ATEs and smaller header ATEs). Erasing flash in NVS is also very fast and do not require an additional write operation compared to ZMS. For these devices, NVS reads/writes will be faster as well than ZMS as it has smaller ATE size.
- If your application needs more than 64K IDs for storage, *ZMS* is recommended here because the ID field is up to 64-bit.
- If your application is working in a FIFO mode (First-in First-out) then *FCB* is the best storage solution for this use case.

More generally to make the right choice between NVS and ZMS, all the blockers should be first verified to make sure that the application could work with one subsystem or the other, then if both solutions could be implemented, the best choice should be based on the calculations of the life expectancy of the device described in this section: *Wear leveling*.

Recommendations to increase performance

Sector size and count

- The total size of the storage partition should be set appropriately to achieve the best performance with ZMS. All the information regarding the effectively available free space in ZMS can be found in the documentation. See *Available space for user data*. It's recommended to choose a storage partition size that is double the size of the key-value pairs that will be written in the storage.
- The sector size needs to be set such that a sector can fit the maximum data size that will be stored. Increasing the sector size will slow down the garbage collection operation and make it occur less frequently. Decreasing its size, on the opposite, will make the garbage collection operation faster but also occur more frequently.
- For some subsystems like *Settings*, all path-value pairs are split into two ZMS entries (ATEs). The headers needed by the two entries should be accounted for when computing the needed storage space.
- Using *small data values* can increase the performance, as this data is written within the entry. For example, for the *Settings* subsystem, choosing a path name that is less than or equal to 8 bytes can make reads and writes faster.

Cache size

- When using the ZMS API directly, the recommendation for the cache size is to make it at least equal to the number of different entries that will be written in the storage.
- Each additional cache entry will add 8 bytes to your RAM usage. Cache size should be carefully chosen.

- If you use ZMS through *Settings*, you have to take into account that each Settings entry is divided into two ZMS entries. The recommendation for the cache size is to make it at least twice the number of Settings entries.

Manual per-instance cache When `CONFIG_ZMS_LOOKUP_CACHE_MANUAL` is enabled, each `zms_fs` instance can provide its own lookup cache buffer instead of using the global `CONFIG_ZMS_LOOKUP_CACHE_SIZE` setting.

Call `zms_set_lookup_cache()` before `zms_mount()` to assign the cache buffer for that instance. If no buffer is assigned, the lookup cache remains disabled for that `zms_fs` instance.

```
static struct zms_fs zms_a;
static struct zms_fs zms_b;
static uint64_t zms_a_cache[512];
static uint64_t zms_b_cache[32];

zms_set_lookup_cache(&zms_a, zms_a_cache, ARRAY_SIZE(zms_a_cache));
zms_set_lookup_cache(&zms_b, zms_b_cache, ARRAY_SIZE(zms_b_cache));
```

ID size

- The 64-bit ID space is expected to be larger than necessary for most applications. Unless you have a particular need for this, it's recommended to stick with 32-bit IDs. This is expected to have a slight impact on code size and performance, even on 64-bit systems, because the byte position of IDs in storage is not aligned to an 8-byte boundary.

API Reference

The ZMS API is provided by `zms.h`:

Memory Management

4.6 Memory Management

This section covers services for managing memory and data buffers, including dynamic allocation, memory attributes and mappings, and network-style buffer pools.

4.6.1 Memory Attributes

It is possible in the devicetree to mark the memory regions with attributes by using the `zephyr,memory-attr` property. This property and the related memory region can then be retrieved at run-time by leveraging a provided helper library.

The set of general attributes that can be specified in the property are defined and explained in include/zephyr/dt-bindings/memory-attr/memory-attr.h.

For example, to mark a memory region in the devicetree as non-volatile, cacheable, out-of-order:

```
mem: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-attr = <(DT_MEM_NON_VOLATILE | DT_MEM_CACHEABLE | DT_MEM_OOO)>;
};
```

Note

The `zephyr,memory-attr` usage does not result in any memory region actually created. When it is needed to create an actual section out of the devicetree defined memory region, it is possible to use the compatible `zephyr,memory-region` that will result (only when supported by the architecture) in a new linker section and region.

The `zephyr,memory-attr` property can also be used to set architecture-specific and software-specific custom attributes that can be interpreted at run time. This is leveraged, among other things, to create MPU regions out of devicetree defined memory regions, for example:

```
mem: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-region = "NOCACHE_REGION";
    zephyr,memory-attr = <DT_MEM_ARM_MPU_RAM_NOCACHE>;
};
```

See include/zephyr/dt-bindings/memory-attr/memory-attr-arm.h and *Memory map and MPU considerations* in the *Arm Cortex-M Developer Guide* for more details about MPU usage. Also see *Caching Basics* for details on how Zephyr handles caching.

The conventional and recommended way to deal and manage with memory regions marked with attributes is by using the provided `mem-attr` helper library by enabling `CONFIG_MEM_ATTR`. When this option is enabled the list of memory regions and their attributes are compiled in a user-accessible array and a set of functions is made available that can be used to query, probe and act on regions and attributes (see next section for more details).

Note

The `zephyr,memory-attr` property is only a descriptive property of the capabilities of the associated memory region, but it does not result in any actual setting for the memory to be set. The user, code or subsystem willing to use this information to do some work (for example creating an MPU region out of the property) must use either the provided `mem-attr` library or the usual devicetree helpers to perform the required work / setting. Note, however, that for some architectures (such as ARM and ARM64) the MPU driver uses this information to properly initialize caching at boot. See `CONFIG_ARM_MPU`, `CONFIG_RISCV_PMP`, etc.

A test for the `mem-attr` library and its usage is provided in `tests/subsys/mem_mgmt/mem_attr/`.

Memory Attributes Heap Allocator

It is possible to leverage the memory attribute property `zephyr,memory-attr` to define and create a set of memory heaps from which the user can allocate memory from with certain attributes / capabilities.

When the `CONFIG_MEM_ATTR_HEAP` is set, every region marked with one of the memory attributes listed in include/zephyr/dt-bindings/memory-attr/memory-attr-sw.h is added to a pool of memory heaps used for dynamic allocation of memory buffers with certain attributes.

Here a non exhaustive list of possible attributes:

```
DT_MEM_SW_ALLOC_CACHE
DT_MEM_SW_ALLOC_NON_CACHE
DT_MEM_SW_ALLOC_DMA
```

For example we can define several memory regions with different attributes and use the appropriate attribute to indicate that it is possible to dynamically allocate memory from those regions:

```
mem_cacheable: memory@10000000 {
    compatible = "mmio-sram";
    reg = <0x10000000 0x1000>;
    zephyr,memory-attr = <(DT_MEM_CACHEABLE | DT_MEM_SW_ALLOC_CACHE)>;
};

mem_non_cacheable: memory@20000000 {
    compatible = "mmio-sram";
    reg = <0x20000000 0x1000>;
    zephyr,memory-attr = <(DT_MEM_NON_CACHEABLE | ATTR_SW_ALLOC_NON_CACHE)>;
};

mem_cacheable_big: memory@30000000 {
    compatible = "mmio-sram";
    reg = <0x30000000 0x10000>;
    zephyr,memory-attr = <(DT_MEM_CACHEABLE | DT_MEM_OOO | DT_MEM_SW_ALLOC_CACHE)>;
};

mem_cacheable_dma: memory@40000000 {
    compatible = "mmio-sram";
    reg = <0x40000000 0x10000>;
    zephyr,memory-attr = <(DT_MEM_CACHEABLE       | DT_MEM_DMA |
                           DT_MEM_SW_ALLOC_CACHE | DT_MEM_SW_ALLOC_DMA)>;
};
```

The user can then dynamically carve memory out of those regions using the provided functions, the library will take care of allocating memory from the correct heap depending on the provided attribute and size:

```
// Init the pool
mem_attr_heap_pool_init();

// Allocate 0x100 bytes of cacheable memory from `mem_cacheable`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_CACHE, 0x100);

// Allocate 0x200 bytes of non-cacheable memory aligned to 32 bytes
// from `mem_non_cacheable`
block = mem_attr_heap_aligned_alloc(ATTR_SW_ALLOC_NON_CACHE, 0x100, 32);

// Allocate 0x100 bytes of cacheable and dma-able memory from `mem_cacheable_dma`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_CACHE | DT_MEM_SW_ALLOC_DMA, 0x100);
```

When several regions are marked with the same attributes, the memory is allocated:

1. From the regions where the `zephyr,memory-attr` property has the requested property (or properties).
2. Among the regions as at point 1, from the smallest region if there is any unallocated space left for the requested size
3. If there is not enough space, from the next bigger region able to accommodate the requested size

The following example shows the point 3:

```
// This memory is allocated from `mem_non_cacheable`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_NON_CACHE, 0x100);

// This memory is allocated from `mem_cacheable_big`
block = mem_attr_heap_alloc(DT_MEM_SW_ALLOC_CACHE, 0x5000);
```

Note

The framework is assuming that the memory regions used to create the heaps are usable by the code and available at init time. The user must take of initializing and setting the memory area before calling `mem_attr_heap_pool_init()`.

That means that the region must be correctly configured in terms of MPU / MMU (if needed) and that an actual heap can be created out of it, for example by leveraging the `zephyr,memory-region` property to create a proper linker section to accommodate the heap.

4.6.2 Network Buffers

- *Overview*
- *Creating buffers*
- *Common Operations*
- *Reference Counting*
- *Ownership*
- *API Reference*

Overview

Network buffers are a core concept of how the networking stack (as well as the Bluetooth stack) pass data around. The API for them is defined in include/zephyr/net_buf.h:.

Creating buffers

Network buffers are created by first defining a pool of them:

```
NET_BUF_POOL_DEFINE(pool_name, buf_count, buf_size, user_data_size, NULL);
```

The pool is a static variable, so if it's needed to be exported to another module a separate pointer is needed.

Once the pool has been defined, buffers can be allocated from it with:

```
buf = net_buf_alloc(&pool_name, timeout);
```

There is no explicit initialization function for the pool or its buffers, rather this is done implicitly as `net_buf_alloc()` gets called.

If there is a need to reserve space in the buffer for protocol headers to be prepended later, it's possible to reserve this headroom with:

```
net_buf_reserve(buf, headroom);
```

In addition to actual protocol data and generic parsing context, network buffers may also contain protocol-specific context, known as user data. Both the maximum data and user data capacity of the buffers is compile-time defined when declaring the buffer pool.

The buffers have native support for being passed through k_fifo kernel objects. Use `k_fifo_put()` and `k_fifo_get()` to pass buffer from one thread to another.

Special functions exist for dealing with buffers in single linked lists, where the `net_buf_slist_put()` and `net_buf_slist_get()` functions must be used instead of `sys_slist_append()` and `sys_slist_get()`.

Common Operations

The network buffer API provides some useful helpers for encoding and decoding data in the buffers. To fully understand these helpers it's good to understand the basic names of operations used with them:

Add
: Add data to the end of the buffer. Modifies the data length value while leaving the actual data pointer intact. Requires that there is enough tailroom in the buffer. Some examples of APIs for adding data:

```
void *net_buf_add(struct net_buf *buf, size_t len);
void *net_buf_add_mem(struct net_buf *buf, const void *mem, size_t len);
uint8_t *net_buf_add_u8(struct net_buf *buf, uint8_t value);
void net_buf_add_le16(struct net_buf *buf, uint16_t value);
void net_buf_add_le32(struct net_buf *buf, uint32_t value);
```

Remove
: Remove data from the end of the buffer. Modifies the data length value while leaving the actual data pointer intact. Some examples of APIs for removing data:

```
void *net_buf_remove_mem(struct net_buf *buf, size_t len);
uint8_t net_buf_remove_u8(struct net_buf *buf);
uint16_t net_buf_remove_le16(struct net_buf *buf);
uint32_t net_buf_remove_le32(struct net_buf *buf);
```

Push
: Prepend data to the beginning of the buffer. Modifies both the data length value as well as the data pointer. Requires that there is enough headroom in the buffer. Some examples of APIs for pushing data:

```
void *net_buf_push(struct net_buf *buf, size_t len);
void *net_buf_push_mem(struct net_buf *buf, const void *mem, size_t len);
void net_buf_push_u8(struct net_buf *buf, uint8_t value);
void net_buf_push_le16(struct net_buf *buf, uint16_t value);
```

Pull
: Remove data from the beginning of the buffer. Modifies both the data length value as well as the data pointer. Some examples of APIs for pulling data:

```
void *net_buf_pull(struct net_buf *buf, size_t len);
void *net_buf_pull_mem(struct net_buf *buf, size_t len);
uint8_t net_buf_pull_u8(struct net_buf *buf);
uint16_t net_buf_pull_le16(struct net_buf *buf);
uint32_t net_buf_pull_le32(struct net_buf *buf);
```

The Add and Push operations are used when encoding data into the buffer, whereas the Remove and Pull operations are used when decoding data from a buffer.

Reference Counting

Each network buffer is reference counted. The buffer is initially acquired from a free buffers pool by calling `net_buf_alloc()`, resulting in a buffer with reference count 1. The reference count can be incremented with `net_buf_ref()` or decremented with `net_buf_unref()`. When the count drops to zero the buffer is automatically placed back to the free buffers pool.

Ownership

Each reference to a buffer has exactly one owner. The owner either releases its reference with `net_buf_unref()` or moves it to a new owner, such as a FIFO, a list or a function that takes ownership of the buffer. After the move the previous owner must no longer use the buffer, unless it holds another reference of its own.

A fragment chain is owned through its head. Each buffer in the chain owns a reference to the next fragment and releases it when the buffer itself is freed, so releasing the last reference to the head releases the chain up to the first fragment that is still referenced elsewhere. `net_buf_frag_insert()` takes ownership of the fragment it is given, and so does `net_buf_frag_add()` when the head is not `NULL`. With a `NULL` head, `net_buf_frag_add()` returns the fragment with a new reference and the caller keeps its own.

A function or callback that is given a buffer does one of the following with the reference, and its documentation should say which:

Borrows
: The function may use the buffer until it returns, but may neither keep nor move it. To keep a borrowed buffer, it acquires a reference of its own with `net_buf_ref()` first.

Takes ownership
: The reference moves to the function on every return, errors included.

Takes ownership on success
: The reference moves only if the function succeeds. On error the caller still owns the buffer.

Two helpers operate on the pointer that holds a reference, so that the previous owner is left with `NULL` instead of a pointer to a buffer it no longer owns. `net_buf_take()` moves the reference out of the pointer, and `net_buf_drop()` releases it. `net_buf_drop()` is meant for a pointer that outlives the release, such as a structure member, or one that may already be `NULL`. A local pointer that holds a reference as it goes out of scope only needs `net_buf_unref()`.

Putting a buffer in a FIFO or a list moves the reference to the queue. The receiving side may process and free the buffer even before `k_fifo_put()` returns, for instance when a higher-priority thread is waiting on the FIFO. Move the reference with `net_buf_take()` in the same expression:

```
k_fifo_put(&tx_queue, net_buf_take(&buf));
```

Do this even where `buf` goes out of scope right after the call: a plain pointer argument looks the same as one that is only borrowed, while `net_buf_take()` shows at the call site that the reference moves.

Passing `net_buf_take(&buf)` as an argument only works for calls that always take ownership, such as `k_fifo_put()`, `net_buf_slist_put()` and `net_buf_frag_insert()`. When a function that

takes ownership only on success is given a plain pointer, the caller's pointer is unchanged either way, and only the return value tells whether the buffer is still its own.

New functions that take ownership should therefore take a pointer to the caller's buffer pointer, and move the reference out with `net_buf_take()` when they take it. The caller's pointer is then `NULL` exactly when ownership has moved, and `net_buf_drop()` is correct after the call whatever the outcome:

```
int foo_send(struct foo *foo, struct net_buf **buf)
{
    if (!foo->ready) {
        return -EAGAIN;
    }

    k_fifo_put(&foo->tx_queue, net_buf_take(buf));

    return 0;
}

err = foo_send(foo, &buf);
if (err != 0) {
    LOG_WRN("Not sent (err %d)", err);
}

/* Releases the buffer only if foo_send() did not take it */
net_buf_drop(&buf);
```

Changing an existing function to this form breaks its callers, so it is best done when the function is reworked anyway.

Power Management

4.7 Power Management

This section covers services for controlling energy consumption and performance: system and device power management, CPU frequency scaling, controlled shutdown, and cooperative resource lifecycle management.

4.7.1 Power Management

Zephyr RTOS power management subsystem provides several means for a system integrator to implement power management support that can take full advantage of the power saving features of SOCs.

Overview

The interfaces and APIs provided by the power management subsystem are designed to be architecture and SOC independent. This enables power management implementations to be easily adapted to different SOCs and architectures.

The architecture and SOC independence is achieved by separating the core PM infrastructure from implementations of the SOC specific components. Thus a coherent abstraction is presented to the rest of the OS and the application layer.

The power management features are classified into the following categories.

- System Power Management
- Device Power Management

System Power Management

Introduction The kernel enters the idle state when it has nothing to schedule. Enabling `CONFIG_PM` allows the kernel to call upon the power management subsystem to put an idle system into one of the supported power states. The kernel requests an amount of time it would like to suspend, then the PM subsystem decides the appropriate power state to transition to based on the configured power management policy.

It is the application's responsibility to set up a wake-up event. A wake-up event will typically be an interrupt triggered by an SoC peripheral module. Examples include a SysTick, RTC, counter, or GPIO. Keep in mind that depending on the SoC and the power mode in question, not all peripherals may be active, and therefore some wake-up sources may not be usable in all power modes.

The following diagram describes system power management:

The idle thread locks interrupts before calling `pm_system_suspend()` and keeps ownership of the original architecture interrupt key. If the PM subsystem enters a low-power state, PM resume bookkeeping runs with interrupts still locked after any system-managed devices have been resumed, including `pm_state_exit_post_ops()`, PM exit notifications, and system clock idle-exit accounting. After that bookkeeping is complete and `pm_system_suspend()` returns, the idle thread restores the original interrupt key.

Architectures and SoCs that do not select `CONFIG_PM_STATE_SET_IRQ_UNLOCKED` use the architecture hooks immediately around the low-power instruction so that it can still observe a wake event without dispatching the wake-source ISR first. In that mode, `pm_state_set()` and `pm_state_exit_post_ops()` must be used for SoC-specific hardware work only, not as final interrupt unmask points.

When this default contract is used, the interrupt ownership sequence is:

SoC implementations that use this default contract must not unmask interrupts from `pm_state_set()` or `pm_state_exit_post_ops()`. Legacy implementations that still call `irq_unlock(0)`, `arch_irq_unlock(0)`, `__enable_irq()`, or equivalent operations from those hooks must select `CONFIG_PM_STATE_SET_IRQ_UNLOCKED` until they are migrated.

> **Note**
>
> The ordering guarantee above applies only to interrupts that `arch_irq_lock()` can mask. Zero-latency interrupts are outside this ordering. See *Zero Latency Interrupts*.

Power States The power management subsystem defines a set of states described by the power consumption and context retention associated with each of them.

The set of power states is defined by `pm_state`. In general, lower power states (higher index in the enum) will offer greater power savings and have higher wake latencies.

Power Management Policies The power management subsystem supports the following power management policies:

- Residency based
- Application defined

The policy manager is the component of the power management subsystem responsible for deciding which power state the system should transition to. The policy manager can only choose

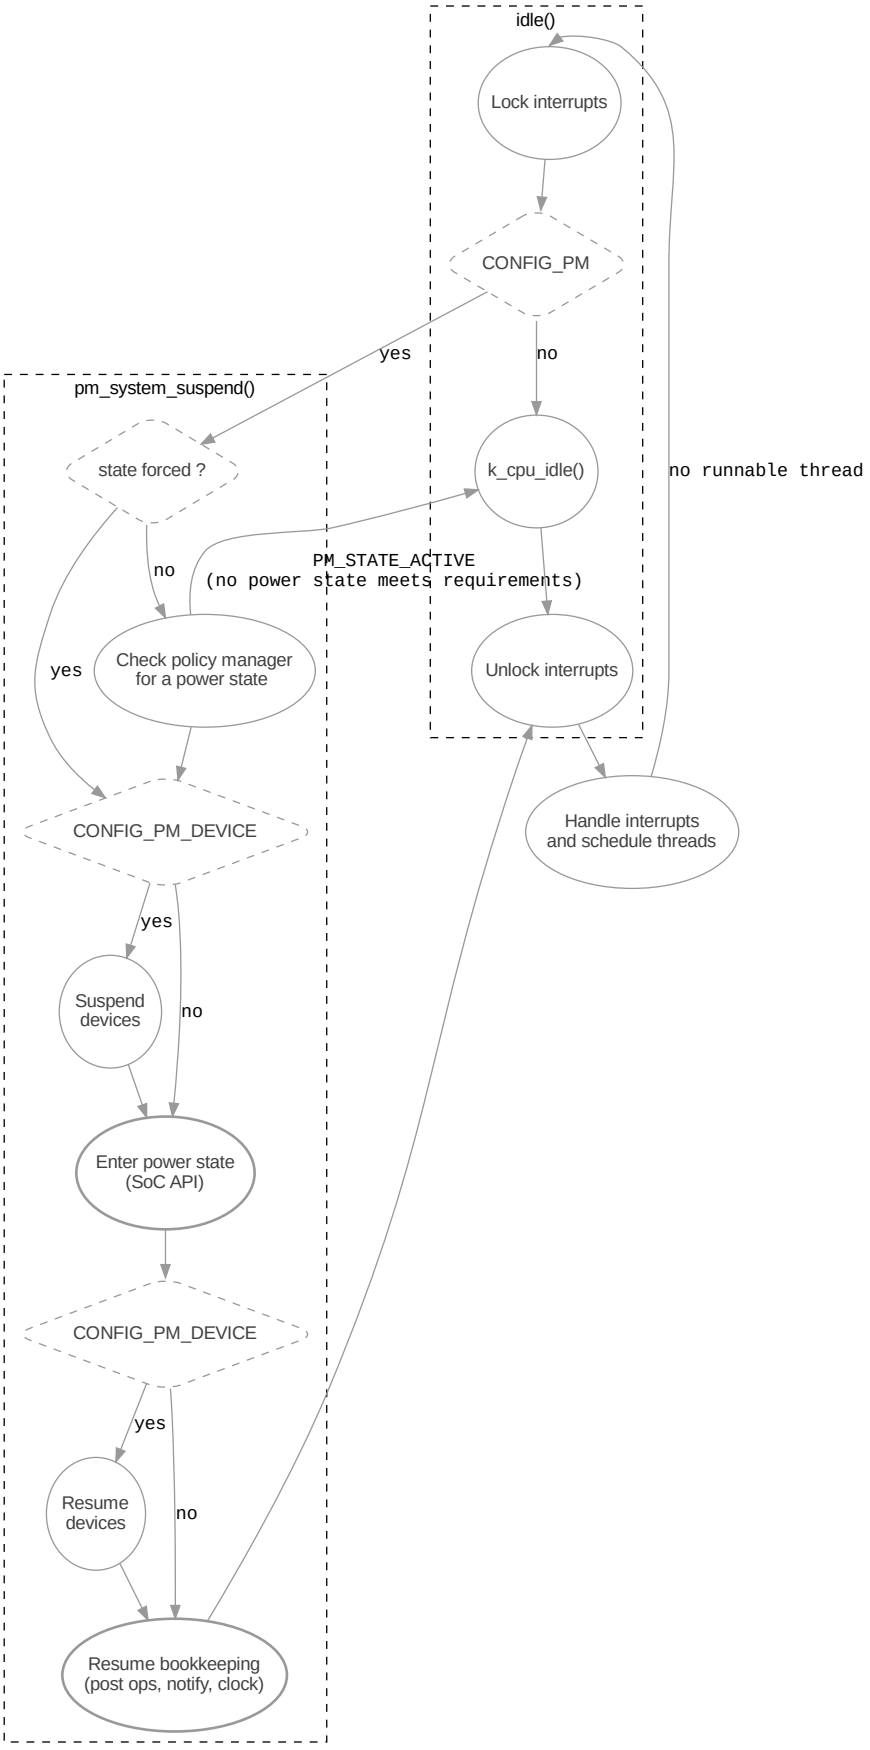

Fig. 38: System power management

Fig. 39: System PM interrupt restore ownership

between states that have been defined for the platform. Other constraints placed upon the decision may include locks disallowing certain power states, or various kinds of minimum and maximum latency values, depending on the policy.

More details on the states definition can be found in the `zephyr,power-state` binding documentation.

Residency Under the residency policy, the system will enter the power state which offers the highest power savings, with the constraint that the sum of the minimum residency value (see `zephyr,power-state`) and the latency to exit the mode must be less than or equal to the system idle time duration scheduled by the kernel.

Thus the core logic can be summarized with the following expression:

```
if (time_to_next_scheduled_event >= (state.min_residency_us + state.exit_latency))
↪{
   return state
}
```

Application The application defines the power management policy by implementing the `pm_policy_next_state()` function. In this policy, the application is free to decide which power state the system should transition to based on the remaining time until the next scheduled timeout.

An example of an application that defines its own policy can be found in tests/subsys/pm/power_mgmt/.

Custom ticks hook In addition to the kernel tick expiration and the PM policy event list, applications and SoC-specific code may need to derive the next wake-up time from proprietary or hardware-specific data sources. Examples include hardware registers, binary-only third-party modules, or complex/legacy data structures that are not practical to model as standard PM policy events.

When `CONFIG_PM_CUSTOM_TICKS_HOOK` is enabled, the PM core calls the optional function `pm_policy_next_custom_ticks()` during `pm_system_suspend()`. The hook returns the ticks to the next custom event, or `K_TICKS_FOREVER` if no custom event needs to be considered.

The PM core then selects the earliest expiration among:

- kernel tick expiration,
- PM policy event list ticks (from `pm_policy_next_event_ticks()`),
- the custom ticks value (from `pm_policy_next_custom_ticks()`).

This mechanism allows boards and applications to integrate additional timing sources into the system power management decisions without modifying the PM event list infrastructure.

Policy and Power States The power management subsystem allows different Zephyr components and applications to configure the policy manager to block the system from transitioning into certain power states. This can be used by devices when executing tasks in background to prevent the system from going to a specific state where it would lose context. See `pm_policy_state_lock_get()`.

Examples Some helpful examples showing different power management features:

- samples/boards/st/power_mgmt/blinky/

- tests/subsys/pm/power_mgmt/
- tests/subsys/pm/power_mgmt_soc/
- tests/subsys/pm/power_states_api/

Device Power Management

Introduction Device Power Management in Zephyr is a feature which presents mechanisms to coherently affect the control of power management actions to be taken by device drivers. This control is based on unambiguous expectations which could be set by any component of the system, and on power-related dependencies that devices may have on each other.

Zephyr supports two methods of device power management:

- *Device Runtime Power Management*
- *System-Managed Device Power Management*

Device Runtime Power Management Device runtime power management involves coordinated interaction between device drivers, subsystems, and applications. While device drivers play a crucial role in directly controlling the power state of devices, the decision to suspend or resume a device can also be influenced by higher layers of the software stack.

Each layer—device drivers, subsystems, and applications—can operate independently without needing to know about the specifics of the other layers because the subsystem uses reference count to check when it needs to suspend or resume a device.

- **Device drivers** are responsible for managing the power state of devices. They interact directly with the hardware to put devices into low-power states (suspend) when they are not in use, and bring them back (resume) when needed. Drivers should use the *device runtime power management APIs* provided by Zephyr to control the power state of devices.
- **Subsystems**, such as sensors, file systems, and network, can also influence device power management. Subsystems may have better knowledge about the overall system state and workload, allowing them to make informed decisions about when to suspend or resume devices. For example, a networking subsystem may decide to keep a network interface powered on if it expects network activity in the near future.
- **Applications** running on Zephyr can impact device power management as well. An application may have specific requirements regarding device usage and power consumption. For example, an application that streams data over a network may need to keep the network interface powered on continuously.

Coordination between device drivers, subsystems, and applications is key to efficient device power management. For example, a device driver may not know that a subsystem will perform a series of sequential operations that require a device to remain powered on. In such cases, the subsystem can use device runtime power management to ensure that the device remains in an active state until the operations are complete.

When using this Device Runtime Power Management, the System Power Management subsystem is able to change power states quickly because it does not need to spend time suspending and resuming devices that are runtime enabled.

For more information, see *Device Runtime Power Management*.

System-Managed Device Power Management The system managed device power management (PM) framework is a method where devices are suspended along with the system entering a CPU (or SoC) power state. It can be enabled by setting `CONFIG_PM_DEVICE_SYSTEM_MANAGED`. When using this method, device power management is mostly done inside `pm_system_suspend()`.

If a decision to enter a CPU lower power state is made, the power management subsystem will check if the selected low power state triggers device power management and then suspend devices before changing state. The subsystem takes care of suspending devices following their initialization order, ensuring that possible dependencies between them are satisfied. As soon as the CPU wakes up from a sleep state, devices are resumed in the opposite order that they were suspended.

The decision about suspending devices when entering a low power state is done based on the state and if it has set the property `zephyr,pm-device-disabled`. Here is an example of a target with two low power states with only one triggering device power management:

```
/* Node in a DTS file */
cpus {
     power-states {
             state0: state0 {
                     compatible = "zephyr,power-state";
                     power-state-name = "standby";
                     min-residency-us = <5000>;
                     exit-latency-us = <240>;
                     zephyr,pm-device-disabled;
             };
             state1: state1 {
                     compatible = "zephyr,power-state";
                     power-state-name = "suspend-to-ram";
                     min-residency-us = <8000>;
                     exit-latency-us = <360>;
             };
     };
};
```

Note

When using *System Power Management*, device transitions can be run from the idle thread. As functions in this context cannot block, transitions that intend to use blocking APIs **must** check whether they can do so with `k_can_yield()`.

This method of device power management can be useful in the following scenarios:

- Systems with no device requiring any blocking operations when suspending and resuming. This implementation is reasonably simpler than device runtime power management.
- For devices that can not make any power management decision and have to be always active. For example a firmware using Zephyr that is controlled by an external entity (e.g Host CPU). In this scenario, some devices have to be always active and should be suspended together with the SoC when requested by this external entity.

It is important to emphasize that this method has drawbacks (see above) and *Device Runtime Power Management* is the **preferred** method for implementing device power management.

Note

When using this method of device power management, the CPU will not enter a low-power state if a device cannot be suspended. For example, if a device returns an error such as `-EBUSY` in response to the `PM_DEVICE_ACTION_SUSPEND` action, indicating it is in the middle of a transaction that cannot be interrupted. Another condition that prevents the CPU from entering a low-power state is if the option `CONFIG_PM_NEED_ALL_DEVICES_IDLE` is set and a device is marked as busy.

Note

Devices are suspended only when the last active core is entering a low power state and devices are resumed by the first core that becomes active.

Device Power Management States The power management subsystem defines device states in `pm_device_state`. This method is used to track power states of a particular device. It is important to emphasize that, although the state is tracked by the subsystem, it is the responsibility of each device driver to handle device actions(`pm_device_action`) which change device state.

Device drivers implement the `pm_device_action_cb_t()` hook internally which receives the `pm_device_action` for the device driver to handle. If the `CONFIG_PM_DEVICE` option is selected, the device drivers implementations of the hooks are exposed to the PM subsystem, enabling runtime power management of the devices.

`pm_device_action` actions have direct and unambiguous relationships with `pm_device_state` states:

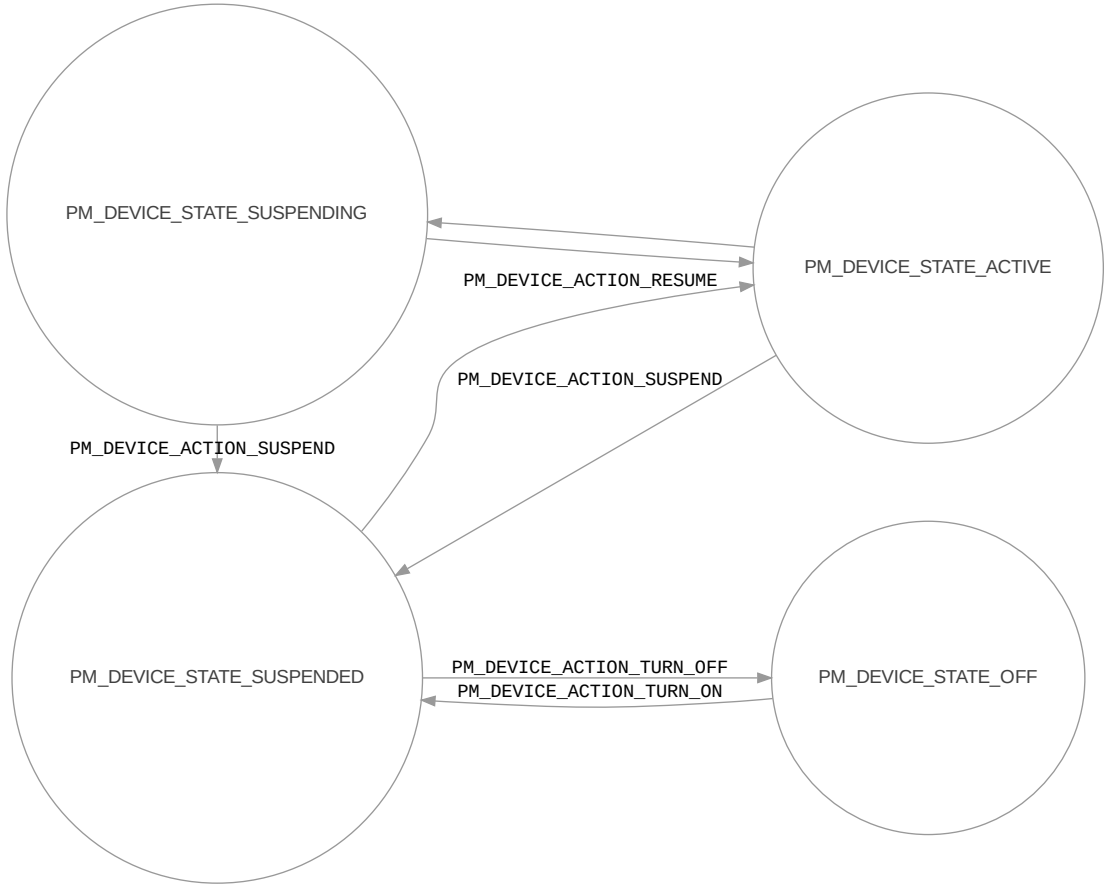

Fig. 40: Device actions x states

As mentioned above, device drivers do not directly change between these states. This is entirely done by the power management subsystem. Instead, drivers are responsible for implementing any hardware-specific tasks needed to handle state changes.

Device Model with Device Power Management Support Drivers initialize devices using macros. See *Device Driver Model* for details on how these macros are used. A driver which implements device power management support must provide these macros with arguments that describe its power management implementation.

Use `PM_DEVICE_DEFINE` or `PM_DEVICE_DT_DEFINE` to define the power management resources required by a driver. These macros allocate the driver-specific context which is required by the power management subsystem.

Drivers can use `PM_DEVICE_GET` or `PM_DEVICE_DT_GET` to get a pointer to this context. These pointers should be passed to `DEVICE_DEFINE` or `DEVICE_DT_DEFINE` to initialize the power management field in each `device`.

The following example code shows how to implement device power management support in a device driver. Note that return values are explicitly ignored for brevity, in real drivers they must be handled.

```
#include <zephyr/pm/device.h>
#include <zephyr/pm/device_runtime.h>

#define DT_DRV_COMPAT dummy_device

struct dummy_driver_data {
        struct gpio_callback int_pin_callback;
        const struct device *dev;
};

struct dummy_driver_config {
        const struct device *bus;
        const struct gpio_dt_spec int_gpio;
        const struct gpio_dt_spec enable_pin;
};

static void dummy_driver_int_pin_handler(const struct device *dev,
                                         struct gpio_callback *cb,
                                         uint32_t pins)
{
        struct dummy_driver_data *dev_data =
                CONTAINER_OF(cb, struct dummy_driver_data, int_pin_callback);
        const struct device *dev = dev_data->dev;
        const struct dummy_driver_config *dev_config = dev->config;

        /* ... */
}

static int dummy_driver_pm_suspend(const struct device *dev)
{

Device Model with Partial Device Power Management Support If CONFIG_PM_DEVICE is not enabled, the device power state is tied to the devices initialization state.

Once a device is initialized, the device driver PM action hook is used to move the device to the expected initial state through calling pm_device_driver_init(). Following the Device actions x states graph and the definition of the OFF state, this results in a call to PM_DEVICE_ACTION_TURN_ON followed by PM_DEVICE_ACTION_RESUME.

If the driver's PM hook returns an error, initialization fails and the device is left in its previous state (for devices that support PM this is typically SUSPENDED or OFF).

Given power domains and buses are "just devices", every power domain and bus will be resumed before its child devices as they are initialized according to the devicetree dependency ordinals. Every device is assumed to be powered, and the devices a device depends on are assumed to be ACTIVE, when device is initialized.

Once a device is deinitialized, the device driver PM action hook is used to move the device to the SUSPENDED state through calling pm_device_driver_deinit(). Following the Device actions x states, and assuming power domains are "always on" this results in a call to PM_DEVICE_ACTION_SUSPEND.

Shell Commands Power management actions can be triggered from shell commands for testing purposes. To do that, enable the CONFIG_PM_DEVICE_SHELL option and issue a pm command on a device from the shell, for example:

```
uart:~$ device list
- buttons (active)
uart:~$ pm suspend buttons
uart:~$ device list
devices:
- buttons (suspended)
```

To print the power management state of a device, enable CONFIG_DEVICE_SHELL and use the device list command, for example:

```
uart:~$ device list
devices:
- i2c@40003000 (active)
- buttons (active, usage=1)
- leds (READY)
```

In this case, `leds` does not support PM, `i2c` supports PM with manual suspend and resume actions and it's currently active, `buttons` supports runtime PM and it's currently active with one user.

Busy Status Indication When the system is idle and the SoC is going to sleep, the power management subsystem can suspend devices, as described in *System-Managed Device Power Management*. This can cause device hardware to lose some states. Suspending a device which is in the middle of a hardware transaction, such as writing to a flash memory, may lead to undefined behavior or inconsistent states. This API guards such transactions by indicating to the kernel that the device is in the middle of an operation and should not be suspended.

When `pm_device_busy_set()` is called, the device is marked as busy and the system will not do power management on it. After the device is no longer doing an operation and can be suspended, it should call `pm_device_busy_clear()`.

Device Power Management X System Power Management When managing power in embedded systems, it's crucial to understand the interplay between device power state and the overall system power state. Some devices may have dependencies on the system power state. For example, certain low-power states of the SoC might not supply power to peripheral devices, leading to problems if the device is in the middle of an operation. Proper coordination is essential to maintain system stability and data integrity.

To avoid this sort of problem, devices must *get and release lock* power states that cause power loss during an operation.

Zephyr provides a mechanism for devices to declare which power states cause power loss and an API that automatically get and put lock on them. This feature is enabled setting `CONFIG_PM_POLICY_DEVICE_CONSTRAINTS` to `y`.

Once this feature is enabled, devices must declare in devicetree which states cause power loss. In the following example, device `test_dev` says that power states `state1` and `state2` cause power loss.

```
power-states {
        state0: state0 {
                compatible = "zephyr,power-state";
                power-state-name = "suspend-to-idle";
                min-residency-us = <10000>;
                exit-latency-us = <100>;
        };

        state1: state1 {
                compatible = "zephyr,power-state";
                power-state-name = "standby";
                min-residency-us = <20000>;
                exit-latency-us = <200>;
        };

        state2: state2 {
                compatible = "zephyr,power-state";
                power-state-name = "suspend-to-ram";
                min-residency-us = <50000>;
                exit-latency-us = <500>;
        };

        state3: state3 {
                compatible = "zephyr,power-state";
                power-state-name = "suspend-to-ram";
                status = "disabled";
        };
```

(continues on next page)

(continued from previous page)

```
};

test_dev: test_dev {
        compatible = "test-device-pm";
        status = "okay";
        zephyr,disabling-power-states = <&state1 &state2>;
};
```

After that devices can lock these state calling `pm_policy_device_power_lock_get()` and release with `pm_policy_device_power_lock_put()`. For example:

```
static void timer_expire_cb(struct k_timer *timer)
{
       struct test_driver_data *data = k_timer_user_data_get(timer);

       data->ongoing = false;
       k_timer_stop(timer);
       pm_policy_device_power_lock_put(data->self);
}

void test_driver_async_operation(const struct device *dev)
{
       struct test_driver_data *data = dev->data;

       data->ongoing = true;
       pm_policy_device_power_lock_get(dev);

       /** Lets set a timer big enough to ensure that any deep
        *  sleep state would be suitable but constraints will
        *  make only state0 (suspend-to-idle) will be used.
        */
       k_timer_start(&data->timer, K_MSEC(500), K_NO_WAIT);
}
```

The same pattern applies to device paths that can produce *zero-latency interrupts*. A zero-latency ISR must not call PM APIs or other kernel APIs. If the ISR depends on resources that are unavailable in some system power states, the normal driver path that arms the interrupt source can hold the device power policy lock while that path is active. The driver should mask or disable the interrupt source before releasing the lock when the path is no longer active.

Wakeup capability Some devices are capable of waking the system up from a sleep state. When a device has such capability, applications can enable or disable this feature on a device dynamically using `pm_device_wakeup_enable()`.

This property can be set on device declaring the property `wakeup-source` in the device node in devicetree. For example, this devicetree fragment sets the `gpio0` device as a "wakeup" source:

```
gpio0: gpio@40022000 {
        compatible = "ti,cc13xx-cc26xx-gpio";
        reg = <0x40022000 0x400>;
        interrupts = <0 0>;
        status = "disabled";
        label = "GPIO_0";
        gpio-controller;
        wakeup-source;
        #gpio-cells = <2>;
};
```

By default, "wakeup" capable devices do not have this functionality enabled during the device initialization. Applications can enable this functionality later calling `pm_device_wakeup_enable()`.

> **Note**
>
> This property is **only** used by the system power management to identify devices that should not be suspended. It is responsibility of driver or the application to do any additional configuration required by the device to support it.

Device Runtime Power Management

Introduction The device runtime power management (PM) framework is an active power management mechanism which reduces the overall system power consumption by suspending the devices which are idle or not used independently of the system state. It can be enabled by setting `CONFIG_PM_DEVICE_RUNTIME`. In this model the device driver is responsible to indicate when it needs the device and when it does not. This information is used to determine when to suspend or resume a device based on usage count.

When device runtime power management is enabled on a device, its state will be initially set to a `PM_DEVICE_STATE_SUSPENDED` indicating it is not used. On the first device request, it will be resumed and so put into the `PM_DEVICE_STATE_ACTIVE` state. The device will remain in this state until it is no longer used. At this point, the device will be suspended until the next device request. If the suspension is performed synchronously the device will be immediately put into the `PM_DEVICE_STATE_SUSPENDED` state, whereas if it is performed asynchronously, it will be put into the `PM_DEVICE_STATE_SUSPENDING` state first and then into the `PM_DEVICE_STATE_SUSPENDED` state when the action is run.

For devices on a power domain (via the devicetree 'power-domains' property), device runtime power management automatically attempts to request and release the dependent domain in response to `pm_device_runtime_get()` and `pm_device_runtime_put()` calls on the child device.

For the previous to automatically control the power domain state, device runtime PM must be enabled on the power domain device. To enable device runtime PM globally, enable `CONFIG_PM_DEVICE_RUNTIME_DEFAULT_ENABLE`. To enable device runtime PM only for select devices, set the `zephyr,pm-device-runtime-auto` devicetree property, or use `pm_device_runtime_enable()` for the select devices.

The device runtime power management framework has been designed to minimize devices power consumption with minimal application work. Device drivers are responsible for indicating when they need the device to be operational and when they do not. Therefore, applications can not manually suspend or resume a device. An application can, however, decide when to disable or enable runtime power management for a device. This can be useful, for example, if an application wants a particular device to be always active.

Design principles When runtime PM is enabled on a device it will no longer be resumed or suspended during system power transitions. Instead, the device is fully responsible to indicate when it needs a device and when it does not. The device runtime PM API uses reference counting to keep track of device's usage. This allows the API to determine when a device needs to be resumed or suspended. The API uses the *get* and *put* terminology to indicate when a device

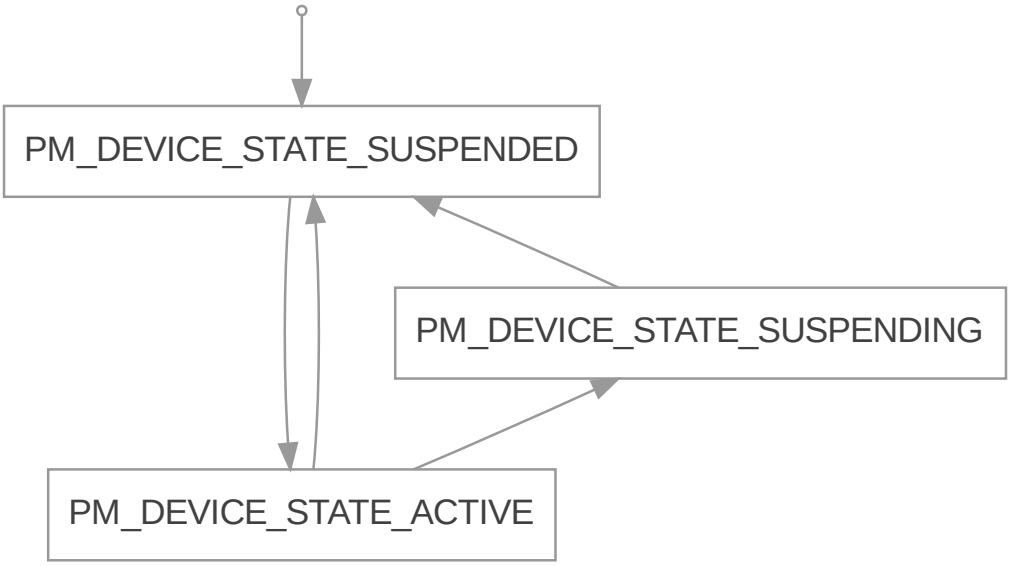

Fig. 41: Device states and transitions

is needed or not, respectively. This mechanism plays a key role when we account for device dependencies. For example, if a bus device is used by multiple sensors, we can keep the bus active until the last sensor has finished using it.

Note

As of today, the device runtime power management API does not manage device dependencies. This effectively means that, if a device depends on other devices to operate (e.g. a sensor may depend on a bus device), the bus will be resumed and suspended on every transaction. In general, it is more efficient to keep parent devices active when their children are used, since the children may perform multiple transactions in a short period of time. Until this feature is added, devices can manually *get* or *put* their dependencies.

The `pm_device_runtime_get()` function can be used by a device driver to indicate it *needs* the device to be active or operational. This function will increase device usage count and resume the device if necessary. Similarly, the `pm_device_runtime_put()` function can be used to indicate that the device is no longer needed. This function will decrease the device usage count and suspend the device if necessary. It is worth to note that in both cases, the operation is carried out synchronously. The sequence diagram shown below illustrates how a device can use this API and the expected sequence of events.

The synchronous model is as simple as it gets. However, it may introduce unnecessary delays since the application will not get the operation result until the device is suspended (in case device is no longer used). It will likely not be a problem if the operation is fast, e.g. a register toggle. However, the situation will not be the same if suspension involves sending packets through a slow bus. For this reason the device drivers can also make use of the `pm_device_runtime_put_async()` function. This function will schedule the suspend operation, again, if device is no longer used.

By default, runtime PM operations are offloaded to the system work queue. However, device drivers must not perform any blocking operations during suspend, as this can stall the system

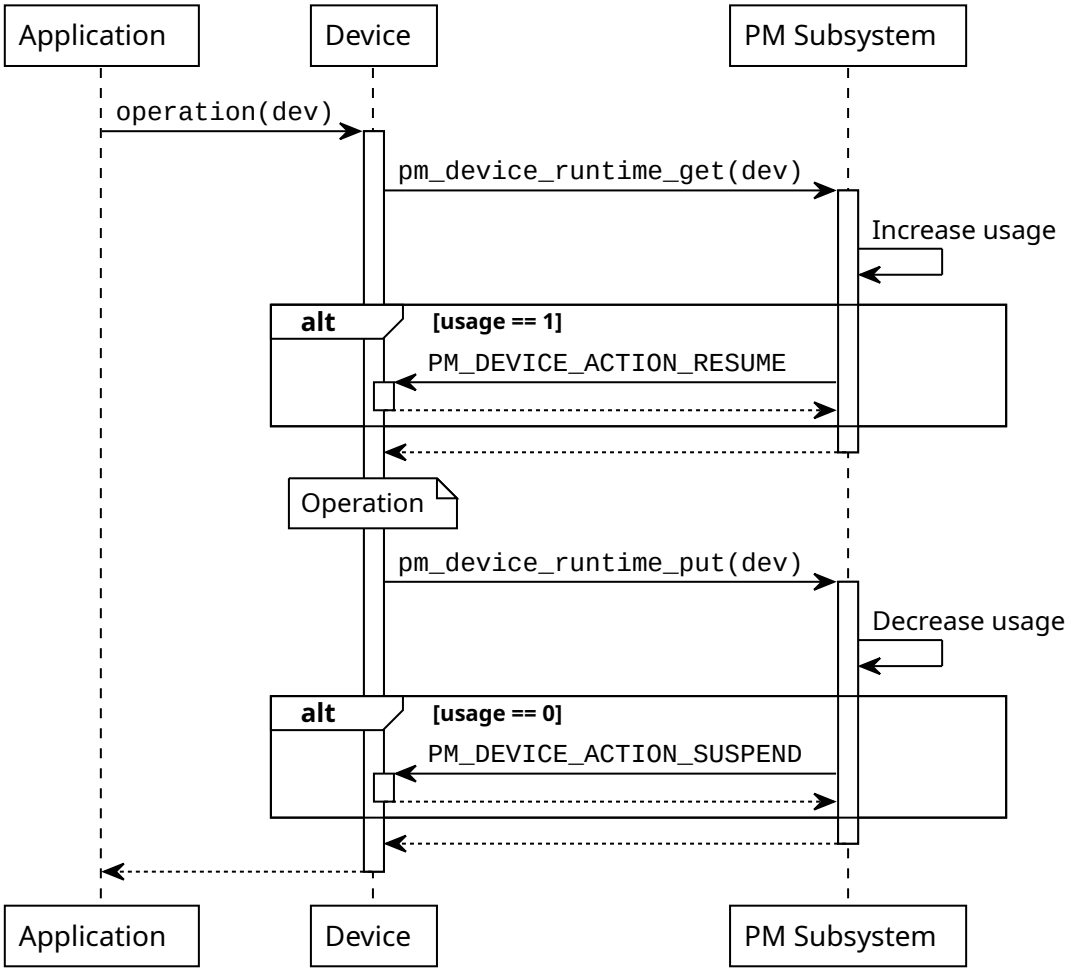

Fig. 42: Synchronous operation on a single device

work queue and negatively impact system responsiveness.

To address this, applications can configure runtime PM to use a dedicated work queue by enabling `CONFIG_PM_DEVICE_RUNTIME_USE_DEDICATED_WQ`.

If blocking behavior is required—for example, when accessing a slow peripheral or waiting for a bus transaction—the PM subsystem work queue must be used instead. Drivers that require this behavior can explicitly request it by enabling `CONFIG_PM_DEVICE_DRIVER_NEEDS_DEDICATED_WQ`.

For targets with constrained resources that do not need asynchronous operations, this functionality can be disabled altogether by de-selecting `CONFIG_PM_DEVICE_RUNTIME_ASYNC`, reducing memory usage and system complexity.

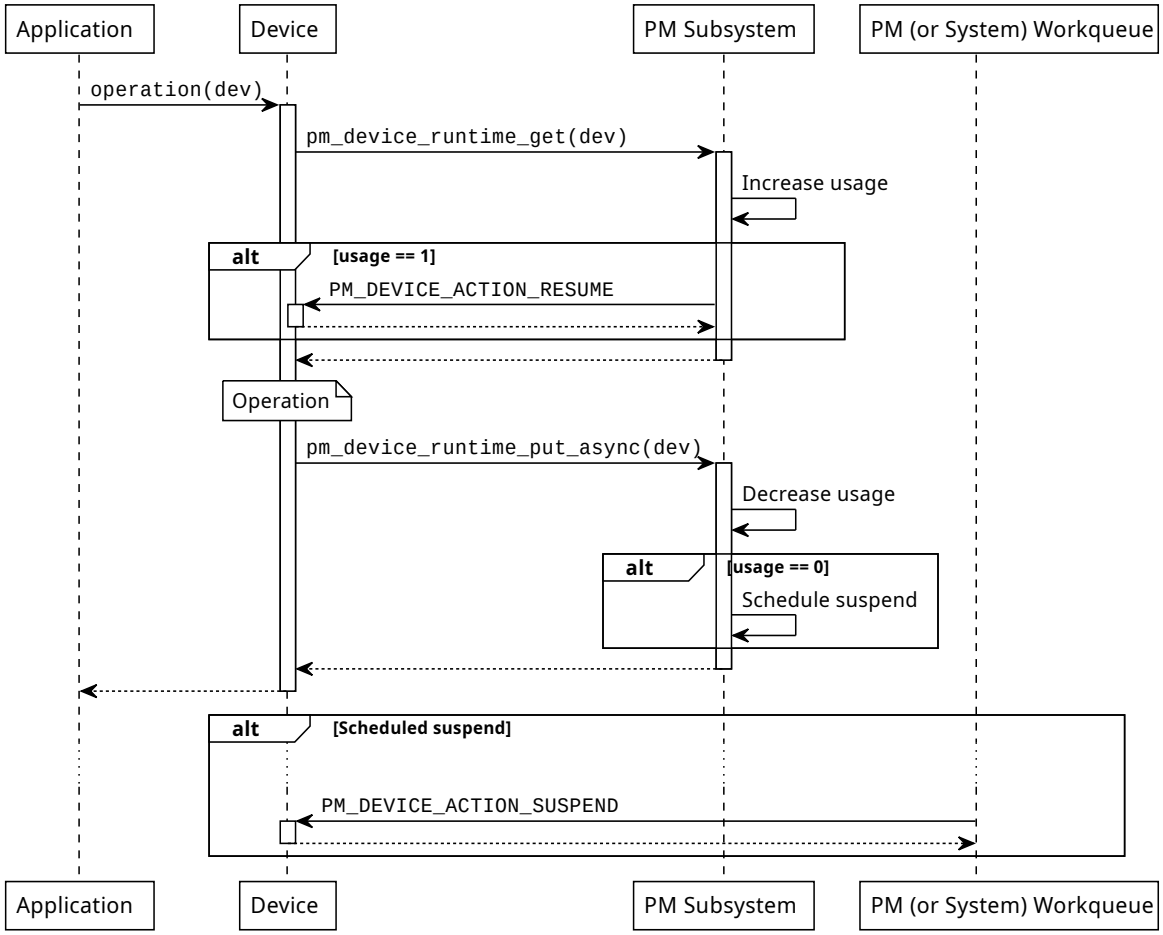

Fig. 43: Asynchronous operation on a single device

Implementation guidelines In a first place, a device driver needs to implement the PM action callback used by the PM subsystem to suspend or resume devices.

```
static int mydev_pm_action(const struct device *dev,
                           enum pm_device_action action)
{
    switch (action) {
    case PM_DEVICE_ACTION_SUSPEND:
        /* suspend the device */
        ...
        break;
    case PM_DEVICE_ACTION_RESUME:
        /* resume the device */
```

(continues on next page)

(continued from previous page)

```
        ...
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

The PM action callback calls are serialized by the PM subsystem, therefore, no special synchronization is required.

To enable device runtime power management on a device, the driver needs to call `pm_device_runtime_enable()` at initialization time. Note that this function will suspend the device if its state is `PM_DEVICE_STATE_ACTIVE`. In case the device is physically suspended, the init function should call `pm_device_init_suspended()` before calling `pm_device_runtime_enable()`.

```
/* device driver initialization function */
static int mydev_init(const struct device *dev)
{
    int ret;
    ...

    /* OPTIONAL: mark device as suspended if it is physically suspended */
    pm_device_init_suspended(dev);

    /* enable device runtime power management */
    ret = pm_device_runtime_enable(dev);
    if (ret < 0) {
        return ret;
    }
}
```

Device runtime power management can also be automatically enabled on a device instance by adding the `zephyr,pm-device-runtime-auto` flag onto the corresponding devicetree node. If enabled, `pm_device_runtime_enable()` is called immediately after the `init` function of the device runs and returns successfully.

```
foo {
    /* ... */
    zephyr,pm-device-runtime-auto;
};
```

Assuming an example device driver that implements an `operation` API call, the *get* and *put* operations could be carried out as follows:

```
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }

    /* do something with the device */
```

(continues on next page)

(continued from previous page)

```
    ...

    /* "put" device (decreases usage count, suspends device if no more users) */
    return pm_device_runtime_put(dev);
}
```

In case the suspend operation is *slow*, the device driver can use the asynchronous API:

```
static int mydev_operation(const struct device *dev)
{
    int ret;

    /* "get" device (increases usage count, resumes device if suspended) */
    ret = pm_device_runtime_get(dev);
    if (ret < 0) {
        return ret;
    }

    /* do something with the device */
    ...

    /* "put" device (decreases usage count, schedule suspend if no more users) */
    return pm_device_runtime_put_async(dev, K_NO_WAIT);
}
```

Examples Some helpful examples showing device runtime power management features:

- tests/subsys/pm/device_runtime_api/
- tests/subsys/pm/device_power_domains/
- tests/subsys/pm/power_domain/

Power Domain

Introduction The Zephyr power domain abstraction is designed to support groupings of devices powered by a common source to be notified of power source state changes in a generic fashion. Application code that is using device A does not need to know that device B is on the same power domain and should also be configured into a low power state.

Power domains are optional on Zephyr, to enable this feature the option `CONFIG_PM_DEVICE_POWER_DOMAIN` has to be set.

When a power domain turns itself on or off, it is the responsibility of the power domain to notify all devices using it through their power management callback called with `PM_DEVICE_ACTION_TURN_ON` or `PM_DEVICE_ACTION_TURN_OFF` respectively. This work flow is illustrated in the diagram below.

Internal Power Domains Most of the devices in an SoC have independent power control that can be turned on or off to reduce power consumption. But there is a significant amount of static current leakage that can't be controlled only using device power management. To solve this problem, SoCs normally are divided into several regions grouping devices that are generally used together, so that an unused region can be completely powered off to eliminate this leakage. These regions are called "power domains", can be present in a hierarchy and can be nested.

External Power Domains Devices external to a SoC can be powered from sources other than the main power source of the SoC. These external sources are typically a switch, a regulator, or

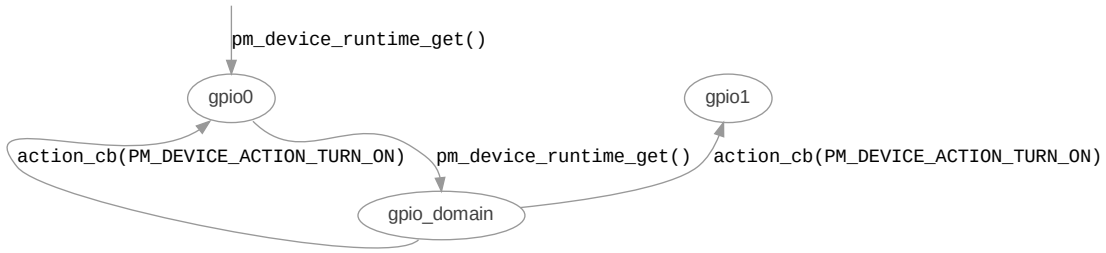

Fig. 44: Power domain work flow

a dedicated power IC. Multiple devices can be powered from the same source, and this grouping of devices is typically called a "power domain".

Placing devices on power domains can be done for a variety of reasons, including to enable devices with high power consumption in low power mode to be completely turned off when not in use.

Implementation guidelines In a first place, a device that acts as a power domain needs to declare compatible with `power-domain`. Taking *Power domain work flow* as example, the following code defines a domain called `gpio_domain`.

```
gpio_domain: gpio_domain@4 {
        compatible = "power-domain";
        ...
};
```

A power domain needs to implement the PM action callback used by the PM subsystem to turn devices on and off.

```
static int mydomain_pm_action(const struct device *dev,
                              enum pm_device_action action)
{
    switch (action) {
    case PM_DEVICE_ACTION_RESUME:
        /* resume the domain */
        ...
        /* notify children domain is now powered */
        pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_ON, NULL);
        break;
    case PM_DEVICE_ACTION_SUSPEND:
        /* notify children domain is going down */
        pm_device_children_action_run(dev, PM_DEVICE_ACTION_TURN_OFF, NULL);
        /* suspend the domain */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_ON:
        /* turn on the domain (e.g. setup control pins to disabled) */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_OFF:
        /* turn off the domain (e.g. reset control pins to default state) */
        ...
```

(continues on next page)

(continued from previous page)

```
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

Devices belonging to this device can be declared referring it in the `power-domain` node's property. The example below declares devices `gpio0` and `gpio1` belonging to domain `gpio_domain`.

```
&gpio0 {
        compatible = "zephyr,gpio-emul";
        gpio-controller;
        power-domains = <&gpio_domain>;
};

&gpio1 {
        compatible = "zephyr,gpio-emul";
        gpio-controller;
        power-domains = <&gpio_domain>;
};
```

All devices under a domain will be notified when the domain changes state. These notifications are sent as actions in the device PM action callback and can be used by them to do any additional work required. They can safely be ignored though.

```
static int mydev_pm_action(const struct device *dev,
                           enum pm_device_action *action)
{
    switch (action) {
    case PM_DEVICE_ACTION_SUSPEND:
        /* suspend the device */
        ...
        break;
    case PM_DEVICE_ACTION_RESUME:
        /* resume the device */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_ON:
        /* configure the device into low power mode */
        ...
        break;
    case PM_DEVICE_ACTION_TURN_OFF:
        /* prepare the device for power down */
        ...
        break;
    default:
        return -ENOTSUP;
    }

    return 0;
}
```

Note

It is responsibility of driver or the application to set the domain as “wakeup” source if a device depending on it is used as “wakeup” source.

4.7.2 CPU Frequency Scaling

CPU Frequency Scaling Policies

On-Demand CPU Frequency Scaling Policy The On-Demand policy evaluates the current CPU load using the *CPU Load*, and compares it to the trigger threshold defined by the SoC P-state definition.

The On-Demand policy will iterate through the defined P-states and select the first P-state for which the CPU load is greater than or equal to the defined threshold.

If no P-state matches (i.e., the CPU load is below all thresholds), the policy will select the last P-state in the soc_pstates array (the lowest performance state). This is intrinsic to the policy: P-states must be defined in decreasing threshold order in devicetree, and the last P-state will be used for loads below all thresholds.

For an example of the on-demand policy refer to the cpu_freq_on_demand sample.

This policy is reactive. Frequency adjustments occur only after a change in system load has been observed, so it cannot anticipate sudden high loads. The policy has no notion of task deadlines and should not be considered as a real-time policy.

Pressure based CPU Frequency Scaling Policy The pressure policy evaluates the current pressure of the ready queue in order to inform system P-state transitions.

Thread pressure is calculated by the following formula:

$$P_{sys} = \frac{\sum_{t \in R}(P_{min} - prio_t + 1)}{\sum_{t \in T}(P_{min} - prio_t + 1)} \times 100$$

where

- R is the set of runnable (queued) threads
- T is the set of all threads considered for pressure
- $w_t = P_{min} - \text{prio}_t + 1$ is the weight of thread t
- P_{min} is the configured minimum priority to consider (the highest value numerically)

This produces a normalized system pressure between 0 and 100 which is then used to select an appropriate P-state as defined by the SoC or overlay file.

Once the normalized system pressure is calculated, it is treated as the system 'load' and the policy will then iterate through the available P-states of the SoC and select the first P-state for which the normalized pressure is greater than or equal to the defined threshold.

If no P-state matches (i.e., the normalized pressure is below all thresholds), the policy will select the last P-state in the soc_pstates array (the lowest performance state).

The user may tune the responsiveness of this policy by adjusting the `CONFIG_CPU_FREQ_POLICY_PRESSURE_LOWEST_PRIO` option which should be set the priority of the lowest priority thread in the system (which numerically would be the highest number). The pressure policy will ignore threads of lower priority than this option, and due to the formulae above, will change the perceived impact of a high-priority thread running.

For an example of the pressure policy, refer to the cpu_freq_pressure sample.

This policy attempts to be proactive in evaluating queued tasks and adjusting the clock frequency ahead of their execution time, although this policy makes no guarantees on performance or determinism of threads achieving their deadlines and avoiding starvation.

Note that the `CONFIG_CPU_FREQ_POLICY_PRESSURE_LOWEST_PRIO` includes `CONFIG_TRACING` introduces overhead to context switching.

Timing Noise CPU Frequency Scaling Policy

Overview The timing noise policy is a CPU frequency scaling policy that periodically selects a random performance state (P-state). The intent is to inject timing variability by jittering the CPU clock, which can disrupt naive cycle-count or wall-clock measurements that assume a stable frequency.

This is a randomized P-state policy. It is not a general side-channel countermeasure.

Primary Mitigation Constant-time and constant-flow implementations that have been reviewed for side-channel leakage remain the primary mitigation against timing attacks. This policy does not replace those practices. At best, it may complicate a particular class of measurement.

Attacker Model This policy considers an adversary that:

- Observes relative execution time via cycle counters, wall-clock timers, or similar software-visible timestamps
- Relies on a stable CPU frequency so that small differences in instruction count or data-dependent paths remain distinguishable across trials

Randomized P-state selection does not defeat such an attack. Given enough samples, an attacker can often average through the noise. The policy only makes those measurements less convenient and less repeatable.

Use Cases This policy may be useful when an application wants additional timing variability as a secondary layer on top of already sound software. It should be treated as a way to disrupt certain analyses, not as a security solution on its own.

It is a poor fit for:

- Hard real-time systems that need deterministic execution time
- Safety-related systems where timing predictability is part of the safety case
- Latency-sensitive workloads that cannot tolerate unexpected slow P-states
- Strict power-budget designs, since frequent P-state changes may increase average power consumption

Configuration Enable the CPU frequency subsystem and select the timing noise policy:

```
CONFIG_CPU_FREQ=y
CONFIG_CPU_FREQ_POLICY_TIMING_NOISE=y
```

The policy uses the standard CPU frequency subsystem update interval, configured with:

```
CONFIG_CPU_FREQ_INTERVAL_MS=<interval>
```

Smaller update intervals increase timing variability, but also increase the number of frequency transitions.

Random Number Generation The policy selects performance states using `sys_rand32_get()`. Selecting `CONFIG_CPU_FREQ_POLICY_TIMING_NOISE` enables the entropy driver on platforms with a hardware entropy source. Prefer routing random draws through that driver when a TRNG is available:

```
CONFIG_ENTROPY_DEVICE_RANDOM_GENERATOR=y
```

Limitations

- It does not eliminate timing side channels
- It cannot compensate for fundamentally insecure software
- It may reduce overall system performance
- It may increase power consumption due to frequent performance state changes
- It offers no guarantees against a determined or well-instrumented attacker

For an example of the timing noise policy, refer to the cpu_freq_timing_noise sample.

CPU Frequency Thermal Cap

The CPU frequency thermal cap is an optional constraint layer for the CPU Frequency Scaling subsystem. The active policy selects the requested P-state, and the thermal cap limits the highest-performance P-state allowed when the configured temperature trip points are active.

This keeps performance demand and thermal mitigation separate:

- the CPU frequency policy selects the requested P-state according to its own metrics and thresholds.
- the thermal cap clamps that request to the highest-performance P-state currently allowed by temperature.

After clamping, the resulting P-state is passed to the SoC P-state driver.

Devicetree Enable the thermal cap by adding a `zephyr,cpu-freq-thermal-cap` node and enabling `CONFIG_CPU_FREQ_THERMAL_CAP`.

Example:

```
cpu_freq_thermal_cap: cpu_freq_thermal_cap {
        compatible = "zephyr,cpu-freq-thermal-cap";
        sensor = <&temp0>;
        sensor-channel = "die-temp";
        polling-delay-ms = <1000>;
        trip-active-polling-delay-ms = <100>;

        trip_0 {
                temperature-millicelsius = <85000>;
                hysteresis-millicelsius = <5000>;
                cap-pstate = <&pstate_1>;
        };

        trip_1 {
                temperature-millicelsius = <95000>;
                hysteresis-millicelsius = <3000>;
                cap-pstate = <&pstate_2>;
        };
};
```

When `trip_0` is active, CPU frequency requests are capped to `pstate_1` or lower. When `trip_1` is active, requests are capped to `pstate_2` or lower. A cap does not force the CPU to run at that P-state; a policy request for a lower-performance P-state is left unchanged.

Thermal cap constraints use the CPU frequency P-state index order. Lower index P-states are higher-performance, higher index P-states are lower-performance and more restrictive. Each `cap-pstate` must reference a P-state in that ordered table by phandle.

Runtime behavior Temperature sampling is done from a delayable work item because sensor drivers may use blocking operations. The CPU frequency timer reads only the cached cap when applying a policy result.

If temperature sampling fails repeatedly, the cap applies the lowest-performance P-state (highest index in the table) as a fail-safe constraint.

Overview

The CPU Frequency Scaling subsystem in Zephyr provides a framework for SoC's to dynamically adjust their processor frequency based on a monitored metric and performance state (P-state) policy algorithm.

Design Goals

The CPU Frequency Scaling subsystem aims to provide a framework that allows for any policy algorithm to work with any P-state driver and allows for each policy to make use of one, or many, metrics to determine an optimal CPU frequency. The subsystem should be flexible enough to allow for SoC vendors to define custom P-states, thresholds and metrics.

P-state Policies

A P-state policy is an algorithm that determines what the optimal P-state is for the CPU based on the metrics it consumes and the thresholds defined per P-state. A policy can consume one, or many, metrics to determine the optimal CPU frequency based on the desired statistics of the system.

See *policies* for a list of standard policies.

Metrics

A P-state policy should include one or more metrics to base decisions. Examples of metrics could include percent CPU load, SoC temperature, etc.

For an example of a metric in use, see the *on_demand* policy.

Thermal Cap

The optional *CPU Frequency Thermal Cap* constrains the highest-performance P-state allowed by the active policy based on temperature trip points. It is a constraint layer, not a P-state policy, used to reduce excess heat generation and protect the SoC from thermal stress.

P-state Drivers

A SoC supporting the CPU Frequency Scaling subsystem must implement a P-state driver that implements `cpu_freq_pstate_set()` which applies the passed in `p_state` to the CPU when called.

A SoC must also provide the available P-states in devicetree by having a `zephyr,pstate` compatible node. The SoC may also define its own P-state binding, which extends `zephyr,pstate` to include additional properties that may be used by the SoC's P-state driver.

Usage considerations

The CPU Frequency Scaling subsystem is designed to work on both UP and SMP system. On SMP systems, it is assumed by default that each of the CPUs are clocked at the same rate. Thus, should one CPU undergo a P-state transition, then all other CPUs will also undergo the same P-state transition. This can be overridden by the SoC by enabling the `CONFIG_CPU_FREQ_PER_CPU_SCALING` configuration option to allow each CPU to be clocked independently.

The SoC supporting CPU Frequency Scaling must uphold Zephyr's requirement that the system timer frequency remains steady over the lifetime of the program. See *Kernel Timing* for more information.

The CPU Frequency Scaling subsystem runs as a handler function to a `k_timer`, which means it runs in interrupt context (IRQ). The SoC P-state driver must ensure that its implementation of `cpu_freq_pstate_set()` is IRQ context safe. If a P-state transition cannot be completed reasonably in an IRQ context, it is recommended that the P-state driver of the SoC implements its task as a workqueue item.

4.7.4 Resource Management

There are various situations where it's necessary to coordinate resource use at runtime among multiple clients. These include power rails, clocks, other peripherals, and binary device power management. The complexity of properly managing multiple consumers of a device in a multi-threaded system, especially when transitions may be asynchronous, suggests that a shared implementation is desirable.

Zephyr provides managers for several coordination policies. These managers are embedded into services that use them for specific functions.

- *On-Off Manager*

On-Off Manager

An on-off manager supports an arbitrary number of clients of a service which has a binary state. Example applications are power rails, clocks, and binary device power management.

The manager has the following properties:

- The stable states are off, on, and error. The service always begins in the off state. The service may also be in a transition to a given state.
- The core operations are request (add a dependency) and release (remove a dependency). Supporting operations are reset (to clear an error state) and cancel (to reclaim client data from an in-progress transition). The service manages the state based on calls to functions that initiate these operations.
- The service transitions from off to on when first client request is received.
- The service transitions from on to off when last client release is received.
- Each service configuration provides functions that implement the transition from off to on, from on to off, and optionally from an error state to off. Transitions must be invokable from both thread and interrupt context.
- The request and reset operations are asynchronous using *Asynchronous Notifications*. Both operations may be cancelled, but cancellation has no effect on the in-progress transition.
- Requests to turn on may be queued while a transition to off is in progress: when the service has turned off successfully it will be immediately turned on again (where context allows) and waiting clients notified when the start completes.

Requests are reference counted, but not tracked. That means clients are responsible for recording whether their requests were accepted, and for initiating a release only if they have previously successfully completed a request. Improper use of the API can cause an active client to be shut out, and the manager does not maintain a record of specific clients that have been granted a request.

Failures in executing a transition are recorded and inhibit further requests or releases until the manager is reset. Pending requests are notified (and cancelled) when errors are discovered.

Transition operation completion notifications are provided through *Asynchronous Notifications*.

Clients and other components interested in tracking all service state changes, including when a service begins turning off or enters an error state, can be informed of state transitions by registering a monitor with onoff_monitor_register(). Notification of changes are provided before issuing completion notifications associated with the new state.

Note

A generic API may be implemented by multiple drivers where the common case is asynchronous. The on-off client structure may be an appropriate solution for the generic API. Where drivers that can guarantee synchronous context-independent transitions a driver may use `onoff_sync_service` and its supporting API rather than `onoff_manager`, with only a small reduction in functionality (primarily no support for the monitor API).

On-Off Service APIs

Security

4.8 Security

This section covers services for protecting a system and its data: cryptographic primitives, authentication and identity, trusted execution, and token handling.

4.8.1 Cryptography

The crypto section contains information regarding the cryptographic primitives supported by the Zephyr kernel. Use the information to understand the principles behind the operation of the different algorithms and how they were implemented.

The following crypto libraries have been included:

PSA Crypto

Overview The PSA (Platform Security Architecture) Crypto API offers a portable programming interface for cryptographic operations and key storage across a wide range of hardware. It is designed to be user-friendly while still providing access to the low-level primitives essential for modern cryptography.

It is created and maintained by Arm. Arm developed the PSA as a comprehensive security framework to address the increasing security needs of connected devices.

In Zephyr, the PSA Crypto API is implemented using Mbed TLS, an open-source cryptographic library that provides the underlying cryptographic functions.

Design Goals The interface is suitable for a vast range of devices: from special-purpose cryptographic processors that process data with a built-in key, to constrained devices running custom application code, such as microcontrollers, and multi-application devices, such as servers. It follows the principle of cryptographic agility.

Algorithm Flexibility
: The PSA Crypto API supports a wide range of cryptographic algorithms, allowing developers to switch between different cryptographic methods as needed. This flexibility is crucial for maintaining security as new algorithms emerge and existing ones become obsolete.

Key Management
: The PSA Crypto API includes robust key management features that support the creation, storage, and use of cryptographic keys in a secure and flexible manner. It uses opaque key identifiers, which allows for easy key replacement and updates without exposing key material.

Implementation Independence
: The PSA Crypto API abstracts the underlying cryptographic library, meaning that the specific implementation can be changed without affecting the application code. This abstraction supports cryptographic agility by enabling the use of different cryptographic libraries or hardware accelerators as needed.

Future-Proofing
: By adhering to cryptographic agility, PSA Crypto ensures that applications can quickly adapt to new cryptographic standards and practices, enhancing long-term security and compliance.

Examples of Applications

Network Security (TLS)
: The API provides all of the cryptographic primitives needed to establish TLS connections.

Secure Storage
: The API provides all primitives related to storage encryption, block or file-based, with master encryption keys stored inside a key store.

Network Credentials
: The API provides network credential management inside a key store, for example, for X.509-based authentication or pre-shared keys on enterprise networks.

Device Pairing
: The API provides support for key agreement protocols that are often used for secure pairing

of devices over wireless channels. For example, the pairing of an NFC token or a Bluetooth device might use key agreement protocols upon first use.

Secure Boot
The API provides primitives for use during firmware integrity and authenticity validation, during a secure or trusted boot process.

Attestation
The API provides primitives used in attestation activities. Attestation is the ability for a device to sign an array of bytes with a device private key and return the result to the caller. There are several use cases; ranging from attestation of the device state, to the ability to generate a key pair and prove that it has been generated inside a secure key store. The API provides access to the algorithms commonly used for attestation.

Factory Provisioning
Most IoT devices receive a unique identity during the factory provisioning process, or once they have been deployed to the field. This API provides the APIs necessary for populating a device with keys that represent that identity.

Usage considerations

Always check for errors
Most functions in the PSA Crypto API can return errors. All functions that can fail have the return type `psa_status_t`. A few functions cannot fail, and thus, return void or some other type.

If an error occurs, unless otherwise specified, the content of the output parameters is undefined and must not be used.

Some common causes of errors include:

- In implementations where the keys are stored and processed in a separate environment from the application, all functions that need to access the cryptography processing environment might fail due to an error in the communication between the two environments.
- If an algorithm is implemented with a hardware accelerator, which is logically separate from the application processor, the accelerator might fail, even when the application processor keeps running normally.
- Most functions might fail due to a lack of resources. However, some implementations guarantee that certain functions always have sufficient memory.
- All functions that access persistent keys might fail due to a storage failure.
- All functions that require randomness might fail due to a lack of entropy. Implementations are encouraged to seed the random generator with sufficient entropy during the execution of `psa_crypto_init()`. However, some security standards require periodic reseeding from a hardware random generator, which can fail.

Shared memory and concurrency
Some environments allow applications to be multithreaded, while others do not. In some environments, applications can share memory with a different security context. In environments with multithreaded applications or shared memory, applications must be written carefully to avoid data corruption or leakage. This specification requires the application to obey certain constraints.

In general, the PSA Crypto API allows either one writer or any number of simultaneous readers, on any given object. In other words, if two or more calls access the same object concurrently, then the behavior is only well-defined if all the calls are only reading from the object and do not modify it. Read accesses include reading memory by input parameters and reading keystore content by using a key. For more details, refer to Concurrent calls

If an application shares memory with another security context, it can pass shared memory blocks as input buffers or output buffers, but not as non-buffer parameters. For more details, refer to Stability of parameters.

Cleaning up after use

To minimize impact if the system is compromised, it is recommended that applications wipe all sensitive data from memory when it is no longer used. That way, only data that is currently in use can be leaked, and past data is not compromised.

Wiping sensitive data includes:

- Clearing temporary buffers in the stack or on the heap.
- Aborting operations if they will not be finished.
- Destroying keys that are no longer used.

- Mbed TLS

Random Number Generation

Overview The random API subsystem provides random number generation APIs in both cryptographically and non-cryptographically secure instances. Which random API to use is based on the cryptographic requirements of the random number. The non-cryptographic APIs will return random values much faster if non-cryptographic values are needed.

- Use `sys_rand_get()` and related functions for non-cryptographic purposes such as randomizing delays, shuffling data, or general-purpose randomization. These functions are faster but not suitable for security applications.
- Use `sys_csrand_get()` for cryptographic purposes such as generating encryption keys, nonces, initialization vectors, or any data that must be unpredictable to an attacker.

Warning

Never use the non-cryptographic random functions (`sys_rand_get()`, `sys_rand8_get()`, `sys_rand16_get()`, `sys_rand32_get()`, `sys_rand64_get()`) for security-sensitive operations. These functions do not provide cryptographically secure random numbers.

API Usage

Non-Cryptographic Random Numbers The following functions provide non-cryptographically secure random numbers:

- `sys_rand_get()` - Fill a buffer with random bytes
- `sys_rand8_get()` - Get a random 8-bit value
- `sys_rand16_get()` - Get a random 16-bit value
- `sys_rand32_get()` - Get a random 32-bit value
- `sys_rand64_get()` - Get a random 64-bit value

Example usage:

```c
#include <zephyr/random/random.h>

void example_random_usage(void)
{
    uint8_t buffer[16];
    uint32_t random_value;

    /* Fill buffer with random bytes */
    sys_rand_get(buffer, sizeof(buffer));

    /* Get a single random 32-bit value */
    random_value = sys_rand32_get();
}
```

Cryptographically Secure Random Numbers For cryptographic purposes, use `sys_csrand_get()`:

```c
#include <zephyr/random/random.h>

int generate_encryption_key(uint8_t *key, size_t key_len)
{
    int ret;

    ret = sys_csrand_get(key, key_len);
    if (ret != 0) {
        /* Handle error - entropy source may have failed */
        return ret;
    }

    return 0;
}
```

Note

`sys_csrand_get()` returns 0 on success, or `-EIO` if the entropy source fails. Always check the return value when generating cryptographic material.

Kconfig Options All configuration options can be found in subsys/random/Kconfig.

General Options

`CONFIG_TEST_RANDOM_GENERATOR`
: For testing, this option allows a non-random number generator to be used and permits random number APIs to return values that are not truly random.

Warning

This option is intended only for testing on platforms that lack hardware entropy support. The random numbers generated when this option is enabled are predictable and not suitable for any security-sensitive use.

Non-Cryptographic Random Generator Selection

`CONFIG_ENTROPY_DEVICE_RANDOM_GENERATOR`
: Uses the hardware entropy driver directly to generate random numbers. This provides

high-quality random numbers but may be slower than pseudo-random alternatives. Select this option when your hardware entropy source has sufficient performance for your application's needs.

CONFIG_XOSHIRO_RANDOM_GENERATOR
: Uses the Xoshiro128++ pseudo-random number generator, seeded from the hardware entropy source. This is a fast, general-purpose PRNG with a 128-bit state that passes all standard randomness tests.

  This is the recommended choice for most applications that need fast non-cryptographic random numbers.

CONFIG_TIMER_RANDOM_GENERATOR
: Uses the system timer to generate pseudo-random numbers. This generator produces predictable values and is intended **only for testing** on platforms without hardware entropy support.

  Requires CONFIG_TEST_RANDOM_GENERATOR to be enabled.

Cryptographically Secure Random Generator Selection The CSPRNG_GENERATOR_CHOICE kconfig choice selects the source for cryptographically secure random number generation.

To override the default in a board or SoC configuration file:

```
choice CSPRNG_GENERATOR_CHOICE
        default PSA_CSPRNG_GENERATOR
endchoice
```

Available generators:

CONFIG_HARDWARE_DEVICE_CS_GENERATOR
: Uses the hardware entropy driver directly as the source for cryptographically secure random numbers. Select this when your hardware random number generator is certified or validated for cryptographic use.

CONFIG_PSA_CSPRNG_GENERATOR
: enables a cryptographically secure random number generator that uses the PSA Crypto API. This CSPRNG implementation leverages the underlying PSA Crypto library's secure random number generation capabilities, which may use hardware entropy sources when available. The PSA CSPRNG provides cryptographically secure random numbers suitable for security-sensitive applications.

CONFIG_TEST_CSPRNG_GENERATOR
: Routes calls to sys_csrand_get() through sys_rand_get(). This allows testing libraries that require CSPRNG on platforms without hardware entropy support.

  Requires CONFIG_TEST_RANDOM_GENERATOR to be enabled.

> **Warning**
>
> This option provides **no cryptographic security**. Use only for testing.

Devicetree Configuration The random subsystem uses the zephyr,entropy chosen node to identify the hardware entropy device:

```
/ {
    chosen {
        zephyr,entropy = &rng;
    };
};
```

Ensure your board's devicetree correctly specifies this chosen node if your platform has a hardware random number generator.

4.8.2 Authentication

The authentication subsystem provides security-token and credential-based authentication services for Zephyr applications.

FIDO2 Authenticator

Overview The FIDO2 authenticator subsystem implements the FIDO2 CTAP2 Specification (Client to Authenticator Protocol), allowing a Zephyr device to act as a hardware security key for passwordless authentication. The subsystem can be enabled with the `CONFIG_FIDO2` option.

FIDO2 security keys are used with the WebAuthn Specification web standard. A relying party (website or service) interacts with the authenticator through a client (browser or OS platform) to register and verify user credentials. The authenticator performs cryptographic operations using on-device keys that never leave the hardware.

The subsystem currently supports the following CTAP2 commands:

- `authenticatorMakeCredential`
- `authenticatorGetAssertion`
- `authenticatorGetInfo`
- `authenticatorClientPIN`
- `authenticatorGetNextAssertion`
- `authenticatorSelection`

Architecture The subsystem is organized into pluggable backend components, each selectable at build time via Kconfig:

Transport
Handles wire-protocol communication between the host and the authenticator. Transports are registered using the `FIDO2_TRANSPORT_DEFINE` macro and are iterated at startup. Available transports:

- **USB HID (CTAPHID)** — `CONFIG_FIDO2_TRANSPORT_USB_HID`
- **Bluetooth LE (CTAPBLE)** — `CONFIG_FIDO2_TRANSPORT_BLE`

User Presence (UP)
Confirms that a human is physically present. Backends are selected via `CONFIG_FIDO2_UP_BACKEND`:

- **Input device** — `CONFIG_FIDO2_UP_INPUT`
- **Always approve** — `CONFIG_FIDO2_UP_ALWAYS`
- **Custom** — `CONFIG_FIDO2_UP_CUSTOM` (application-provided)

Credential Storage
Persists discoverable (resident) credentials. Backends are selected via `CONFIG_FIDO2_STORAGE_BACKEND`:

- **Settings subsystem** — `CONFIG_FIDO2_STORAGE_SETTINGS`
- **None** — `CONFIG_FIDO2_STORAGE_NONE` (non-discoverable credentials only)

Attestation
Signs newly created credentials to prove their origin. Backends are selected via `CONFIG_FIDO2_ATTESTATION_BACKEND`:

- **Self attestation** — `CONFIG_FIDO2_ATTESTATION_SELF` (default)
- **None** — `CONFIG_FIDO2_ATTESTATION_NONE`
- **Custom** — `CONFIG_FIDO2_ATTESTATION_CUSTOM` (application-provided)

Usage To use the FIDO2 subsystem, include the main header:

```
#include <zephyr/authentication/fido2/fido2.h>
```

Basic Initialization At least one transport must be enabled for the authenticator to communicate with a host.

See fido2 for a complete initialization sequence.

Runtime State Monitoring The subsystem exposes a runtime state callback that applications can use to drive status indicators such as LEDs:

```
#include <zephyr/authentication/fido2/fido2.h>

static void on_state_change(enum fido2_runtime_state state, void *user_data)
{
    switch (state) {
    case FIDO2_RUNTIME_STATE_IDLE:
        /* LED off */
        break;
    case FIDO2_RUNTIME_STATE_WAITING_USER_PRESENCE:
        /* Blink LED */
        break;
```

(continues on next page)

(continued from previous page)

```
    case FIDO2_RUNTIME_STATE_PROCESSING:
        /* LED on solid */
        break;
    default:
        break;
    }
}

fido2_set_state_callback(on_state_change, NULL);
```

Extensions CTAP2 extensions are not implemented yet. The following Kconfig options exist for future implementation:

- **credProtect** — `CONFIG_FIDO2_EXT_CRED_PROTECT`
- **hmac-secret** — `CONFIG_FIDO2_EXT_HMAC_SECRET`
- **largeBlobKey** — `CONFIG_FIDO2_EXT_LARGE_BLOB_KEY`
- **credBlob** — `CONFIG_FIDO2_EXT_CRED_BLOB`
- **thirdPartyPayment** — `CONFIG_FIDO2_EXT_THIRD_PARTY_PAYMENT`

4.8.3 JSON Web Token (JWT)

Overview

JSON Web Tokens (JWT) are an open, industry standard (**RFC 7519**) method for representing claims securely between two parties. Although JWT is fairly flexible, this API is limited to creating the simplistic tokens needed to authenticate with the Google Core IoT infrastructure.

At a high level, a JWT is just a signed blob of JSON that a client can present as a token instead of sending, for example, their username/password every time.

Usage To use the JWT API, include the header file:

```
#include <zephyr/data/jwt.h>
```

Generating a JWT The JWT subsystem provides a lightweight, builder-based API for constructing JSON Web Tokens (JWT). It allows for the creation of tokens where the payload (claims) contains: expiration time, issued-at time, and audience. The token is then signed using a provided private key.

```c
#include <zephyr/data/jwt.h>

struct jwt_builder builder;
char buffer[1024];
int ret;

/* Initialize the builder */
ret = jwt_init_builder(&builder, buffer, sizeof(buffer));
if (ret < 0) {
    /* Handle error */
}

/* Add payload: expiration, issued at, audience */
ret = jwt_add_payload(&builder, 1767221999, 1764605987, "project-id");
if (ret < 0) {
    /* Handle error */
}

/* Sign the token using a DER-encoded private key */
ret = jwt_sign(&builder, private_key_der, private_key_der_len);
if (ret < 0) {
    /* Handle error */
}

/*
 * buffer now contains the JWT; it can be passed to a third-party service that␣
↪will be able
 * to validate it against the public key associated with `private_key_der`.
 */
```

Configuration

4.8.4 Trusted Firmware-M (TF-M)

Trusted Firmware-M Overview

Trusted Firmware-M (TF-M) is a reference implementation of the Platform Security Architecture (PSA) IoT Security Framework. It defines and implements an architecture and a set of software components that aim to address some of the main security concerns in IoT products.

Zephyr RTOS has been PSA Certified since Zephyr 2.0.0 with TF-M 1.0, and is currently integrated with TF-M 2.1.0.

What Does TF-M Offer? Through a set of secure services and by design, TF-M provides:

- Isolation of secure and non-secure resources
- Embedded-appropriate crypto

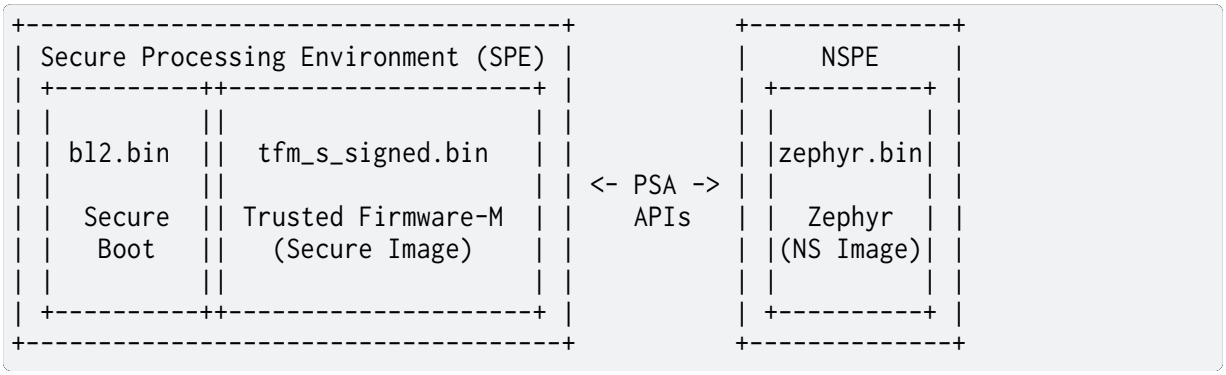
- Management of device secrets (keys, etc.)
- Firmware verification (and encryption)
- Protected off-chip data storage and retrieval
- Proof of device identity (device attestation)
- Audit logging

Build System Integration When using TF-M with a supported platform, TF-M will be automatically built and link in the background as part of the standard Zephyr build process. This build process makes a number of assumptions about how TF-M is being used, and has certain implications about what the Zephyr application image can and can not do:

- The secure processing environment (secure boot and TF-M) starts first
- Resource allocation for Zephyr relies on choices made in the secure image.

Architecture Overview A TF-M application will, generally, have the following three parts, from most to least trusted, left-to-right, with code execution happening in the same order (secure boot > secure image > ns image).

While the secure bootloader is optional, it is enabled by default, and secure boot is an important part of providing a secure solution:



Communication between the (Zephyr) Non-Secure Processing Environment (NSPE) and the (TF-M) Secure Processing Environment image happens based on a set of PSA APIs, and normally makes use of an IPC mechanism that is included as part of the TF-M build, and implemented in Zephyr (see modules/trusted-firmware-m/interface).

Root of Trust (RoT) Architecture TF-M is based upon a **Root of Trust (RoT)** architecture. This allows for hierarchies of trust from most, to less, to least trusted, providing a sound foundation upon which to build or access trusted services and resources.

The benefit of this approach is that less trusted components are prevented from accessing or compromising more critical parts of the system, and error conditions in less trusted environments won't corrupt more trusted, isolated resources.

The following RoT hierarchy is defined for TF-M, from most to least trusted:

- PSA Root of Trust (**PRoT**), which consists of:
  - PSA Immutable Root of Trust: secure boot
  - PSA Updateable Root of Trust: most trusted secure services
- Application Root of Trust (**ARoT**): isolated secure services

The **PSA Immutable Root of Trust** is the most trusted piece of code in the system, to which subsequent Roots of Trust are anchored. In TF-M, this is the secure boot image, which verifies that

the secure and non-secure images are valid, have not been tampered with, and come from a reliable source. The secure bootloader also verifies new images during the firmware update process, thanks to the public signing key(s) built into it. As the name implies, this image is **immutable**.

The **PSA Updateable Root of Trust** implements the most trusted secure services and components in TF-M, such as the Secure Partition Manager (SPM), and shared secure services like PSA Crypto, Internal Trusted Storage (ITS), etc. Services in the PSA Updateable Root of Trust have access to other resources in the same Root of Trust.

The **Application Root of Trust** is a reduced-privilege area in the secure processing environment which, depending on the isolation level chosen when building TF-M, has limited access to the PRoT, or even other ARoT services at the highest isolation levels. Some standard services exist in the ARoT, such as Protected Storage (PS), and generally custom secure services that you implement should be placed in the ARoT, unless a compelling reason is present to place them in the PRoT.

These divisions are distinct from the **untrusted code**, which runs in the non-secure environment, and has the least privilege in the system. This is the Zephyr application image in this case.

Isolation Levels At present, there are three distinct **isolation levels** defined in TF-M, with increasingly rigid boundaries between regions. The isolation level used will depend on your security requirements, and the system resources available to you.

- **Isolation Level 1** is the lowest isolation level, and the only major boundary is between the secure and non-secure processing environment, usually by means of Arm TrustZone on Armv8-M processors. There is no distinction here between the PSA Updateable Root of Trust (PRoT) and the Application Root of Trust (ARoT). They execute at the same privilege level. This isolation level will lead to the smallest combined application images.
- **Isolation Level 2** builds upon level one by introducing a distinction between the PSA Updateable Root of Trust and the Application Root of Trust, where ARoT services have limited access to PRoT services, and can only communicate with them through public APIs exposed by the PRoT services. ARoT services, however, are not strictly isolated from one another.
- **Isolation Level 3** is the highest isolation level, and builds upon level 2 by isolating ARoT services from each other, so that each ARoT is essentially silo'ed from other services. This provides the highest level of isolation, but also comes at the cost of additional overhead and code duplication between services.

The current isolation level can be checked via `CONFIG_TFM_ISOLATION_LEVEL`.

Secure Boot The default secure bootloader in TF-M is based on MCUBoot, and is referred to as `BL2` in TF-M (for the second-stage bootloader, potentially after a HW-based bootloader on the secure MCU, etc.).

All images in TF-M are hashed and signed, with the hash and signature verified by MCUBoot during the firmware update process.

Some key features of MCUBoot as used in TF-M are:

- Public signing key(s) are baked into the bootloader
- S and NS images can be signed using different keys
- Firmware images can optionally be encrypted
- Client software is responsible for writing a new image to the secondary slot
- By default, uses static flash layout of two identically-sized memory regions
- Optional security counter for rollback protection

When dealing with (optionally) encrypted images:

- Only the payload is encrypted (header, TLVs are plain text)

- Hashing and signing are applied over the un-encrypted data
- Uses `AES-CTR-128` or `AES-CTR-256` for encryption
- Encryption key randomized every encryption cycle (via `imgtool`)
- The `AES-CTR` key is included in the image and can be encrypted using:
  - `RSA-OAEP`
  - `AES-KW` (128 or 256 bits depending on the `AES-CTR` key length)
  - `ECIES-P256`
  - `ECIES-X25519`

Key config properties to control secure boot in Zephyr are:

- `CONFIG_TFM_BL2` toggles the bootloader (default = `y`).
- `CONFIG_TFM_KEY_FILE_S` overrides the secure signing key.
- `CONFIG_TFM_KEY_FILE_NS` overrides the non-secure signing key.

Secure Processing Environment Once the secure bootloader has finished executing, a TF-M based secure image will begin execution in the **secure processing environment**. This is where our device will be initially configured, and any secure services will be initialised.

Note that the starting state of our device is controlled by the secure firmware, meaning that when the non-secure Zephyr application starts, peripherals may not be in the HW-default reset state. In case of doubts, be sure to consult the board support packages in TF-M, available in the `platform/ext/target/` folder of the TF-M module (which is in `modules/tee/tf-m/trusted-firmware-m/` within a default Zephyr west workspace.)

Secure Services As of TF-M 1.8.0, the following secure services are generally available (although vendor support may vary):

- Crypto
- Firmware Update (FWU)
- Initial Attestation
- Platform
- Secure Storage, which has two parts:
  - Internal Trusted Storage (ITS)
  - Protected Storage (PS)

A template also exists for creating your own custom services.

For full details on these services, and their exposed APIs, please consult the TF-M Documentation.

Key Management and Derivation Key and secret management is a critical part of any secure device. You need to ensure that key material is available to regions that require it, but not to anything else, and that it is stored securely in a way that makes it difficult to tamper with or maliciously access.

The **Internal Trusted Storage** service in TF-M is used by the **PSA Crypto** service (which itself makes use of mbedtls) to store keys, and ensure that private keys are only ever accessible to the secure processing environment. Crypto operations that make use of key material, such as when signing payloads or when decrypting sensitive data, all take place via key handles. At no point should the key material ever be exposed to the NS environment.

One exception is that private keys can be provisioned into the secure processing environment as a one-way operation, such as during a factory provisioning process, but even this should be

avoided where possible, and a request should be made to the SPE (via the PSA Crypto service) to generate a new private key itself, and the public key for that can be requested during provisioning and logged in the factory. This ensures the private key material is never exposed, or even known during the provisioning phase.

TF-M also makes extensive use of the **Hardware Unique Key (HUK)**, which every TF-M device must provide. This device-unique key is used by the **Protected Storage** service, for example, to encrypt information stored in external memory. For example, this ensures that the contents of flash memory can't be decrypted if they are removed and placed on a new device, since each device has its own unique HUK used while encrypting the memory contents the first time.

HUKs provide an additional advantage for developers, in that they can be used to derive new keys, and the **derived keys** don't need to be stored since they can be regenerated from the HUK at startup, using an additional salt/seed value (depending on the key derivation algorithm used). This removes the storage issue and a frequent attack vector. The HUK itself it usually highly protected in secure devices, and inaccessible directly by users.

`TFM_CRYPTO_ALG_HUK_DERIVATION` identifies the default key derivation algorithm used if a software implementation is used. The current default algorithm is `HKDF` (**RFC 5869**) with a SHA-256 hash. Other hardware implementations may be available on some platforms.

Non-Secure Processing Environment Zephyr is used for the NSPE, using a board that is supported by TF-M where the `CONFIG_BUILD_WITH_TFM` flag has been enabled.

Generally, you simply need to select the `*/ns` board target of a valid board (for example `mps2/an521/cpu0/ns`), which will configure your Zephyr application to run in the NSPE, correctly build and link it with the TF-M secure images, sign the secure and non-secure images, and merge the three binaries into a single `tfm_merged.hex` file. The *west flash* command will flash `tfm_merged.hex` by default in this configuration.

At present, Zephyr can not be configured to be used as the secure processing environment.

TF-M Requirements

The following are some of the boards that can be used with TF-M:

Board	NSPE board name
mps2_an521_board	`mps2/an521/cpu0/ns` (qemu supported)
mps3	• `mps3/corstone300/fvp/ns` (armfvp supported) • `mps3/corstone310/fvp/ns` (armfvp supported)
mps4	• `mps4/corstone315/fvp/ns` (armfvp supported) • `mps4/corstone320/fvp/ns` (armfvp supported)
bl5340_dvk	`bl5340_dvk/nrf5340/cpuapp/ns`
lpcxpresso55s69	`lpcxpresso55s69_ns`
nrf9160dk_nrf9160	`nrf9160dk/nrf9160/ns`
nrf5340dk	`nrf5340dk/nrf5340/cpuapp/ns`
b_u585i_iot02a	`b_u585i_iot02a/stm32u585xx/ns`
nucleo_l552ze_q	`nucleo_l552ze_q/stm32l552xx/ns`
stm32l562e_dk	`stm32l562e_dk/stm32l562xx/ns`
v2m_musca_b1	`v2m_musca_b1/musca_b1/ns`

To make sure TF-M is supported for a board in its output, check that `CONFIG_TRUSTED_EXECUTION_NONSECURE` is set to `y` in that board's default configuration.

Software Requirements The Python modules required when building TF-M binaries are listed in the TF-M repository under `tools/requirements.txt`.

You can install them via:

```
$ pip3 install -r "$(west list trusted-firmware-m -f '{abspath}')/
↪tools/requirements.txt"
```

They are used by TF-M's signing utility to prepare firmware images for validation by the bootloader.

Part of the process of generating binaries for QEMU and merging signed secure and non-secure binaries on certain platforms also requires the use of the `srec_cat` utility.

This can be installed on Linux via:

```
$ sudo apt-get install srecord
```

And on OS X via:

```
$ brew install srecord
```

For Windows-based systems, please make sure you have a copy of the utility available on your system path. See, for example: SRecord for Windows

TF-M Build System

When building a valid `_ns` board target, TF-M will be built in the background, and linked with the Zephyr non-secure application. No knowledge of TF-M's build system is required in most cases, and the following will build a TF-M and Zephyr image pair, and run it in qemu with no additional steps required:

```
$ west build -p auto -b mps2/an521/cpu0/ns␣
↪samples/tfm_integration/psa_protected_storage/ -t run
```

The outputs and certain key steps in this build process are described here, however, since you will need to understand and interact with the outputs, and deal with signing the secure and non-secure images before deploying them.

Images Created by the TF-M Build The TF-M build system creates the following executable files:

- tfm_s - TF-M secure firmware
- tfm_ns - TF-M non-secure app (only used by regression tests).
- bl2 - TF-M MCUboot, if enabled

For each of these, it creates .bin, .hex, .elf, and .axf files.

The TF-M build system also creates signed variants of tfm_s and tfm_ns, and a file which combines them:

- tfm_s_signed
- tfm_ns_signed
- tfm_s_ns_signed

For each of these, only .bin files are created.

The TF-M non-secure app is discarded in favor of Zephyr non-secure app except when running the TF-M regression test suite.

The Zephyr build system usually signs both tfm_s and the Zephyr non-secure app itself. See below for details.

The 'tfm' target contains properties for all these paths. For example, the following will resolve to `<path>/tfm_s.hex`:

```
$<TARGET_PROPERTY:tfm,TFM_S_HEX_FILE>
```

See the top level CMakeLists.txt file in the tfm module for an overview of all the properties.

Signing Images When CONFIG_TFM_BL2 is set to y, TF-M uses a secure bootloader (BL2) and firmware images must be signed with a private key. The firmware image is validated by the bootloader during updates using the corresponding public key, which is stored inside the secure bootloader firmware image.

By default, <tfm-dir>/bl2/ext/mcuboot/root-rsa-3072.pem is used to sign secure images, and <tfm-dir>/bl2/ext/mcuboot/root-rsa-3072_1.pem is used to sign non-secure images. These default .pem keys can (and **should**) be overridden using the CONFIG_TFM_KEY_FILE_S and CONFIG_TFM_KEY_FILE_NS config flags.

To satisfy PSA Certified Level 1 requirements, **You MUST replace the default .pem file with a new key pair!**

To generate a new public/private key pair, run the following commands:

```
$ imgtool keygen -k root-rsa-3072_s.pem -t rsa-3072
$ imgtool keygen -k root-rsa-3072_ns.pem -t rsa-3072
```

You can then place the new .pem files in an alternate location, such as your Zephyr application folder, and reference them in the prj.conf file via the CONFIG_TFM_KEY_FILE_S and CONFIG_TFM_KEY_FILE_NS config flags.

> **Warning**
>
> Be sure to keep your private key file in a safe, reliable location! If you lose this key file, you will be unable to sign any future firmware images, and it will no longer be possible to update your devices in the field!

After the built-in signing script has run, it creates a tfm_merged.hex (and tfm_merged.bin) file that contains all three binaries: bl2, tfm_s, and the zephyr app. These files can then be flashed to your development board or run in QEMU.

Output Files Upon completion of the Zephyr TF-M build, the following output files exist:

Table 55: TF-M Output Files

Filename	Created From	Bootloader Flags	Usage
tfm_s_signed.{hex/bin}	TF-M Secure	Signed	OTA Upgrades (CONFIG_TFM_MCUBOOT_IMAGE_NUMBER == 2)
zephyr_ns_signed.{hex/bin}	Zephyr Nonsecure	Signed	OTA Upgrades (CONFIG_TFM_MCUBOOT_IMAGE_NUMBER == 2)
tfm_s_zephyr_ns_sig{hex/bin}	TF-M Secure, Zephyr Nonsecure	Signed	OTA Upgrades (CONFIG_TFM_MCUBOOT_IMAGE_NUMBER == 1)
tfm_merged.{hex/bin}	Bootloader, TF-M Secure, Zephyr Nonsecure	Signed, Confirmed	Production Programming, flashed by west flash

Custom CMake arguments When building a Zephyr application with TF-M it might be necessary to control the CMake arguments passed to the TF-M build.

Zephyr TF-M build offers several Kconfig options for controlling the build, but doesn't cover every CMake argument supported by the TF-M build system.

The `TFM_CMAKE_OPTIONS` property on the `zephyr_property_target` can be used to pass custom CMake arguments to the TF-M build system.

To pass the CMake argument `-DFOO=bar` to the TF-M build system, place the following CMake snippet in your CMakeLists.txt file.

```
set_property(TARGET zephyr_property_target
             APPEND PROPERTY TFM_CMAKE_OPTIONS
             -DFOO=bar
)
```

Note

The `TFM_CMAKE_OPTIONS` is a list so it is possible to append multiple options. Also CMake generator expressions are supported, such as `$<1:-DFOO=bar>`

Since `TFM_CMAKE_OPTIONS` is a list argument it will be expanded before it is passed to the TF-M build system. Options that have list arguments must therefore be properly escaped to avoid being expanded as a list.

```
set_property(TARGET zephyr_property_target
             APPEND PROPERTY TFM_CMAKE_OPTIONS
             -DFOO="bar\\\;baz"
)
```

Footprint and Memory Usage The build system offers targets to view and analyse RAM and ROM usage in generated images. The tools run on the final images and give information about size of symbols and code being used in both RAM and ROM. For more information on these tools look here: *Footprint and Memory Usage*

Use the `tfm_ram_report` to get the RAM report for TF-M secure firmware (tfm_s).

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t tfm_ram_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild tfm_ram_report
```

Use the `tfm_rom_report` to get the ROM report for TF-M secure firmware (tfm_s).

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t tfm_rom_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild tfm_rom_report
```

Use the `bl2_ram_report` to get the RAM report for TF-M MCUboot, if enabled.

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t bl2_ram_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild bl2_ram_report
```

Use the `bl2_rom_report` to get the ROM report for TF-M MCUboot, if enabled.

Using west:

```
# From the root of the zephyr repository
west build -b mps2/an521/cpu0/ns samples/hello_world
west build -t bl2_rom_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=mps2/an521/cpu0/ns samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild bl2_rom_report
```

Trusted Firmware-M Integration

The Trusted Firmware-M (TF-M) section contains information about the integration between TF-M and Zephyr RTOS. Use this information to help understand how to integrate TF-M with Zephyr for Cortex-M platforms and make use of its secure run-time services in Zephyr applications.

Board Definitions TF-M will be built for the secure processing environment along with Zephyr if the `CONFIG_BUILD_WITH_TFM` flag is set to `y`.

Generally, this value should never be set at the application level, however, and all config flags required for TF-M should be set in a board variant with the `_ns` suffix.

This board variant must define an appropriate flash, SRAM and peripheral configuration that takes into account the initialisation process in the secure processing environment. `CONFIG_TFM_BOARD` must also be set via modules/trusted-firmware-m/Kconfig.tfm to the board name that TF-M expects for this target, so that it knows which target to build for the secure processing environment.

Example: mps2/an521/cpu0/ns The mps2/an521/cpu0 board target is a dual-core Arm Cortex-M33 evaluation board that generates a secure Zephyr binary.

The optional mps2/an521/cpu0/ns board target, however, sets these additional kconfig flags that indicate that Zephyr should be built as a non-secure image, linked with TF-M as an external project, and optionally the secure bootloader:

- CONFIG_TRUSTED_EXECUTION_NONSECURE y
- CONFIG_ARM_TRUSTZONE_M y

Comparing the boards/arm/mps2/mps2_an521_cpu0.dts and boards/arm/mps2/mps2_an521_cpu0_ns.dts files, we can see that the ns version defines offsets in flash and SRAM memory, which leave the required space for TF-M and the secure bootloader:

```
reserved-memory {
            #address-cells = <1>;
            #size-cells = <1>;
            ranges;

            /* The memory regions defined below must match what the TF-M
             * project has defined for that board - a single image boot is
             * assumed. Please see the memory layout in:
             *␣
↪https://git.trustedfirmware.org/TF-M/trusted-firmware-m.git/tree/platform/ext/target/mps2/an521
             */

            code: memory@100000 {
                    reg = <0x00100000 DT_SIZE_K(512)>;
            };

            ram: memory@28100000 {
                    reg = <0x28100000 DT_SIZE_M(1)>;
            };
    };
```

This reserves 1 MB of code memory and 1 MB of RAM for secure boot and TF-M, such that our non-secure Zephyr application code will start at 0x10000, with RAM at 0x28100000. 512 KB code memory is available for the NS zephyr image, along with 1 MB of RAM.

This matches the flash memory layout we see in flash_layout.h in TF-M:

```
* 0x0000_0000 BL2 - MCUBoot (0.5 MB)
* 0x0008_0000 Secure image     primary slot (0.5 MB)
* 0x0010_0000 Non-secure image primary slot (0.5 MB)
* 0x0018_0000 Secure image     secondary slot (0.5 MB)
* 0x0020_0000 Non-secure image secondary slot (0.5 MB)
* 0x0028_0000 Scratch area (0.5 MB)
* 0x0030_0000 Protected Storage Area (20 KB)
* 0x0030_5000 Internal Trusted Storage Area (16 KB)
* 0x0030_9000 NV counters area (4 KB)
* 0x0030_A000 Unused (984 KB)
```

mps2/an521 will be passed in to Tf-M as the board target, specified via CONFIG_TFM_BOARD.

Test Suites

TF-M includes two sets of test suites:

- tf-m-tests - Standard TF-M specific regression tests
- psa-arch-tests - Test suites for specific PSA APIs (secure storage, etc.)

These test suites can be run from Zephyr via an appropriate sample application in the samples/tfm_integration folder.

TF-M Regression Tests The regression test suite can be run via the tests/modules/tf-m/regression test.

It tests various services and communication mechanisms across the NS/S boundary via the PSA APIs. They provide a useful sanity check for proper integration between the NS RTOS (Zephyr in this case) and the secure application (TF-M).

PSA Arch Tests The PSA Arch Test suite, available via tfm_psa_test, contains a number of test suites that can be used to validate that PSA API specifications are being followed by the secure application, TF-M being an implementation of the Platform Security Architecture (PSA).

Only one of these suites can be run at a time, with the available test suites described via `CONFIG_TFM_PSA_TEST_*` KConfig flags:

Purpose The output of these test suites is required to obtain PSA Certification for your specific board, RTOS (Zephyr here), and PSA implementation (TF-M in this case).

They also provide a useful test case to validate any PRs that make meaningful changes to TF-M, such as enabling a new TF-M board target, or making changes to the core TF-M module(s). They should generally be run as a coherence check before publishing a new PR for new board support, etc.

4.8.5 UUID

Overview

Universally Unique Identifiers (UUID), also known as Globally Unique IDentifiers (GUIDs), are 128-bit identifiers intended to guarantee uniqueness across space and time. They are defined by **RFC 9562**.

The UUID subsystem provides utility functions for the generation, parsing, and manipulation of UUIDs. It supports generating version 4 (random) and version 5 (name-based) UUIDs.

Usage To use the UUID API, include the header file:

```
#include <zephyr/sys/uuid.h>
```

Generating a UUIDv4 UUIDv4 is based on random numbers (hence requires an entropy generator), and can be generated using the `uuid_generate_v4()` function. `CONFIG_UUID_V4` must also be enabled.

```
struct uuid my_uuid;
char uuid_str[UUID_STR_LEN];

int ret = uuid_generate_v4(&my_uuid);

if (ret != 0) {
    printk("Failed to generate UUID v4 (err %d)\n", ret);
    return ret;
}

ret = uuid_to_string(&my_uuid, uuid_str);
if (ret != 0) {
    printk("Failed to convert UUID to string (err %d)\n", ret);
```

(continues on next page)

(continued from previous page)

```
    return ret;
}

 printk("UUID: %s\n", uuid_str);
```

Generating a UUIDv5 UUIDv5 is generated from a namespace UUID and a name (binary data), and can be generated using the `uuid_generate_v5()` function. `CONFIG_UUID_V5` must also be enabled.

UUIDv5 is deterministic: the same namespace and name will always result in the same UUID.

```
struct uuid ns_uuid;
struct uuid my_uuid;
char uuid_str[UUID_STR_LEN];

/* Well-known namespace ID for URLs (RFC 9562) */
uuid_from_string("6ba7b811-9dad-11d1-80b4-00c04fd430c8", &ns_uuid);

const char *name = "https://zephyrproject.org/";
int ret = uuid_generate_v5(&ns_uuid, name, strlen(name), &my_uuid);

if (ret != 0) {
    printk("Failed to generate UUID v5 (err %d)\n", ret);
    return ret;
}

ret = uuid_to_string(&my_uuid, uuid_str);
if (ret != 0) {
    printk("Failed to convert UUID to string (err %d)\n", ret);
    return ret;
}

/* outputs: "UUID: abdb72b5-b342-5882-925b-4ce0e3cb4790" */
printk("UUID: %s\n", uuid_str);
```

Device Management

4.9 Device Management

This section covers services for managing a device throughout its lifecycle, such as firmware updates and querying metadata embedded in the firmware image.

4.9.1 MCUmgr

Overview

The management subsystem allows remote management of Zephyr-enabled devices. The following management operations are available:

- *OS management*
- *Image management*
- *Statistics management*
- *Settings (config) management*
- *File system management*
- *Shell management*
- *Enumeration management*
- *Transport management*
- *Zephyr basic management*

The management subsystem is based on the Simple Management Protocol (SMP) provided by MCUmgr, an open source project that provides a management subsystem that is portable across multiple real-time operating systems.

The management subsystem is located in subsys/mgmt/ inside of the Zephyr tree.

Additionally, there is a sample server that provides management functionality over Bluetooth LE and serial.

Supported transports

MCUmgr supports a wide range of transports in-tree of Zephyr, additional transports can be added and submitted upstream or used out-of-tree in downstream projects without needing to fork the Zephyr repository.

The following transports are supported in Zephyr:

Name	Kconfigs	Extra details	Mode support		*Transport group management support*	
			Serv	Clier	Incoming	Outgoing
UART	`CONFIG_MCUMGR_TRANSPORT_UART`	*UART SMP over console encoding*	✓		✓	✓
Raw UART	`CONFIG_MCUMGR_TRANSPORT_RAW_UART`		✓		✓	✓
Shell	`CONFIG_MCUMGR_TRANSPORT_SHELL`	*UART SMP over console encoding*	✓		✓	×
Bluetooth	`CONFIG_MCUMGR_TRANSPORT_BT`	*Bluetooth Low Energy*	✓		✓	✓
UDP (IPv4)	`CONFIG_MCUMGR_TRANSPORT_UDP` and `CONFIG_MCUMGR_TRANSPORT_UDP_IPV4`	Optional DTLS support	✓		×	×
UDP (IPv6)	`CONFIG_MCUMGR_TRANSPORT_UDP` and `CONFIG_MCUMGR_TRANSPORT_UDP_IPV6`	Optional DTLS support	✓		×	×
LoRaWAN	`CONFIG_MCUMGR_TRANSPORT_LORAWAN`		✓		×	×
SPI	`CONFIG_MCUMGR_TRANSPORT_SPI`		✓		×	×
The following are designed for usage in tests:						
Dummy	`CONFIG_MCUMGR_TRANSPORT_DUMMY`	Virtual	✓		✓	✓
Raw Dummy	`CONFIG_MCUMGR_TRANSPORT_RAW_DUMM`	*UART SMP over console encoding*, virtual	✓		✓	✓

Tools/libraries

There are various tools and libraries available which enable usage of MCUmgr functionality on a device which are listed below. Note that these tools are not part of or related to the Zephyr project.

Table 56: Tools and Libraries for MCUmgr

Name	OS support	Transports	Groups									Type	Language
			OS	IMG	Stat	Settings	FS	Shel	Enur	Transport	Zephyr		
AuTerm	Windows, Linux, macOS	Serial, Serial (raw), Bluetooth, UDP, LoRaWAN	✓	✓	✓	✓	✓	✓	✓	×	✓	App	C++ (Qt)
mcumgr-client	Windows, Linux, macOS	Serial	×	✓	×	×	×	×	×	×	×	App	Rust
mcumgr-web	Windows, Linux, macOS	Bluetooth	×	✓	×	×	×	×	×	×	×	Web (chrome only)	Javascript
mcumgr-mac	macOS	Bluetooth	✓	✓	×	×	×	×	×	×	×	App	Rust
nRF Connect Device Manager: Android and iOS	iOS, Android	Bluetooth	✓	✓	✓	✓	✓	✓	×	×	✓	Library, App	Java, Kotlin, Swift
smp	Windows, Linux, macOS, iOS, Android	N/A	✓	✓	✓	✓	✓	✓	✓	×	✓	Library	Python
smpclient	Windows, Linux, macOS	Serial, Bluetooth, UDP	✓	✓	✓	✓	✓	✓	✓	×	✓	Library	Python
smpmgr	Windows, Linux, macOS	Serial, Bluetooth, UDP	✓	✓	✓	×	✓	✓	✓	×	×	App	Python
mcumgr-toolkit (CLI: mcumgrctl)	Windows, Linux, macOS	Serial, Bluetooth, UDP	✓	✓	✓	✓	✓	✓	✓	×	✓	Library, App	Rust, Python
Zephyr MCUmgr client (in-tree)	Linux, Zephyr	Serial, Serial (raw)	✓	✓	×	×	×	×	×	×	×	Library	C

Note that a tick for a particular group indicates basic support for that group in the code, it is possible that not all commands/features of a group are supported by the implementation.

J-Link Virtual MSD Interaction Note

On boards where a J-Link OB is present which has both CDC and MSC (virtual Mass Storage Device, also known as drag-and-drop) support, the MSD functionality can prevent MCUmgr commands over the CDC UART port from working due to how USB endpoints are configured in the J-Link firmware (for example on the nrf52840dk board) because of limiting the maximum packet size (most likely to occur when using image management commands for updating firmware). This issue can be resolved by disabling MSD functionality on the J-Link device, follow the instructions on nordic_segger_msd to disable MSD support.

Bootloader Integration

The *Device Firmware Upgrade* subsystem integrates the management subsystem with the bootloader, providing the ability to send and upgrade a Zephyr image to a device.

Currently only the MCUboot bootloader is supported. See *MCUboot* for more information.

API Reference

Management

4.9.2 MCUmgr handlers

Overview

MCUmgr functions by having group handlers which identify a group of functions relating to a specific management area, which is addressed with a 16-bit identification value, `mcumgr_group_t` contains the management groups available in Zephyr with their corresponding group ID values. The group ID is included in SMP headers to identify which group a command belongs to, there is also an 8-bit command ID which identifies the function of that group to execute - see *SMP Protocol Specification* for details on the SMP protocol and header. There can only be one registered group per unique ID.

Implementation

MCUmgr handlers can be added externally by application code or by module code, they do not have to reside in the upstream Zephyr tree to be usable. The first step to creating a handler is to create the folder structure for it, the typical Zephyr MCUmgr group layout is as follows:

```
<dir>/grp/<grp_name>_mgmt/
├── CMakeLists.txt
├── Kconfig
├── include
├──── <grp_name>_mgmt.h
├──── <grp_name>_mgmt_callbacks.h
├── src
└──── <grp_name>_mgmt.c
```

Note that the header files in upstream Zephyr MCUmgr handlers reside in the `zephyr/include/zephyr/mgmt/mcumgr/grp/<grp_name>_mgmt` directory to allow the files to be globally included by applications.

Initial header <grp_name>_mgmt.h The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_EXAMPLE_MGMT_
#define H_EXAMPLE_MGMT_

#ifdef __cplusplus
extern "C" {
#endif

/**
 * Group ID for example management group.
 */
#define MGMT_GROUP_ID_EXAMPLE  MGMT_GROUP_ID_PERUSER

/**
 * Command IDs for example management group.
 */
#define EXAMPLE_MGMT_ID_TEST   0
#define EXAMPLE_MGMT_ID_OTHER  1

/**
 * Command result codes for example management group.
 */
enum example_mgmt_err_code_t {
        /** No error, this is implied if there is no ret value in the response */
        EXAMPLE_MGMT_ERR_OK = 0,

        /** Unknown error occurred. */
        EXAMPLE_MGMT_ERR_UNKNOWN,

        /** The provided value is not wanted at this time. */
        EXAMPLE_MGMT_ERR_NOT_WANTED,

        /** The provided value was rejected by a hook. */
        EXAMPLE_MGMT_ERR_REJECTED_BY_HOOK,
};

#ifdef __cplusplus
}
#endif

#endif
```

This provides the defines for 2 command `test` and `other` and sets up the SMP version 2 error responses (which have unique error codes per group as opposed to the legacy SMP version 1 error responses that return a `mcumgr_err_t` - there should always be an OK error code with the value 0 and an unknown error code with the value 1. The above example then adds an error code

of `not wanted` with value 2. In addition, the group ID is set to be `MGMT_GROUP_ID_PERUSER`, which is the start group ID for user-defined groups, note that group IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute group IDs more easily.

Initial header <grp_name>_mgmt_callbacks.h The purpose of the header file is to provide defines which can be used by the MCUmgr handler itself and application code, e.g. to reference the command IDs for executing functions. An example file would look similar to:

```
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */
#ifndef H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#define H_MCUMGR_EXAMPLE_MGMT_CALLBACKS_
#include <stdint.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#ifdef __cplusplus
extern "C" {
#endif

/* This is the event ID for the example group */
#define MGMT_EVT_GRP_EXAMPLE MGMT_EVT_GRP_USER_CUSTOM_START

/* MGMT event opcodes for example management group */
enum example_mgmt_group_events {
        /* Callback when the other command is received, data is␣
↪example_mgmt_other_data */
        MGMT_EVT_OP_EXAMPLE_OTHER = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_EXAMPLE, 0),

        /* Used to enable all smp_group events */
        MGMT_EVT_OP_EXAMPLE_MGMT_ALL  = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_EXAMPLE),
};

/* Structure provided in the #MGMT_EVT_OP_EXAMPLE_OTHER notification callback */
struct example_mgmt_other_data {
        /* Contains the user supplied value */
        uint32_t user_value;
};

#ifdef __cplusplus
}
#endif

#endif
```

This sets up a single event which application (or module) code can register for to receive a callback when the function handler is executed, which allows the flow of the handler to be changed (i.e. to return an error instead of continuing). The event group ID is set to `MGMT_EVT_GRP_USER_CUSTOM_START`, which is the start event ID for user-defined groups, note that event IDs need to be unique so other custom groups should use different values, a central index header file (as upstream Zephyr has) can be used to distribute event IDs more easily.

Initial source <grp_name>_mgmt.c The purpose of this source file is to handle the incoming MCUmgr commands, provide responses, and register the transport with MCUmgr so that commands will be sent to it. An example file would look similar to:

```c
/*
 * Copyright (c) 2023 Nordic Semiconductor ASA
 *
 * SPDX-License-Identifier: Apache-2.0
 */

        case EXAMPLE_MGMT_ERR_REJECTED_BY_HOOK:
                rc = MGMT_ERR_EBADSTATE;
                break;

        case EXAMPLE_MGMT_ERR_UNKNOWN:
        default:
                rc = MGMT_ERR_EUNKNOWN;
        }

        return rc;
}
#endif

static const struct mgmt_handler example_mgmt_handlers[] = {
        [EXAMPLE_MGMT_ID_TEST] = {
                .mh_read = example_mgmt_test,
                .mh_write = NULL,
        },
        [EXAMPLE_MGMT_ID_OTHER] = {
                .mh_read = NULL,
                .mh_write = example_mgmt_other,
        },
};

static struct mgmt_group example_mgmt_group = {
        .mg_handlers = example_mgmt_handlers,
        .mg_handlers_count = ARRAY_SIZE(example_mgmt_handlers),
        .mg_group_id = MGMT_GROUP_ID_EXAMPLE,
#ifdef CONFIG_MCUMGR_SMP_SUPPORT_ORIGINAL_PROTOCOL
        .mg_translate_error = example_mgmt_translate_error_code,
#endif
};

static void example_mgmt_register_group(void)
{
        /* This function is called during system init before main() is invoked, if the
         * handler needs to set anything up before it can be used, it should do it here.
         * This register the group so that clients can call the function handlers.
         */
        mgmt_register_group(&example_mgmt_group);
}

MCUMGR_HANDLER_DEFINE(example_mgmt, example_mgmt_register_group);
```

The above code creates 2 function handlers, `test` which supports read requests and takes 2 required parameters, and `other` which supports write requests and takes 1 optional parameter, this function handler has an optional notification callback feature that allows other parts of the code to listen for the event and take any required actions that are necessary or prevent further execution of the function by returning an error, further details on MCUmgr callback functionality can be found on *MCUmgr Callbacks*.

Note that other code referencing callbacks for custom MCUmgr handlers needs to include both the base Zephyr callback include file and the custom handler callback file, only in-tree Zephyr

handler headers are included when including the upstream Zephyr callback header file.

Initial Kconfig The purpose of the Kconfig file is to provide options which users can enable or change relating to the functionality of the handler being implemented. An example file would look similar to:

```
# Copyright Nordic Semiconductor ASA 2023. All rights reserved.
# SPDX-License-Identifier: Apache-2.0
# The Kconfig file is dedicated to example management group of
# of MCUmgr subsystem and provides Kconfig options to configure
# group commands behaviour and other aspects.
#
# Options defined in this file should be prefixed:
#  MCUMGR_GRP_EXAMPLE_ -- general group options;
#
# When adding Kconfig options, that control the same feature,
# try to group them together by the same stem after prefix.
if MCUMGR

menuconfig MCUMGR_GRP_EXAMPLE_APP
        bool "MCUmgr handlers for example management (app)"
        select MCUMGR_SMP_CBOR_MIN_DECODING_LEVEL_2
        default y
        help
          Enables MCUmgr handlers for example management. This demonstrates the
          file at application-level.

if MCUMGR_GRP_EXAMPLE_APP
config MCUMGR_GRP_EXAMPLE_OTHER_HOOK
        bool "Other hook"
        depends on MCUMGR_MGMT_NOTIFICATION_HOOKS
        help
          Allows applications to receive callback when the "other" example
          management function is called

module = MCUMGR_GRP_EXAMPLE
module-str = mcumgr_grp_example
source "subsys/logging/Kconfig.template.log_config"

endif

endif

source "Kconfig.zephyr"
```

Initial CMakeLists.txt The CMakeLists.txt file is used by the build system to setup files to compile, include directories to add and specify options that can be changed. A basic file only need to include the source files if the Kconfig options are enabled. An example file would look similar to:

Zephyr module

```
# Copyright (c) 2023 Nordic Semiconductor ASA
# SPDX-License-Identifier: Apache-2.0

if(CONFIG_MCUMGR_GRP_EXAMPLE_MODULE)
  zephyr_library()
```

(continues on next page)

(continued from previous page)

```
  # The below should be updated with the real name of the file
  zephyr_library_sources(src/example_mgmt.c)
  zephyr_include_directories(include)
endif()
```

Application

```
if(CONFIG_MCUMGR_GRP_EXAMPLE_APP)
  target_sources(app PRIVATE example_as_module/src/example_mgmt.c)
  zephyr_include_directories(example_as_module/include)
endif()
```

Including from application

Application-specific MCUmgr handlers can be added by creating/editing application build files. Example modifications are shown below.

Example CMakeLists.txt The application `CMakeLists.txt` file can load the CMake file for the example MCUmgr handler by adding the following:

```
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig The application Kconfig file can include the Kconfig file for the example MCUmgr handler by adding the following to the `Kconfig` file in the application directory (or creating it if it does not exist):

```
rsource "mcumgr/grp/<grp_name>/Kconfig"

# Include Zephyr's Kconfig
source "Kconfig.zephyr"
```

Including from Zephyr Module

Zephyr *Modules (External projects)* can be used to add custom MCUmgr handlers to multiple different applications without needing to duplicate the code in each application's source tree, see *Module yaml file description* for details on how to set up the module files. Example files are shown below.

Example zephyr/module.yml This is an example file which can be used to load the Kconfig and CMake files from the root of the module directory, and would be placed at `zephyr/module.yml`:

```
build:
  kconfig: Kconfig
  cmake: .
```

Example CMakeLists.txt This is an example CMakeLists.txt file which loads the CMake file for the example MCUmgr handler, and would be placed at `CMakeLists.txt`:

```
add_subdirectory(mcumgr/grp/<grp_name>)
```

Example Kconfig This is an example Kconfig file which loads the Kconfig file for the example MCUmgr handler, and would be placed at `Kconfig`:

```
rsource "mcumgr/grp/<grp_name>/Kconfig"
```

Demonstration handler

There is a demonstration project which includes configuration for both application and zephyr module-MCUmgr handlers which can be used as a basis for created your own in tests/subsys/mgmt/mcumgr/handler_demo/.

4.9.3 MCUmgr Callbacks

Overview

MCUmgr has a customisable callback/notification system that allows application (and module) code to receive callbacks for MCUmgr events that they are interested in and react to them or return a status code to the calling function that provides control over if the action should be allowed or not. An example of this is with the fs_mgmt group, whereby file access can be gated, the callback allows the application to inspect the request path and allow or deny access to said file, or it can rewrite the provided path to a different path for transparent file redirection support.

Implementation

Enabling The base callback/notification system can be enabled using `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` which will compile the registration and notification system into the code. This will not provide any callbacks by default as the callbacks that are supported by a build must also be selected by enabling the Kconfig's for the required callbacks (see *Events* for further details). A callback function with the `mgmt_cb` type definition can then be declared and registered by calling `mgmt_callback_register()` for the desired event inside of a `mgmt_callback` structure. Handlers are called in the order that they were registered.

With the system enabled, a basic handler can be set up and defined in application code as per:

```
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                int32_t *rc, uint16_t *group, bool *abort_more,
                                void *data, size_t data_size)
{
    if (event == MGMT_EVT_OP_CMD_DONE) {
        /* This is the event we registered for */
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_CMD_DONE;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the `MGMT_EVT_OP_CMD_DONE` event, which will be called after a

MCUmgr command has been processed and output generated, note that this requires that CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS be enabled to receive this callback.

Multiple callbacks can be setup to use a single function as a common callback, and many different functions can be used for each event by registering each group once, or all notifications for a whole group can be enabled by using one of the MGMT_EVT_OP_*_ALL events, alternatively a handler can setup for every notification by using MGMT_EVT_OP_ALL. When setting up handlers, events can be combined that are in the same group only, for example 5 img_mgmt callbacks can be setup with a single registration call, but to also setup a callback for an os_mgmt callback, this must be done as a separate registration. Group IDs are numerical increments, event IDs are bitmask values, hence the restriction.

As an example, the following registration is allowed, which will register for 3 SMP events with a single callback function in a single registration:

```
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_CMD_RECV |
                        MGMT_EVT_OP_CMD_STATUS |
                        MGMT_EVT_OP_CMD_DONE);
mgmt_callback_register(&my_callback);
```

The following code is not allowed, and will cause undefined operation, because it mixes the IMG management group with the OS management group whereby the group is **not** a bitmask value, only the event is:

```
my_callback.callback = my_function;
my_callback.event_id = (MGMT_EVT_OP_IMG_MGMT_DFU_STARTED |
                        MGMT_EVT_OP_OS_MGMT_RESET);
mgmt_callback_register(&my_callback);
```

Events Events can be selected by enabling their corresponding Kconfig option:

- **CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS**
  MCUmgr command status (MGMT_EVT_OP_CMD_RECV, MGMT_EVT_OP_CMD_STATUS, MGMT_EVT_OP_CMD_DONE)
- **CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK**
  fs_mgmt file access (MGMT_EVT_OP_FS_MGMT_FILE_ACCESS)
- **CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK**
  img_mgmt upload check (MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK)
- **CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS**
  img_mgmt upload status (MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED, MGMT_EVT_OP_IMG_MGMT_DFU_STARTED, MGMT_EVT_OP_IMG_MGMT_DFU_PENDING, MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED)
- **CONFIG_MCUMGR_GRP_OS_RESET_HOOK**
  os_mgmt reset check (MGMT_EVT_OP_OS_MGMT_RESET)
- **CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK**
  settings_mgmt access (MGMT_EVT_OP_SETTINGS_MGMT_ACCESS)

Actions Some callbacks expect a return status to either allow or disallow an operation, an example is the fs_mgmt access hook which allows for access to files to be allowed or denied. With these handlers, the first non-OK error code returned by a handler will be returned to the MCUmgr client.

An example of selectively denying file access:

```c
#include <zephyr/kernel.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>
#include <string.h>

struct mgmt_callback my_callback;

enum mgmt_cb_return my_function(uint32_t event, enum mgmt_cb_return prev_status,
                                int32_t *rc, uint16_t *group, bool *abort_more,
                                void *data, size_t data_size)
{
    /* Only run this handler if a previous handler has not failed */
    if (event == MGMT_EVT_OP_FS_MGMT_FILE_ACCESS && prev_status == MGMT_CB_OK) {
        struct fs_mgmt_file_access *fs_data = (struct fs_mgmt_file_access *)data;

        /* Check if this is an upload and deny access if it is, otherwise check
         * the path and deny if is matches a name
         */
        if (fs_data->access == FS_MGMT_FILE_ACCESS_WRITE) {
            /* Return an access denied error code to the client and abort calling
             * further handlers
             */
            *abort_more = true;
            *rc = MGMT_ERR_EACCESSDENIED;

            return MGMT_CB_ERROR_RC;
        } else if (strcmp(fs_data->filename, "/lfs1/false_deny.txt") == 0) {
            /* Return a no entry error code to the client, call additional handlers
             * (which will have failed set to true)
             */
            *rc = MGMT_ERR_ENOENT;

            return MGMT_CB_ERROR_RC;
        }
    }

    /* Return OK status code to continue with acceptance to underlying handler */
    return MGMT_CB_OK;
}

int main()
{
    my_callback.callback = my_function;
    my_callback.event_id = MGMT_EVT_OP_FS_MGMT_FILE_ACCESS;
    mgmt_callback_register(&my_callback);
}
```

This code registers a handler for the `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` event, which will be called after a fs_mgmt file read/write command has been received to check if access to the file should be allowed or not, note that this requires that `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` be enabled to receive this callback. Two types of errors can be returned, the `rc` parameter can be set to an `mcumgr_err_t` error code and `MGMT_CB_ERROR_RC` can be returned, or a group error code (introduced with version 2 of the MCUmgr protocol) can be set by setting the `group` value to the group and `rc` value to the group error code and returning `MGMT_CB_ERROR_ERR`.

MCUmgr Command Callback Usage/Adding New Event Types To add a callback to a MCUmgr command, `mgmt_callback_notify()` can be called with the event ID and, optionally, a data struct

to pass to the callback (which can be modified by handlers). If no data needs to be passed back, NULL can be used instead, and size of the data set to 0.

An example MCUmgr command handler:

```
#include <zephyr/kernel.h>
#include <zcbor_common.h>
#include <zcbor_encode.h>
#include <zephyr/mgmt/mcumgr/smp/smp.h>
#include <zephyr/mgmt/mcumgr/mgmt/mgmt.h>
#include <zephyr/mgmt/mcumgr/mgmt/callbacks.h>

#define MGMT_EVT_GRP_USER_ONE MGMT_EVT_GRP_USER_CUSTOM_START

enum user_one_group_events {
    /** Callback on first post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_FIRST  = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 0),

    /** Callback on second post, data is test_struct. */
    MGMT_EVT_OP_USER_ONE_SECOND = MGMT_DEF_EVT_OP_ID(MGMT_EVT_GRP_USER_ONE, 1),

    /** Used to enable all user_one events. */
    MGMT_EVT_OP_USER_ONE_ALL    = MGMT_DEF_EVT_OP_ALL(MGMT_EVT_GRP_USER_ONE),
};

struct test_struct {
    uint8_t some_value;
};

static int test_command(struct mgmt_ctxt *ctxt)
{
    int rc;
    int err_rc;
    uint16_t err_group;
    zcbor_state_t *zse = ctxt->cnbe->zs;
    bool ok;
    struct test_struct test_data = {
        .some_value = 8,
    };

    rc = mgmt_callback_notify(MGMT_EVT_OP_USER_ONE_FIRST, &test_data,
                              sizeof(test_data), &err_rc, &err_group);

    if (rc != MGMT_CB_OK) {
        /* A handler returned a failure code */
        if (rc == MGMT_CB_ERROR_RC) {
            /* The failure code is the RC value */
            return err_rc;
        }

        /* The failure is a group and ID error value */
        ok = smp_add_cmd_err(zse, err_group, (uint16_t)err_rc);
        goto end;
    }

    /* All handlers returned success codes */
    ok = zcbor_tstr_put_lit(zse, "output_value") &&
         zcbor_int32_put(zse, 1234);
```

(continues on next page)

(continued from previous page)

```
end:
    rc = (ok ? MGMT_ERR_EOK : MGMT_ERR_EMSGSIZE);

    return rc;
}
```

If no response is required for the callback, the function call be called and casted to void.

Migration

If there is existing code using the previous callback system(s) in Zephyr 3.2 or earlier, then it will need to be migrated to the new system. To migrate code, the following callback registration functions will need to be migrated to register for callbacks using `mgmt_callback_register()` (note that `CONFIG_MCUMGR_MGMT_NOTIFICATION_HOOKS` will need to be set to enable the new notification system in addition to any migrations):

- **mgmt_evt**
  Using `MGMT_EVT_OP_CMD_RECV`, `MGMT_EVT_OP_CMD_STATUS`, or `MGMT_EVT_OP_CMD_DONE` as drop-in replacements for events of the same name, where the provided data is `mgmt_evt_op_cmd_arg`. `CONFIG_MCUMGR_SMP_COMMAND_STATUS_HOOKS` needs to be set.
- **fs_mgmt_register_evt_cb**
  Using `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` where the provided data is `fs_mgmt_file_access`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` needs to be set.
- **img_mgmt_register_callbacks**
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_STARTED` if `dfu_started_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_STOPPED` if `dfu_stopped_cb` was used, `MGMT_EVT_OP_IMG_MGMT_DFU_PENDING` if `dfu_pending_cb` was used or `MGMT_EVT_OP_IMG_MGMT_DFU_CONFIRMED` if `dfu_confirmed_cb` was used. These callbacks do not have any return status. `CONFIG_MCUMGR_GRP_IMG_STATUS_HOOKS` needs to be set.
- **img_mgmt_set_upload_cb**
  Using `MGMT_EVT_OP_IMG_MGMT_DFU_CHUNK` where the provided data is `img_mgmt_upload_check`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_IMG_UPLOAD_CHECK_HOOK` needs to be set.
- **os_mgmt_register_reset_evt_cb**
  Using `MGMT_EVT_OP_OS_MGMT_RESET`. Instead of returning true to allow the action or false to deny, a MCUmgr result code needs to be returned, `MGMT_ERR_EOK` will allow the action, any other return code will disallow it and return that code to the client (`MGMT_ERR_EACCESSDENIED` can be used for an access denied error). `CONFIG_MCUMGR_GRP_OS_RESET_HOOK` needs to be set.

4.9.4 SMP Protocol Specification

This is description of Simple Management Protocol, SMP, that is used by MCUmgr to pass requests to devices and receive responses from them.

SMP is an application layer protocol. The underlying transport layer is not in scope of this documentation.

> **Note**
>
> SMP in this context refers to SMP for MCUmgr (Simple Management Protocol), it is unrelated to SMP in Bluetooth (Security Manager Protocol), but there is an MCUmgr SMP transport for Bluetooth.

Frame: The envelope

Each frame consists of a header and data. The `Data Length` field in the header may be used for reassembly purposes if underlying transport layer supports fragmentation. Frames are encoded in "Big Endian" (Network endianness) when fields are more than one byte long, and takes the following form:

3								2								1								0							
7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0	7	6	5	4	3	2	1	0
Res			Ver		OP			Flags								Data Length															
Group ID																Sequence Num								Command ID							
Data ...																															

> **Note**
>
> The original specification states that SMP should support receiving both the "Little-endian" and "Big-endian" frames but in reality the MCUmgr library is hardcoded to always treat "Network" side as "Big-endian".

Data is optional and is not present when `Data Length` is zero. The encoding of data depends on the target of group/ID.

A description of the various fields and their meaning:

Field	Description
Res	This is reserved, not-used field and must be always set to 0.
Ver (Version)	This indicates the version of the protocol being used, this should be set to 0b01 to use the newer SMP transport where error codes are more detailed and returned in the map, otherwise left as 0b00 to use the legacy SMP protocol. Versions 0b10 and 0b11 are reserved for future use and should not be used.
OP	mcumgr_op_t, determines whether information is written to a device or requested from it and whether a packet contains request to an SMP server or response from it.
Flags	Reserved for flags; there are no flags defined yet, the field should be set to 0
Data Length	Length of the Data field
Group ID	mcumgr_group_t, see *Management Group ID's* for further details.
Sequence Num	This is a frame sequence number. The number is increased by one with each request frame. The Sequence Num of a response should match the one in the request.
Command ID	This is a command, within Group.
Data	This is data payload of the Data Length size. It is optional as Data Length may be set to zero, which means that no data follows the header.

Note

Contents of Data depends on a value of an OP, a Group ID, and a Command ID.

Management Group ID's The SMP protocol supports predefined common groups and allows user defined groups. The following table presents a list of common groups:

Decimal ID	Group description
0	*Default/OS Management Group*
1	*Application/software image management group*
2	*Statistics management*
3	*Settings (Config) Management Group*
4	Application/system log management (currently not used by Zephyr)
5	Run-time tests (unused by Zephyr)
6	Split image management (unused by Zephyr)
7	Test crashing application (unused by Zephyr)
8	*File system management*
9	*Shell management*
63	*Zephyr Management Group*
64	This is the base group for defining an application specific management groups.

The payload for above groups, except for user groups (64 and above) is always CBOR encoded. The group 64, and above can define their own scheme for data communication.

Minimal response

Regardless of a command issued, as long as there is SMP client on the other side of a request, a response should be issued containing the header followed by CBOR map container. Lack of response is only allowed when there is no SMP service or device is non-responsive.

Minimal response SMP data Minimal response is:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note that in the case of a successful command, an empty map will be returned (`rc`/`err` is only returned if there is an error condition, therefore if only an empty map is returned or a response lacks these, the request can be considered as being successful. For SMP version 2, errors relating to SMP itself that are not group specific will still be returned as `rc` errors, SMP version 2 clients must therefore be able to handle both types of errors.

Specifications of management groups supported by Zephyr

Default/OS Management Group OS management group defines following commands:

Command ID	Command description
0	Echo
1	Console/Terminal echo control; unimplemented by Zephyr
2	Task Statistics
3	Memory pool statistics
4	Date-time string
5	System reset
6	MCUMGR parameters
7	OS/Application info
8	Bootloader information

Echo command Echo command responses by sending back string that it has received.

Echo request Echo request header fields:

OP	Group ID	Command ID
0 or 2	0	0

CBOR data of request:

```
{
    (str)"d" : (str)
}
```

where:

“d”	string to be replied by echo service.

Echo response Echo response header fields:

OP	Group ID	Command ID	Note
1	0	0	When request OP was 0
3	0	0	When request OP was 2

CBOR data of successful response:

```
{
    (str)"r"        : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“r”	replying echo string.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Task statistics command The command responds with some system statistics.

Task statistics request Task statistics request header fields:

OP	Group ID	Command ID
0	0	2

The command sends an empty CBOR map as data.

Task statistics response Task statistics response header fields:

OP	Group ID	Command ID
1	0	2

CBOR data of successful response:

```
{
    (str)"tasks" : {
        (str)<task_name> : {
            (str)"prio"          : (uint)
            (str)"tid"           : (uint)
            (str)"state"         : (uint)
            (str)"stkuse"        : (uint)
            (str)"stksiz"        : (uint)
            (str)"cswcnt"        : (uint)
            (str)"runtime"       : (uint)
            (str)"last_checkin" : (uint)
            (str)"next_checkin" : (uint)
        }
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<task_nam	string identifying task.
“prio”	task priority.
“tid”	numeric task ID.
“state”	numeric task state.
“stkuse”	task’s/thread’s stack usage.
“stksiz”	task’s/thread’s stack size.
“cswcnt”	task’s/thread’s context switches.
“run-time”	task’s/thread’s runtime in “ticks”.
“last_check	set to 0 by Zephyr.
“next_chec	set to 0 by Zephyr.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note

The unit for “stkuse” and “stksiz” is system dependent and in case of Zephyr this is number of 4 byte words.

Memory pool statistics The command is used to obtain information on memory pools active in running system.

Memory pool statistic request Memory pool statistics request header fields:

OP	Group ID	Command ID
0	0	3

The command sends an empty CBOR map as data.

Memory pool statistics response Memory pool statistics response header fields:

OP	Group ID	Command ID
1	0	3

CBOR data of successful response:

```
{
    (str)"mpools" : {
        (str)<pool_name> : {
            (str)"blksiz"   : (int)
            (str)"nblks"    : (int)
            (str)"nfree"    : (int)
            (str)"min'      : (int)
        }
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<pool_na	string representing the pool name, used as a key for dictionary with pool statistics data.
"blk-siz"	size of the memory block in the pool. This value is always 1 in Zephyr, it can be omitted from responses by enabling `CONFIG_MCUMGR_GRP_OS_MPSTAT_ONLY_SUPPORTED_STATS`.
"nblks"	number of blocks in the pool.
"nfree"	number of free blocks.
"min"	lowest number of free blocks the pool reached during run-time.
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Date-time command The command allows to obtain string representing current time-date on a device or set a new time to a device. The time format used, by both set and get operations, is:

"yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ"

Date-time get The command allows to obtain date-time from a device.

Date-time get request Date-time request header fields:

OP	Group ID	Command ID
0	0	4

The command sends an empty CBOR map as data.

Date-time get response Date-time get response header fields:

OP	Group ID	Command ID
1	0	4

CBOR data of successful response:

```
{
    (str)"datetime" : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“datetime”	String in format: `yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ`.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Date-time set The command allows to set date-time to a device.

Date-time set request Date-time set request header fields:

OP	Group ID	Command ID
2	0	4

CBOR data of response:

```
{
    (str)"datetime" : (str)
}
```

where:

“datetime”	String in format: `yyyy-MM-dd'T'HH:mm:ss.SSSSSSZZZZZ`.

Date-time set response Date-time set response header fields:

OP	Group ID	Command ID
3	0	4

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

System reset Performs reset of system. The device should issue response before resetting so that the SMP client could receive information that the command has been accepted. By default, this command is accepted in all conditions, however if the `CONFIG_MCUMGR_GRP_OS_RESET_HOOK` is enabled and an application registers a callback, the callback will be called when this command is issued and can be used to perform any necessary tidy operations prior to the module rebooting, or to reject the reset request outright altogether with an error response. For details on this functionality, see *MCUmgr Callbacks*.

System reset request System reset request header fields:

OP	Group ID	Command ID
2	0	5

Normally the command sends an empty CBOR map as data, but if a previous reset attempt has responded with "rc" equal to `MGMT_ERR_EBUSY` then the following map may be sent to force a reset:

```
{
    (opt)"force"        : (int)
    (opt)"boot_mode"    : (uint)
}
```

where:

"force"	Force reset if value > 0, optional if 0.
"boot_mo	Specifies boot mode for image or application mode/selection, requires `CONFIG_MCUMGR_GRP_OS_RESET_BOOT_MODE` to be enabled.

System reset response System reset response header fields

OP	Group ID	Command ID
3	0	5

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

MCUmgr Parameters Used to obtain parameters of mcumgr library.

MCUmgr Parameters Request MCUmgr parameters request header fields:

OP	Group ID	Command ID
0	0	6

The command sends an empty CBOR map as data.

MCUmgr Parameters Response MCUmgr parameters response header fields

OP	Group ID	Command ID
1	0	6

CBOR data of successful response:

```
{
    (str)"buf_size"     : (uint)
    (str)"buf_count"    : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“buf_size”	Single SMP buffer size, this includes SMP header and CBOR payload.
“buf_count	Number of SMP buffers supported.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

OS/Application Info Used to obtain information on running image, similar functionality to the linux uname command, allowing details such as kernel name, kernel version, build date/time, processor type and application-defined details to be returned. This functionality can be enabled with `CONFIG_MCUMGR_GRP_OS_INFO`.

OS/Application Info Request OS/Application info request header fields:

OP	Group ID	Command ID
0	0	7

CBOR data of request:

```
{
    (str,opt)"format"       : (str)
}
```

where:

“format’	Format specifier of returned response, fields are appended in their natural ascending index order, not the order of characters that are received by the command. Format specifiers: * `s` Kernel name * `n` Node name * `r` Kernel release * `v` Kernel version * `b` Build date and time (requires `CONFIG_MCUMGR_GRP_OS_INFO_BUILD_DATE_TIME`) * `m` Machine * `p` Processor * `i` Hardware platform * `o` Operating system * `a` All fields (shorthand for all above options) If this option is not provided, the `s` Kernel name option will be used.

OS/Application Info Response OS/Application info response header fields

OP	Group ID	Command ID
1	0	7

CBOR data of successful response:

```
{
    (str)"output"       : (str)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“output”	Text response including requested parameters.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Bootloader Information Allows retrieving information about the on-board bootloader and its parameters.

Bootloader Information Request Bootloader information request header:

OP	Group ID	Command ID
0	0	8

CBOR data of request:

```
{
    (str,opt)"query"  : (str)
}
```

where:

“que	Is string representing query for parameters, with no restrictions how the query looks like as processing of query is left for bootloader backend. If there is no query, then response will return string identifying the bootloader.

Bootloader Information Response Bootloader information response header:

OP	Group ID	Command ID
1	0	8

In case when no “query” has been provided in request, CBOR data of response:

```
{
    (str)"bootloader"      : (str)
}
```

where:

“bootloader”	String representing bootloader name

In case when “query” is provided:

```
{
    (str,opt)<response>   : ()
    ...
}
```

where:

<re- spor	Response to “query”. This is optional and may be left out in case when query yields no response, SMP version 2 error code of *OS_MGMT_ERR_QUERY_YIELDS_NO_ANSWER* is expected. Response may have more than one parameter reported back or it may be a map, that is dependent on bootloader backednd and query.
...	Parameter characteristic information.

Parameter may be accompanied by additional, parameter specific, information keywords with assigned values.

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Bootloader Information: MCUboot In case when MCUboot is application bootloader, empty request will be responded with:

```
{
    (str)"bootloader"       : (str)"MCUboot"
}
```

Currently “MCUboot” supports querying for mode of operation:

```
{
    (str)"query"            : (str)"mode"
}
```

Response to “mode” is:

```
{
    (str)"mode"                     : (int)
    (str,opt)"no-downgrade"         : (bool)
}
```

where “mode” is one of:

-1	Unknown mode of MCUboot.
0	MCUboot is in single application mode.
1	MCUboot is in swap using scratch partition mode.
2	MCUboot is in overwrite (upgrade-only) mode.
3	MCUboot is in swap without scratch mode.
4	MCUboot is in DirectXIP without revert mode.
5	MCUboot is in DirectXIP with revert mode.
6	MCUboot is in RAM loader mode.

The `no-downgrade` field is a flag, which is always sent when true, indicating that MCUboot has downgrade prevention enabled; downgrade prevention means that if the uploaded image has a lower version than the currently running application, it will not be used for an update by MCUboot.

MCUmgr may reject images with a lower version in this configuration.

Application/software image management group Application/software image management group defines following commands:

Command ID	Command description
0	State of images
1	Image upload
2	File (reserved but not supported by Zephyr)
3	Corelist (reserved but not supported by Zephyr)
4	Coreload (reserved but not supported by Zephyr)
5	Image erase
6	Slot info

Notion of "slots" and "images" in Zephyr The "slot" and "image" definition comes from mcuboot where "image" would consist of two "slots", further named "primary" and "secondary"; the application is supposed to run from the "primary slot" and update is supposed to be uploaded to the "secondary slot"; the mcuboot is responsible in swapping slots on boot. This means that pair of slots is dedicated to single upgradable application. In case of Zephyr this gets a little bit confusing because DTS will use "slot0_partition" and "slot1_partition", as label of `fixed-partitions` or `zephyr,mapped-partition` dedicated to single application, but will name them as "image-0" and "image-1" respectively.

Currently Zephyr supports at most two images, in which case mapping is as follows:

Image	Slot labels	Slot Names
1	"slot0_partition" "slot1_partition"	"image-0" "image-1"
2	"slot2_partition" "slot3_partition"	"image-2" "image-3"

State of images The command is used to set state of images and obtain list of images with their current state.

Get state of images request Get state of images request header fields:

OP	Group ID	Command ID
0	1	0

The command sends an empty CBOR map as data.

Get state of images response Get state of images response header fields:

OP	Group ID	Command ID
1	1	0

Note

Below definition of the response contains "image" field that has been marked as optional(opt): the field may not appear in response when target application does not support more than one image. The field is mandatory when application supports more than one application image to allow identifying which image information is listed.

A response will only contain information for valid images, if an image can not be identified as valid it is simply skipped.

CBOR data of successful response:

```
{
    (str)"images" : [
        {
            (str,opt)"image"        : (uint)
            (str)"slot"             : (uint)
            (str)"version"          : (str)
            (str,opt*)"hash"        : (byte str)
            (str,opt)"bootable"     : (bool)
            (str,opt)"pending"      : (bool)
            (str,opt)"confirmed"    : (bool)
            (str,opt)"active"       : (bool)
            (str,opt)"permanent"    : (bool)
        }
        ...
    ]
    (str,opt)"splitStatus" : (int)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

"image"	semi-optional image number; the field is not required when only one image is supported by the running application.
"slot"	slot number within "image"; each image has two slots : primary (running one) = 0 and secondary (for DFU dual-bank purposes) = 1.
"version"	string representing image version, as set with `imgtool`.
"hash"	SHA256 hash of the image header and body. Note that this will not be the same as the SHA256 of the whole file, it is the field in the MCUboot TLV section that contains a hash of the data which is used for signature verification purposes. This field is optional but only optional when using MCUboot's serial recovery feature with one pair of image slots, Kconfig `CONFIG_BOOT_SERIAL_IMG_GRP_HASH` can be disabled to remove support for hashes in this configuration. MCUmgr in applications must support sending hashes. **Note** See `IMAGE_TLV_SHA256` in the MCUboot image format documentation link below.
"bootable"	true if image has bootable flag set; this field does not have to be present if false.
"pending"	true if image is set for next swap; this field does not have to be present if false.
"confirmed"	true if image has been confirmed; this field does not have to be present if false.
"active"	true if image is currently active application; this field does not have to be present if false.
"permanent"	true if image is to stay in primary slot after the next boot; this does not have to be present if false.
"splitStatus"	states whether loader of split image is compatible with application part; this is unused by Zephyr.
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
"rsn"	optional string that clarifies reason for an error; specifically useful when `rc` is `MGMT_ERR_EUNKNOWN`.

Note

For more information on how does image/slots function, please refer to the MCUBoot documentation https://docs.mcuboot.com/design.html#image-slots For information on MCUboot image format, please reset to the MCUboot documentation https://docs.mcuboot.com/design.html#image-format

Set state of image request Set state of image request header fields:

OP	Group ID	Command ID
2	1	0

CBOR data of request:

```
{
    (str,opt)"hash"     : (byte str)
    (str)"confirm"      : (bool)
}
```

If “confirm” is false or not provided, an image with the “hash” will be set for test, which means that it will not be marked as permanent and upon hard reset the previous application will be restored to the primary slot. In case when “confirm” is true, the “hash” is optional as the currently running application will be assumed as target for confirmation.

Set state of image response The response takes the same format as *Get state of images response*

Image upload The image upload command allows to update application image.

Image upload request The image upload request is sent for each chunk of image that is uploaded, until complete image gets uploaded to a device.

Image upload request header fields:

OP	Group ID	Command ID
2	1	1

CBOR data of request:

```
{
    (str,opt)"image"    : (uint)
    (str,opt)"len"      : (uint)
    (str)"off"          : (uint)
    (str,opt)"sha"      : (byte str)
    (str)"data"         : (byte str)
    (str,opt)"upgrade"  : (bool)
}
```

where:

“image”	optional image number, it does not have to appear in request at all, in which case it is assumed to be 0. Should only be present when “off” is 0.
“len”	optional length of an image. Must appear when “off” is 0.
“off”	offset of image chunk the request carries.
“sha	SHA256 hash of an upload; this is used to identify an upload session (e.g. to allow MCUmgr to continue a broken session), and for image verification purposes. This must be a full SHA256 hash of the whole image being uploaded, or not included if the hash is not available (in which case, upload session continuation and image verification functionality will be unavailable). Should only be present when “off” is 0.
“dat	image data to write at provided offset.
“upgrad	optional flag that states that only upgrade should be allowed, so if the version of uploaded software is not higher then already on a device, the image upload will be rejected. Zephyr compares major, minor and revision (x.y.z) by default unless `CONFIG_MCUMGR_GRP_IMG_VERSION_CMP_USE_BUILD_NUMBER` is set, whereby it will compare build numbers too. Should only be present when “off” is 0.

Note

There is no field representing size of chunk that is carried as “data” because that information is embedded within “data” field itself.

Note

It is possible that a server will respond to an upload with “off” of 0, this may happen if an upload on another transport (or outside of MCUmgr entirely) is started, if the device has re-booted or if a packet has been lost. If this happens, a client must re-send all the required and optional fields that it sent in the original first packet so that the upload state can be re-created by the server. If the original fields are not included, the upload will be unable to continue.

The MCUmgr library uses “sha” field to tag ongoing update session, to be able to continue it in case when it gets broken, and for upload verification purposes. If library gets request with “off” equal zero it checks stored “sha” within its state and if it matches it will respond to update client application with offset that it should continue with. If this hash is not available (e.g. because a file is being streamed) then it must not be provided, image verification and upload session continuation features will be unavailable in this case.

Image upload response Image upload response header fields:

OP	Group ID	Command ID
3	1	1

CBOR data of successful response:

```
{
    (str,opt)"off"    : (uint)
    (str,opt)"match"  : (bool)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

“off”	offset of last successfully written byte of update.
“match”	indicates if the uploaded data successfully matches the provided SHA256 hash or not, only sent in the final packet if `CONFIG_IMG_ENABLE_IMAGE_CHECK` is enabled.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
“rsn”	optional string that clarifies reason for an error; specifically useful when `rc` is `MGMT_ERR_EUNKNOWN`.

The “off” field is only included in responses to successfully processed requests; if “rc” is negative then “off” may not appear.

Image erase The command is used for erasing image slot on a target device.

> **Note**
>
> This is synchronous command which means that a sender of request will not receive response until the command completes, which can take a long time.

Image erase request Image erase request header fields:

OP	Group ID	Command ID
2	1	5

CBOR data of request:

```
{
    (str,opt)"slot"     : (uint)
}
```

where:

“slot”	optional slot number, it does not have to appear in the request at all, in which case it is assumed to be 1.

Image erase response Image erase response header fields:

OP	Group ID	Command ID
3	1	5

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
```

(continues on next page)

(continued from previous page)

```
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
    (str,opt)"rsn"  : (str)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.
"rsn"	optional string that clarifies reason for an error; specifically useful when `rc` is `MGMT_ERR_EUNKNOWN`.

Note

Response from Zephyr running device may have "rc" value of `MGMT_ERR_EBADSTATE`, which means that the secondary image has been marked for next boot already and may not be erased.

Slot info The command is used for fetching information on slots that are available. This command can be enabled with `CONFIG_MCUMGR_GRP_IMG_SLOT_INFO`.

Slot info request Slot info request header fields:

OP	Group ID	Command ID
0	1	6

The command sends an empty CBOR map as data.

Slot info response Slot info response header fields:

OP	Group ID	Command ID
1	1	6

CBOR data of successful response:

```
{
    (str)"images" : [
        {
            (str)"image"                        : (uint)
```

(continues on next page)

(continued from previous page)

```
            (str)"slots" : [
                {
                    (str)"slot"                 : (uint)
                    (str)"size"                 : (uint)
                    (str,opt)"upload_image_id"  : (uint)
                }
                ...
            ]
            (str,opt)"max_image_size"           : (uint)
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“image”	the image number being enumerated.
“slot”	the slot inside the image being enumerated (note: this will be 0 or 1, it is the slot of the image not the physical slot number).
“size”	the size of the slot.
“upload_im	optional field (only present if `CONFIG_MCUMGR_GRP_IMG_DIRECT_UPLOAD` is enabled to allow direct image uploads) which specifies the image ID that can be used by external tools to upload an image to that slot.
“max_ir	optional field (only present if `CONFIG_MCUMGR_GRP_IMG_TOO_LARGE_SYSBUILD` or `CONFIG_MCUMGR_GRP_IMG_TOO_LARGE_BOOTLOADER_INFO` are enabled) which specifies the maximum size of an application that can be uploaded to that image number.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears ifnon-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Statistics management Statistics management allows to obtain data gathered by Statistics subsystem of Zephyr, enabled with `CONFIG_STATS`.

Statistics management group defines commands:

Command ID	Command description
0	Group data
1	List groups

Statistics: group data The command is used to obtain data for group specified by a name. The name is one of group names as registered, with `STATS_INIT_AND_REG` macro or `stats_init_and_reg()` function call, within module that gathers the statistics.

Statistics: group data request Statistics group data request header:

OP	Group ID	Command ID
0	2	0

CBOR data of request:

```
{
    (str)"name" :  (str)
}
```

where:

“name”	group name.

Statistics: group data response Statistics group data response header:

OP	Group ID	Command ID
1	2	0

CBOR data of successful response:

```
{
    (str)"name"     : (str)
    (str)"fields"   : {
        (str)<entry_name> : (uint)
        ...
    }
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“name”	this is name of group the response contains data for.
“fields”	this is map of entries within groups that consists of pairs where the entry name is mapped to value it represents in statistics.
<entry_name>	single entry to value mapping; value is hardcoded to unsigned integer type, in a CBOR meaning.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Statistics: list of groups The command is used to obtain list of groups of statistics that are gathered on a device. This is a list of names as given to groups with `STATS_INIT_AND_REG` macro or `stats_init_and_reg()` function calls, within module that gathers the statistics; this means that this command may be considered optional as it is known during compilation what groups will be included into build and listing them is not needed prior to issuing a query.

Statistics: list of groups request Statistics group list request header:

OP	Group ID	Command ID
0	2	1

The command sends an empty CBOR map as data.

Statistics: list of groups response Statistics group list request header:

OP	Group ID	Command ID
1	2	1

CBOR data of successful response:

```
{
    (str)"stat_list" :  [
        (str)<stat_group_name>, ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
```

(continues on next page)

(continued from previous page)

```
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“stat_list”	array of strings representing group names; this array may be empty if there are no groups.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Settings (Config) Management Group Settings management group (known as Configuration Manager in the original MCUmgr repository) defines the following commands:

Command ID	Command description
0	Read/write setting
1	Delete setting
2	Commit settings
3	Load/Save settings

Note that the Zephyr version adds additional commands and features which are not supported by the original upstream version, however, the original client functionality should work for read/write functionality.

Read/write setting command Read/write setting command allows updating a setting entry on a device or getting the current value of a setting from a device.

Read setting request Read setting request header fields:

OP	Group ID	Command ID
0	3	0

CBOR data of request:

```
{
    (str)"name"         : (str)
    (str,opt)"max_size" : (uint)
}
```

where:

“name”	string of the setting to retrieve
“max_size”	optional maximum size of data to return

Read setting response Read setting response header fields:

OP	Group ID	Command ID
1	3	0

CBOR data of successful response:

```
{
    (str)"val"          : (bstr)
    (str,opt)"max_size" : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“val”	binary string of the returned data, note that the underlying data type cannot be specified through this and must be known by the client.
“max_s	will be set if the maximum supported data size is smaller than the maximum requested data size, and contains the maximum data size which the device supports, equivalent to kconfig:option:*CONFIG_MCUMGR_GRP_SETTINGS_NAME_LEN*.
“err” -> “group	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Write setting request Write setting request header fields:

OP	Group ID	Command ID
2	3	0

CBOR data of request:

```
{
    (str)"name"     : (str)
```

(continues on next page)

(continued from previous page)

```
    (str)"val"      : (bstr)
}
```

where:

“name”	string of the setting to update/set
“val”	value to set the setting to

Write setting response Write setting response header fields:

OP	Group ID	Command ID
3	3	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Delete setting command Delete setting command allows deleting a setting on a device.

Delete setting request Delete setting request header fields:

OP	Group ID	Command ID
2	3	1

CBOR data of request:

```
{
    (str)"name"   : (str)
}
```

where:

“name”	string of the setting to delete

Delete setting response Delete setting response header fields:

OP	Group ID	Command ID
3	3	1

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Commit settings command Commit settings command allows committing all settings that have been set but not yet applied on a device.

Commit settings request Commit settings request header fields:

OP	Group ID	Command ID
2	3	2

The command sends an empty CBOR map as data.

Commit settings response Commit settings response header fields:

OP	Group ID	Command ID
3	3	2

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Load/Save settings command Load/Save settings command allows loading/saving all serialized items from/to persistent storage on a device.

Load settings request Load settings request header fields:

OP	Group ID	Command ID
0	3	3

The command sends an empty CBOR map as data.

Load settings response Load settings response header fields:

OP	Group ID	Command ID
1	3	3

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Save settings request Save settings request header fields:

OP	Group ID	Command ID
2	3	3

CBOR data of request:

```
{
    (str,opt)"name" : (str)
}
```

where:

“nan	If provided, contains the settings subtree name to save (can also be a single setting name if `CONFIG_SETTINGS_SAVE_SINGLE_SUBTREE_WITHOUT_MODIFICATION` is enabled), if not then will save all settings.

Save settings response Save settings response header fields:

OP	Group ID	Command ID
3	3	3

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Settings access callback There is a settings access MCUmgr callback available (see *MCUmgr Callbacks* for details on callbacks) which allows for applications/modules to know when settings management commands are used and, optionally, block access (for example through the use of a security mechanism). This callback can be enabled with `CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK`, registered with the event `MGMT_EVT_OP_SETTINGS_MGMT_ACCESS`, whereby the supplied callback data is `settings_mgmt_access`.

File system management The file system management group provides commands that allow to upload and download files to/from a device.

File management group defines following commands:

Command ID	Command description
0	File download/upload
1	File status
2	File hash/checksum
3	Supported file hash/checksum types
4	File close

File download Command allows to download contents of an existing file from specified path of a target device. Client applications must keep track of data they have already downloaded and where their position in the file is (MCUmgr will cache these also), and issue subsequent requests, with modified offset, to gather the entire file. Request does not carry size of requested chunk, the size is specified by application itself. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

Note

By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` (see *MCUmgr callbacks*), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

File download request File download request header:

OP	Group ID	Command ID
0	8	0

CBOR data of request:

```
{
    (str)"off" :  (uint)
    (str)"name" : (str)
}
```

where:

“off”	offset to start download at
“name”	absolute path to a file

File download response File download response header:

OP	Group ID	Command ID
1	8	0

CBOR data of successful response:

```
{
    (str)"off"      : (uint)
    (str)"data"     : (byte str)
    (str,opt)"len"  : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“off”	offset the response is for.
“data”	chunk of data read from file; it is CBOR encoded stream of bytes with embedded size; “data” appears only in responses where “rc” is 0.
“len”	length of file, this field is only mandatory when “off” is 0.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File upload Allows to upload a file to a specified location. Command will automatically overwrite existing file or create a new one if it does not exist at specified path. The protocol supports stateless upload where each requests carries different chunk of a file and it is client side responsibility to track progress of upload.

Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached, but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed. Note that file handles will remain open for consecutive requests (as long as an idle timeout has not been reached and another transport does not make use of uploading/downloading files using fs_mgmt), but files are not exclusively owned by MCUmgr, for the time of download session, and may change between requests or even be removed.

Note

Weirdly, the current Zephyr implementation is half-stateless as is able to hold single upload context, holding information on ongoing upload, that consists of bool flag indicating in-progress upload, last successfully uploaded offset and total length only.

Note

By default, all file upload/download requests are unconditionally allowed. However, if the Kconfig option `CONFIG_MCUMGR_GRP_FS_FILE_ACCESS_HOOK` is enabled, then an application can register a callback handler for `MGMT_EVT_OP_FS_MGMT_FILE_ACCESS` (see *MCUmgr callbacks*), which allows for allowing or declining access to reading/writing a particular file, or for rewriting the path supplied by the client.

File upload request File upload request header:

OP	Group ID	Command ID
2	8	0

CBOR data of request:

```
{
    (str)"off"      : (uint)
    (str)"data"     : (str)
    (str)"name"     : (str)
    (str,opt)"len"  : (uint)
}
```

where:

“off”	offset to start/continue upload at.
“data”	chunk of data to write to the file; it is CBOR encoded with length embedded.
“name”	absolute path to a file.
“len”	length of file, this field is only mandatory when “off” is 0.

File upload response File upload response header:

OP	Group ID	Command ID
3	8	0

CBOR data of successful response:

```
{
    (str)"off"      : (uint)
}
```

In case of error the CBOR data takes the form:

where:

“off”	offset of last successfully written data.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File status Command allows to retrieve status of an existing file from specified path of a target device.

File status request File status request header:

OP	Group ID	Command ID
0	8	1

CBOR data of request:

```
{
    (str)"name" : (str)
}
```

where:

“name”	absolute path to a file.

File status response File status response header:

OP	Group ID	Command ID
1	8	1

CBOR data of successful response:

```
{
    (str)"len"      : (uint)
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"len"	length of file (in bytes).
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File hash/checksum Command allows to generate a hash/checksum of an existing file at a specified path on a target device. Note that kernel heap memory is required for buffers to be allocated for this to function, and large stack memory buffers are required for generation of the output hash/checksum. Requires `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH` to be enabled for the base functionality, supported hash/checksum are opt-in with `CONFIG_MCUMGR_GRP_FS_CHECKSUM_IEEE_CRC32` or `CONFIG_MCUMGR_GRP_FS_HASH_SHA256`.

File hash/checksum request File hash/checksum request header:

OP	Group ID	Command ID
0	8	2

CBOR data of request:

```
{
    (str)"name"     : (str)
    (str,opt)"type" : (str)
    (str,opt)"off"  : (uint)
    (str,opt)"len"  : (uint)
}
```

where:

"name"	absolute path to a file.
"type"	type of hash/checksum to perform *Hash/checksum types* or omit to use default.
"off"	offset to start hash/checksum calculation at (optional, 0 if not provided).
"len"	maximum length of data to read from file to generate hash/checksum with (optional, full file size if not provided).

Hash/checksum types

String name	Hash/checksum	Byte string	Size (bytes)
crc32	IEEE CRC32 checksum	No	4
sha256	SHA256 (Secure Hash Algorithm)	Yes	32

Note that the default type will be crc32 if it is enabled, or sha256 if crc32 is not enabled.

File hash/checksum response File hash/checksum response header:

OP	Group ID	Command ID
1	8	2

CBOR data of successful response:

```
{
    (str)"type"     : (str)
    (str,opt)"off"  : (uint)
    (str)"len"      : (uint)
    (str)"output"   : (uint or bstr)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“type”	type of hash/checksum that was performed *Hash/checksum types*.
“off”	offset that hash/checksum calculation started at (only present if not 0).
“len”	length of input data used for hash/checksum generation (in bytes).
“output”	output hash/checksum.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Supported file hash/checksum types Command allows listing which hash and checksum types are available on a device. Requires Kconfig `CONFIG_MCUMGR_GRP_FS_CHECKSUM_HASH_SUPPORTED_CMD` to be enabled.

Supported file hash/checksum types request Supported file hash/checksum types request header:

OP	Group ID	Command ID
0	8	3

The command sends empty CBOR map as data.

Supported file hash/checksum types response Supported file hash/checksum types response header:

OP	Group ID	Command ID
1	8	3

CBOR data of successful response:

```
{
    (str)"types" : {
        (str)<hash_checksum_name> : {
            (str)"format"       : (uint)
            (str)"size"         : (uint)
        }
        ...
    }
}
```

In case of error the CBOR data takes form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

<hash_checksur	name of the hash/checksum type *Hash/checksum types*.
“format”	format that the hash/checksum returns where 0 is for numerical and 1 is for byte array.
“size”	size (in bytes) of output hash/checksum response.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

File close Command allows closing any open file handles held by fs_mgmt upload/download requests that might have stalled or be incomplete.

File close request File close request header:

OP	Group ID	Command ID
2	8	4

The command sends empty CBOR map as data.

File close response File close response header:

OP	Group ID	Command ID
3	8	4

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Shell management Shell management allows passing commands to the shell subsystem over the SMP protocol.

Shell management group defines following commands:

Command ID	Command description
0	Shell command line execute

Shell command line execute The command allows to execute command line in a similar way to typing it into a shell, but both a request and a response are transported over SMP.

Shell command line execute request Execute command request header:

OP	Group ID	Command ID
2	9	0

CBOR data of request:

```
{
    (str)"argv"     : [
        (str)<cmd>
        (str,opt)<arg>
        ...
    ]
}
```

where:

“argv”	array consisting of strings representing command and its arguments.
<cmd>	command to be executed.
<arg>	optional arguments to command.

Shell command line execute response Command line execute response header fields:

OP	Group ID	Command ID
3	9	0

CBOR data of successful response:

```
{
    (str)"o"            : (str)
    (str)"ret"          : (int)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1 (and non-group SMP version 2)

```
{
    (str)"rc"       : (int)
}
```

where:

“o”	command output.
“ret”	return code from shell command execution.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Note

In older versions of Zephyr, “rc” was used for both the mcumgr status code and shell command execution return code, this legacy behaviour can be restored by enabling `CONFIG_MCUMGR_GRP_SHELL_LEGACY_RC_RETURN_CODE`

Enumeration Management Group Enumeration management group defines the following commands:

Command ID	Command description
0	Count of supported groups
1	List supported groups
2	Fetch single group ID
3	Details on supported groups

Count of supported groups command Count of supported groups returns the total number of MCUmgr command groups that a device supports.

Count of supported groups request Read setting request header fields:

OP	Group ID	Command ID
0	10	0

The command sends an empty CBOR map as data.

Count of supported groups response Count of supported groups response header fields:

OP	Group ID	Command ID
1	10	0

CBOR data of successful response:

```
{
    (str)"count"        : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"count"	contains the total number of supported MCUmgr groups on the device.
"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

List supported groups command List supported groups command allows listing the group IDs of supported MCUmgr groups on the device.

List supported groups request List supported groups request header fields:

OP	Group ID	Command ID
0	10	1

The command sends an empty CBOR map as data.

List supported groups response List supported groups response header fields:

OP	Group ID	Command ID
1	10	1

CBOR data of successful response:

```
{
    (str)"groups" : [
        (uint)
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“groups”	contains a list of the supported MCUmgr group IDs on the device.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Fetch single group ID command Fetch single group ID command allows listing the group IDs of supported MCUmgr groups on the device, one by one.

Fetch single group ID request Fetch single group ID request header fields:

OP	Group ID	Command ID
0	10	2

CBOR data of request:

```
{
    (str,opt)"index" : (uint)
}
```

where:

“index”	contains the (0-based) index of the group to return information on, can be omitted to return the first group’s details.

Fetch single group ID response Fetch single group ID response header fields:

OP	Group ID	Command ID
1	10	2

CBOR data of successful response:

```
{
    (str)"group"    : (uint)
```

(continues on next page)

(continued from previous page)

```
    (str,opt)"end"  : (bool)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“group”	contains the list of the supported MCUmgr group IDs on the device.
“end”	will be set to true if the listed group is the final supported group on the device, otherwise will be omitted.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Details on supported groups command Details on supported groups command allows fetching details on each supported MCUmgr group, such as the name and number of handlers. A device can specify an allow list of groups to return details on or details on all groups can be returned.

This command is optional, it can be enabled using `CONFIG_MCUMGR_GRP_ENUM_DETAILS`. The optional name and number of handlers can be enabled/disabled with `CONFIG_MCUMGR_GRP_ENUM_DETAILS_NAME` and `CONFIG_MCUMGR_GRP_ENUM_DETAILS_HANDLERS`.

Details on supported groups request Details on supported groups request header fields:

OP	Group ID	Command ID
0	10	3

Details on all groups

The command sends an empty CBOR map as data.

Details on specified groups

CBOR data of request:

```
{
    (str)"groups" : [
        (uint)
        ...
    ]
}
```

where:

“groups”	contains a list of the MCUmgr group IDs to fetch details on.

Details on supported groups response Details on supported groups response header fields:

OP	Group ID	Command ID
1	10	3

CBOR data of successful response:

```
{
    (str)"groups" : [
        {
            (str)"group"          : (uint)
            (str,opt)"name"       : (str)
            (str,opt)"handlers"   : (uint)
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“group”	the group ID of the MCUmgr command group.
“name”	the name of the MCUmgr command group.
“handlers”	the number of handlers that the MCUmgr command group supports.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Details on supported groups callback There is a details on supported groups MCUmgr callback available (see *MCUmgr Callbacks* for details on callbacks) which allows for applications/modules to add additional fields to this response. This callback can be enabled with `CONFIG_MCUMGR_GRP_ENUM_DETAILS_HOOK`, registered with the event `MGMT_EVT_OP_ENUM_MGMT_DETAILS`, whereby the supplied callback data is `enum_mgmt_detail_output`. Note that `CONFIG_MCUMGR_GRP_ENUM_DETAILS_STATES` will need incrementing by the number of additional extra fields that are added.

Transport Management Group Transport management group defines the following commands:

Command ID	Command description
0	Connect (bridge) transport
1	Disconnect bridged transport
2	Fetch bridge/transport status
6	List transports
7	Details on transport modes
8	Details on transport configuration

Note

Transport management is experimental and subject to change without notice.

Connect (bridge) transport command Bridge the transport which received the MCUmgr packet to another MCUmgr transport.

Connect (bridge) transport request Connect (bridge) transport request header fields:

OP	Group ID	Command ID
2	11	0

CBOR data of request:

```
{
    (str)"transport" : (uint)
    (str,opt)"mode"  : (uint)
    ...
}
```

where:

"transport"	`smp_transport_type` contains the tranport type for which to bridge (connect) from the transport to.
"mode"	contains the configuration mode of the transport to use, may be omitted to use the default value of 0.
...	there might be additional fields that the transport requires in order to make a connection, these are not described here as are transport-specific.

Connect (bridge) transport response Connect (bridge) transport response header fields:

OP	Group ID	Command ID
3	11	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Disconnect bridged transport command Disconnect the current transport's bridge, or disconnect all transport bridges.

Disconnect bridged transport request Disconnect bridged transport request header fields:

OP	Group ID	Command ID
2	11	1

CBOR data of request:

Disconnect bridge of current transport

The command sends an empty CBOR map as data.

Disconnect an active bridge

```
{
    (str)"transport" : (uint)
}
```

Disconnect all bridges

```
{
    (str)"all" :       (bool)
}
```

where:

"transport"	`smp_transport_type` contains the tranport type for which to disconnect the bridge from, this must not be provided if `all` is provided.
"all"	set to true to disconnect all active bridged transports, this must not be provided if `transport` is provided.

Disconnect bridged transport response Disconnect bridged transport response header fields:

OP	Group ID	Command ID
3	11	1

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Fetch bridge/transport status command Return information on active bridges and what the device supports.

Fetch bridge/transport status request Fetch bridge/transport status request header fields:

OP	Group ID	Command ID
0	11	2

The command sends an empty CBOR map as data.

Fetch bridge/transport status response Fetch bridge/transport status response header fields:

OP	Group ID	Command ID
1	11	2

CBOR data of successful response:

```
{
    (str)"supported"      : (uint)
    (str)"active"         : (uint)
    (str,opt)"bridged"    : (bool)
    (str,opt)"transport"  : (uint)
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“supported”	contains how many bridges can be active at a given time.
“active”	contains how many bridges are currently active.
“bridged”	will be present and true if the current transport is bridged, otherwise will be omitted.
“transport”	the transport ID of the MCUmgr transport that the transport is bridged to. Only appears if the transport is bridged.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

List transports command Return information on transports that the device supports.

List transports request List transports request header fields:

OP	Group ID	Command ID
0	11	6

The command sends an empty CBOR map as data.

List transports response List transports response header fields:

OP	Group ID	Command ID
1	11	6

CBOR data of successful response:

```
{
    (str)"transports" : [
        {
            (str)"id"         : (uint)
            (str,opt)"name"   : (str)
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“id”	the transport ID of the MCUmgr transport that supports bridging.
“name”	optional name of the MCUmgr transport (if available).
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Details on transport modes command Return information on modes of a transport that the device supports.

Details on transport mode request Details on transport modes request header fields:

OP	Group ID	Command ID
0	11	7

CBOR data of request:

```
{
    (str)"transport" : (uint)
}
```

where:

“transport”	`smp_transport_type` contains the tranport type for which to get details on.

Details on transport modes response Details on transport modes response header fields:

OP	Group ID	Command ID
1	11	7

CBOR data of successful response:

```
{
    (str)"modes" : [
        {
            (str)"id"            : (uint)
            (str)"description"   : (str)
            (str,opt)"incoming"  : (bool)
            (str,opt)"outgoing"  : (bool)
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“id”	the ID of the transport mode.
“description”	description of the transport mode.
“incoming”	will be set to true if transport mode supports incoming bridge connections.
“outgoing”	will be set to true if transport mode supports outgoing bridge connections.
“err” -> “group”	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err” -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Details on transport configuration command Return information on transport configuration that is supported.

Details on transport configuration request Details on transport configuration request header fields:

OP	Group ID	Command ID
0	11	8

CBOR data of request:

```
{
    (str)"transport" : (uint)
    (str)"mode"      : (uint)
}
```

where:

“transport”	`smp_transport_type` contains the tranport type for which to get configuration information for.
“mode”	contains the configuration mode of the tranport type which to get configuration information for.

Details on transport configuration response Details on transport configuration response header fields:

OP	Group ID	Command ID
1	11	8

CBOR data of successful response:

```
{
    (str)"configs" : [
        {
            (str)"name"          : (str)
            (str)"type"          : (uint)
            (str,opt)"required"  : (bool)
```

(continues on next page)

(continued from previous page)

```
        }
        ...
    ]
}
```

In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

“nar	name of the configuration item.
“typ	**the type of the configuration item, using the following mapping:** • 0: uint • 1: int • 2: bool • 3: string • 4: byte string
“re-quir	will be present and set to true if the parameter is required.
“err -> “gro	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
“err -> “rc”	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
“rc”	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

Zephyr Management Group Zephyr management group defines the following commands:

Command ID	Command description
0	Erase storage

Erase storage command Erase storage command allows clearing the `storage_partition` flash partition on a device, generally this is used when switching to a new application build if the application uses storage that should be cleared (application dependent).

Erase storage request Erase storage request header fields:

OP	Group ID	Command ID
2	63	0

The command sends sends empty CBOR map as data.

Erase storage response Read setting response header fields:

OP	Group ID	Command ID
3	63	0

The command sends an empty CBOR map as data if successful. In case of error the CBOR data takes the form:

SMP version 2

```
{
    (str)"err" : {
        (str)"group"    : (uint)
        (str)"rc"       : (uint)
    }
}
```

SMP version 1

```
{
    (str)"rc"       : (int)
}
```

where:

"err" -> "group"	`mcumgr_group_t` group of the group-based error code. Only appears if an error is returned when using SMP version 2.
"err" -> "rc"	contains the index of the group-based error code. Only appears if non-zero (error condition) when using SMP version 2.
"rc"	`mcumgr_err_t` only appears if non-zero (error condition) when using SMP version 1 or for SMP errors when using SMP version 2.

4.9.5 SMP Transport Specification

The documents specifies information needed for implementing server and client side SMP transports.

Bluetooth Low Energy (LE)

MCUmgr Clients need to use following Bluetooth Characteristics, when implementing SMP client:

- **Service UUID**: `8D53DC1D-1DB7-4CD3-868B-8A527460AA84`
- **Characteristic UUID**: `DA2E7828-FBCE-4E01-AE9E-261174997C48`

All SMP communication utilizes a single GATT characteristic. An SMP request is sent via a GATT Write Without Response command. An SMP response is sent in the form of a GATT Notification

If an SMP request or response is too large to fit in a single GATT command, the sender fragments it across several packets. No additional framing is introduced when a request or response is fragmented; the payload is simply split among several packets. Since GATT guarantees ordered

delivery of packets, the SMP header in the first fragment contains sufficient information for reassembly.

UART/serial and console

SMP protocol specification by MCUmgr subsystem of Zephyr uses basic framing of data to allow multiplexing of UART channel. Multiplexing requires prefixing each frame with two byte marker and terminating it with newline. Currently MCUmgr imposes a 127 byte limit on frame size, although there are no real protocol constraints that require that limit. The limit includes the prefix and the newline character, so the allowed payload size is actually 124 bytes.

Although no such transport exists in Zephyr, it is possible to implement MCUmgr client/server over UART transport that does not have framing at all, or uses hardware serial port control, or other means of framing.

Frame fragmenting SMP protocol over serial is fragmented into frames of up to 127 bytes; each frame consists of two byte start marker, body and terminating newline character.

There are four types of types of frames: initial, partial, partial-final and initial-final; each frame type differs by start marker and/or body contents.

Frame formats Initial frame requires to be followed by optional sequence of partial frames and finally by partial-final frame. Body is always Base64 encoded, so the body size, here described as MTU - 3, is able to actually carry N = (MTU - 3) / 4 * 3 bytes of raw data.

Body of initial frame is preceded by two byte total packet length, encoded in Big Endian, and equals size of a raw body plus two bytes, size of CRC16; this means that actual body size allowed into an initial frame is N - 2.

If a body size is smaller than N - 4, than it is possible to carry entire body with preceding length and following it CRC in a single frame, here called initial-final; for the description of initial-final frame look below.

Initial frame format:

Content	Size	Description
0x06 0x09	2 bytes	Frame start marker
<base64-i>	no more than MTU - 3 bytes	Base64 encoded body
0x0a	1 byte	Frame termination

<base64-i> is Base64 encoded body of format:

Content	Size	Description
total length	2 bytes	Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.
body	no more than MTU - 5	Raw body data fragment

Initial-final frame format is similar to initial frame format, but differs by <base64-i> definition.

<base64-i> of initial-final frame, is Base64 encoded data taking form:

Content	Size	Description
total length	2 bytes	Big endian 16-bit value representing total length of body + 2 bytes for CRC16; note that size of total length field is not added to total length value.
body	no more than MTU - 7	Raw body data fragment
crc16	2 bytes	CRC16 of entire packet body, preceding length not included.

Partial frame is continuation after previous initial or other partial frame. Partial frame takes form:

Content	Size	Description
0x04 0x14	2 bytes	Frame start marker
<base64-i>	no more than MTU - 3 bytes	Base64 encoded body
0x0a	1 byte	Frame termination

The `<base64-i>` of partial frame is Base64 encoding of data, taking form:

Content	Size	Description
body	no more than MTU - 3	Raw body data fragment

The `<base64-i>` of partial-final frame is Base64 encoding of data, taking form:

Content	Size	Description
body	no more than MTU - 5	Raw body data fragment
crc16	2 bytes	CRC16 of entire packet body, preceding length not included.

CRC Details The CRC16 included in final type frames is calculated over only raw data and does not include packet length. CRC16 polynomial is 0x1021 and initial value is 0.

Raw UART/serial (without console)

In Zephyr, an alternative transport is available for UART which does not use Base64 as the SMP over console transport does, this allows for smaller code size and faster transfers - but cannot be used on devices which have shell or log output on the same UART or are connected to terminals that are displaying ASCII data, as all communication is done using the raw binary SMP protocol.

To use this protocol, use `CONFIG_MCUMGR_TRANSPORT_RAW_UART`, it requires the MCUmgr UART console driver to be enabled in raw mode.

Timeout Because there is no framing when using this transport, it is possible that there might be invalid data received on the UART which causes the system to wait for e.g. a very long packet which is not going to arrive. To prevent this, a timeout system exists whereby if the full packet is not received within a specific timeframe, the whole receive buffer is cleared. It is recommended that this option should be enabled on UART ports, for transports like USB CDC whereby it is a "virtual" UART and the data can be verified before being passed, this option is not needed. The option can be enabled with `CONFIG_MCUMGR_TRANSPORT_RAW_UART_INPUT_TIMEOUT`, the timeout for this can be set with `CONFIG_MCUMGR_TRANSPORT_RAW_UART_INPUT_TIMEOUT_TIME_MS`.

API Reference

SMP transport

4.9.6 Device Firmware Upgrade

Overview

The Device Firmware Upgrade subsystem provides the necessary frameworks to upgrade the image of a Zephyr-based application at run time. It currently consists of two different modules:

- subsys/dfu/boot/: Interface code to bootloaders
- subsys/dfu/img_util/: Image management code

The DFU subsystem deals with image management, but not with the transport or management protocols themselves required to send the image to the target device. For information on these protocols and frameworks please refer to the *Device Management* section.

Flash Image The flash image API as part of the Device Firmware Upgrade (DFU) subsystem provides an abstraction on top of Flash Stream to simplify writing firmware image chunks to flash.

API Reference

Flash image API

MCUBoot API The MCUboot API is provided to get version information and boot status of application images. It allows to select application image and boot type for the next boot.

API Reference

MCUboot image control API

Bootloaders

MCUboot Zephyr is directly compatible with the open source, cross-RTOS MCUboot boot loader. It interfaces with MCUboot and is aware of the image format required by it, so that Device Firmware Upgrade is available when MCUboot is the boot loader used with Zephyr. The source code itself is hosted in the MCUboot GitHub Project page.

In order to use MCUboot with Zephyr you need to take the following into account:

1. You will need to define the flash partitions required by MCUboot; see *Flash map* for details.
2. You will have to specify your flash partition as the chosen code partition

```
/ {
   chosen {
      zephyr,code-partition = &slot0_partition;
   };
};
```

3. Your application's `.conf` file needs to enable the `CONFIG_BOOTLOADER_MCUBOOT` Kconfig option in order for Zephyr to be built in an MCUboot-compatible manner
4. You need to build and flash MCUboot itself on your device
5. You might need to take precautions to avoid mass erasing the flash and also to flash the Zephyr application image at the correct offset (right after the bootloader)

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUboot with Zephyr documentation page on the MCUboot website.

4.9.7 Over-the-Air Update

Overview

Over-the-Air (OTA) Update is a method for delivering firmware updates to remote devices using a network connection. Although the name implies a wireless connection, updates received over a wired connection (such as Ethernet) are still commonly referred to as OTA updates. This approach requires server infrastructure to host the firmware binary and implement a method of signaling when an update is available. Security is a concern with OTA updates; firmware binaries should be cryptographically signed and verified before upgrading.

The *Device Firmware Upgrade* section discusses upgrading Zephyr firmware using MCUboot. The same method can be used as part of OTA. The binary is first downloaded into an unoccupied code partition, usually named `slot1_partition`, then upgraded using the *MCUboot* process.

Examples of OTA

Golioth Golioth is an IoT management platform that includes OTA updates. Devices are configured to observe your available firmware revisions on the Golioth Cloud. When a new version is available, the device downloads and flashes the binary. In this implementation, the connection between cloud and device is secured using TLS/DTLS, and the signed firmware binary is confirmed by MCUboot before the upgrade occurs.

1. A working sample can be found on the Golioth Firmware SDK repository
2. The Golioth OTA documentation includes complete information about the versioning process

Plain HTTP download The *Firmware Over-the-Air over HTTP* library fetches a signed image from any HTTP server, writes it into the secondary slot and requests the swap. No management protocol or dedicated update server is needed. MCUboot verifies the image signature before the upgrade occurs.

There is a fota-http sample included in the Zephyr mgmt section.

Eclipse hawkBit™ Eclipse hawkBit™ is an update server framework that uses polling on a REST api to detect firmware updates. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is a hawkbit-api sample included in the Zephyr mgmt section.

UpdateHub UpdateHub is a platform for remotely updating embedded devices. Updates can be manually triggered or monitored via polling. When a new update is detected, the binary is downloaded and installed. MCUboot can be used to verify the signature before upgrading the firmware.

There is an updatehub-fota sample included in the Zephyr mgmt section.

SMP Server A Simple Management Protocol (SMP) server can be used to update firmware via Bluetooth Low Energy (LE) or UDP. *MCUmgr* is used to send a signed firmware binary to the remote device where it is verified by MCUboot before the upgrade occurs.

There is an smp-svr sample included in the Zephyr mgmt section.

Lightweight M2M (LwM2M) The *Lightweight M2M (LwM2M)* protocol includes support for firmware update via `CONFIG_LWM2M_FIRMWARE_UPDATE_OBJ_SUPPORT`. Devices securely connect to an LwM2M server using DTLS. A lwm2m-client sample is available but it does not demonstrate the firmware update feature.

mender-mcu mender-mcu enables robust firmware updates on resource-constrained devices by integrating with Zephyr. It implements an Update Module interface and provides a default Update Module that integrates with MCUboot to provide A/B updates. This allows microcontroller units (MCUs) to perform atomic, fail-safe OTA updates with automatic rollback on failure.

See external_module_mender_mcu for integration details and examples.

Memfault and nRF Cloud powered by Memfault Memfault is a IoT observability platform that includes OTA management. Devices check-in with Memfault's service periodically for an OTA update, and when an update is available, download and install the binary.

See external_module_memfault_firmware_sdk for overall integration details and examples.

4.9.8 Firmware Over-the-Air over HTTP

Overview

The FOTA HTTP library downloads a firmware image from an HTTP server and writes it straight into the MCUboot slot that is not currently running. It then lets the application request the swap, confirm the new image or erase the slot. Unlike *hawkBit or UpdateHub*, no device management protocol is involved: any web server able to serve a file can act as the update source, which makes it a good fit for simple deployments and for bench testing.

The image is streamed to flash through the *Flash Image* as it arrives, so its size is not limited by RAM. The slot is erased progressively during the write, and the MCUboot trailer of the slot is cleared before the first byte lands, so a leftover from a previous image can never be mistaken for a pending swap.

After the download the library reads the MCUboot header back from flash and fails with `-ENOEXEC` when the data is not an image. It does not verify the signature: MCUboot does that before the image is ever booted, and that check decides whether the image runs. An optional SHA-256 comparison against a digest supplied by the caller is available with `CONFIG_FOTA_HTTP_SHA256_CHECK` to catch a corrupted transfer before the reboot. An image rejected by that comparison, or by the downgrade check below, is erased from the slot. After a download that failed part way, `fota_http_apply()` refuses the slot until another download into it succeeds, while the partial data stays in place for a resume.

Update cycle

The typical sequence is:

1. `fota_http_download()` or `fota_http_download_async()` fetches the image into the secondary slot. The optional `fota_http_download_params` members `sha256`, `resume` and the TLS ones only exist when their Kconfig option is enabled.
2. `fota_http_apply()` marks the image for a test boot, or as permanent.
3. The device reboots and MCUboot swaps the image in.
4. On a test boot the application validates itself and calls `fota_http_confirm()`. Without that call, the next reboot makes MCUboot revert to the previous image.

The revert step requires an MCUboot mode with revert support, such as swap-using-move or swap-using-offset. In overwrite-only mode the previous image is gone as soon as the swap happens and confirmation has no effect, so check which mode the board's sysbuild configuration selects.

While a test image runs, the secondary slot holds the image MCUboot would revert to, so `fota_http_download()` refuses with `-EPERM` until `fota_http_confirm()` has been called.

Threads and stack

`fota_http_download()` blocks the calling thread for the whole transfer and needs enough stack for the HTTP client and, with https, the TLS handshake. With `CONFIG_FOTA_HTTP_ASYNC`, `fota_http_download_async()` runs the same transfer on a thread owned by the library, sized by `CONFIG_FOTA_HTTP_THREAD_STACK_SIZE`, and reports the result through a completion callback. The shell command selects the asynchronous variant so the shell stack size does not matter. Applications that only call `fota_http_download()` leave it disabled and do not pay for the thread stack.

Only one download runs at a time. `fota_http_cancel()` aborts the transfer in progress when the next fragment arrives or the request times out.

Redirects and resume

Responses with status 301, 302, 303, 307 or 308 are followed up to `CONFIG_FOTA_HTTP_MAX_REDIRECTS` times. Both absolute and path-only `Location` headers are accepted.

With `CONFIG_FOTA_HTTP_RESUME` the download offset is saved in settings while the transfer runs and when it fails. A later download with the `resume` parameter set continues from that offset with an HTTP `Range` request. The offset is only reused when the URL and image index match the interrupted download, and when the server sent an `ETag` or `Last-Modified` header the request carries `If-Range` with it, so a file that changed on the server is fetched again from the start. A server that ignores the `Range` header and answers with the full file restarts the transfer from zero, and so does a `416 Range Not Satisfiable` answer, which is what a server sends when the file grew shorter than the saved offset. A validator too long to store also drops the saved progress, so the next download starts from the beginning rather than resuming against a file that may have changed. The offset is cleared once the image is complete.

Multiple images

In a layout with more than one updateable image, the `image_index` parameter selects which secondary slot the download goes to. `fota_http_apply()` and `fota_http_confirm()` both take the same index, so a layout that carries firmware for a second device confirms only what this device validated. When several images must run together, download and apply every one of them before rebooting: MCUboot validates the whole set and swaps it in one go, and confirm each one afterwards, because an image left unconfirmed is reverted on its own. `fota_http_confirm_pending()` only reports image 0, so an application that updates several images tracks the rest itself. A downgrade check with `CONFIG_FOTA_HTTP_REJECT_DOWNGRADE` only covers image 0.

With direct-XIP bootloaders the slot an image runs from is fixed at link time, so the device must fetch the image variant built for the free slot. `fota_http_get_download_slot()` reports which slot that is. This only covers single-image layouts: for every image after the first the library always uploads to the odd-numbered slot of the pair, which is correct for the swap and overwrite modes but not for direct-XIP.

Downgrade protection

`CONFIG_FOTA_HTTP_REJECT_DOWNGRADE` compares the version in the downloaded header with the running image and fails the download when it is older, erasing the rejected image so it cannot be applied by mistake. This is a convenience check for the application. An enforced policy belongs in the bootloader, see the MCUboot downgrade prevention and hardware rollback protection options.

TLS

`https` URLs are accepted when `CONFIG_FOTA_HTTP_TLS` is enabled. The CA certificate of the server is looked up under `CONFIG_FOTA_HTTP_TLS_SEC_TAG`, or under the tags passed in

the download parameters, and can be registered with `fota_http_tls_add_ca()` or directly with `tls_credential_add()`. For mutual TLS, register the client certificate and key with `fota_http_tls_add_client_cert()`.

Peer verification is required by default and `CONFIG_FOTA_HTTP_TLS_PEER_VERIFY` should stay at its default in production. The host name from the URL is verified against the certificate. When the URL carries an IP address and the certificate has no matching entry, pass the expected name in the `tls_hostname` parameter.

Certificate validity dates are only enforced when `CONFIG_MBEDTLS_HAVE_TIME_DATE` is enabled, which requires a correct wall clock on the device before the first download. TLS 1.3 can be selected with `CONFIG_FOTA_HTTP_TLS_VERSION_1_3`.

Shell commands

With `CONFIG_FOTA_HTTP_SHELL` enabled, a `fota` command exposes the library from the console:

```
fota download <url> [resume] [image=<n>]   download an image
fota cancel                                abort the download in progress
fota apply [permanent] [image=<n>]         boot the downloaded image on the next␣
↪reset
fota confirm [image]                       confirm the running image
fota status                                show images and confirmation state
fota erase [image]                         erase the secondary slot
```

See the fota-http sample for a complete walkthrough.

4.9.9 EC Host Command

Overview

The host command protocol defines the interface for a host, or application processor, to communicate with a target embedded controller (EC). The EC Host command subsystem implements the target side of the protocol, generating responses to commands sent by the host. The host command protocol interface supports multiple versions, but this subsystem implementation only support protocol version 3.

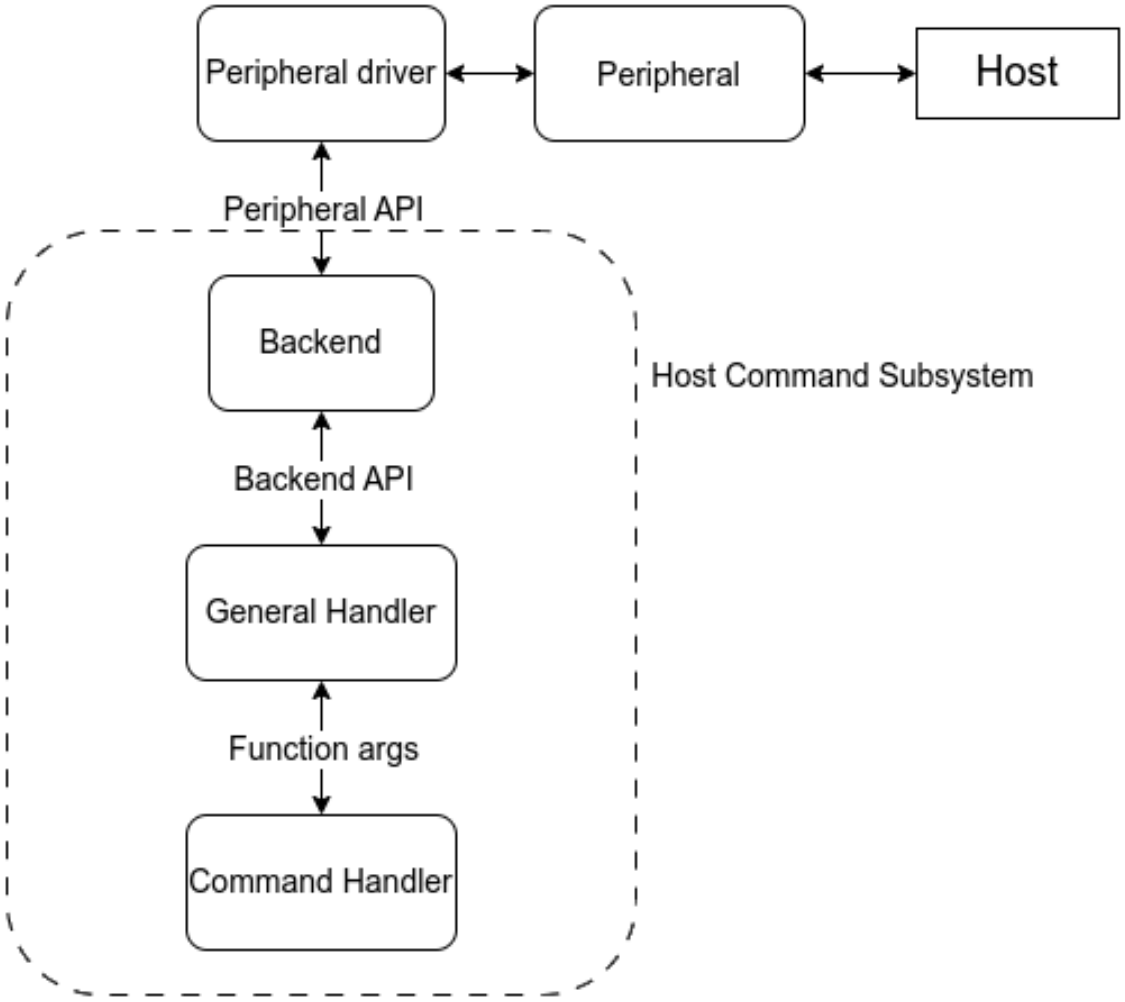
Architecture

The Host Command subsystem contains a few components:

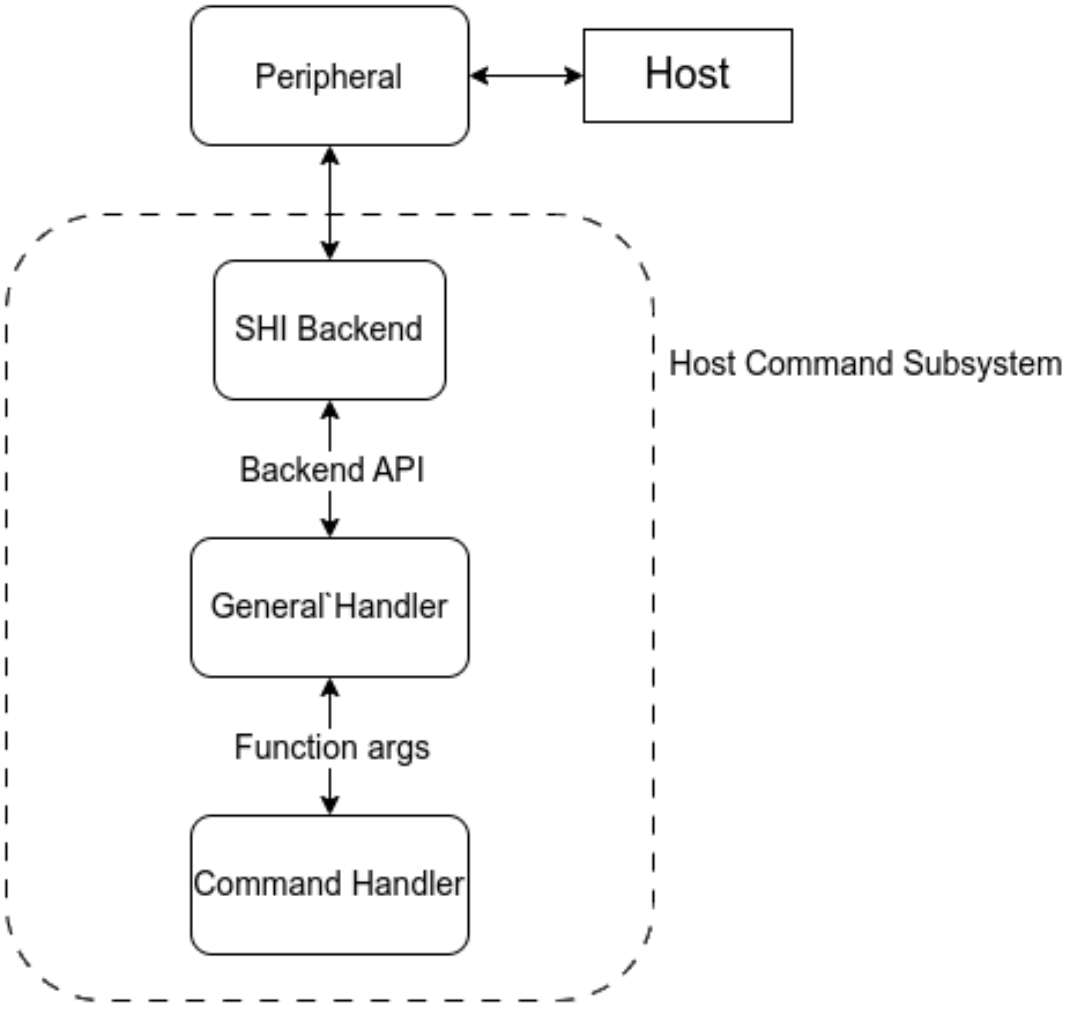
- Backend
- General handler
- Command handler

The backend is a layer between a peripheral driver and the general handler. It is responsible for sending and receiving commands via chosen peripheral.

The general handler validates data from the backend e.g. check sizes, checksum, etc. If the command is valid and the user has provided a handler for a received command id, the command handler is called.



SHI (Serial Host Interface) is different to this because it is used only for communication with a host. SHI does not have API itself, thus the backend and peripheral driver layers are combined into one backend layer.



Another case is SPI. Unfortunately, the current SPI API can't be used to handle the host commands communication. The main issues are unknown command size sent by the host (the SPI transaction sends/receives specific number of bytes) and need to constant sending status byte (the SPI module is enabled and disabled per transaction). It forces implementing the SPI driver within a backend, as it is done for SHI. That means a SPI backend has to be implemented per chip family. However, it can be changed in the future once the SPI API is extended to host command needs. Please check the discussion.

That approach requires configuring the SPI dts node in a special way. The main compatible string of a SPI node has changed to use the Host Command version of a SPI driver. The rest of the properties should be configured as usual. Example of the SPI node for STM32:

```
&spi1 {
        /* Change the compatible string to use the Host Command version of the
         * STM32 SPI driver
         */
        compatible = "st,stm32-spi-host-cmd";
        status = "okay";

        dmas = <&dma2 3 3 0x38440 0x03>,
             <&dma2 0 3 0x38480 0x03>;
        dma-names = "tx", "rx";
        /* This field is used to point at our CS pin */
```

(continues on next page)

(continued from previous page)

```
        cs-gpios = <&gpioa 4 (GPIO_ACTIVE_LOW | GPIO_PULL_UP)>;
};
```

The STM32 SPI host command backend driver supports the `st,stm32h7-spi` and `st,stm32-spi-fifo` variant implementations. To enable these variants, append the corresponding compatible string. For example, to enable FIFO support and support for the STM32H7 SoCs, modify the compatible string as shown.

```
&spi1 {
    compatible = "st,stm32h7-spi", "st,stm32-spi-fifo", "st,stm32-spi-host-cmd";
    ...
};
```

The chip that runs Zephyr is a SPI slave and the `cs-gpios` property is used to point our CS pin. For the SPI, it is required to set the backend chosen node `zephyr,host-cmd-spi-backend`.

The supported backend and peripheral drivers:

- Simulator
- SHI - ITE and NPCX
- eSPI - any eSPI slave driver that support `CONFIG_ESPI_PERIPHERAL_EC_HOST_CMD` and `CONFIG_ESPI_PERIPHERAL_CUSTOM_OPCODE`
- UART - any UART driver that supports the asynchronous API
- SPI - STM32

Initialization

If the application configures one of the following backend chosen nodes and `CONFIG_EC_HOST_CMD_INITIALIZE_AT_BOOT` is set, then the corresponding backend initializes the host command subsystem by calling `ec_host_cmd_init()`:

- `zephyr,host-cmd-espi-backend`
- `zephyr,host-cmd-shi-backend`
- `zephyr,host-cmd-uart-backend`
- `zephyr,host-cmd-spi-backend`

If no backend chosen node is configured, the application must call the `ec_host_cmd_init()` function directly. This way of initialization is useful if a backend is chosen in runtime based on e.g. GPIO state.

Buffers

The host command communication requires buffers for rx and tx. The buffers are be provided by the general handler if `CONFIG_EC_HOST_CMD_HANDLER_RX_BUFFER_SIZE` > 0 for rx buffer and `CONFIG_EC_HOST_CMD_HANDLER_TX_BUFFER_SIZE` > 0 for the tx buffer. The shared buffers are useful for applications that use multiple backends. Defining separate buffers by every backend would increase the memory usage. However, some buffers can be defined by a peripheral driver e.g. eSPI. These ones should be reused as much as possible.

Logging

The host command has an embedded logging system of the ongoing communication. The are a few logging levels:

- `LOG_INF` is used to log a command id of a new command and not success responses. Repeats of the same command are not logged

- `LOG_DBG` logs every command, even repeats
- `LOG_DBG` + `CONFIG_EC_HOST_CMD_LOG_DBG_BUFFERS` logs every command and responses with the data buffers

API Reference

EC Host Command Interface

4.9.10 Binary Descriptors

Binary Descriptors are constant data objects storing information about the binary executable. Unlike "regular" constants, binary descriptors are linked to a known offset in the binary, making them accessible to other programs, such as a different image running on the same device or a host tool. A few examples of constants that would make useful binary descriptors are: kernel version, app version, build time, compiler version, environment variables, compiling host name, etc.

Binary descriptors are created by using the `DEFINE_BINDESC_*` macros. For example:

```
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(my_string, 2, "Hello world!"); // Unique ID is 2
```

`my_string` could then be accessed using:

```
printk("my_string: %s\n", BINDESC_GET_STR(my_string));
```

But it could also be retrieved by `west bindesc`:

```
$ west bindesc custom_search STR 2 build/zephyr/zephyr.bin
"Hello world!"
```

Internals

Binary descriptors are implemented with a TLV (tag, length, value) header linked to a known offset in the binary image. This offset may vary between architectures, but generally the descriptors are linked as close to the beginning of the image as possible. In architectures where the image must begin with a vector table (such as ARM), the descriptors are linked right after the vector table. The reset vector points to the beginning of the text section, which is after the descriptors. In architectures where the image must begin with executable code (e.g. x86), a jump instruction is injected at the beginning of the image, in order to skip over the binary descriptors, which are right after the jump instruction.

Each tag is a 16 bit unsigned integer, where the most significant nibble (4 bits) is the type (currently uint, string or bytes), and the rest is the ID. The ID is globally unique to each descriptor. For example, the ID of the app version string is `0x800`, and a string is denoted by 0x1, making the app version tag `0x1800`. The length is a 16 bit number equal to the length of the data in bytes. The data is the actual descriptor value. All binary descriptor numbers (magic, tags, uints) are laid out in memory in the endianness native to the SoC. `west bindesc` assumes little endian by default, so if the image belongs to a big endian SoC, the appropriate flag should be given to the tool.

The binary descriptor header starts with the magic number `0xb9863e5a7ea46046`. It's followed by the TLVs, and ends with the `DESCRIPTORS_END` (`0xffff`) tag. The tags are always aligned to 32 bits. If the value of the previous descriptor had a non-aligned length, zero padding will be added to ensure that the current tag is aligned.

Putting it all together, here is what the example above would look like in memory (of a little endian SoC):

```
 46 60 a4 7e 5a 3e 86 b9 02 10  0d 00  48 65 6c 6c 6f 20 77 6f 72 6c 64 21 00 00␣
↪00 00 ff ff 00 00
|         magic         | tag |length| H  e  l  l  o     w  o  r  l  d  !    |  ␣
↪pad  |    end    |
```

Usage

Binary descriptors are always created by the `BINDESC_*_DEFINE` macros. As shown in the example above, a descriptor can be generated from any string or integer, with any ID. However, it is recommended to comply with the standard tags defined in `include/zephyr/bindesc.h`, as that would have the following benefits:

1. The `west bindesc` tool would be able to recognize what the descriptor means and print a meaningful tag
2. It would enforce consistency between various apps from various sources
3. It allows upstream-ability of descriptor generation (see Standard Descriptors)

To define a descriptor with a standard tag, just use the tags included from `bindesc.h`:

```
#include <zephyr/bindesc.h>

BINDESC_STR_DEFINE(app_version, BINDESC_ID_APP_VERSION_STRING, "1.2.3");
```

Standard Descriptors Some descriptors might be trivial to implement, and could therefore be implemented in a standard way in upstream Zephyr. These could then be enabled via Kconfig, instead of requiring every user to reimplement them. These include build times, kernel version, and host info. For example, to add the build date and time as a string, the following configs should be enabled:

```
# Enable binary descriptors
CONFIG_BINDESC=y

# Enable definition of binary descriptors
CONFIG_BINDESC_DEFINE=y

# Enable default build time binary descriptors
CONFIG_BINDESC_DEFINE_BUILD_TIME=y
CONFIG_BINDESC_BUILD_DATE_TIME_STRING=y
```

To avoid collisions with user defined descriptors, the standard descriptors were allotted the range between `0x800-0xfff`. This leaves `0x000-0x7ff` to users. For more information read the `help` sections of these Kconfig symbols. By convention, each Kconfig symbol corresponds to a binary descriptor whose name is the Kconfig name (with `CONFIG_BINDESC_` removed) in lower case. For example, `CONFIG_BINDESC_KERNEL_VERSION_STRING` creates a descriptor that can be accessed using `BINDESC_GET_STR(kernel_version_string)`.

Reading Descriptors It's also possible to read and parse binary descriptors from an application. This can be useful both for an image trying to read its own descriptors, and for an image trying to read another image's descriptors. Reading can be performed through one of three backends:

1. RAM - assuming the descriptors have been copied to RAM (e.g. by a bootloader), they can be read from the buffer they reside in.
2. Memory mapped flash - If the flash where the image to be read resides in flash and is accessible through the program's address space, it can be read directly from flash. This option

uses the least amount of RAM, but will not work if the flash is not memory mapped, and is not recommended to read a bootloader's descriptors for security concerns.

3. Flash - Using an internal buffer, the descriptors are read one by one using the flash API, and given to the user while they're in the buffer.

To enable reading descriptors, enable `CONFIG_BINDESC_READ`. The three backends are enabled by these Kconfig symbols, respectively: `CONFIG_BINDESC_READ_RAM`, `CONFIG_BINDESC_READ_MEMORY_MAPPED_FLASH`, and `CONFIG_BINDESC_READ_FLASH`.

To read the descriptors, a handle to the descriptors should first be initialized:

```
struct bindesc_handle handle;

/* Assume buffer holds a copy of the descriptors */
bindesc_open_ram(&handle, buffer);
```

The `bindesc_open_*` functions are the only functions concerned with the backend used. The rest of the API is agnostic to where the data is. After the handle has been initialized, it can be used with the rest of the API:

```
char *version;
bindesc_find_str(&handle, BINDESC_ID_KERNEL_VERSION_STRING, &version);
printk("Kernel version: %s\n", version);
```

west bindesc tool `west` is able to parse and display binary descriptors from a given executable image.

For more information refer to `west bindesc --help` or the *documentation*.

Algorithms & Data

4.10 Algorithms & Data

This section covers services for transforming, encoding, and validating data, including checksums, digital signal processing, and serialization.

4.10.1 CRC

Overview

The CRC subsystem provides software implementations of various Cyclic Redundancy Check algorithms for data integrity verification. CRCs are commonly used to detect accidental changes to data in storage and communication systems.

The subsystem offers a comprehensive set of CRC algorithms including CRC-4, CRC-7, CRC-8, CRC-16, CRC-24, and CRC-32 variants, and provides optional hardware acceleration support when available.

Note

This library is distinct from the *CRC hardware driver API*, which provides an interface to hardware CRC acceleration peripherals.

When a hardware CRC unit is available and the `zephyr,crc` property has been set in the `/chosen` node in Devicetree, the library functions will default to using hardware acceleration for improved performance (can be disabled by setting `CONFIG_CRC_HW_HANDLER` to `n`).

Usage To compute a CRC, include the appropriate header and call the desired function:

```
#include <zephyr/sys/crc.h>

uint8_t data[] = {0x01, 0x02, 0x03, 0x04};
uint32_t checksum = crc32_ieee(data, sizeof(data));
```

For streaming data processed in chunks, use the "update" variants:

```
uint32_t crc = 0;
crc = crc32_ieee_update(crc, chunk1, len1);
crc = crc32_ieee_update(crc, chunk2, len2);
/* Final CRC value is in 'crc' */
```

The generic `crc_by_type()` function provides a unified interface to select the CRC algorithm at runtime.

Configuration

Related configuration options:

- `CONFIG_CRC` - Enable CRC support
- `CONFIG_CRC_HW_HANDLER` - Enable hardware CRC acceleration
- `CONFIG_CRC_SHELL` - Enable CRC shell commands
- `CONFIG_CRC[0-9].*` - Enable software implementations of specific CRC algorithms

- Cyclic Redundancy Check Subsystem (CRC Subsys)Compute and verify a CRC computation using the CRC subsys API.

4.10.2 Digital Signal Processing (DSP)

- *Using zDSP*
- *Optimizing for your architecture*
- *API Reference*

The DSP API provides an architecture agnostic way for signal processing. Currently, the API will work on any architecture but will likely not be optimized. The status of the various architectures can be found below:

Architecture	Status
ARC	Optimized
ARM	Optimized
ARM64	Optimized
MIPS	Unoptimized
POSIX	Unoptimized
RISCV	Unoptimized
RISCV64	Unoptimized
SPARC	Unoptimized
X86	Unoptimized
XTENSA	Unoptimized

Using zDSP

zDSP provides various backend options which are selected automatically for the application. By default, including the CMSIS module will enable all architectures to use the zDSP APIs. This can be done by setting:

```
CONFIG_CMSIS_DSP=y
```

If your application requires some additional customization, it's possible to enable `CONFIG_DSP_BACKEND_CUSTOM` which means that the application is responsible for providing the implementation of the zDSP library.

Optimizing for your architecture

If your architecture is showing as `Unoptimized`, it's possible to add a new zDSP backend to better support it. To do that, a new Kconfig option should be added to `subsys/dsp/Kconfig` along with the required dependencies and the `default` set for `DSP_BACKEND` Kconfig choice.

Next, the implementation should be added at `subsys/dsp/<backend>/` and linked in at `subsys/dsp/CMakeLists.txt`. To add architecture-specific attributes, its corresponding Kconfig option should be added to `subsys/dsp/Kconfig` and use them to update `DSP_DATA` and `DSP_STATIC_DATA` in `include/zephyr/dsp/dsp.h`.

API Reference

DSP (Digital Signal Processing)

4.10.3 Serialization

Zephyr has support for several data serialization subsystems. These can be used to encode/decode structured data with a known format on-the-wire.

CBOR

CBOR (Concise Binary Object Representation) is a data format whose design goals include the possibility of extremely small code size, fairly small message size, and extensibility without the need for version negotiation.

Zephyr provides support for CBOR via the zcbor library, which is pulled in as a West module.

Configuration To enable CBOR support, enable the `CONFIG_ZCBOR` Kconfig option.

API Reference The zcbor library provides its own API documentation, please refer to it for more information.

JSON

Zephyr provides a JSON library that can be used to encode and decode JSON data.

Usage

Defining the Data Structure First, define the C structure that corresponds to the JSON object and the descriptor that maps the structure fields to JSON tokens.

```
#include <zephyr/data/json.h>

struct foo {
    int bar;
    const char *baz;
};

static const struct json_obj_descr foo_descr[] = {
    JSON_OBJ_DESCR_PRIM(struct foo, bar, JSON_TOK_NUMBER),
    JSON_OBJ_DESCR_PRIM(struct foo, baz, JSON_TOK_STRING),
};
```

Encoding To encode a C structure into a JSON string, use `json_obj_encode_buf()`.

```
void encode_example(void)
{
    struct foo data = { .bar = 42, .baz = "hello" };
    char buffer[128];
    int ret;

    ret = json_obj_encode_buf(foo_descr, ARRAY_SIZE(foo_descr),
                              &data,
                              buffer, sizeof(buffer));
    if (ret < 0) {
        /* handle error */
    }
}
```

Decoding To decode a JSON string into a C structure, use `json_obj_parse()`.

```
void decode_example(void)
{
    struct foo data;
```

(continues on next page)

(continued from previous page)

```
    const char *json_text = "{\"bar\": 42, \"baz\": \"hello\"}";
    int ret;

    ret = json_obj_parse(json_text, strlen(json_text),
                         foo_descr, ARRAY_SIZE(foo_descr),
                         &data);
    if (ret < 0) {
        /* handle error */
    }
}
```

Configuration To enable JSON support, enable the `CONFIG_JSON_LIBRARY` Kconfig option.

Nanopb

Nanopb is a C implementation of Google's Protocol Buffers.

Requirements Nanopb uses the protocol buffer compiler to generate source and header files, make sure the `protoc` executable is installed and available.

Ubuntu

Use `apt` to install dependency:

```
sudo apt install protobuf-compiler
```

macOS

Use `brew` to install dependency:

```
brew install protobuf
```

Windows

Use `choco` to install dependency:

```
choco install protoc
```

Configuration Make sure to include `nanopb` within your `CMakeLists.txt` file as follows:

```
list(APPEND CMAKE_MODULE_PATH ${ZEPHYR_BASE}/modules/nanopb)
include(nanopb)
```

Adding `proto` files can be done with the `zephyr_nanopb_sources()` CMake function which ensures the generated header and source files are created before building the specified target.

Nanopb has generator options that can be used to configure messages or fields. This allows to set fixed sizes or skip fields entirely.

The internal CMake generator has an extension to configure `*.options.in` files automatically with CMake variables.

See samples/modules/nanopb/src/simple.options.in and samples/modules/nanopb/CMakeLists.txt for usage example.

Frameworks

4.11 Frameworks

This section covers high-level frameworks and libraries that help structure application logic, load code at runtime, stream media, and model sensors.

4.11.1 Linkable Loadable Extensions (LLEXT)

The LLEXT subsystem provides a toolbox for extending the functionality of an application at runtime with linkable loadable code.

Extensions are precompiled executables in ELF format that can be verified, loaded, and linked with the main Zephyr binary. Extensions can be manipulated and introspected to some degree, as well as unloaded when no longer needed.

Configuration

The following Kconfig options are available for the LLEXT subsystem.

Harvard architecture `CONFIG_HARVARD`

Architecture uses separate instruction and data memory.

`CONFIG_HARVARD` is not a Kconfig defined by the LLEXT subsystem. Instead, it must be defined and selected by the board or SoC to signal that LLEXT should be built with Harvard architecture support. The board or SoC must also implement `arch_is_instr_mem()`.

Heap size The LLEXT subsystem needs a heap to be allocated for extension related data. The following option controls this allocation, when allocating a static heap.

`CONFIG_LLEXT_HEAP_SIZE`

Size of the LLEXT heap in kilobytes.

For boards using the Harvard architecture, the LLEXT heap is split into two: one heap in instruction memory and another in data memory. The following options control these allocations.

`CONFIG_LLEXT_INSTR_HEAP_SIZE`

Size of the LLEXT heap in instruction memory in kilobytes.

`CONFIG_LLEXT_DATA_HEAP_SIZE`

Size of the LLEXT heap in data memory in kilobytes.

Alternatively the application can configure a dynamic heap using the following option.

`CONFIG_LLEXT_HEAP_DYNAMIC`

Some applications require loading extensions into the memory which does not exist during the boot time and cannot be allocated statically. Make the application responsible for LLEXT heap allocation. Do not allocate LLEXT heap statically.

Application must call `llext_heap_init()` in order to assign a buffer to be used as the LLEXT heap, otherwise LLEXT modules will not load. When the application does not need LLEXT functionality any more, it should call `llext_heap_uninit()` which releases control of the buffer back to the application.

Note

When *user mode* is enabled, the heap size must be large enough to allow the extension sections to be allocated with the alignment required by the architecture.

Note

On Harvard architectures, applications must call `llext_heap_init_harvard()`.

The backing data structure for the LLEXT heap is by default a `k_heap`, but it can be changed to `sys_mem_blocks_t` for non-metadata (i.e., extension regions) by selecting `CONFIG_LLEXT_HEAP_MEMBLK` for `CONFIG_LLEXT_HEAP_MANAGEMENT`.

`CONFIG_LLEXT_HEAP_MANAGEMENT`

Select the memory management API used to store extension regions in LLEXT heap memory. This choice does not affect LLEXT metadata, which is always managed with `k_heap`.

`CONFIG_LLEXT_HEAP_MEMBLK`

Use `sys_mem_blocks_t` API to manage LLEXT heap memory for extension regions. A minimum of one block will be allocated per region. Block size must be selected with care to ensure proper alignment for extension regions.

Note

`CONFIG_LLEXT_HEAP_MEMBLK` does not support `CONFIG_LLEXT_HEAP_DYNAMIC`.

The heap will be split into two, with the size of each sub-heap controlled by the following options.

`CONFIG_LLEXT_EXT_HEAP_SIZE`

Heap size in kilobytes available for LLEXT extension sections. Must be a multiple of `CONFIG_LLEXT_HEAP_MEMBLK_BLOCK_SIZE`. Replaced by `CONFIG_LLEXT_INSTR_HEAP_SIZE` and `CONFIG_LLEXT_DATA_HEAP_SIZE` if `CONFIG_HARVARD` is selected.

`CONFIG_LLEXT_METADATA_HEAP_SIZE`

Heap size in kilobytes available for LLEXT metadata.

Another option controls block size.

`CONFIG_LLEXT_HEAP_MEMBLK_BLOCK_SIZE`

Block size in bytes for LLEXT `sys_mem_blocks_t` heap(s). Must be equal to or a multiple of `LLEXT_PAGE_SIZE` if MMU or MPU are enabled. The block size must also be equal to or a multiple of the largest alignment needed for any extension region. If `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT` is selected and regions are large, an unreasonably large block size may be needed to satisfy alignment requirements.

Heap placement The LLEXT heap(s) have custom sections. Non-Harvard heap sections (`.llext_heap`, or `.llext_metadata_heap` and `.llext_ext_heap` if `CONFIG_LLEXT_HEAP_MEMBLK` is selected) are placed alongside `.noinit` sections in the file `include/zephyr/linker/common-noinit.ld`. If none of your linker scripts include this file, you will need to place the non-Harvard LLEXT heap sections manually. One way to do this is by including `snippets-noinit.ld` in your linker script after your `.noinit` sections.

```
/* Located in generated directory. This file is populated by the
 * zephyr_linker_sources() CMake function.
 */
#include <snippets-noinit.ld>
```

Add the file as a linker source in your board, SoC, or architecture `CMakeFiles.txt`.

```
zephyr_linker_sources(NOINIT snippets-noinit.ld)
```

Then create a file in the same directory as your `CMakeFiles.txt` named `noinit.ld`.

```
#if defined(CONFIG_LLEXT) && !defined(CONFIG_LLEXT_CUSTOM_HEAP_PLACEMENT)
*(.llext_heap)
*(.llext_ext_heap)
*(.llext_metadata_heap)
#endif /* CONFIG_LLEXT && !CONFIG_LLEXT_CUSTOM_HEAP_PLACEMENT */
```

For ARC, the Harvard instruction and data heap sections (`.llext_instr_heap` and `.llext_data_heap`) are placed in instruction and data memory at the architecture level. If you are using a non-ARC board with a Harvard architecture, you will need to manually place `.llext_instr_heap` and `.llext_data_heap`.

Warning

LLEXT will be unable to load extensions if the instruction memory `.llext_instr_heap` is placed in is not writable at the time the extensions are loaded and linked.

Placements can also be specified by providing a custom linker script.

`CONFIG_CUSTOM_LINKER_SCRIPT`

> Path to the linker script to be used instead of the one defined by the board.
>
> The linker script must be based on a version provided by Zephyr since the kernel can expect a certain layout/certain regions.
>
> This is useful when an application needs to add sections into the linker script and avoid having to change the script provided by Zephyr.

While using a custom linker script, you may need to override default placements. For example, you may wish to include `include/zephyr/linker/common-noinit.ld` in your linker script but place the heap section(s) elsewhere. To do this, select the following option.

`CONFIG_LLEXT_CUSTOM_HEAP_PLACEMENT`

> Remove default placements of LLEXT heap sections in the linker script, allowing the user to place the heap(s) themselves.

Word granular access instruction memory heap Word granular access instruction memory is a type of instruction memory that is byte addressable, but can only be accessed with word-sized and aligned loads and stores. The LLEXT subsystem currently supports the placement of the instruction heap in word granular access instruction memory on the Xtensa architecture only. Support for non-Xtensa architectures will be added in the future on request.

To use LLEXT with the instruction heap in word granular access instruction memory, your Xtensa SoC or board must select the following option in addition to CONFIG_HARVARD.

CONFIG_ARCH_HAS_WORD_GRANULAR_ACCESS_INSTR_MEM

> This option enables support for access to byte addressable and word granular access instruction memory.

If using the default backing data structure for the heap, k_heap, enable the following option.

CONFIG_SYS_HEAP_BIG_ONLY

> Select this to optimize the code for big heaps only. This can accommodate any heap size but memory usage won't be as efficient with small sized heaps.

Unaligned and narrow accesses to instruction memory will be performed during the instruction heap initialization if this option is not selected.

Next, place the LLEXT instruction heap in that instruction memory following the instructions for heap placement above. Make sure your SoC or board implements arch_memcpy_to_instr() and arch_memcpy_from_instr() in addition to arch_is_instr_mem(). The word granular access library memcpy_to_word_granular() and memcpy_from_word_granular() functions may be helpful.

You may place your ELF buffer in RAM. At load time, the LLEXT subsystem will force the text region onto the instruction heap (even when the ELF buffer is writable) so that it is executable, and respect word granular access constraints when accessing the text region during loading and linking.

Warning

You may only use the buffer loader (llext_buf_loader) to load the ELF when the instruction heap is in word granular access instruction memory.

Note that the extension itself is responsible for ensuring any subsequent accesses to instruction memory also respect these constraints.

If you still encounter load / store exceptions, you can enable the unsigned load / store exception handler for Xtensa with the following option.

CONFIG_XTENSA_EMULATE_UNSUPPORTED_UNSIGNED_LOAD_STORE

> When an unsigned load / store instruction triggers an unsupported load / store exception, the exception handler will perform the operation itself with supported word sized and aligned loads / stores. Does not currently support VLIW.

As mentioned in the option description, to use this option you must also disable VLIW, as enabling VLIW causes the compiler to generate signed load / store instructions.

CONFIG_COMPILER_CODEGEN_VLIW_DISABLED

> Explicitly instructs the compiler to NEVER generate VLIW instructions.

ELF object type The LLEXT subsystem supports loading different types of extensions; the type can be set by choosing among the following Kconfig options:

CONFIG_LLEXT_TYPE_ELF_OBJECT

> Build and expect relocatable files as binary object type for the LLEXT subsystem. A single compiler invocation is used to generate the object file.

CONFIG_LLEXT_TYPE_ELF_RELOCATABLE

> Build and expect relocatable (partially linked) files as the binary object type for the LLEXT subsystem. These object files are generated by the linker by combining multiple object files into a single one.

`CONFIG_LLEXT_TYPE_ELF_SHAREDLIB`

Build and expect shared libraries as binary object type for the LLEXT subsystem. The standard linking process is used to generate the shared library from multiple object files.

> **Note**
>
> This is not currently supported on ARM architectures.

Minimize allocations The LLEXT subsystem loading mechanism, by default, uses a seek/read abstraction and copies all data into allocated memory; this is done to allow the extension to be loaded from any storage medium. Sometimes, however, data is already in a buffer in RAM and copying it is not necessary. The following option allows the LLEXT subsystem to optimize memory footprint in this case.

`CONFIG_LLEXT_STORAGE_WRITABLE`

Allow the extension to be loaded by directly referencing section data into the ELF buffer. To be effective, this requires the use of an ELF loader that supports the peek functionality, such as the `llext_buf_loader`.

> **Warning**
>
> The application must ensure that the buffer used to load the extension remains allocated until the extension is unloaded.

> **Note**
>
> This will directly modify the contents of the buffer during the link phase. Once the extension is unloaded, the buffer must be reloaded before it can be used again in a call to `llext_load()`.

Symbol Groups All LLEXT symbols belong to a group, with the inclusion of each group in the exported symbol table controlled by a corresponding Kconfig symbol. Exporting a symbol as part of a group is done with the `EXPORT_GROUP_SYMBOL` and `EXPORT_GROUP_SYMBOL_NAMED` macros. For example the following exports the symbol `memcpy` as part of the `LIBC` group:

```
EXPORT_GROUP_SYMBOL(LIBC, memcpy);
```

Group names are arbitrary, but they must be all uppercase. For each group used in C code, there **MUST** be a corresponding Kconfig symbol of the form:

```
config LLEXT_EXPORT_SYMBOL_GROUP_{GROUP_NAME}
   bool "Export all symbols from the {GROUP_NAME} group"
```

The default group for symbols (those declared with `EXPORT_SYMBOL` or `EXPORT_SYMBOL_NAMED`) is the `UNASSIGNED` group. As per the above rules, the inclusion of this group is controlled by `CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_UNASSIGNED`.

The groups currently defined by Zephyr are:

Table 57: Zephyr LLEXT symbol groups

Group Name	Kconfig Symbol	Description
UNASSIGNED	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_UNAS	Symbols without an explicit group
SYSCALL	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_SYSC	Zephyr kernel system calls
LIBC	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_LIBC	C standard library functions (`memcpy()` etc)
DEVICE	CONFIG_LLEXT_EXPORT_SYMBOL_GROUP_DEVI	Devicetree devices

Using SLID for symbol lookups When an extension is loaded, the LLEXT subsystem must find the address of all the symbols residing in the main application that the extension references. To this end, the main binary contains a LLEXT-dedicated symbol table, filled with one symbol-name-to-address mapping entry for each symbol exported by the main application to extensions. This table can then be searched into by the LLEXT linker at extension load time. This process is pretty slow due to the nature of string comparisons, and the size consumed by the table can become significant as the number of exported symbols increases.

`CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID`

Perform an extra processing step on the Zephyr binary and on all extensions being built, converting every string in the symbol tables to a pointer-sized hash called Symbol Link Identifier (SLID), which is stored in the binary.

This speeds up the symbol lookup process by allowing usage of integer-based comparisons rather than string-based ones. Another benefit of SLID-based linking is that storing symbol names in the binary is no longer necessary, which provides a significant decrease in symbol table size.

> **Note**
>
> This option is not currently compatible with the *LLEXT EDK*.

> **Note**
>
> Using a different value for this option in the main binary and in extensions is not supported. For example, if the main application is built with `CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID=y`, it is forbidden to load an extension that was compiled with `CONFIG_LLEXT_EXPORT_BUILTINS_BY_SLID=n`.

EDK configuration Options influencing the generation and behavior of the LLEXT EDK are described in *LLEXT EDK Kconfig options*.

Building extensions

The LLEXT subsystem allows for the creation of extensions that can be loaded into a running Zephyr application. When building these extensions, it's very often useful to have access to the headers and compiler flags used by the main Zephyr application.

The easiest path to achieve this is to build the extension as part of the Zephyr application, using the *native Zephyr CMake features*. This will result in a single build providing both the main Zephyr application and the extension(s), which will all automatically be built with the same parameters.

In some cases, involving the full Zephyr build system may not be feasible or convenient; maybe the extension is built using a different compiler suite or as part of a different project altogether. In this case, the extension developer needs to export the headers and compiler flags used by the main Zephyr application. This can be done using the *LLEXT Extension Development Kit*.

Using the Zephyr CMake features The Zephyr build system provides a set of features that can be used to build extensions as part of the Zephyr application. This is the simplest way to build extensions, as it requires minimal additions to an application build system.

Building the extension An extension can be defined in the app's `CMakeLists.txt` by invoking the *`add_llext_target()`* function, providing the target name, the output and the source files. Usage is similar to the standard `add_custom_target` CMake function:

```
add_llext_target(
    <target_name>
    OUTPUT <ext_file.llext>
    SOURCES <src1> [<src2>...]
)
```

where:

- `<target_name>` is the name of the final CMake target that will result in the LLEXT binary being created;
- `<ext_file.llext>` is the name of the output file that will contain the packaged extension;
- `<src1> [<src2>...]` is the list of source files that will be compiled to create the extension.

The exact steps of the extension building process depend on the currently selected *ELF object format*.

The following custom properties of `<target_name>` are defined and can be retrieved using the `get_target_property()` CMake function:

`lib_target`

Target name for the source compilation and/or link step.

`lib_output`

The binary file resulting from compilation and/or linking steps.

`pkg_input`

The file to be used as input for the packaging step.

`pkg_output`

The final extension file name.

Tweaking the build process The following CMake functions can be used to modify the build system behavior during the extension build process to a fine degree. Each of the below functions takes the LLEXT target name as its first argument; it is otherwise functionally equivalent to the common Zephyr `target_*` version.

- *`llext_compile_definitions()`*
- *`llext_compile_features()`*
- *`llext_compile_options()`*
- *`llext_include_directories()`*
- *`llext_link_options()`*

Custom build steps The `add_llext_command` CMake function can be used to add custom build steps that will be executed during the extension build process. The command will be run at the specified build step and can refer to the properties of the target for build-specific details.

The function signature is:

```
add_llext_command(
    TARGET <target_name>
    [PRE_BUILD | POST_BUILD | POST_PKG]
    COMMAND <command> [args...]
)
```

The different build steps are:

`PRE_BUILD`

> Before the extension code is linked, if the architecture uses dynamic libraries. This step can access `lib_target` and its own properties.

`POST_BUILD`

> After the extension code is built, but before packaging it in an `.llext` file. This step is expected to create a `pkg_input` file by reading the contents of `lib_output`.

`POST_PKG`

> After the extension output file has been created. The command can operate on the final llext file `pkg_output`.

Anything else after `COMMAND` will be passed to `add_custom_command()` as-is (including multiple commands and other options).

LLEXT Extension Development Kit (EDK) When building extensions as a standalone project, outside of the main Zephyr build system, it's important to have access to the same set of generated headers and compiler flags used by the main Zephyr application, since they have a direct impact on how Zephyr headers are interpreted and the extension is compiled in general.

This can be achieved by asking Zephyr to generate an Extension Development Kit (EDK) from the build artifacts of the main Zephyr application, by running the following command which uses the `llext-edk` target:

```
west build -t llext-edk
```

The generated EDK can be found in the build directory under the `zephyr` directory. It's a tarball that contains the headers and compile flags needed to build extensions. The extension developer can then include the headers and use the compile flags in their build system to build the extension.

EDK definition files The EDK includes several convenience files which define a set of variables that contain the compile flags needed by the project, as well as other build-related information, when enabled. The information is currently exported in the following formats:

- `Makefile.cflags`, for Makefile-based projects;
- `cmake.cflags`, for CMake-based projects.

Paths to the headers and flags are prefixed by the EDK root directory. This is automatically obtained for CMake projects from `CMAKE_CURRENT_LIST_DIR`; other formats refer to an `LLEXT_EDK_INSTALL_DIR` variable, which must be set by the user with the path where the EDK is installed before including the generated file.

Note

The LLEXT_EDK prefix in the variable name may be changed with the CONFIG_LLEXT_EDK_NAME option.

Compile flags The full list of flags needed to build an extension is provided by LLEXT_CFLAGS. Also provided is a more granular set of flags that can be used in support of different use cases, such as when building mocks for unit tests:

LLEXT_INCLUDE_CFLAGS

Compiler flags to add directories containing non-autogenerated headers to the compiler's include search paths.

LLEXT_GENERATED_INCLUDE_CFLAGS

Compiler flags to add directories containing autogenerated headers to the compiler's include search paths.

LLEXT_ALL_INCLUDE_CFLAGS

Compiler flags to add all directories containing headers used in the build to the compiler's include search paths. This is a combination of LLEXT_INCLUDE_CFLAGS and LLEXT_GENERATED_INCLUDE_CFLAGS.

LLEXT_GENERATED_IMACROS_CFLAGS

Compiler flags for autogenerated headers that must be included in the build via -imacros.

LLEXT_BASE_CFLAGS

Other compiler flags that control code generation for the target CPU. None of these flags are included in the above lists.

LLEXT_CFLAGS

All flags required to build an extension. This is a combination of LLEXT_ALL_INCLUDE_CFLAGS, LLEXT_GENERATED_IMACROS_CFLAGS and LLEXT_BASE_CFLAGS.

Target information The EDK includes information that identifies the target of the current Zephyr build. The following variables are currently defined and mirror the information available in the Zephyr build system:

LLEXT_EDK_BOARD_NAME
The board name used in the Zephyr build.

LLEXT_EDK_BOARD_QUALIFIERS
The board qualifiers, if provided, used in the Zephyr build.

LLEXT_EDK_BOARD_REVISION
The board revision, if provided, used in the Zephyr build.

LLEXT_EDK_BOARD_TARGET
The fully qualified board target used in the Zephyr build.

Note

The LLEXT_EDK prefix in the variable names may be changed with the CONFIG_LLEXT_EDK_NAME option.

LLEXT EDK Kconfig options The LLEXT EDK can be configured using the following Kconfig options:

`CONFIG_LLEXT_EDK_NAME`
: The name of the generated EDK tarball. This is also used as the prefix for several variables defined in the EDK files.

`CONFIG_LLEXT_EDK_USERSPACE_ONLY`
: If set, the EDK will include headers that do not contain code to route syscalls to the kernel. This is useful when building extensions that will run exclusively in user mode.

EDK Sample Refer to llext-edk for an example of how to use the LLEXT EDK.

Loading extensions

Once an extension is built and the ELF file is available, it can be loaded into the Zephyr application using the LLEXT API, which provides a way to load the extension into memory, access its symbols and call its functions.

Loading an extension An extension may be loaded using any implementation of a `llext_loader` which has a set of function pointers that provide the necessary functionality to read the ELF data. A loader also provides some minimal context (memory) needed by the `llext_load()` function. Several loaders are already provided:

- An implementation over a buffer containing an ELF in addressable memory in memory is available as `llext_buf_loader`. To use this kind of loader, it is helpful to use one of the `LLEXT_TEMPORARY_BUF_LOADER`, `LLEXT_PERSISTENT_BUF_LOADER`, or `LLEXT_WRITABLE_BUF_LOADER` macros to tell LLEXT the appropriate type of memory buffer.
- An implementation that reads data from a file in the filesystem is available as the `llext_fs_loader`. The path to the file must be provided when creating the loader with the `LLEXT_FS_LOADER` macro.
- An implementation that uses semihosting to read from a file in the host filesystem is available as the `llext_semihost_loader`. The path to the file must be provided when creating the loader with the `LLEXT_SEMIHOST_LOADER` macro.

The extensions are loaded with a call to the `llext_load()` function, passing in the extension name and the configured loader. Once that completes successfully, the extension is loaded into memory and is ready to be used.

> **Note**
>
> When *User Mode* is enabled, the extension will not be included in any user memory domain. To allow access from user mode, the `llext_add_domain()` function must be called.

Initializing and cleaning up the extension The extension may define a number of initialization functions that must be called after loading but before any function in it can be used; this is typical in languages such as C++ that provide the concept of object constructors. The same is true for cleanup functions that must be called before unloading the extension.

LLEXT supports calling the functions listed in the `.preinit_array` and `.init_array` sections of the ELF file with the `llext_bringup()` function, and the functions listed in the `.fini_array` section with the `llext_teardown()` function. These APIs are compatible with *User Mode*, and thus can be called from either kernel or user context.

Important

The code run by these functions is fully determined by the contents of the ELF file. This may have security implications if its origin is untrusted.

If the extension requires a dedicated thread, the `llext_bootstrap()` function can be used to minimize boilerplate code. This function has a signature that is compatible with the `k_thread_create()` API, and will call `llext_bringup()`, then a user-specified function in the same context, and finally `llext_teardown()` before returning.

Accessing code and data To interact with the newly loaded extension, the host application must use the `llext_find_sym()` function to get the address of the exported symbol. The returned `void *` can then be cast to the appropriate type and used.

A wrapper for calling a function with no arguments is provided in `llext_call_fn()`.

Advanced users that need direct access to areas of the newly loaded extension may want to refer to `llext_get_section_info()` and other LLEXT inspection APIs.

Cleaning up after use The `llext_unload()` function must be called to free the memory used by the extension once it is no longer required. After this call completes, all pointers to symbols in the extension that were obtained will be invalid.

Troubleshooting

This feature is being actively developed and as such it is possible that some issues may arise. Since linking does modify the binary code, in case of errors the results are difficult to predict. Some common issues may be:

- Results from `llext_find_sym()` point to an invalid address;
- Constants and variables defined in the extension do not have the expected values;
- Calling a function defined in an extension results in a hard fault, or memory in the main application is corrupted after returning from it.

If any of this happens, the following tips may help understand the issue:

- Make sure `CONFIG_LLEXT_LOG_LEVEL` is set to `DEBUG`, then obtain a log of the `llext_load()` invocation.
- If possible, disable memory protection (MMU/MPU) and see if this results in different behavior.
- Try to simplify the extension to the minimum possible code that reproduces the issue.
- Use a debugger to inspect the memory and registers to try to understand what is happening. See *Debugging extensions* for more details.

If the issue persists, please open an issue in the GitHub repository, including all the above information.

Debugging extensions

Debugging extensions is a complex task. Since the extension code is by definition not built with the Zephyr application, the final Zephyr ELF file does not contain the symbols for extension code. Furthermore, the extension is dynamically relocated by `llext_load()` at runtime, so even if the symbols were available, it would be impossible for the debugger to know the final locations of the symbols in the extension code.

Setting up the debugger session properly in this case requires a few manual steps. The following sections will provide some tips on how to do it with the Zephyr SDK and the debug features provided by `west`, but the instructions can be adapted to any GDB-based debugging environment.

Extension debugging process

1. Make sure the project is set up to display the verbose LLEXT debug output (`CONFIG_LOG` and `CONFIG_LLEXT_LOG_LEVEL_DBG` are set).
2. Build the Zephyr application and the extensions.

   For each target `name` included in the current build, two files will be generated into the `llext` subdirectory of the build root:

   `name_ext_debug.elf`

   An intermediate ELF file with full debugging information.

   `name.llext`

   The final extension binary, stripped to the essential data required for loading into the Zephyr application.

   Other files may be present, depending on the target architecture and the build configuration.
3. Start a debugging session of the main Zephyr application. This is described in the *Debugging* section of the documentation; on supported boards it is as easy as running `west debug`, perhaps with some additional arguments.
4. Set a breakpoint just after the `llext_load()` function in your code and let it run. This will load the extension into memory and relocate it. The output logs will contain a line with `gdb add-symbol-file flags:`, followed by lines all starting with `-s`.
5. Type this command in the GDB console to load this extension's symbols:

   ```
   add-symbol-file <path-to-debug.elf> <load-addresses>
   ```

   where `<path-to-debug.elf>` is the full path of the ELF file with debug information identified in step 2, and `<load-addresses>` is a space separated list of all the `-s` lines collected from the log in the previous step.
6. The extension symbols are now available to the debugger. You can set breakpoints, inspect variables, and step through the code as usual.

Steps 4-6 can be repeated for every extension that is loaded by the application, if there are several.

Warning

It is almost certain that the loaded symbols will be shadowed by others in the main application; for example, they may be located inside the memory area of the ELF buffer or the LLEXT heap.

In this case GDB chooses the first known symbol and therefore associates the addresses to some `elf_buffer+0x123` instead of an expected `ext_fn`. This further confuses its high-level operations like source stepping or inspecting locals, since they are meaningless in that context.

Symbol lookup issues Two possible solutions to this problem are discussed in the following paragraphs.

Discard all Zephyr symbols The simplest option is to drop all the Zephyr application symbols from GDB by invoking `add-symbol-file` with no arguments, before step 5. This will however focus the debugging session to the llext only, as all information about the Zephyr application will be lost. For example, the debugger may not be able to properly follow stack traces outside the extension code.

It is possible to use the same technique multiple times in the same session to switch between the main and extension symbol tables as required, but it rapidly becomes cumbersome.

Edit the ELF file This alternative is more complex but allows for a more seamless debugging experience. The idea is to edit the main Zephyr ELF file to remove information about the symbols that overlap with the extension that is to be debugged, so that when the extension symbols are loaded, GDB will not have any ambiguity. This can be done by using `objcopy` with the `-N <symbol>` option.

Identifying the offending symbols is however an iterative trial-and-error procedure, as there can be many different layers; for example, the ELF buffer may be itself contained in a symbol for the data segment. Fortunately, this knowledge can then be used several times as the list is unlikely to change for a given project.

Example debugging session This example demonstrates how to debug the `detached_fn` extension in the `tests/subsys/llext` project (specifically, the `writable` case), on an emulated `mps2/an385` board which is based on an ARM Cortex-M3.

Note

The logs below have been obtained using Zephyr version 4.1 and the Zephyr SDK version 0.17.0. However, the exact addresses may still vary between runs even when using the same versions. Adjust the commands below to match the results of your own session.

The following command will build the project and start the emulator in debugging mode:

Listing 13: Terminal 1 (build, QEMU emulator, GDB server)

```
zephyr$ west build -p -b mps2/an385 tests/subsys/llext/ -T llext.writable -t␣
↪debugserver_qemu
-- west build: generating a build system
[...]
-- west build: running target debugserver_qemu
[...]
[186/187] To exit from QEMU enter: 'CTRL+a, x'[QEMU] CPU: cortex-m3
```

On a separate terminal, set `ZEPHYR_SDK_INSTALL_DIR` to the directory for the Zephyr SDK on your installation, then start the GDB client for the target:

Listing 14: Terminal 2 (GDB client)

```
zephyr$ export LLEXT_SDK_INSTALL_DIR=/opt/zephyr-sdk-0.17.0
zephyr$ ${LLEXT_SDK_INSTALL_DIR}/arm-zephyr-eabi/bin/arm-zephyr-eabi-gdb␣
↪build/zephyr/zephyr.elf
GNU gdb (Zephyr SDK 0.17.0) 12.1
[...]
Reading symbols from build/zephyr/zephyr.elf...
(gdb)
```

Connect, set a breakpoint on the `llext_load` function and run until it finishes:

Listing 15: Terminal 2 (GDB client)

```
(gdb) target extended-remote :1234

#6  0x00000000 in ?? ()
```

The symbol associated with the breakpoint location and the last stack frames mistakenly reference the ELF buffer in the Zephyr application instead of the extension symbols. Note that GDB however knows both:

Listing 18: Terminal 2 (GDB client)

```
(gdb) info sym 0x200001d0
test_detached_ext + 464 in section datas of zephyr/build/zephyr/zephyr.elf
detached_entry in section .detach of zephyr/build/llext/detached_fn_ext_debug.elf
(gdb) info sym 0x200000ac
test_detached_ext + 172 in section datas of zephyr/build/zephyr/zephyr.elf
test_entry + 8 in section .text of zephyr/build/llext/detached_fn_ext_debug.elf
```

It is also impossible to inspect the variables in the extension or step through code properly:

Listing 19: Terminal 2 (GDB client)

```
(gdb) print bss_cnt
No symbol "bss_cnt" in current context.
(gdb) print data_cnt
No symbol "data_cnt" in current context.
(gdb) next
Single stepping until exit from function test_detached_ext,
which has no line number information.

Breakpoint 2, 0x200001ea in test_detached_ext ()
(gdb)
```

Discarding symbols Discarding the Zephyr symbols and only focusing on the extension restores full debugging functionality at the cost of losing the global context (note the backtrace stops outside the extension):

Listing 20: Terminal 2 (GDB client)

```
(gdb) symbol-file
Discard symbol table from `zephyr/build/zephyr/zephyr.elf'? (y or n) y

(gdb) print data_cnt
$2 = -2
(gdb)
```

Editing the ELF file In this alternative approach, the patches to the Zephyr ELF file must be performed after building the Zephyr binary and starting the emulator on Terminal 1, but before starting the GDB client on Terminal 2.

The above debugging session already identified `test_detached_ext`, the char array that holds the ELF file, as an offending symbol, so that will be removed in a first pass. Performing the same steps multiple times, `__data_start` and `__data_region_start` can also be found to overlap the memory area of interest.

The following commands will remove all of these from the Zephyr ELF file, then start a debugging session on the modified file:

Listing 21: Terminal 2 (GDB client)

```
zephyr$ export LLEXT_SDK_INSTALL_DIR=/opt/zephyr-sdk-0.17.0
zephyr$ ${LLEXT_SDK_INSTALL_DIR}/arm-zephyr-eabi/bin/arm-zephyr-eabi-objcopy -N␣
↪test_detached_ext -N __data_start -N __data_region_start build/zephyr/zephyr.elf␣
↪build/zephyr/zephyr-edit.elf
zephyr$ ${LLEXT_SDK_INSTALL_DIR}/arm-zephyr-eabi/bin/arm-zephyr-eabi-gdb␣
↪build/zephyr/zephyr-edit.elf
GNU gdb (Zephyr SDK 0.17.0) 12.1
[...]
Reading symbols from build/zephyr/zephyr-edit.elf...
(gdb)
```

The same steps used in the previous run can be performed again to attach to the GDB server and load both the extension and its debug symbols. This time, however, the result is rather different:

- the `break` command includes line number information;
- the output from `backtrace` contains functions from both the extension and the Zephyr ap-

plication;

- the local variables can be properly inspected.

Listing 22: Terminal 2 (GDB client)

```

- *API Reference*

Overview

The Multimedia Pipeline subsystem (mpipe) builds a media stream out of self-contained processing components called **elements**. An application declares the elements it needs, links them into a graph, and drives that graph through a state machine; mpipe negotiates the data format between neighboring elements, settles which buffer pool provides the buffers, and moves those buffers from one element to the next.

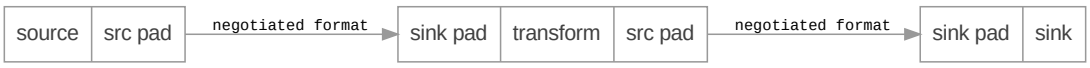

Fig. 45: A pipeline is a graph of elements joined at their pads.

mpipe provides the pieces and the rules by which they fit together rather than finished solutions, so a pipeline is assembled much like building with LEGO bricks: the same graph runs on a different board by binding its elements to different devices, and a new requirement is usually one more element rather than a rewrite.

The elements themselves live in **plugins**, grouped by media domain. A plugin brings its own directory, its own Kconfig and its own headers, and the build picks it up without any edit to the framework, so a silicon vendor or a middleware provider can ship elements without altering the core.

mpipe performs no dynamic allocation: buffers come from pools sized while the pipeline starts, and everything on the negotiation path is fixed-size and held by value. The cost lands on the

stack instead. Negotiation runs inside `mpipe_element_set_state()`, on whichever thread calls it, and holds several capabilities live at once - budget for it on that thread, which for the example below is the one running `main`.

mpipe is optional, and it is not always the right tool. An application driving a single device is better served by that device's API directly. mpipe earns its place once several devices have to agree on a format and hand buffers to each other.

Building a pipeline

An application includes <zephyr/mpipe/mpipe.h>, and only that, for the whole core API; each element it instantiates adds that element's own header.

Elements are plain objects the application owns; mpipe allocates none of them. Each element type has its own init function taking that type and an id:

```
/* Concrete element types come from plugins; each has its own header. */
static struct mpipe pipe;
static struct my_src source;
static struct my_sink sink;

ret = mpipe_pipeline_init(&pipe, PIPE_ID);
ret = my_src_init(&source, SRC_ID);
ret = my_sink_init(&sink, SINK_ID);
```

Ids only have to be unique within the pipeline. Elements are configured through properties, which is how an element is set up without the caller knowing its concrete type:

```
ret = mpipe_object_set_properties((struct mpipe_object *)&source,
                                  MY_SRC_PROP_PATH, "/SD:/in.bin",
                                  MPIPE_PROP_LIST_END);
```

They are then added to the pipeline, in any order, and linked in stream order:

```
ret = mpipe_bin_add((struct mpipe_bin *)&pipe,
                    (struct mpipe_element *)&source,
                    (struct mpipe_element *)&sink, NULL);

ret = mpipe_element_link((struct mpipe_element *)&source,
                         (struct mpipe_element *)&sink, NULL);
```

The casts are well defined because every element embeds its base as its first member. Linking refuses a pair of elements whose capabilities cannot possibly intersect, so an impossible graph fails while it is being built rather than when it is started.

Setting the pipeline to `MPIPE_STATE_PLAYING` is not a jump to that state. The pipeline and its children step through the states in order, `READY` to `PAUSED` to `PLAYING`, which is why the format is negotiated and the pools are started along the way.

The application then observes the pipeline's message channel, both to learn how the run ends and to act on failures. An error message names the element that raised it and the phase it was in, so an application can report that capability negotiation failed at element 3 rather than only that the run stopped. Returning the graph to `MPIPE_STATE_READY` tears it down:

```
/* Needs CONFIG_ZBUS_MSG_SUBSCRIBER=y */
ZBUS_MSG_SUBSCRIBER_DEFINE(main_sub);

struct zbus_channel *bus = mpipe_element_get_bus_chan((struct mpipe_element *)&
↪pipe);
```

(continues on next page)

(continued from previous page)

```
ret = zbus_chan_add_obs(bus, &main_sub, K_FOREVER);

if (mpipe_element_set_state((struct mpipe_element *)&pipe, MPIPE_STATE_PLAYING) !=␣
↪0) {
        /* the element that refused is still in its previous state */
}

do {
        ret = zbus_sub_wait_msg(&main_sub, &chan, &msg, K_FOREVER);
} while ((msg.type & (MPIPE_MESSAGE_ERROR | MPIPE_MESSAGE_EOS)) == 0);

(void)mpipe_element_set_state((struct mpipe_element *)&pipe, MPIPE_STATE_READY);
```

Elements, pads and links

Every mpipe *element* derives from `mpipe_object` by embedding it as its first member. The object layer carries what the framework needs of anything it holds: an id, the container that holds it, list linkage, and the property callbacks. On top of it, `mpipe_element` adds the state machine and the pads, and the element bases specialize it. The types that only carry data - a capability, a message, a dispatch - are plain structs outside that hierarchy:

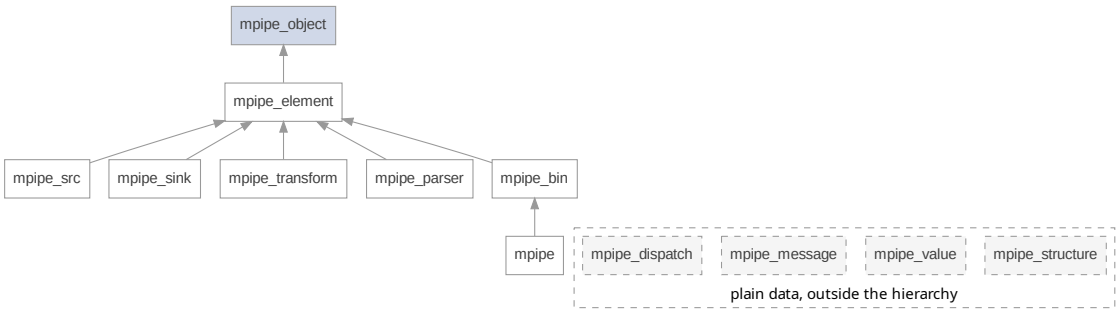

Fig. 46: Inheritance is struct embedding, so upcasting is a plain C cast.

- `mpipe_src` produces buffers and has source pads only. It also drives the negotiation, because it sits at the head of the graph.
- `mpipe_sink` consumes them and has sink pads only.
- `mpipe_transform` has one of each and turns input into output.
- `mpipe_parser` cuts a formless byte stream into whole frames, which is a different job from transforming one format into another.
- `mpipe_bin` holds other elements and forwards state changes to them in the order the transition requires.
- `mpipe` is the top-level bin: it owns the streaming thread and the message channel.

A `mpipe_pad` is where two elements meet. It carries a direction (source or sink), the peer it is linked to, the capability negotiated on it, and the callbacks the framework dispatches to: `chain_fn` receives a buffer, `query_fn` answers a query, and `event_fn` handles an event. Linking two elements links a source pad to a sink pad, and every hop of the stream is one such pair.

The state machine

An element is in one of three states and moves between neighbors one step at a time:

Fig. 47: What each transition does.

READY means constructed and linked, holding no format and no buffers. The READY to PAUSED transition is where the work happens: the source drives capability negotiation across the whole graph, the buffer pool query settles who provides buffers and how many, and the pools start.

Which way a transition goes determines the order a bin works through its children:

- Going **up**, children transition from the sink towards the source, so a downstream element is ready before anything is pushed into it.
- Going **down**, children transition from the source towards the sink, so nothing keeps producing into an element that has already been torn down.

Nothing unwinds a failed transition. An element that refuses one stays where it was while the elements that already moved keep their new state, which is deliberate: the resulting graph shows exactly which element refused and in which transition.

Capability negotiation

A **capability** describes the data crossing a link: a media type plus a set of fields, each an `mpipe_caps_field` identifier paired with an `mpipe_value`. It is a `mpipe_structure`, a fixed-size type held by value:

```
struct mpipe_structure s;

mpipe_structure_init_fields(&s, MPIPE_MEDIA_VIDEO,
    MPIPE_CAPS_PIXEL_FORMAT, MPIPE_TYPE_UINT, VIDEO_PIX_FMT_RGB565,
    MPIPE_CAPS_IMAGE_WIDTH, MPIPE_TYPE_UINT_RANGE, 16, 1280, 2,
    MPIPE_CAPS_IMAGE_HEIGHT, MPIPE_TYPE_UINT_RANGE, 16, 720, 2,
    MPIPE_CAPS_END);
```

A field holds either a single value or a range written `[min, max, step]`, so the capability above covers every width from 16 to 1280 in steps of 2. Two capabilities intersect when they share a media type, have at least one field identifier in common, and every shared field has intersecting values. The result is the union of both: a shared field holds the intersected value, and a field only one side carries passes through unchanged, which is what lets a constraint travel down a chain of elements that do not themselves care about it. An *ANY* capability constrains nothing and intersects with anything - it is what a pad carries before it has negotiated - while an *empty* one carries no field and intersects with nothing.

The source drives the negotiation on READY to PAUSED, in two passes:

Fig. 48: Capability negotiation, driven by the source on READY to PAUSED

A caps query travels downstream, each element narrowing it against what it supports before asking its own downstream, and the answer comes back narrowed to what the whole chain has in common. If an element refuses, the source simply offers the next format it supports rather than failing the negotiation.

A transform is the interesting case, because its two sides may speak different formats: a decoder takes one format in and produces another out. They need not - an element working in place rewrites the buffer where it lies, so the same format crosses it - but where they do differ, the `transform_caps` hook is what maps a capability from one side of the element to what the other side could then be. The query crosses the element through it in both directions: out to ask the downstream peer, and back to express the answer in terms of the input side again.

The answer may still hold ranges, so the source **fixates** it - each range reduced to a single value - and announces the result downstream as a caps event. Every element applies its side through its `set_caps` hook, which is where hardware is actually configured.

Because a pad holds one capability rather than a set, an element that supports several formats is walked by index: the framework asks it for capability 0, then 1, and so on until it reports there are no more. An element whose formats come from a device answers each index by asking its driver, so nothing has to be materialized in advance.

Buffer pool negotiation

Formats alone do not say how many buffers a graph needs, how large they must be, how they must be aligned, or whose pool provides them. A second query settles that, immediately after the format is fixed and in the same transition:

Fig. 49: Buffer pool negotiation, immediately after the format is fixed

The query travels down to the sink and proposals are written on the way back up, so an element always has its downstream's proposal in hand before it decides anything.

A transform's two sides are settled independently: `decide_buffer_pool` uses what its downstream proposed to settle the **output** pool, while `propose_buffer_pool` answers the upstream query with what the element needs on its **input**. The exception is passthrough, where one buffer crosses the element and there is only one pool to settle.

A proposal is either an entire pool or a bare config. Offering the pool lets the upstream element adopt it and avoid a copy; offering a config states requirements without handing anything over. Either way, a demand reaches a pool its proposer still owns only through `mpipe_buffer_pool_set_config()`, and the pool's owner validates, clamps or refuses it.

Whoever starts a pool is who stops it, on `PAUSED` to `READY`. That symmetry is what makes a stop and replay behave like a first run.

Buffer flow

Buffer flow is zero-copy. Each element that produces data owns a `mpipe_buffer_pool`, and a pool is a vtable - `configure`, `set_config`, `start`, `stop`, `acquire_buffer`, `release_buffer` - over whatever backs it. That indirection is what lets a plugin hand out the buffer its driver already owns rather than a copy of it, so a frame captured by a camera reaches the display without ever being moved. What travels between elements is a reference, not the pixels.

Buffers are Zephyr `net_buf` allocations, with an `mpipe_buffer_meta` alongside carrying what the framework needs to know about one: the pool that owns it, how much of it is valid, a timestamp.

`mpipe_push_buffer()` walks a buffer downstream: for each hop it takes the source pad's peer, checks that pad's flushing gate, calls its `chain_fn`, and follows the buffer the element produced to the next element. A NULL output means the buffer was consumed and the walk stops. The chain function owns the buffer it is given and releases it even when it fails, so ownership never depends on the error path taken.

Pipeline runtime

The pipeline's own thread drives the source: it acquires a buffer and pushes it downstream until the source reports the end of its data, at which point it sends an end-of-stream event downstream

and pauses itself. An element that needs to decouple two halves of a graph onto separate threads does so by placing a queuing element between them.

Tearing a running graph down is ordered carefully, and the order is what keeps it from losing data or deadlocking:

- `PLAYING` to `PAUSED` only pauses the source thread. Whatever is queued is preserved, so resuming continues without loss. This is a pause, not a teardown.
- `PAUSED` to `READY` raises a flushing gate on every pad *before* the children dismantle their pools, so a buffer still in flight is dropped rather than pushed into an element that has already been torn down. The streaming thread is joined only *after* the children have drained, because a child still holding that thread in a full queue would otherwise deadlock the join.

Messages travel to the application on the pipeline's message channel, a zbus channel reachable with `mpipe_element_get_bus_chan()`. A message carries where something happened - the element that emitted it - and what happened: a type, plus, on a failure, a domain naming the phase that failed and an errno saying why. It carries no human-facing string; the sentence describing a failure belongs in the log at the site that detected it, while an application branches on the domain and the errno.

A pipeline with several sinks produces one end-of-stream message per sink. The pipeline counts them and passes on only the last, so the application is notified exactly once and never tears the graph down while a branch is still running.

Writing an element

An element is written outside the framework and requires no change to it. It embeds one of the bases as its first member, calls that base's init with its own id, and overrides only what it cares about:

```
struct my_sink {
        struct mpipe_sink sink;   /* must be first */
        const struct device *dev;
};

int my_sink_init(struct my_sink *self, uint8_t id)
{
        int ret = mpipe_sink_init(&self->sink, id);

        if (ret != 0) {
                return ret;
        }

        self->sink.sink_pad.enum_caps_fn = my_sink_enum_caps;
        self->sink.set_caps = my_sink_set_caps;

        return 0;
}
```

An element that overrides `change_state` must chain to its base, which is what performs the capability reset and the pool teardown every element is expected to do.

The other half is saying what the element supports. A capability known at build time is a `static const struct mpipe_structure` the element copies out of, and `MPIPE_STRUCTURE_DEFINE` places one in `.rodata`; several are an array of them. An element backed by a device instead builds each capability inside its `enum_caps_fn` by asking the driver, and one configured by the application takes it from a property.

Configuration Options

- `CONFIG_MPIPE` enables the framework. Each plugin has its own option and contributes its own Kconfig file.
- `CONFIG_MPIPE_STRUCTURE_MAX_FIELDS` sizes one capability. Size it for the largest union of fields that can meet in one intersection, not for the number of fields an element sets, since an intersection carries through the fields only one side constrains.
- `CONFIG_MPIPE_NET_BUF_POOL_COUNT` sizes the shared `net_buf` pool: the sum of the in-flight buffers of every pipeline.
- `CONFIG_MPIPE_BIN_MAX_CHILDREN` bounds the elements in one bin, which sizes the arrays used to order them during a state change.
- `CONFIG_MPIPE_THREADS_NUM`, `CONFIG_MPIPE_THREAD_STACK_SIZE` and `CONFIG_MPIPE_THREAD_DEFAULT_PRIORITY` configure the pooled threads a pipeline draws from.
- `CONFIG_MPIPE_WORKQUEUE` lets elements offload finite work items onto a shared priority work queue.
- `CONFIG_MPIPE_RPC` builds the client-side elements that run their processing on another core.
- `CONFIG_MPIPE_FAKE_SRC` provides a source of synthetic data, used to exercise a graph where a real source would need hardware.

4.11.3 Sensing Subsystem

- *Overview*
- *Configurability*
- *Main Features*
- *Major Flows*
- *Sensor Types And Instance*
- *Sensor Instance Handler*
- *Sensor Sample Value*
- *Device Tree Configuration*
- *API Reference*

Overview

Sensing Subsystem is a high level sensor framework inside the OS user space service layer. It is a framework focused on sensor fusion, client arbitration, sampling, timing, scheduling and sensor based power management.

Key concepts in Sensing Subsystem include physical sensor and virtual sensor objects, and a scheduling framework over sensor object relationships. Physical sensors do not depend on any other sensor objects for input, and will directly interact with existing zephyr sensor device drivers. Virtual sensors rely on other sensor objects (physical or virtual) as report inputs.

The sensing subsystem relies on Zephyr sensor device APIs (existing version or update in future) to leverage Zephyr's large library of sensor device drivers (100+).

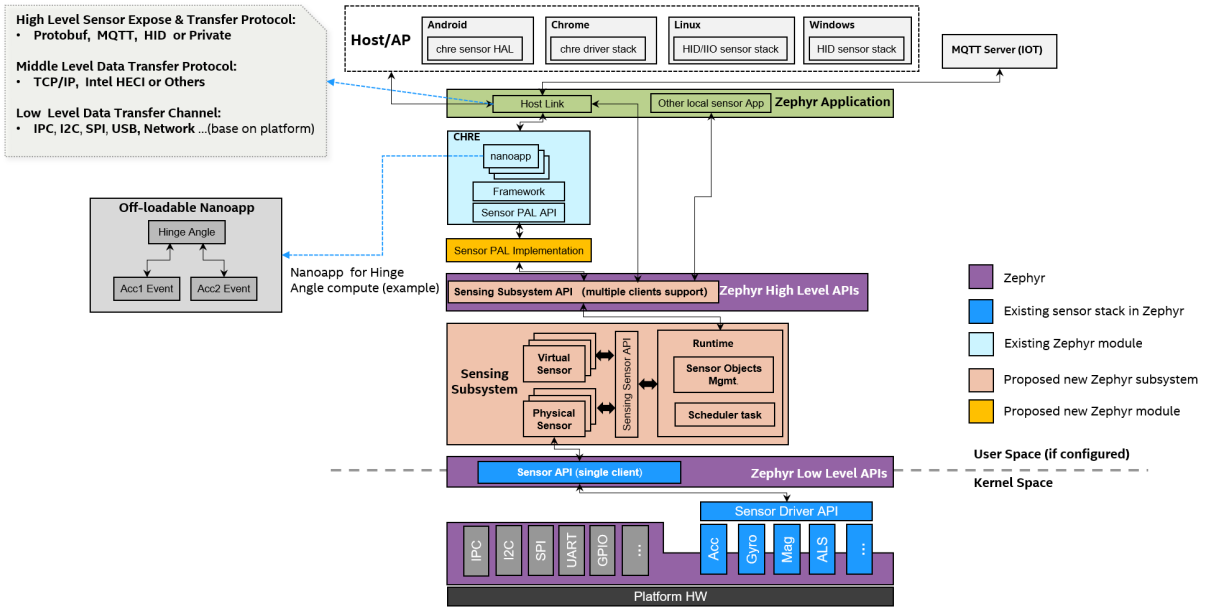
Use of the sensing subsystem is optional. Applications that only need to access simple sensors devices can use the Zephyr *Sensors* API directly.

Since the sensing subsystem is separated from device driver layer or kernel space and could support various customizations and sensor algorithms in user space with virtual sensor concepts. The existing sensor device driver can focus on low layer device side works, can keep simple as much as possible, just provide device HW abstraction and operations etc. This is very good for system stability.

The sensing subsystem is decoupled with any sensor expose/transfer protocols, the target is to support various up-layer frameworks and Applications with different sensor expose/transfer protocols, such as CHRE, HID sensors Applications, MQTT sensor Applications according different products requirements. Or even support multiple Applications with different up-layer sensor protocols at the same time with it's multiple clients support design.

Sensing subsystem can help build a unified Zephyr sensing architecture for cross host OSes support and as well as IoT sensor solutions.

The diagram below illustrates how the Sensing Subsystem integrates with up-layer frameworks.



Configurability

- Reusable and configurable standalone subsystem.
- Based on Zephyr existing low-level Sensor API (reuse 100+ existing sensor device drivers)
- Provide Zephyr high-level Sensing Subsystem API for Applications.
- Separate option CHRE Sensor PAL Implementation module to support CHRE.
- Decoupled with any host link protocols, it's Zephyr Application's role to handle different protocols (MQTT, HID or Private, all configurable)

Main Features

Scope
: Focus on framework for sensor fusion, multiple clients, arbitration, data sampling, timing management and scheduling.

Sensor Abstraction

- **Physical sensor**: interacts with Zephyr sensor device drivers, focus on data collecting.
- **Virtual sensor**: relies on other sensor(s), **physical** or **virtual**, focus on data fusion.

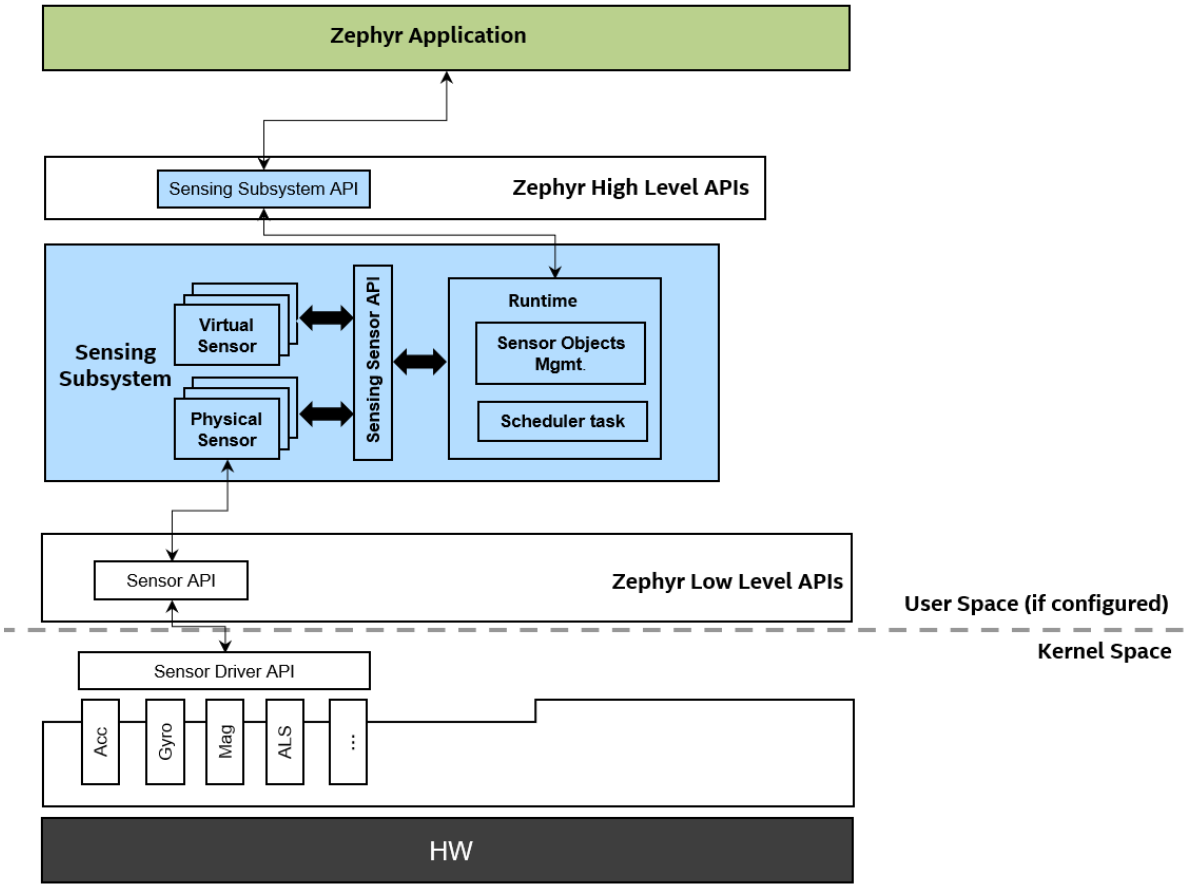
Data Driven Model

- **Polling mode**: periodical sampling rate
- **Interrupt mode**: data ready, threshold interrupt etc.

Scheduling
Single thread main loop for all sensor objects sampling and process.

Buffer Mode for Batching
Configurable Via Devicetree

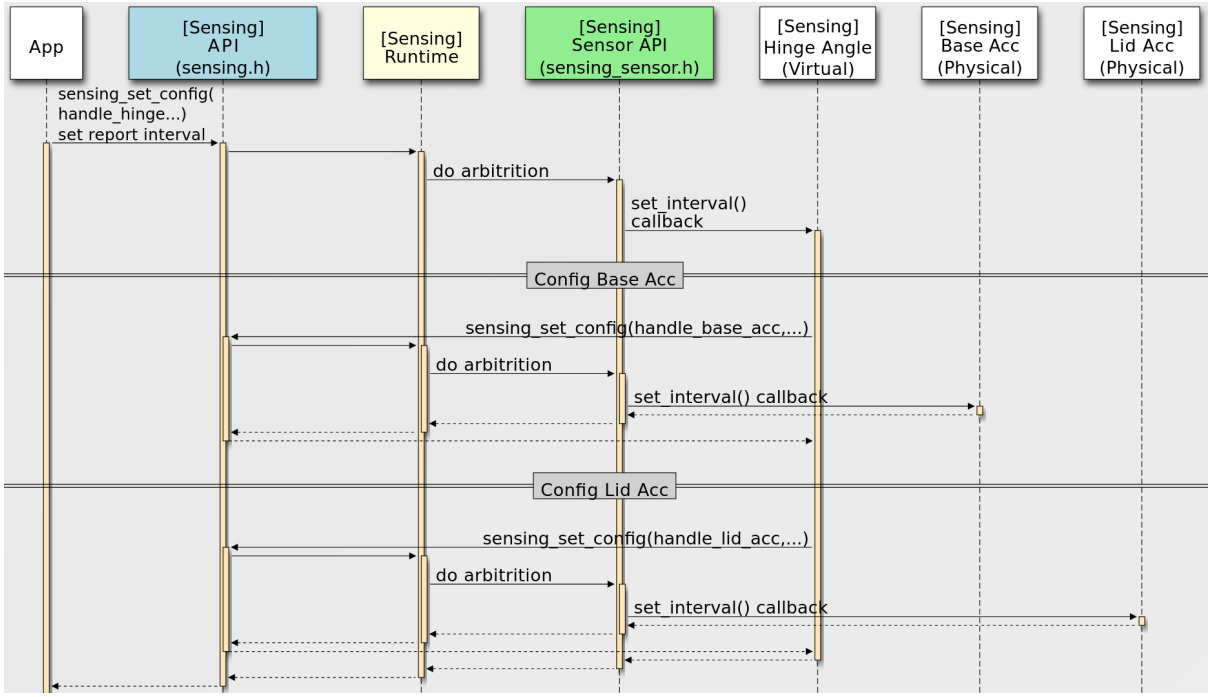
Below diagram shows the API position and scope:



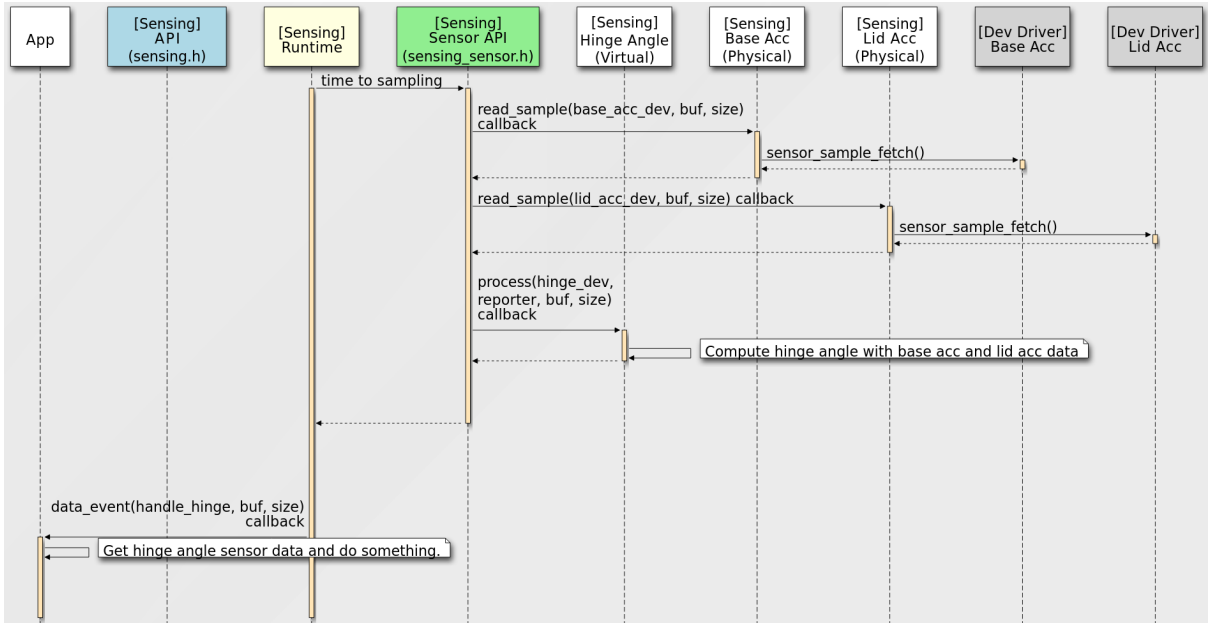
`Sensing Subsystem API` is for Applications. `Sensing Sensor API` is for development sensors.

Major Flows

- Sensor Configuration Flow



- Sensor Data Flow



Sensor Types And Instance

The `Sensing Subsystem` supports multiple instances of the same sensor type, there're two methods for Applications to identify and open an unique sensor instance:

- Enumerate all sensor instances

  `sensing_get_sensors()` returns all current board configuration supported sensor instances' information in a `sensing_sensor_info` pointer array .

  Then Applications can use `sensing_open_sensor()` to open specific sensor instance for future accessing, configuration and receive sensor data etc.

  This method is suitable for supporting some up-layer frameworks like `CHRE`, `HID` which need to dynamically enumerate the underlying platform's sensor instances.

- Open the sensor instance by devicetree node directly

  Applications can use `sensing_open_sensor_by_dt()` to open a sensor instance directly with sensor devicetree node identifier.

  For example:

```
sensing_open_sensor_by_dt(DEVICE_DT_GET(DT_NODELABEL(base_accel)), cb_list,␣
↪handle);
sensing_open_sensor_by_dt(DEVICE_DT_GET(DT_CHOSEN(zephyr_sensing_base_accel)),␣
↪cb_list, handle);
```

This method is useful and easy use for some simple Application which just want to access specific sensor(s).

`Sensor type` follows the HID standard sensor types definition.

See include/zephyr/sensing/sensing_sensor_types.h

Sensor Instance Handler

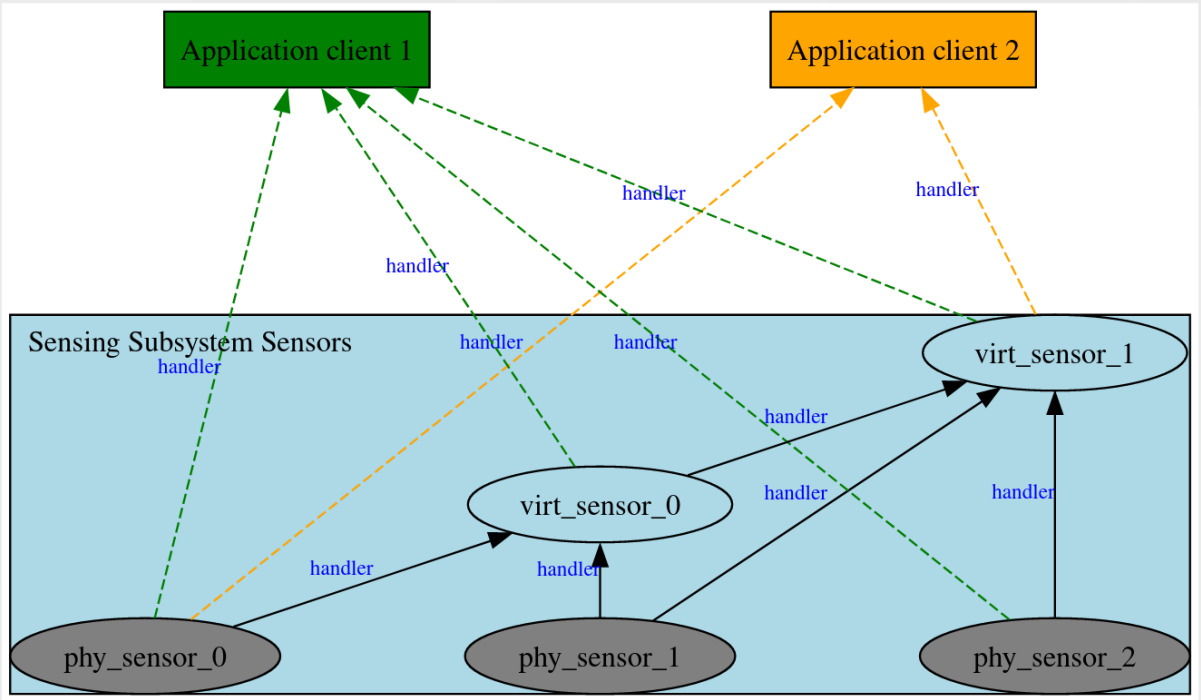
Clients using a `sensing_sensor_handle_t` type handler to handle a opened sensor instance, and all subsequent operations on this sensor instance need use this handler, such as set configurations, read sensor sample data, etc.

For a sensor instance, could have two kinds of clients: `Application clients` and `Sensor clients`.

`Application clients` can use `sensing_open_sensor()` to open a sensor instance and get it's handler.

For `Sensor clients`, there is no open API for opening a reporter, because the client-report relationship is built at the sensor's registration stage with devicetree.

The `Sensing Subsystem` will auto open and create `handlers` for client sensor to it's reporter sensors. `Sensor clients` can get it's reporters' handlers via `sensing_sensor_get_reporters()`.



Note

Sensors inside the Sensing Subsystem, the reporting relationship between them are all auto generated by Sensing Subsystem according devicetree definitions, handlers between client sensor and reporter sensors are auto created. Application(s) need to call `sensing_open_sensor()` to explicitly open the sensor instance.

Sensor Sample Value

- Data Structure

  Each sensor sample value defines as a common `header + readings[]` data structure, like `sensing_sensor_value_3d_q31`, `sensing_sensor_value_q31`, and `sensing_sensor_value_uint32`.

  The `header` definition `sensing_sensor_value_header()`.

- Time Stamp

  Time stamp unit in sensing subsystem is `micro seconds`.

  The `header` defines a **base_timestamp**, and each element in the **readings[]** array defines **timestamp_delta**.

  The **timestamp_delta** is in relation to the previous **readings** (or the **base_timestamp**)

  For example:

  – timestamp of `readings[0]` is `header.base_timestamp + readings[0].timestamp_delta`.

  – timestamp of `readings[1]` is `timestamp of readings[0] + readings[1].timestamp_delta`.

  Since timestamp unit is micro seconds, the max **timestamp_delta** (`uint32_t`) is `4295` seconds.

  If a sensor has batched data where two consecutive readings differ by more than `4295` seconds, the sensing subsystem runtime will split them across multiple instances of the readings structure, and send multiple events.

  This concept is referred from CHRE Sensor API.

- Data Format

  `Sensing Subsystem` uses per sensor type defined data format structure, and support `Q Format` defined in include/zephyr/dsp/types.h for zdsp lib support.

  For example `sensing_sensor_value_3d_q31` can be used by 3D IMU sensors like `SENSING_SENSOR_TYPE_MOTION_ACCELEROMETER_3D`, `SENSING_SENSOR_TYPE_MOTION_UNCALIB_ACCELEROMETER_3D`, and `SENSING_SENSOR_TYPE_MOTION_GYROMETER_3D`.

  `sensing_sensor_value_uint32` can be used by `SENSING_SENSOR_TYPE_LIGHT_AMBIENTLIGHT` sensor,

  and `sensing_sensor_value_q31` can be used by `SENSING_SENSOR_TYPE_MOTION_HINGE_ANGLE` sensor

  See include/zephyr/sensing/sensing_datatypes.h

Device Tree Configuration

Sensing subsystem using device tree to configuration all sensor instances and their properties, reporting relationships.

See the example samples/subsys/sensing/simple/boards/native_sim.overlay

4.11.4 State Machine Framework

Overview

The State Machine Framework (SMF) is an application agnostic framework that provides an easy way for developers to integrate state machines into their application. The framework can be added to any project by enabling the `CONFIG_SMF` option.

State Creation

A state is represented by three functions, where one function implements the Entry actions, another function implements the Run actions, and the last function implements the Exit actions. The prototype for the entry and exit functions are as follows: `void funct(void *obj)`, and the prototype for the run action is `enum smf_state_result funct(void *obj)` where the `obj` parameter is a user defined structure that has the state machine context, `smf_ctx`, as its first member. For example:

```
struct user_object {
   struct smf_ctx ctx;
   /* All User Defined Data Follows */
};
```

The `smf_ctx` member must be first because the state machine framework's functions casts the user defined object to the `smf_ctx` type with the `SMF_CTX` macro.

For example instead of doing this `(struct smf_ctx *)&user_obj`, you could use `SMF_CTX(&user_obj)`.

By default, a state can have no ancestor states, resulting in a flat state machine. But to enable the creation of a hierarchical state machine, the `CONFIG_SMF_ANCESTOR_SUPPORT` option must be enabled.

The return value of the run action, `smf_state_result` determines if the state machine propagates the event to parent run actions (`SMF_EVENT_PROPAGATE`) or if the event was handled by the run action (`SMF_EVENT_HANDLED`). Flat state machines do not have parent actions, so the return code is ignored; returning `SMF_EVENT_HANDLED` is recommended.

Calling `smf_set_state()` prevents calling parent run actions, even if `SMF_EVENT_PROPAGATE` is returned.

By default, the hierarchical state machines do not support initial transitions to child states on entering a superstate. To enable them the `CONFIG_SMF_INITIAL_TRANSITION` option must be enabled.

The following macro can be used for easy state creation:

- `SMF_CREATE_STATE` Create a state

State Machine Creation

A state machine is created by defining a table of states that's indexed by an enum. For example, the following creates three flat states:

```
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
   [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, NULL, NULL),
   [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, NULL, NULL),
   [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, NULL, NULL)
};
```

And this example creates three hierarchical states:

```
enum demo_state { S0, S1, S2 };

const struct smf_state demo_states[] = {
   [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, parent_s0, NULL),
   [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, parent_s12, NULL),
   [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, parent_s12, NULL)
};
```

This example creates three hierarchical states with an initial transition from parent state S0 to child state S2:

```
enum demo_state { S0, S1, S2 };

/* Forward declaration of state table */
const struct smf_state demo_states[];

const struct smf_state demo_states[] = {
   [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, NULL, demo_states[S2]),
   [S1] = SMF_CREATE_STATE(s1_entry, s1_run, s1_exit, demo_states[S0], NULL),
   [S2] = SMF_CREATE_STATE(s2_entry, s2_run, s2_exit, demo_states[S0], NULL)
};
```

To set the initial state, the `smf_set_initial()` function should be called.

To transition from one state to another, the `smf_set_state()` function is used.

Note

If `CONFIG_SMF_INITIAL_TRANSITION` is not set, `smf_set_initial()` and `smf_set_state()` function should not be passed a parent state as the parent state does not know which child state to transition to. Transitioning to a parent state is OK if an initial transition to a child state is defined. A well-formed HSM should have initial transitions defined for all parent states.

Note

While the state machine is running, `smf_set_state()` should only be called from the Entry or Run function. Calling `smf_set_state()` from Exit functions will generate a warning in the log and no transition will occur.

State Machine Execution

To run the state machine, the `smf_run_state()` function should be called in some application dependent way. An application should cease calling smf_run_state if it returns a non-zero value.

State Machine Termination

To terminate the state machine, the `smf_set_terminate()` function should be called. It can be called from the entry, run, or exit actions. The function takes a non-zero user defined value that will be returned by the `smf_run_state()` function.

Retrieving the Current State

Leaf State: In the context of a hierarchical state machine, a *leaf state* is a state that does not contain any child states. It represents the most granular level of state in the hierarchy, where no further decomposition is possible.

Executing State: The *executing state* refers to the state whose entry, run, or exit action is currently being executed by the state machine. This may be a parent or leaf state, depending on the current operation.

To retrieve the current leaf state, the `smf_get_current_leaf_state()` function should be called. For example:

```
const struct smf_state *leaf_state = smf_get_current_leaf_state(SMF_CTX(&s_obj));
```

Note

If `CONFIG_SMF_INITIAL_TRANSITION` is not enabled, or if the initial state of a parent state is not defined, always set the state to a leaf state. Otherwise, the state machine may enter a parent state directly, and `smf_get_current_leaf_state()` may return a parent state instead of a leaf state. Ensure initial transitions are properly configured for all parent states to avoid malformed hierarchical state machines.

To retrieve the state whose entry, run, or exit action is currently being executed, use the `smf_get_current_executing_state()` function.

UML State Machines

SMF follows UML hierarchical state machine rules for transitions i.e., the entry and exit actions of the least common ancestor are not executed on transition, unless said transition is a transition to self.

The UML Specification for StateMachines may be found in chapter 14 of the UML specification available here: https://www.omg.org/spec/UML/

SMF breaks from UML rules in:

1. Executing the actions associated with the transition within the context of the source state, rather than after the exit actions are performed.
2. Only allowing external transitions to self, not to sub-states. A transition from a superstate to a child state is treated as a local transition.
3. Prohibiting transitions using `smf_set_state()` in exit actions.

SMF also does not provide any pseudostates except the Initial Pseudostate. Terminate pseudostates can be modelled by calling `smf_set_terminate()` from the entry action of a 'terminate' state. Orthogonal regions are modelled by calling `smf_run_state()` for each region.

State Machine Examples

Flat State Machine Example This example turns the following state diagram into code using the SMF, where the initial state is S0.

Code:

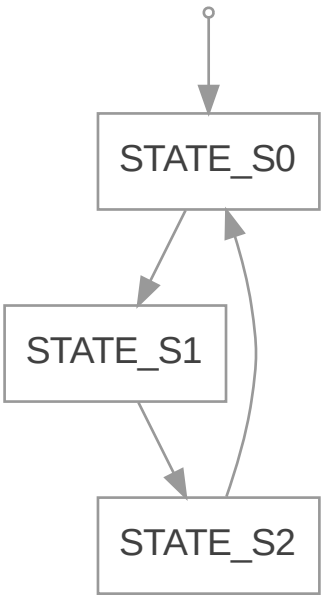

Fig. 50: Flat state machine diagram

```
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { S0, S1, S2 };

/* User defined object */
struct s_object {
        /* This must be first */
        struct smf_ctx ctx;

        /* Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o)
{
        /* Do something */
}
static enum smf_state_result s0_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
        return SMF_EVENT_HANDLED;
}
static void s0_exit(void *o)
{
```

(continues on next page)

(continued from previous page)

```
        /* Do something */
}

/* State S1 */
static enum smf_state_result s1_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S2]);
        return SMF_EVENT_HANDLED;
}
static void s1_exit(void *o)
{
        /* Do something */
}

/* State S2 */
static void s2_entry(void *o)
{
        /* Do something */
}
static enum smf_state_result s2_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
        return SMF_EVENT_HANDLED;
}

/* Populate state table */
static const struct smf_state demo_states[] = {
        [S0] = SMF_CREATE_STATE(s0_entry, s0_run, s0_exit, NULL, NULL),
        /* State S1 does not have an entry action */
        [S1] = SMF_CREATE_STATE(NULL, s1_run, s1_exit, NULL, NULL),
        /* State S2 does not have an exit action */
        [S2] = SMF_CREATE_STATE(s2_entry, s2_run, NULL, NULL, NULL),
};

int main(void)
{
        int32_t ret;

        /* Set initial state */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

        /* Run the state machine */
        while(1) {
                /* State machine terminates if a non-zero value is returned */
                ret = smf_run_state(SMF_CTX(&s_obj));
                if (ret) {
                        /* handle return code and terminate state machine */
                        break;
                }
                k_msleep(1000);
        }
}
```

Hierarchical State Machine Example This example turns the following state diagram into code using the SMF, where S0 and S1 share a parent state and S0 is the initial state.

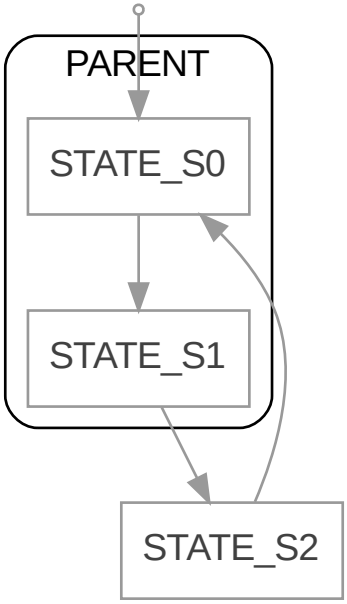

Fig. 51: Hierarchical state machine diagram

Code:

```
#include <zephyr/smf.h>

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
enum demo_state { PARENT, S0, S1, S2 };

/* User defined object */
struct s_object {
        /* This must be first */
        struct smf_ctx ctx;

        /* Other state specific data add here */
} s_obj;

/* Parent State */
static void parent_entry(void *o)
{
        /* Do something */
}
static void parent_exit(void *o)
{
        /* Do something */
}
```

(continues on next page)

(continued from previous page)

```
/* State S0 */
static enum smf_state_result s0_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
        return SMF_EVENT_HANDLED;
}

/* State S1 */
static enum smf_state_result s1_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S2]);
        return SMF_EVENT_HANDLED;
}

/* State S2 */
static enum smf_state_result s2_run(void *o)
{
        smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
        return SMF_EVENT_HANDLED;
}

/* Populate state table */
static const struct smf_state demo_states[] = {
        /* Parent state does not have a run action */
        [PARENT] = SMF_CREATE_STATE(parent_entry, NULL, parent_exit, NULL, NULL),
        /* Child states do not have entry or exit actions */
        [S0] = SMF_CREATE_STATE(NULL, s0_run, NULL, &demo_states[PARENT], NULL),
        [S1] = SMF_CREATE_STATE(NULL, s1_run, NULL, &demo_states[PARENT], NULL),
        /* State S2 do not have entry or exit actions and no parent */
        [S2] = SMF_CREATE_STATE(NULL, s2_run, NULL, NULL, NULL),
};

int main(void)
{
        int32_t ret;

        /* Set initial state */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

        /* Run the state machine */
        while(1) {
                /* State machine terminates if a non-zero value is returned */
                ret = smf_run_state(SMF_CTX(&s_obj));
                if (ret) {
                        /* handle return code and terminate state machine */
                        break;
                }
                k_msleep(1000);
        }
}
```

When designing hierarchical state machines, the following should be considered:

- Ancestor entry actions are executed before the sibling entry actions. For example, the parent_entry function is called before the s0_entry function.
- Transitioning from one sibling to another with a shared ancestry does not re-execute the ancestor's entry action or execute the exit action. For example, the parent_entry function

is not called when transitioning from S0 to S1, nor is the parent_exit function called.

- Ancestor exit actions are executed after the exit action of the current state. For example, the s1_exit function is called before the parent_exit function is called.
- The parent_run function only executes if the child_run function does not call either `smf_set_state()` or return `SMF_EVENT_HANDLED`.
- Avoid malformed hierarchical state machines by ensuring the state always transitions to a leaf state when `CONFIG_SMF_INITIAL_TRANSITION` is not enabled, or when a parent state's initial state is undefined.

Event Driven State Machine Example Events are not explicitly part of the State Machine Framework but an event driven state machine can be implemented using Zephyr *Events*.

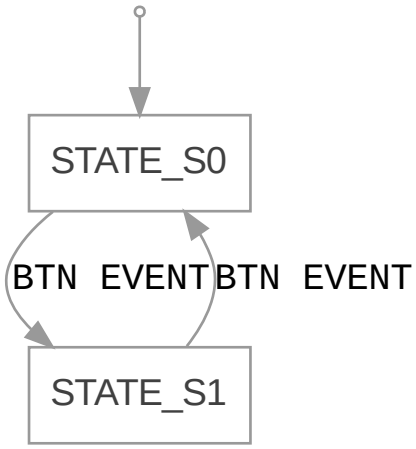

Fig. 52: Event driven state machine diagram

Code:

```
#include <zephyr/kernel.h>
#include <zephyr/drivers/gpio.h>
#include <zephyr/smf.h>

#define SW0_NODE        DT_ALIAS(sw0)

/* List of events */
#define EVENT_BTN_PRESS BIT(0)

static const struct gpio_dt_spec button =
        GPIO_DT_SPEC_GET_OR(SW0_NODE, gpios, {0});

static struct gpio_callback button_cb_data;

/* Forward declaration of state table */
static const struct smf_state demo_states[];

/* List of demo states */
```

(continues on next page)

(continued from previous page)

```
enum demo_state { S0, S1 };

/* User defined object */
struct s_object {
        /* This must be first */
        struct smf_ctx ctx;

        /* Events */
        struct k_event smf_event;
        int32_t events;

        /* Other state specific data add here */
} s_obj;

/* State S0 */
static void s0_entry(void *o)
{
        printk("STATE0\n");
}

static enum smf_state_result s0_run(void *o)
{
        struct s_object *s = (struct s_object *)o;

        /* Change states on Button Press Event */
        if (s->events & EVENT_BTN_PRESS) {
                smf_set_state(SMF_CTX(&s_obj), &demo_states[S1]);
        }
        return SMF_EVENT_HANDLED;
}

/* State S1 */
static void s1_entry(void *o)
{
        printk("STATE1\n");
}

static enum smf_state_result s1_run(void *o)
{
        struct s_object *s = (struct s_object *)o;

        /* Change states on Button Press Event */
        if (s->events & EVENT_BTN_PRESS) {
                smf_set_state(SMF_CTX(&s_obj), &demo_states[S0]);
        }
        return SMF_EVENT_HANDLED;
}

/* Populate state table */
static const struct smf_state demo_states[] = {
        [S0] = SMF_CREATE_STATE(s0_entry, s0_run, NULL, NULL, NULL),
        [S1] = SMF_CREATE_STATE(s1_entry, s1_run, NULL, NULL, NULL),
};

void button_pressed(const struct device *dev,
                struct gpio_callback *cb, uint32_t pins)
```

(continues on next page)

(continued from previous page)

```
{
        /* Generate Button Press Event */
        k_event_post(&s_obj.smf_event, EVENT_BTN_PRESS);
}

int main(void)
{
        int ret;

        if (!gpio_is_ready_dt(&button)) {
                printk("Error: button device %s is not ready\n",
                        button.port->name);
                return;
        }

        ret = gpio_pin_configure_dt(&button, GPIO_INPUT);
        if (ret != 0) {
                printk("Error %d: failed to configure %s pin %d\n",
                        ret, button.port->name, button.pin);
                return;
        }

        ret = gpio_pin_interrupt_configure_dt(&button,
                GPIO_INT_EDGE_TO_ACTIVE);
        if (ret != 0) {
                printk("Error %d: failed to configure interrupt on %s pin %d\n",
                        ret, button.port->name, button.pin);
                return;
        }

        gpio_init_callback(&button_cb_data, button_pressed, BIT(button.pin));
        gpio_add_callback(button.port, &button_cb_data);

        /* Initialize the event */
        k_event_init(&s_obj.smf_event);

        /* Set initial state */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

        /* Run the state machine */
        while(1) {
                /* Block until an event is detected */
                s_obj.events = k_event_wait(&s_obj.smf_event,
                                EVENT_BTN_PRESS, true, K_FOREVER);

                /* State machine terminates if a non-zero value is returned */
                ret = smf_run_state(SMF_CTX(&s_obj));
                if (ret) {
                        /* handle return code and terminate state machine */
                        break;
                }
        }
}
```

State Machine Example With Initial Transitions And Transition To Self tests/lib/smf/src/test_lib_self_transition_smf.c defines a state machine for testing the initial

transitions and transitions to self in a parent state. The statechart for this test is below.

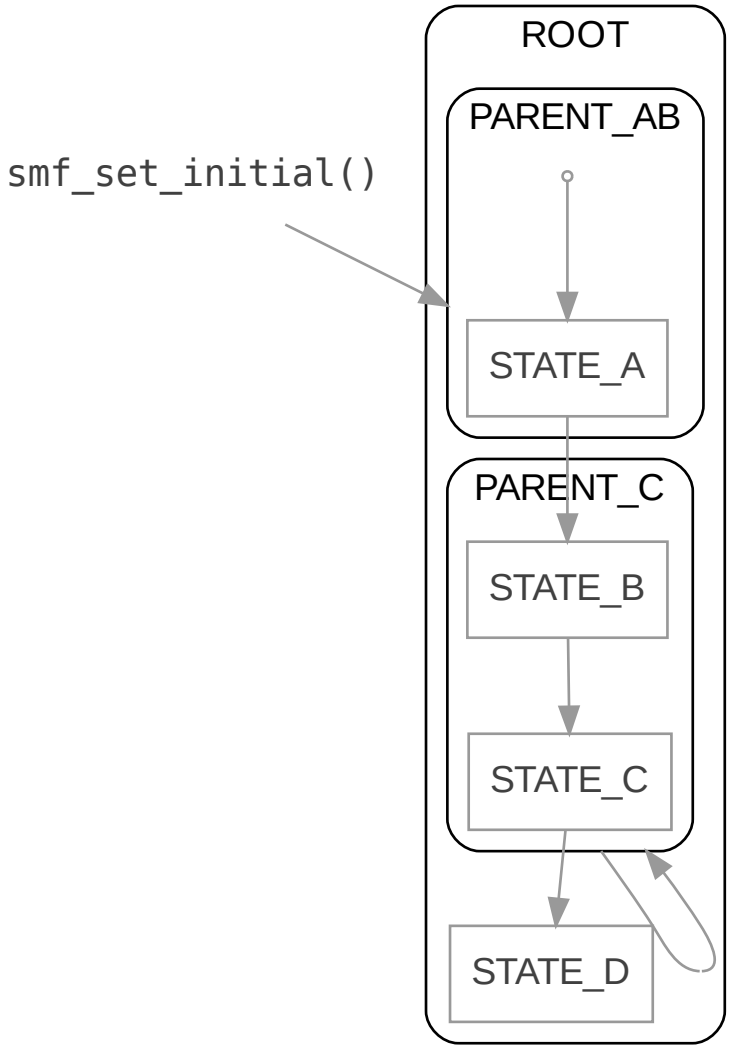

Fig. 53: Test state machine for UML State Transitions

Test Instrumentation

The SMF provides optional instrumentation hooks for observing state machine behavior during testing. To enable them, set `CONFIG_SMF_INSTRUMENTATION`.

When enabled, three hook callbacks can be registered on a state machine context via `smf_set_hooks()`:

- **on_action** — called before each entry, run, or exit action executes.
- **on_transition** — called after the current state pointer is updated but before the new state's entry actions execute.

- **on_error** — called when an invalid operation is detected (e.g. a NULL transition target or a transition attempted from an exit action).

Important

`smf_set_hooks()` must be called **after** `smf_set_initial()`, because `smf_set_initial()` resets the hooks pointer to `NULL`. As a consequence, entry actions executed during `smf_set_initial()` (i.e. the initial state's entry actions and those of its ancestors) will **not** be captured by the hooks.

Example:

```
#include <zephyr/smf.h>

static void on_action(struct smf_ctx *ctx,
                      const struct smf_state *state,
                      smf_action_type action_type)
{
        /* Log or record the action */
}

static void on_transition(struct smf_ctx *ctx,
                          const struct smf_state *source,
                          const struct smf_state *dest)
{
        /* Log or record the transition */
}

static const struct smf_hooks hooks = {
        .on_action = on_action,
        .on_transition = on_transition,
        /* .on_error = NULL - any member may be NULL */
};

void test_example(void)
{
        struct s_object s_obj;

        /* Set the initial state first */
        smf_set_initial(SMF_CTX(&s_obj), &demo_states[S0]);

        /* Install hooks after init - initial entry actions are not captured */
        smf_set_hooks(SMF_CTX(&s_obj), &hooks);

        /* Run the state machine - hooks fire on every action and transition */
        while (!smf_run_state(SMF_CTX(&s_obj))) {
                /* ... */
        }
}
```

When `CONFIG_SMF_INSTRUMENTATION` is not set, all instrumentation code is compiled out and there is zero runtime overhead.

OS Abstraction

4.12 OS Abstraction

OS abstraction layers (OSAL) provide wrapper function APIs that encapsulate common system functions offered by any operating system. These APIs make it easier and quicker to develop for, and port code to multiple software and hardware platforms.

These sections describe the software and hardware abstraction layers supported by the Zephyr RTOS.

4.12.1 POSIX

Overview

The Portable Operating System Interface (POSIX) is a family of standards specified by the IEEE Computer Society for maintaining compatibility between operating systems. Zephyr implements a subset of the standard POSIX API specified by IEEE 1003.1-2017 (also known as POSIX-1.2017).

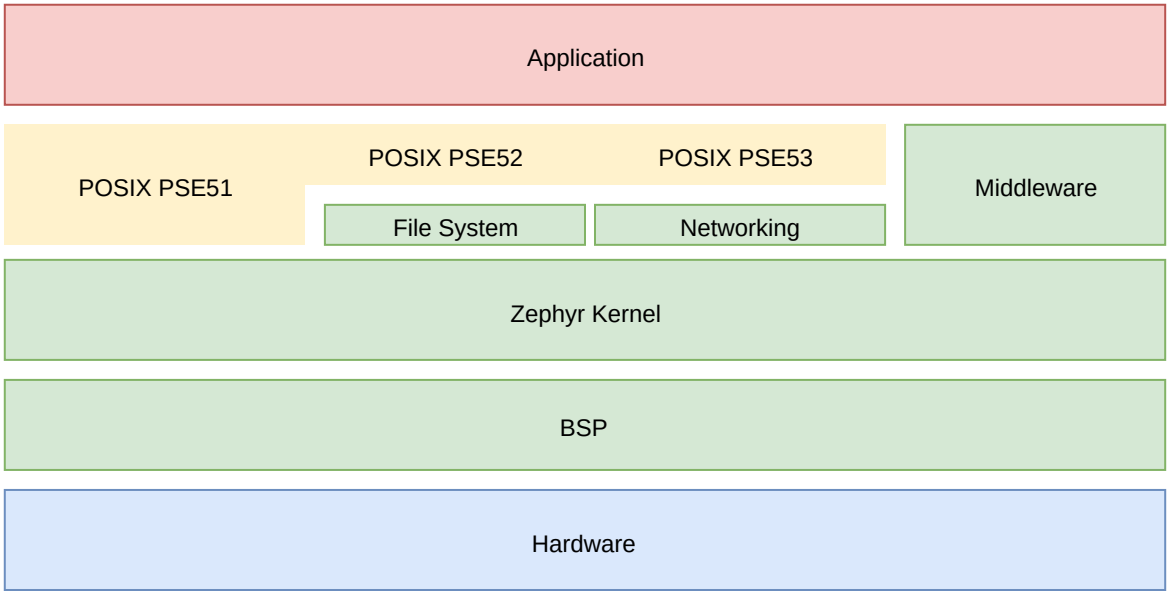

Fig. 54: POSIX support in Zephyr

Note

This page does not document Zephyr's POSIX architecture, which is used to run Zephyr as a native application under the host operating system for prototyping, test, and diagnostic purposes.

With the POSIX support available in Zephyr, an existing POSIX conformant application can be ported to run on the Zephyr kernel, and therefore leverage Zephyr features and functionality.

Additionally, a library designed to be POSIX conformant can be ported to Zephyr kernel based applications with no changes.

The POSIX API is an increasingly popular OSAL (operating system abstraction layer) for IoT and embedded applications, as can be seen in Zephyr, AWS:FreeRTOS, TI-RTOS, and NuttX.

Benefits of POSIX support in Zephyr include:

- Offering a familiar API to non-embedded programmers, especially from Linux
- Enabling reuse (portability) of existing libraries based on POSIX APIs
- Providing an efficient API subset appropriate for small (MCU) embedded systems

POSIX Subprofiles While Zephyr supports running multiple *threads* (possibly in an *SMP* configuration), as well as *Virtual Memory and MMUs*, Zephyr code and data normally share a common address space that is partitioned into separate *Memory Domains*. The Zephyr kernel executable code and the application executable code are typically compiled into the same binary artifact. From that perspective, Zephyr apps can be seen as running in the context of a single process.

While multi-purpose operating systems (OS) offer full POSIX conformance, Real-Time Operating Systems (RTOS) such as Zephyr typically serve a fixed-purpose, have limited hardware resources, and experience limited user interaction. In such systems, full POSIX conformance can be impractical and unnecessary.

For that reason, POSIX defined the following *Application Environment Profiles (AEP)* as part of IEEE 1003.13-2003 (also known as POSIX.13-2003). Each AEP adds incrementally more features over the required *POSIX System Interfaces*.

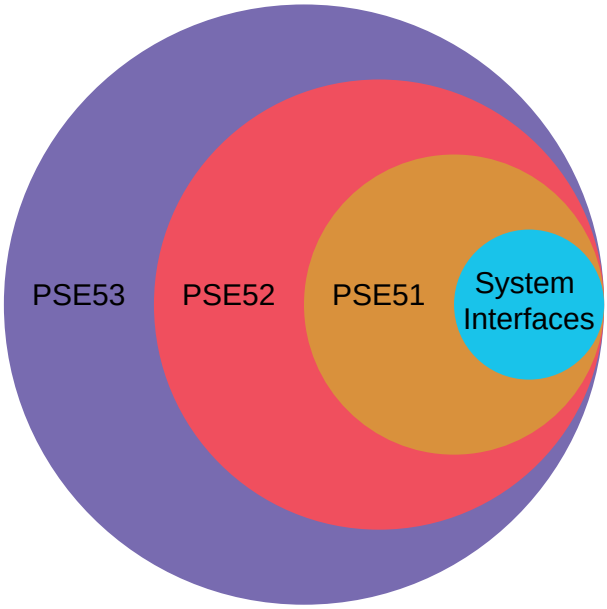

Fig. 55: POSIX Application Environment Profiles (AEP)

- Minimal Realtime System Profile (*PSE51*)
- Realtime Controller System Profile (*PSE52*)
- Dedicated Realtime System Profile (*PSE53*)
- Multi-Purpose Realtime System (PSE54)

POSIX.13-2003 AEP were formalized in 2003 via "Units of Functionality" but the specification is now inactive (for reference only). Nevertheless, the intent is still captured as part of POSIX-1.2017 via *Options* and *Option Groups*.

For more information, please see IEEE 1003.1-2017, Section E, Subprofiling Considerations.

POSIX Applications in Zephyr A POSIX app in Zephyr is *built like any other app* and therefore requires the usual `prj.conf`, `CMakeLists.txt`, and source code. For example, the app below leverages the `nanosleep()` and `perror()` POSIX functions.

Listing 23: *prj.conf* for a simple POSIX app in Zephyr

```
CONFIG_POSIX_API=y
```

Listing 24: A simple app that uses Zephyr's POSIX API

```
#include <stddef.h>
#include <stdio.h>
#include <time.h>

void megasleep(size_t megaseconds)
{
    struct timespec ts = {
        .tv_sec = megaseconds * 1000000,
        .tv_nsec = 0,
    };

    printf("See you in a while!\n");
    if (nanosleep(&ts, NULL) == -1) {
        perror("nanosleep");
    }
}

int main()
{
    megasleep(42);
    return 0;
}
```

For more examples of POSIX applications, please see the POSIX sample applications.

Configuration Like most features in Zephyr, POSIX features are *highly configurable* but disabled by default. Users must explicitly choose to enable POSIX options via *Kconfig* selection.

Subprofiles Enable one of the Kconfig options below to quickly configure a pre-defined *POSIX subprofile*.

- `CONFIG_POSIX_AEP_CHOICE_BASE` (*Base*)
- `CONFIG_POSIX_AEP_CHOICE_PSE51` (*PSE51*)
- `CONFIG_POSIX_AEP_CHOICE_PSE52` (*PSE52*)
- `CONFIG_POSIX_AEP_CHOICE_PSE53` (*PSE53*)

Additional POSIX *Options and Option Groups* may be enabled as needed via Kconfig (e.g. `CONFIG_POSIX_C_LIB_EXT=y`). Further fine-tuning may be accomplished via *additional POSIX-related Kconfig options*.

Subprofiles, Options, and Option Groups should be considered the preferred way to configure POSIX in Zephyr going forward.

Legacy Historically, Zephyr used `CONFIG_POSIX_API` to configure a set of POSIX features that was overloaded and always increasing in size.

- `CONFIG_POSIX_API`

The option is now frozen, and can be considered equivalent to the following:

- `CONFIG_POSIX_AEP_CHOICE_PSE51`
- `CONFIG_POSIX_FD_MGMT`
- `CONFIG_POSIX_MESSAGE_PASSING`
- `CONFIG_POSIX_NETWORKING`

However, `CONFIG_POSIX_API` should be considered legacy and should not be used for new Zephyr applications.

POSIX Conformance

As per IEEE 1003.1-2017, this section details Zephyr's POSIX conformance.

_POSIX_THREAD_PROCESS_SHARED	-1	

Note

Some features may exhibit undefined behaviour as they fall beyond the scope of Zephyr's current design and capabilities. For example, multi-processing, ad-hoc memory-mapping, multiple users, or regular expressions are features that are uncommon in low-footprint embedded systems. Such undefined behaviour is denoted with the † (obelus) symbol. Additional details *here*.

Note

Features listed in various POSIX Options or Option Groups may be provided in whole or in part by a conformant C library implementation. This includes (but is not limited to) POSIX Extensions to the ISO C Standard (CX).

POSIX Application Environment Profiles (AEP)

Although inactive, IEEE 1003.13-2003 defined a number of AEP that inspired the modern subprofiling options of IEEE 1003.1-2017. The single-purpose realtime system profiles are listed below, for reference, in terms that agree with the current POSIX-1 standard. PSE54 is not considered at this time.

System Interfaces The required POSIX *System Interfaces* are supported for each Application Environment Profile.

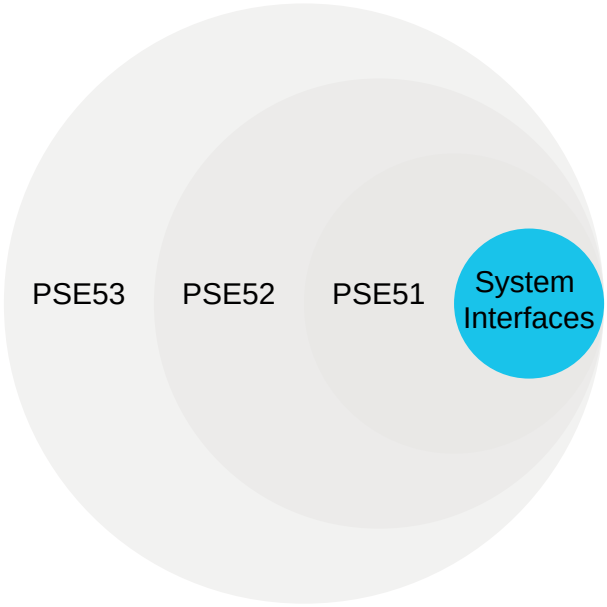

Fig. 56: System Interfaces

Implementation Details

In many ways, Zephyr provides support like any POSIX OS; API bindings are provided in the C programming language, POSIX headers are available in the standard include path, when configured.

Unlike other multi-purpose POSIX operating systems

- Zephyr is not “a POSIX OS”. The Zephyr kernel was not designed around the POSIX standard, and POSIX support is an opt-in feature
- Zephyr apps are not linked separately, nor do they execute as subprocesses

- Zephyr, libraries, and application code are compiled and linked together, running similarly to a single-process application, in a single (possibly virtual) address space
- Zephyr does not provide a POSIX shell, compiler, utilities, and is not self-hosting.

Note

Unlike the Linux kernel or FreeBSD, Zephyr does not maintain a static table of system call numbers for each supported architecture, but instead generates system calls dynamically at build time. See *System Calls* for more information.

Design As a library, Zephyr's POSIX API implementation makes an effort to be a thin abstraction layer between the application, middleware, and the Zephyr kernel.

Some general design considerations:

- The POSIX interface and implementations should be part of Zephyr's POSIX library, and not elsewhere, unless required both by the POSIX API implementation and some other feature. An example where the implementation should remain part of the POSIX implementation is `getopt()`. Examples where the implementation should be part of separate libraries are multithreading and networking.
- When the POSIX API and another Zephyr subsystem both rely on a feature, the implementation of that feature should be as a separate Zephyr library that can be used by both the POSIX API and the other library or subsystem. This reduces the likelihood of dependency cycles in code. When practical, that rule should expand to include macros. In the example below, `libposix` depends on `libzfoo` for the implementation of some functionality "foo" in Zephyr. If `libzfoo` also depends on `libposix`, then there is a dependency cycle. The cycle can be removed via mutual dependency, `libcommon`.

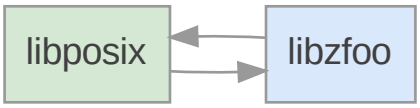

Fig. 60: Dependency cycle between POSIX and another Zephyr library

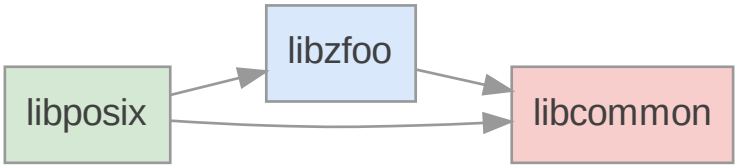

Fig. 61: Mutual dependencies between POSIX and other Zephyr libraries

- POSIX API calls should be provided as regular callable C functions; if a Zephyr *System Call* is needed as part of the implementation, the declaration and the implementation of that system call should be hidden behind the POSIX API.

POSIX Option and Option Group Details

POSIX Option Groups

POSIX_BARRIERS Enable this option group with `CONFIG_POSIX_BARRIERS`.

Table 73: POSIX_BARRIERS

API	Supported
pthread_barrier_destroy()	yes
pthread_barrier_init()	yes
pthread_barrier_wait()	yes
pthread_barrierattr_destroy()	yes
pthread_barrierattr_init()	yes

POSIX_C_LANG_JUMP The `POSIX_C_LANG_JUMP` Option Group is included in the ISO C standard.

> **Note**
>
> When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the `POSIX_C_LANG_JUMP` Option Group is considered supported.

Table 74: POSIX_C_LANG_JUMP

API	Supported
setjmp()	yes
longjmp()	yes

POSIX_C_LANG_MATH The `POSIX_C_LANG_MATH` Option Group is included in the ISO C standard.

> **Note**
>
> When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the `POSIX_C_LANG_MATH` Option Group is considered supported.

Please refer to Subprofiling Considerations for details on the `POSIX_C_LANG_MATH` Option Group.

POSIX_C_LANG_SUPPORT The POSIX_C_LANG_SUPPORT option group contains the general ISO C Library.

Note

When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the entire `POSIX_C_LANG_SUPPORT` Option Group is considered supported.

Please refer to Subprofiling Considerations for details on the `POSIX_C_LANG_SUPPORT` Option Group.

For more information on developing Zephyr applications in the C programming language, please refer to *details*.

POSIX_C_LANG_SUPPORT_R Enable this option group with `CONFIG_POSIX_C_LANG_SUPPORT_R`.

Table 75: POSIX_C_LANG_SUPPORT_R

API	Supported
asctime_r()	yes
ctime_r()	yes
gmtime_r()	yes
localtime_r()	yes
rand_r()	yes
strerror_r()	yes
strtok_r()	yes

POSIX_C_LIB_EXT Enable this option group with `CONFIG_POSIX_C_LIB_EXT`.

Table 76: POSIX_C_LIB_EXT

API	Supported
fnmatch()	yes
getopt()	yes
getsubopt()	
optarg	yes
opterr	yes
optind	yes
optopt	yes
stpcpy()	
stpncpy()	
strcasecmp()	
strdup()	
strfmon()	
strncasecmp()	yes
strndup()	
strnlen()	yes

POSIX_CLOCK_SELECTION Enable this option group with `CONFIG_POSIX_CLOCK_SELECTION`.

Table 77: POSIX_CLOCK_SELECTION

API	Supported
pthread_condattr_getclock()	yes
pthread_condattr_setclock()	yes
clock_nanosleep()	yes

POSIX_DEVICE_IO Enable this option group with `CONFIG_POSIX_DEVICE_IO`.

> **Note**
>
> When using Newlib, Picolibc, or other C libraries conforming to the ISO C Standard, the C89 components of the `POSIX_DEVICE_IO` Option Group are considered supported.

Table 78: POSIX_DEVICE_IO

API	Supported

funlockfile()	
getc_unlocked()	
getchar_unlocked()	
putc_unlocked()	
putchar_unlocked()	

POSIX_FILE_SYSTEM Enable this option group with `CONFIG_POSIX_FILE_SYSTEM`.

Table 81: POSIX_FILE_SYSTEM

API	Supported
access()	
chdir()	
closedir()	yes
creat()	
fchdir()	
fpathconf()	
fstat()	yes
fstatvfs()	
getcwd()	
link()	
mkdir()	yes
mkstemp()	
opendir()	yes
pathconf()	
readdir()	yes
remove()	yes
rename()	yes
rewinddir()	
rmdir()	yes
stat()	yes
statvfs()	
tmpfile()	
tmpnam()	
truncate()	
unlink()	yes
utime()	

POSIX_FILE_SYSTEM_R Enable this option with `CONFIG_POSIX_FILE_SYSTEM_R`.

Table 82: POSIX_FILE_SYSTEM_R

API	Supported
readdir_r()	yes

POSIX_MAPPED_FILES Enable this option group with `CONFIG_POSIX_MAPPED_FILES`.

Table 83: POSIX_MAPPED_FILES

API	Supported
mmap()	yes
msync()	yes
munmap()	yes

POSIX_MEMORY_PROTECTION Enable this option group with `CONFIG_POSIX_MEMORY_PROTECTION`.

Table 84: POSIX_MEMORY_PROTECTION

API	Supported
mprotect()	yes †

POSIX_MULTI_PROCESS Enable this option group with `CONFIG_POSIX_MULTI_PROCESS`.

Table 85: POSIX_MULTI_PROCESS

API	Supported
_Exit()	yes
_exit()	yes
assert()	yes
atexit()	†
clock()	
execl()	†
execle()	†
execlp()	†
execv()	†
execve()	†
execvp()	†
exit()	yes
fork()	†
getpgrp()	†
getpgid()	†
getpid()	yes †
getppid()	†
getsid()	†
setsid()	†
sleep()	yes
times()	
wait()	†
waitid()	†
waitpid()	†

POSIX_NETWORKING The function `sockatmark()` is not yet supported and is expected to fail setting `errno` to `ENOSYS` †.

Enable this option group with `CONFIG_POSIX_NETWORKING`.

Table 86: POSIX_NETWORKING

API	Supported
accept()	yes
bind()	yes
connect()	yes
endhostent()	yes
endnetent()	yes
endprotoent()	yes
endservent()	yes
freeaddrinfo()	yes
gai_strerror()	yes
getaddrinfo()	yes
gethostent()	yes
gethostname()	yes
getnameinfo()	yes
getnetbyaddr()	yes
getnetbyname()	yes

POSIX_PIPE

Table 87: POSIX_PIPE

API	Supported
pipe()	

POSIX_REALTIME_SIGNALS Enable this option group with `CONFIG_POSIX_REALTIME_SIGNALS`.

Table 88: POSIX_REALTIME_SIGNALS

API	Supported
sigqueue()	
sigtimedwait()	
sigwaitinfo()	

POSIX_RW_LOCKS Enable this option with `CONFIG_POSIX_RW_LOCKS`.

Table 89: POSIX_RW_LOCKS

API	Supported
pthread_rwlock_destroy()	yes
pthread_rwlock_init()	yes
pthread_rwlock_rdlock()	yes
pthread_rwlock_tryrdlock()	yes
pthread_rwlock_trywrlock()	yes
pthread_rwlock_unlock()	yes
pthread_rwlock_wrlock()	yes
pthread_rwlockattr_destroy()	yes
pthread_rwlockattr_getpshared()	yes
pthread_rwlockattr_init()	yes
pthread_rwlockattr_setpshared()	yes

POSIX_SEMAPHORES Enable this option group with `CONFIG_POSIX_SEMAPHORES`.

Table 90: POSIX_SEMAPHORES

API	Supported
sem_close()	yes
sem_destroy()	yes
sem_getvalue()	yes
sem_init()	yes
sem_open()	yes
sem_post()	yes
sem_trywait()	yes
sem_unlink()	yes
sem_wait()	yes

POSIX_SIGNAL_JUMP

Table 91: POSIX_SIGNAL_JUMP

API	Supported
siglongjmp()	
sigsetjmp()	

POSIX_SIGNALS Enable this option group with `CONFIG_POSIX_SIGNALS`.

Note

As processes are not yet supported in Zephyr, the ISO C functions `abort()`, `signal()`, and `raise()`, as well as the other POSIX functions listed below, may exhibit undefined behaviour. The POSIX functions `kill()`, `pause()`, `sigaction()`, `sigpending()`, `sigsuspend()`, and `sigwait()` are implemented to ensure that conformant applications can link, but they are expected to fail, setting errno to `ENOSYS` †.

Table 92: POSIX_SIGNALS

API	Supported
abort()	yes †
alarm()	yes †
kill()	yes †
pause()	yes †
raise()	yes †
sigaction()	yes †
sigaddset()	yes
sigdelset()	yes
sigemptyset()	yes
sigfillset()	yes
sigismember()	yes
signal()	yes †
sigpending()	yes †
sigprocmask()	yes
sigsuspend()	yes †
sigwait()	yes †
strsignal()	yes

POSIX_SINGLE_PROCESS The POSIX_SINGLE_PROCESS option group contains services for single process applications.

Enable this option group with `CONFIG_POSIX_SINGLE_PROCESS`.

Table 93: POSIX_SINGLE_PROCESS

API	Supported
confstr()	yes
environ	yes
errno	yes
getenv()	yes
setenv()	yes
sysconf()	yes
uname()	yes
unsetenv()	yes

POSIX_SPIN_LOCKS Enable this option group with `CONFIG_POSIX_SPIN_LOCKS`.

Table 94: POSIX_SPIN_LOCKS

API	Supported
pthread_spin_destroy()	yes
pthread_spin_init()	yes
pthread_spin_lock()	yes
pthread_spin_trylock()	yes
pthread_spin_unlock()	yes

POSIX_THREADS_BASE The basic assumption in this profile is that the system consists of a single (implicit) process with multiple threads. Therefore, the standard requires all basic thread services, except those related to multiple processes.

Enable this option group with `CONFIG_POSIX_THREADS`.

Table 95: POSIX_THREADS_BASE

API	Supported
pthread_atfork()	yes
pthread_attr_destroy()	yes
pthread_attr_getdetachstate()	yes
pthread_attr_getschedparam()	yes
pthread_attr_init()	yes
pthread_attr_setdetachstate()	yes
pthread_attr_setschedparam()	yes
pthread_barrier_destroy()	yes
pthread_barrier_init()	yes
pthread_barrier_wait()	yes
pthread_barrierattr_destroy()	yes
pthread_barrierattr_getpshared()	yes
pthread_barrierattr_init()	yes
pthread_barrierattr_setpshared()	yes
pthread_cancel()	yes
pthread_cleanup_pop()	yes
pthread_cleanup_push()	yes
pthread_cond_broadcast()	yes

pthread_exit()	yes
pthread_getspecific()	yes
pthread_join()	yes
pthread_key_create()	yes
pthread_key_delete()	yes
pthread_kill()	
pthread_mutex_destroy()	yes
pthread_mutex_init()	yes
pthread_mutex_lock()	yes
pthread_mutex_trylock()	yes

continues on next page

Table 95 – continued from previous page

API	Supported
pthread_mutex_unlock()	yes
pthread_mutexattr_destroy()	yes
pthread_mutexattr_init()	yes
pthread_once()	yes
pthread_self()	yes
pthread_setcancelstate()	yes
pthread_setcanceltype()	yes
pthread_setspecific()	yes
pthread_sigmask()	yes
pthread_testcancel()	yes
sched_yield()	yes

POSIX_THREADS_EXT Enable this option group with `CONFIG_POSIX_THREADS_EXT`.

Table 96: POSIX_THREADS_EXT

API	Supported
pthread_attr_getguardsize()	yes
pthread_attr_setguardsize()	yes
pthread_mutexattr_gettype()	yes
pthread_mutexattr_settype()	yes

POSIX_TIMERS Enable this option group with `CONFIG_POSIX_TIMERS`.

Table 97: POSIX_TIMERS

API	Supported
clock_getres()	yes
clock_gettime()	yes
clock_settime()	yes
nanosleep()	yes
timer_create()	yes
timer_delete()	yes
timer_gettime()	yes
timer_getoverrun()	yes
timer_settime()	yes

XSI_REALTIME The `XSI_REALTIME` option group indicates that the *_POSIX_FSYNC*, *_POSIX_MEMLOCK*, *_POSIX_MEMLOCK_RANGE*, *_POSIX_MESSAGE_PASSING*, *_POSIX_PRIORITY_SCHEDULING*, *_POSIX_SHARED_MEMORY_OBJECTS*, and *_POSIX_SYNCHRONIZED_IO* options are enabled.

Enable this option group with `CONFIG_XSI_REALTIME`.

When this option group is enabled, the `_XOPEN_REALTIME` feature test macro will be defined to a value other than -1.

XSI_SINGLE_PROCESS Enable this option group with `CONFIG_XSI_SINGLE_PROCESS`.

Table 98: XSI_SINGLE_PROCESS

API	Supported
gethostid()	yes
gettimeofday()	yes
putenv()	yes

XSI_SYSTEM_LOGGING Enable this option group with `CONFIG_XSI_SYSTEM_LOGGING`.

Table 99: XSI_SYSTEM_LOGGING

API	Supported
closelog()	yes
openlog()	yes
setlogmask()	yes
syslog()	yes

XSI_THREADS_EXT The XSI_THREADS_EXT option group is required because it provides functions to control a thread's stack. This is considered useful for any real-time application.

Enable this option group with `CONFIG_XSI_THREADS_EXT`.

Table 100: XSI_THREADS_EXT

API	Supported
pthread_attr_getstack()	yes
pthread_attr_setstack()	yes
pthread_getconcurrency()	yes
pthread_setconcurrency()	yes

POSIX Options

_POSIX_ASYNCHRONOUS_IO Functions part of the `_POSIX_ASYNCHRONOUS_IO` Option are not implemented in Zephyr but are provided so that conformant applications can still link. These functions will fail, setting `errno` to `ENOSYS`†.

Enable this option with `CONFIG_POSIX_ASYNCHRONOUS_IO`.

Table 101: _POSIX_ASYNCHRONOUS_IO

API	Supported
aio_cancel()	yes †
aio_error()	yes †
aio_fsync()	yes †
aio_read()	yes †
aio_return()	yes †
aio_suspend()	yes †
aio_write()	yes †
lio_listio()	yes †

_POSIX_CPUTIME Enable this option with `CONFIG_POSIX_CPUTIME`.

Table 102: _POSIX_CPUTIME

API	Supported
CLOCK_PROCESS_CPUTIME_ID	yes

_POSIX_FSYNC Enable this option with `CONFIG_POSIX_FSYNC`.

Table 103: _POSIX_FSYNC

API	Supported
fsync()	yes

_POSIX_IPV6 Internet Protocol Version 6 is supported.

For more information, please refer to *Networking*.

Enable this option with `CONFIG_POSIX_IPV6`.

_POSIX_MEMLOCK Zephyr's *Demand Paging API* does not yet support pinning or unpinning all virtual memory regions. The functions below are expected to fail and set `errno` to `ENOSYS` †.

Enable this option with `CONFIG_POSIX_MEMLOCK`.

Table 104: _POSIX_MEMLOCK

API	Supported
mlockall()	yes
munlockall()	yes

_POSIX_MEMLOCK_RANGE Enable this option with `CONFIG_POSIX_MEMLOCK_RANGE`.

Table 105: _POSIX_MEMLOCK_RANGE

API	Supported
mlock()	yes
munlock()	yes

_POSIX_MESSAGE_PASSING Enable this option with `CONFIG_POSIX_MESSAGE_PASSING`.

Table 106: _POSIX_MESSAGE_PASSING

API	Supported
mq_close()	yes
mq_getattr()	yes
mq_notify()	yes
mq_open()	yes
mq_receive()	yes
mq_send()	yes
mq_setattr()	yes
mq_unlink()	yes

_POSIX_MONOTONIC_CLOCK Enable this option with `CONFIG_POSIX_MONOTONIC_CLOCK`.

Table 107: _POSIX_MONOTONIC_CLOCK

API	Supported
CLOCK_MONOTONIC	yes

_POSIX_PRIORITY_SCHEDULING As processes are not yet supported in Zephyr, the functions `sched_rr_get_interval()`, `sched_setparam()`, and `sched_setscheduler()` are expected to fail setting `errno` to `ENOSYS`†.

Enable this option with `CONFIG_POSIX_PRIORITY_SCHEDULING`.

Table 108: _POSIX_PRIORITY_SCHEDULING

API	Supported
sched_get_priority_max()	yes
sched_get_priority_min()	yes
sched_getparam()	yes
sched_getscheduler()	yes
sched_rr_get_interval()	yes †
sched_setparam()	yes †
sched_setscheduler()	yes †

_POSIX_RAW_SOCKETS Raw sockets are supported.

For more information, please refer to `CONFIG_NET_SOCKETS_PACKET`.

Enable this option with `CONFIG_POSIX_RAW_SOCKETS`.

_POSIX_SHARED_MEMORY_OBJECTS Enable this option with `CONFIG_POSIX_SHARED_MEMORY_OBJECTS`.

Table 109: _POSIX_SHARED_MEMORY_OBJECTS

API	Supported
mmap()	yes
munmap()	yes
shm_open()	yes
shm_unlink()	yes

_POSIX_SYNCHRONIZED_IO Enable this option with `CONFIG_POSIX_SYNCHRONIZED_IO`.

Table 110: _POSIX_SYNCHRONIZED_IO

API	Supported
fdatasync()	yes
fsync()	yes
msync()	yes

_POSIX_THREAD_ATTR_STACKADDR Enable this option with `CONFIG_POSIX_THREAD_ATTR_STACKADDR`.

Table 111: _POSIX_THREAD_ATTR_STACKADDR

API	Supported
pthread_attr_getstackaddr()	yes
pthread_attr_setstackaddr()	yes

_POSIX_THREAD_ATTR_STACKSIZE Enable this option with CONFIG_POSIX_THREAD_ATTR_STACKSIZE.

Table 112: _POSIX_THREAD_ATTR_STACKSIZE

API	Supported
pthread_attr_getstacksize()	yes
pthread_attr_setstacksize()	yes

_POSIX_THREAD_CPUTIME Enable this option with CONFIG_POSIX_THREAD_CPUTIME.

Table 113: _POSIX_THREAD_CPUTIME

API	Supported
CLOCK_THREAD_CPUTIME_ID	yes
pthread_getcpuclockid()	yes

_POSIX_THREAD_PRIO_INHERIT Enable this option with CONFIG_POSIX_THREAD_PRIO_INHERIT.

Table 114: _POSIX_THREAD_PRIO_INHERIT

API	Supported
pthread_mutexattr_getprotocol()	yes
pthread_mutexattr_setprotocol()	yes

_POSIX_THREAD_PRIO_PROTECT Enable this option with CONFIG_POSIX_THREAD_PRIO_PROTECT.

Table 115: _POSIX_THREAD_PRIO_PROTECT

API	Supported
pthread_mutex_getprioceiling()	yes
pthread_mutex_setprioceiling()	yes
pthread_mutexattr_getprioceiling()	yes
pthread_mutexattr_getprotocol()	yes
pthread_mutexattr_setprioceiling()	yes
pthread_mutexattr_setprotocol()	yes

_POSIX_THREAD_PRIORITY_SCHEDULING Enable this option with CONFIG_POSIX_THREAD_PRIORITY_SCHEDULING.

Table 116: _POSIX_THREAD_PRIORITY_SCHEDULING

API	Supported
pthread_attr_getinheritsched()	yes
pthread_attr_getschedpolicy()	yes
pthread_attr_getscope()	yes
pthread_attr_setinheritsched()	yes
pthread_attr_setschedpolicy()	yes
pthread_attr_setscope()	yes
pthread_getschedparam()	yes
pthread_setschedparam()	yes
pthread_setschedprio()	yes

_POSIX_THREAD_SAFE_FUNCTIONS Enable this option with `CONFIG_POSIX_THREAD_SAFE_FUNCTIONS`.

Table 117: _POSIX_THREAD_SAFE_FUNCTIONS

API	Supported
asctime_r()	yes
ctime_r()	yes (UTC timezone only)
flockfile()	
ftrylockfile()	
funlockfile()	
getc_unlocked()	
getchar_unlocked()	
getgrgid_r()	yes †
getgrnam_r()	yes †
getpwnam_r()	yes †
getpwuid_r()	yes †
gmtime_r()	yes
localtime_r()	yes (UTC timezone only)
putc_unlocked()	
putchar_unlocked()	
rand_r()	yes
readdir_r()	yes
strerror_r()	yes
strtok_r()	yes

_POSIX_TIMEOUTS Enable this option with `CONFIG_POSIX_TIMEOUTS`.

Table 118: _POSIX_TIMEOUTS

API	Supported
mq_timedreceive()	yes
mq_timedsend()	yes
pthread_mutex_timedlock()	yes
pthread_rwlock_timedrdlock()	yes
pthread_rwlock_timedwrlock()	yes
sem_timedwait()	yes
posix_trace_timedgetnext_event()	

_XOPEN_STREAMS With the exception of `ioctl()`, functions in the `_XOPEN_STREAMS` option group are not implemented in Zephyr but are provided so that conformant applications can still link. Unimplemented functions in this option group will fail, setting `errno` to `ENOSYS` †.

Enable this option with `CONFIG_XSI_STREAMS`.

Table 119: _XOPEN_STREAMS

API	Supported
fattach()	yes †
fdetach()	yes †
getmsg()	yes †
getpmsg()	yes †
ioctl()	yes
isastream()	yes †
putmsg()	yes †
putpmsg()	yes †

Additional Configuration Options

Below is a non-exhaustive list of additional *Configuration System (Kconfig)* options relating to Zephyr's implementation of the POSIX API.

- `CONFIG_DYNAMIC_THREAD`
- `CONFIG_DYNAMIC_THREAD_POOL_SIZE`
- `CONFIG_EVENTFD`
- `CONFIG_GETOPT_LONG`
- `CONFIG_MAX_PTHREAD_SPINLOCK_COUNT`
- `CONFIG_MQUEUE_NAMELEN_MAX`
- `CONFIG_POSIX_MQ_OPEN_MAX`
- `CONFIG_MSG_SIZE_MAX`
- `CONFIG_NET_SOCKETPAIR`
- `CONFIG_NET_SOCKETS`
- `CONFIG_ZVFS_POLL_MAX`
- `CONFIG_ZVFS_OPEN_MAX`
- `CONFIG_POSIX_API`
- `CONFIG_POSIX_OPEN_MAX`
- `CONFIG_POSIX_PTHREAD_ATTR_GUARDSIZE_BITS`
- `CONFIG_POSIX_PTHREAD_ATTR_GUARDSIZE_DEFAULT`
- `CONFIG_POSIX_PTHREAD_ATTR_STACKSIZE_BITS`
- `CONFIG_POSIX_RTSIG_MAX`
- `CONFIG_POSIX_SIGNAL_STRING_DESC`
- `CONFIG_POSIX_THREAD_KEYS_MAX`
- `CONFIG_POSIX_THREAD_THREADS_MAX`
- `CONFIG_POSIX_UNAME_NODENAME_LEN`
- `CONFIG_POSIX_UNAME_VERSION_LEN`
- `CONFIG_PTHREAD_CREATE_BARRIER`

- CONFIG_PTHREAD_RECYCLER_DELAY_MS
- CONFIG_POSIX_SEM_NAMELEN_MAX
- CONFIG_POSIX_SEM_NSEMS_MAX
- CONFIG_POSIX_SEM_VALUE_MAX
- CONFIG_TIMER_CREATE_WAIT
- CONFIG_THREAD_STACK_INFO
- CONFIG_ZVFS_EVENTFD_MAX
- CONFIG_ZVFS_FDTABLE

4.12.2 CMSIS RTOS v1

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v1, please refer to the CMSIS-RTOS1 Documentation.

4.12.3 CMSIS RTOS v2

Cortex-M Software Interface Standard (CMSIS) RTOS is a vendor-independent hardware abstraction layer for the ARM Cortex-M processor series and defines generic tool interfaces. Though it was originally defined for ARM Cortex-M microcontrollers alone, it could be easily extended to other microcontrollers making it generic. For more information on CMSIS RTOS v2, please refer to the CMSIS-RTOS2 Documentation.

Features not supported in Zephyr implementation

Kernel
: `osKernelGetState`, `osKernelSuspend`, `osKernelResume`, `osKernelInitialize` and `osKernelStart` are not supported.

Mutex
: `osMutexPrioInherit` is supported by default and is not configurable, you cannot select/unselect this attribute.

  `osMutexRecursive` is also supported by default. If this attribute is not set, an error is thrown when the same thread tries to acquire it the second time.

  `osMutexRobust` is not supported in Zephyr.

Return values not supported in the Zephyr implementation

`osKernelUnlock`, `osKernelLock`, `osKernelRestoreLock`
: `osError` (Unspecified error) is not supported.

`osSemaphoreDelete`
: `osErrorResource` (the semaphore specified by parameter semaphore_id is in an invalid semaphore state) is not supported.

`osMutexDelete`
: `osErrorResource` (mutex specified by parameter mutex_id is in an invalid mutex state) is not supported.

`osTimerDelete`
: `osErrorResource` (the timer specified by parameter timer_id is in an invalid timer state) is not supported.

`osMessageQueueReset`
: `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.

`osMessageQueueDelete`
: `osErrorResource` (the message queue specified by parameter msgq_id is in an invalid message queue state) is not supported.

`osMemoryPoolFree`
: `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.

`osMemoryPoolDelete`
: `osErrorResource` (the memory pool specified by parameter mp_id is in an invalid memory pool state) is not supported.

`osEventFlagsSet`, `osEventFlagsClear`
: `osFlagsErrorUnknown` (Unspecified error) and osFlagsErrorResource (Event flags object specified by parameter ef_id is not ready to be used) are not supported.

`osEventFlagsDelete`
: `osErrorParameter` (the value of the parameter ef_id is incorrect) is not supported.

`osThreadFlagsSet`
: `osFlagsErrorUnknown` (Unspecified error) and `osFlagsErrorResource` (Thread specified by parameter thread_id is not active to receive flags) are not supported.

`osThreadFlagsClear`
: `osFlagsErrorResource` (Running thread is not active to receive flags) is not supported.

`osDelayUntil`
: `osParameter` (the time cannot be handled) is not supported.

Chapter 5

Build and Configuration Systems

5.1 Build System (CMake)

CMake is used to build your application together with the Zephyr kernel. A CMake build is done in two stages. The first stage is called **configuration**. During configuration, the CMakeLists.txt build scripts are executed. After configuration is finished, CMake has an internal model of the Zephyr build, and can generate build scripts that are native to the host platform.

CMake supports generating scripts for several build systems, but only Ninja and Make are tested and supported by Zephyr. After configuration, you begin the **build** stage by executing the generated build scripts. These build scripts can recompile the application without involving CMake following most code changes. However, after certain changes, the configuration step must be executed again before building. The build scripts can detect some of these situations and reconfigure automatically, but there are cases when this must be done manually.

Zephyr uses CMake's concept of a 'target' to organize the build. A target can be an executable, a library, or a generated file. For application developers, the library target is the most important to understand. All source code that goes into a Zephyr build does so by being included in a library target, even application code.

Library targets have source code, that is added through CMakeLists.txt build scripts like this:

```
target_sources(app PRIVATE src/main.c)
```

In the above `CMakeLists.txt`, an existing library target named `app` is configured to include the source file `src/main.c`. The `PRIVATE` keyword indicates that we are modifying the internals of how the library is being built. Using the keyword `PUBLIC` would modify how other libraries that link with app are built. In this case, using `PUBLIC` would cause libraries that link with `app` to also include the source file `src/main.c`, behavior that we surely do not want. The `PUBLIC` keyword could however be useful when modifying the include paths of a target library.

When introducing build system code using CMake or adding new CMake files, please follow the style guidelines outlined *here*.

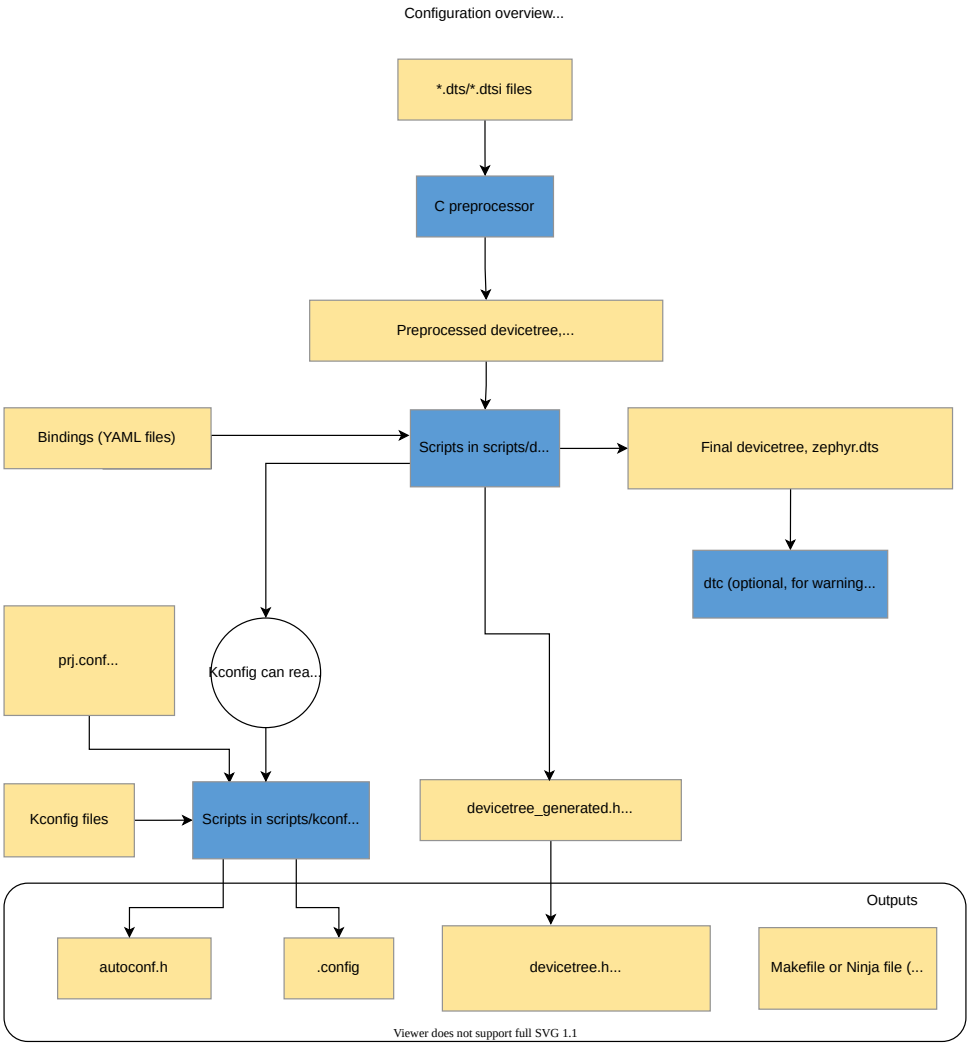
The *CMake Reference* section provides a reference for all CMake commands, variables, and modules used by Zephyr and available to application developers.

5.1.1 Build and Configuration Phases

The Zephyr build process can be divided into two main phases: a configuration phase (driven by CMake) and a build phase (driven by Make or Ninja).

Configuration Phase

The configuration phase begins when the user invokes *CMake* to generate a build system, specifying a source application directory and a board target.



CMake begins by processing the `CMakeLists.txt` file in the application directory, which refers to the `CMakeLists.txt` file in the Zephyr top-level directory, which in turn refers to `CMakeLists.txt` files throughout the build tree (directly and indirectly). Its primary output is a set of Makefiles or Ninja files to drive the build process, but the CMake scripts also do some processing of their own, which is explained here.

Note that paths beginning with `build/` below refer to the build directory you create when running CMake.

Devicetree

`*.dts` (*devicetree source*) and `*.dtsi` (*devicetree source include*) files are collected from the target's architecture, SoC, board, and application directories.

`*.dtsi` files are included by `*.dts` files via the C preprocessor (often abbreviated *cpp*, which should not be confused with C++). The C preprocessor is also used to merge in any devicetree `*.overlay` files, and to expand macros in `*.dts`, `*.dtsi`, and `*.overlay` files. The preprocessor output is placed in `build/zephyr/zephyr.dts.pre`.

The preprocessed devicetree sources are parsed by gen_defines.py to generate a `build/zephyr/include/generated/zephyr/devicetree_generated.h` header with preprocessor macros.

Source code should access preprocessor macros generated from devicetree by including the devicetree.h header, which includes `devicetree_generated.h`.

`gen_defines.py` also writes the final devicetree to `build/zephyr/zephyr.dts` in the build directory. This file's contents may be useful for debugging.

If the devicetree compiler `dtc` is installed, it is run on `build/zephyr/zephyr.dts` to catch any extra warnings and errors generated by this tool. The output from `dtc` is unused otherwise, and this step is skipped if `dtc` is not installed.

The above is just a brief overview. For more information on devicetree, see *Devicetree Guide*.

Kconfig

`Kconfig` files define available configuration options for the target architecture, SoC, board, and application, as well as dependencies between options.

Kconfig configurations are stored in *configuration files*. The initial configuration is generated by merging configuration fragments from the board and application (e.g. `prj.conf`).

The output from Kconfig is an `autoconf.h` header with preprocessor assignments, and a `.config` file that acts both as a saved configuration and as configuration output (used by CMake). The definitions in `autoconf.h` are automatically exposed at compile time, so there is no need to include this header.

Information from devicetree is available to Kconfig, through the functions defined in kconfigfunctions.py.

See *the Kconfig section of the manual* for more information.

Build Phase

The build phase begins when the user invokes `make` or `ninja`. Its ultimate output is a complete Zephyr application in a format suitable for loading/flashing on the desired target board (`zephyr.elf`, `zephyr.hex`, etc.) The build phase can be broken down, conceptually, into four stages: the pre-build, first-pass binary, final binary, and post-processing.

Pre-build Pre-build occurs before any source files are compiled, because during this phase header files used by the source files are generated.

Build-time constants generation

Some constants must be derived from C struct layouts at build time rather than hardcoded. The CMake function `zephyr_constants_library()` automates this: it compiles a C source file containing `GEN_ABSOLUTE_SYM()` declarations into an OBJECT library, then runs `gen_offset_header.py` to extract symbols ending in `_OFFSET` or `_SIZEOF` and emit them as `#define` lines in a generated header under `include/generated/zephyr/`.

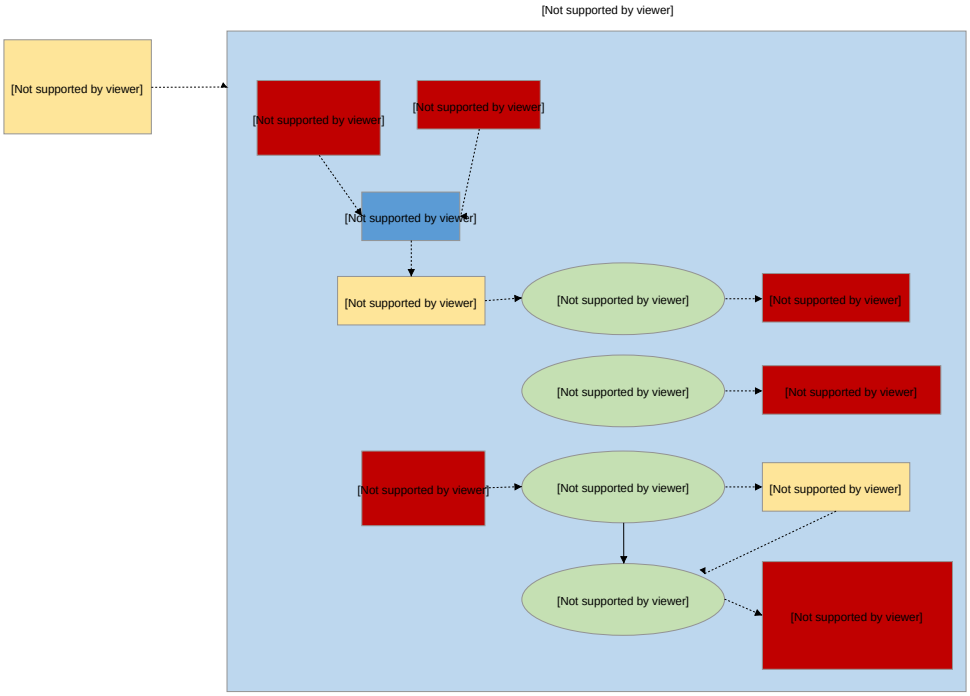
This mechanism is used in two places:

- **offsets.h**: Architecture-specific offsets for assembly code that needs access to high-level data structures when the definitions of those structures are not immediately accessible. The source file is `arch/<arch>/core/offsets/offsets.c`.
- **heap_constants.h**: Heap sizing constants (`Z_HEAP_MIN_SIZE`, `Z_HEAP_MIN_SIZE_FOR`) computed from actual heap struct layouts, replacing previously hardcoded values in `kernel.h`. The source file is `lib/heap/heap_constants.c`.

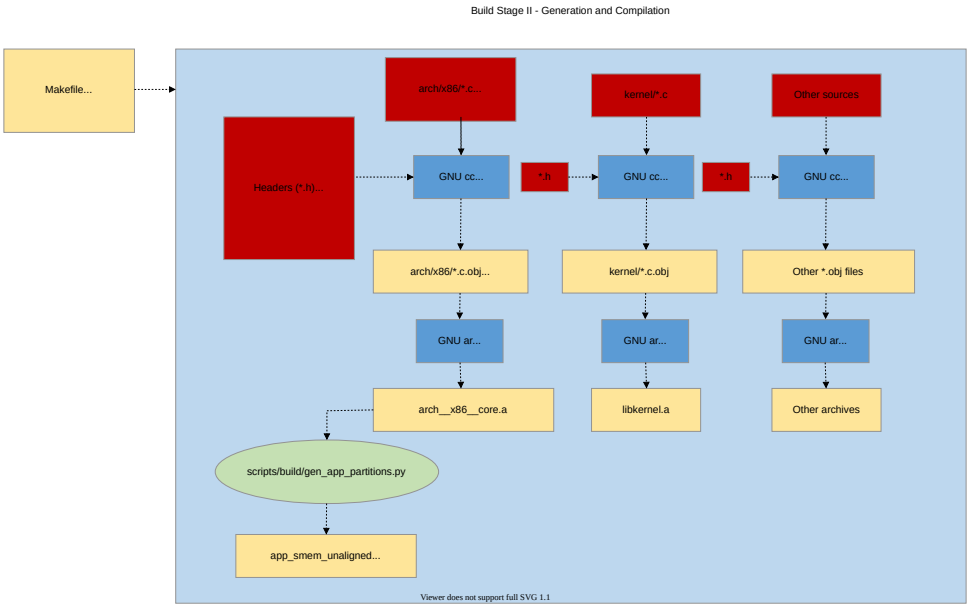
To add new build-time constants, create a C source file that includes `<gen_offset.h>` and uses `GEN_ABSOLUTE_SYM()` to declare each constant, then call `zephyr_constants_library()` from your `CMakeLists.txt`. If the new library's source includes a header generated by another constants library, use the `DEPENDS` parameter to declare that ordering (e.g., `DEPENDS heap_constants`). The resulting OBJECT library can also be linked into the final binary (as offsets.h does via `$<TARGET_OBJECTS:offsets>` in linker scripts).

System call boilerplate

The *gen_syscall.py* and *parse_syscalls.py* scripts work together to bind potential system call functions with their implementations.



Intermediate binaries Compilation proper begins with the first intermediate binary. Source files (C and assembly) are collected from various subsystems (which ones is decided during the configuration phase), and compiled into archives (with reference to header files in the tree, as well as those generated during the configuration phase and the pre-build stage(s)).



The exact number of intermediate binaries is decided during the configuration phase.

If memory protection is enabled, then:

Partition grouping

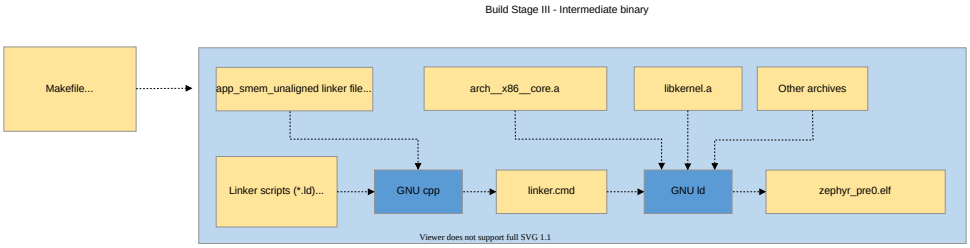
The *gen_app_partitions.py* script scans all the generated archives and outputs linker scripts

to ensure that application partitions are properly grouped and aligned for the target's memory protection hardware.

Then *cpp* is used to combine linker script fragments from the target's architecture/SoC, the kernel tree, optionally the partition output if memory protection is enabled, and any other fragments selected during the configuration process, into a *linker.cmd* file. The compiled archives are then linked with *ld* as specified in the *linker.cmd*.

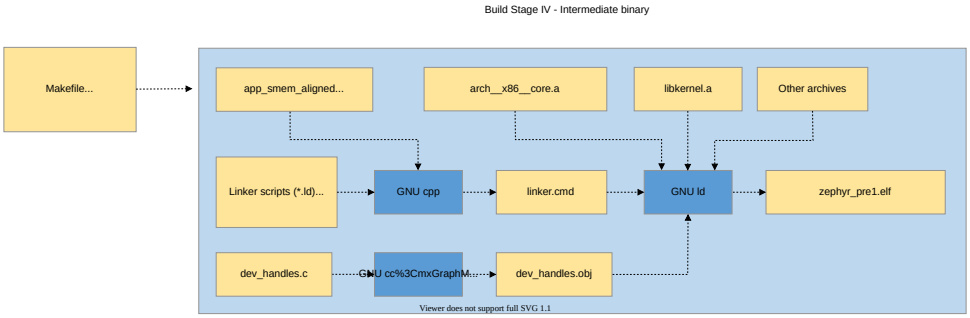
Unfixed size binary

The unfixed size intermediate binary is produced when *User Mode* is enabled or *Devicetree* is in use. It produces a binary where sizes are not fixed and thus it may be used by post-process steps that will impact the size of the final binary.



Fixed size binary

The fixed size intermediate binary is produced when *User Mode* is enabled or when generated IRQ tables are used, `CONFIG_GEN_ISR_TABLES` It produces a binary where sizes are fixed and thus the size must not change between the intermediate binary and the final binary.



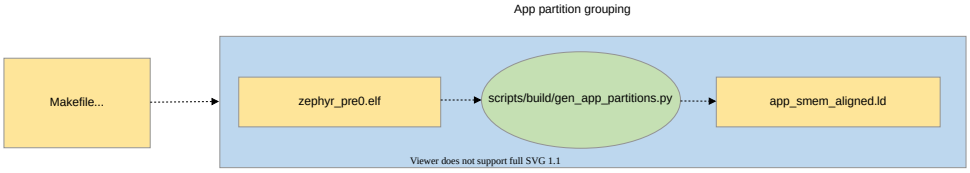
Intermediate binaries post-processing The binaries from the previous stage are incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

To complete the build procedure the following scripts are executed on the intermediate binaries to produce the missing pieces needed for the final binary.

When *User Mode* is enabled:

Partition alignment

The *gen_app_partitions.py* script scans the unfixed size binary and generates an app shared memory aligned linker script snippet where the partitions are sorted in descending order.

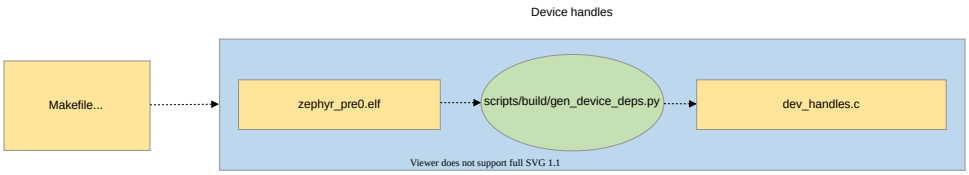


When *Devicetree* is used:

Device dependencies

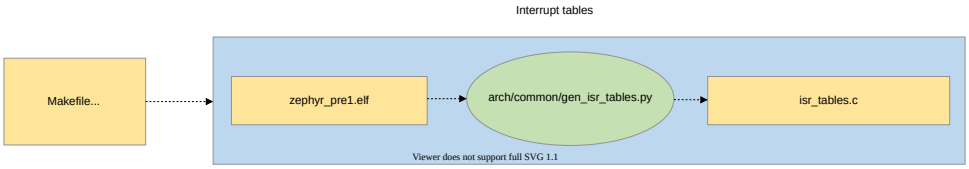
The *gen_device_deps.py* script scans the unfixed size binary to determine relationships be-

tween devices that were recorded from devicetree data, and replaces the encoded relationships with values that are optimized to locate the devices actually present in the application.



When `CONFIG_GEN_ISR_TABLES` is enabled:

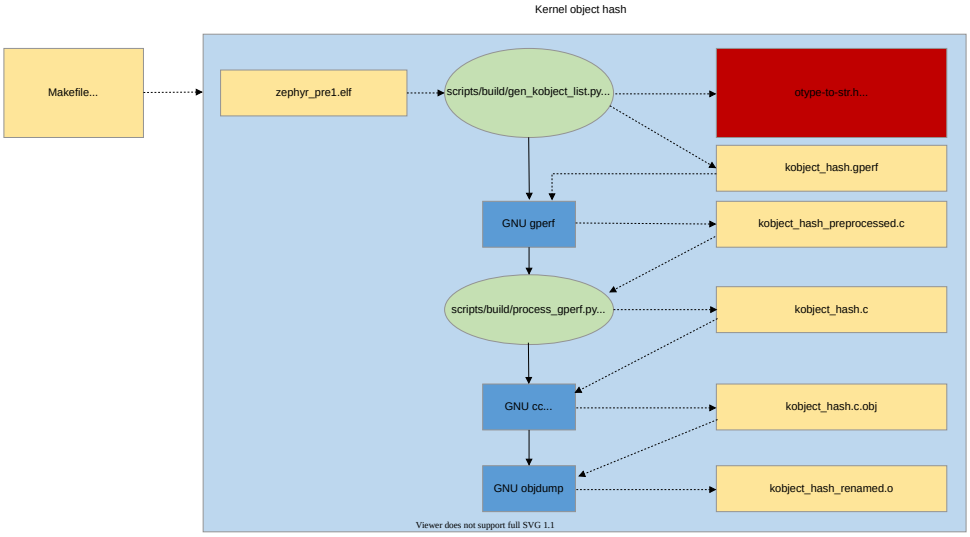
The *gen_isr_tables.py* script scans the fixed size binary and creates an isr_tables.c source file with a hardware vector table and/or software IRQ table.



When *User Mode* is enabled:

Kernel object hashing

The *gen_kobject_list.py* scans the *ELF DWARF* debug data to find the address of the all kernel objects. This list is passed to *gperf*, which generates a perfect hash function and table of those addresses, then that output is optimized by *process_gperf.py*, using known properties of our special case.

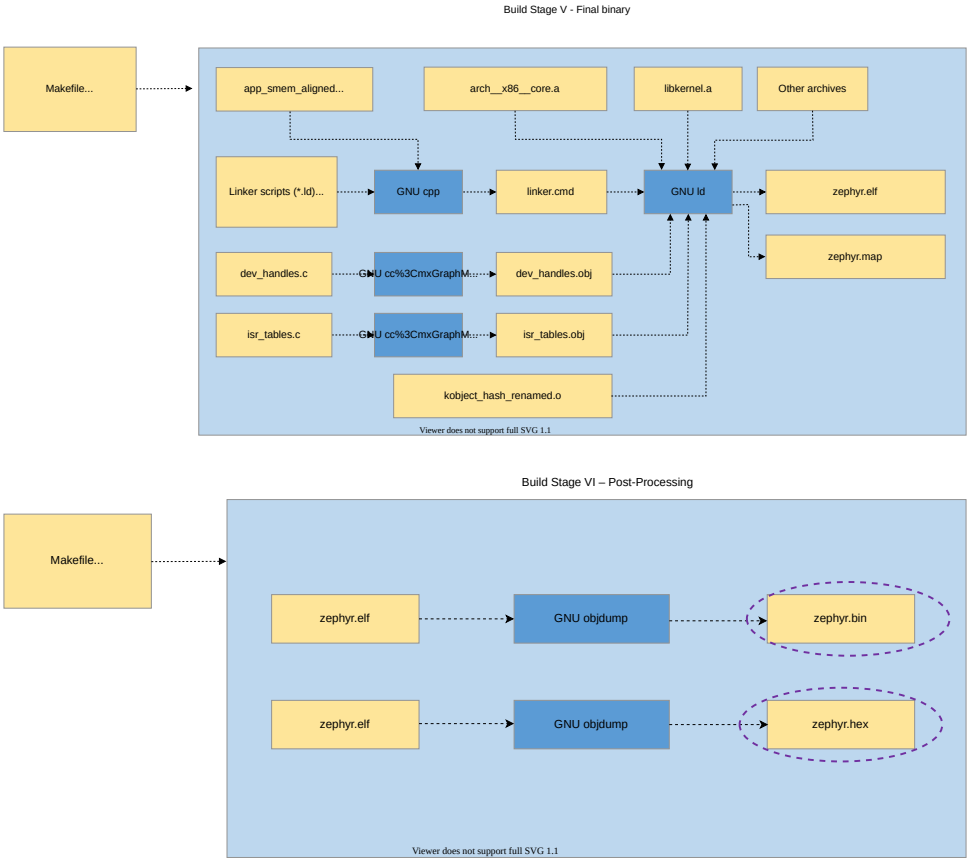


When no intermediate binary post-processing is required then the first intermediate binary will be directly used as the final binary.

Final binary The binary from the previous stage is incomplete, with empty and/or placeholder sections that must be filled in by, essentially, reflection.

The link from the previous stage is repeated, this time with the missing pieces populated.

Post processing Finally, if necessary, the completed kernel is converted from *ELF* to the format expected by the loader and/or flash tool required by the target. This is accomplished in a straightforward manner with *objdump*.



5.1.2 Supporting Scripts and Tools

The following is a detailed description of the scripts used during the build process.

scripts/build/gen_syscalls.py

Script to generate system call invocation macros

This script parses the system call metadata JSON file emitted by parse_syscalls.py to create several files:

- A file containing weak aliases of any potentially unimplemented system calls, as well as the system call dispatch table, which maps system call type IDs to their handler functions.
- A header file defining the system call type IDs, as well as function prototypes for all system call handler functions.
- A directory containing header files. Each header corresponds to a header that was identified as containing system call declarations. These generated headers contain the inline invocation functions for each system call in that header.

scripts/build/gen_device_deps.py

Translate generic handles into ones optimized for the application.

Immutable device data includes information about dependencies, e.g. that a particular sensor is controlled through a specific I2C bus and that it signals event on a pin on a specific GPIO controller. This information is encoded in the first-pass binary using identifiers derived from the devicetree. This script extracts those identifiers and replaces them with ones optimized for use with the devices actually present.

For example the sensor might have a first-pass handle defined by its devicetree ordinal 52, with the I2C driver having ordinal 24 and the GPIO controller ordinal 14. The runtime ordinal is

the index of the corresponding device in the static devicetree array, which might be 6, 5, and 3, respectively.

The output is a C source file that provides alternative definitions for the array contents referenced from the immutable device objects. In the final link these definitions supersede the ones in the driver-specific object file.

scripts/build/gen_kobject_list.py

Script to generate gperf tables of kernel object metadata

User mode threads making system calls reference kernel objects by memory address, as the kernel/driver APIs in Zephyr are the same for both user and supervisor contexts. It is necessary for the kernel to be able to validate accesses to kernel objects to make the following assertions:

- That the memory address points to a kernel object
- The kernel object is of the expected type for the API being invoked
- The kernel object is of the expected initialization state
- The calling thread has sufficient permissions on the object

For more details see the *Kernel Objects* section in the documentation.

The zephyr build generates an intermediate ELF binary, zephyr_prebuilt.elf, which this script scans looking for kernel objects by examining the DWARF debug information to look for instances of data structures that are considered kernel objects. For device drivers, the API struct pointer populated at build time is also examined to disambiguate between various device driver instances since they are all 'struct device'.

This script can generate five different output files:

- A gperf script to generate the hash table mapping kernel object memory addresses to kernel object metadata, used to track permissions, object type, initialization state, and any object-specific data.
- A header file containing generated macros for validating driver instances inside the system call handlers for the driver subsystem APIs.
- A code fragment included by kernel.h with one enum constant for each kernel object type and each driver instance.
- The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping the kernel object types and driver instances to their human-readable representation in the otype_to_str() function.
- The inner cases of a switch/case C statement, included by kernel/userspace.c, mapping kernel object types to their sizes. This is used for allocating instances of them at runtime (CONFIG_DYNAMIC_OBJECTS) in the obj_size_get() function.

scripts/build/gen_offset_header.py

This script scans a specified object file and generates a header file that defined macros for the offsets of various found structure members (particularly symbols ending with `_OFFSET` or `_SIZEOF`), primarily intended for use in assembly code.

scripts/build/parse_syscalls.py

Script to scan Zephyr include directories and emit system call and subsystem metadata

System calls require a great deal of boilerplate code in order to implement completely. This script is the first step in the build system's process of auto-generating this code by doing a text scan of directories containing C or header files, and building up a database of system calls and

their function call prototypes. This information is emitted to a generated JSON file for further processing.

This script also scans for struct definitions such as __subsystem and __net_socket, emitting a JSON dictionary mapping tags to all the struct declarations found that were tagged with them.

If the output JSON file already exists, its contents are checked against what information this script would have outputted; if the result is that the file would be unchanged, it is not modified to prevent unnecessary incremental builds.

arch/x86/gen_idt.py

Generate Interrupt Descriptor Table for x86 CPUs.

This script generates the interrupt descriptor table (IDT) for x86. Please consult the IA Architecture SW Developer Manual, volume 3, for more details on this data structure.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the IDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols. From the kernel binary we read a special section "intList" which contains the desired interrupt routing configuration for the kernel, populated by instances of the IRQ_CONNECT() macro.

This script outputs three binary tables:

1. The interrupt descriptor table itself.
2. A bitfield indicating which vectors in the IDT are free for installation of dynamic interrupts at runtime.
3. An array which maps configured IRQ lines to their associated vector entries in the IDT, used to program the APIC at runtime.

arch/x86/gen_gdt.py

Generate a Global Descriptor Table (GDT) for x86 CPUs.

For additional detail on GDT and x86 memory management, please consult the IA Architecture SW Developer Manual, vol. 3.

This script accepts as input the zephyr_prebuilt.elf binary, which is a link of the Zephyr kernel without various build-time generated data structures (such as the GDT) inserted into it. This kernel image has been properly padded such that inserting these data structures will not disturb the memory addresses of other symbols.

The input kernel ELF binary is used to obtain the following information:

- Memory addresses of the Main and Double Fault TSS structures so GDT descriptors can be created for them
- Memory addresses of where the GDT lives in memory, so that this address can be populated in the GDT pseudo descriptor
- whether userspace or HW stack protection are enabled in Kconfig

The output is a GDT whose contents depend on the kernel configuration. With no memory protection features enabled, we generate flat 32-bit code and data segments. If hardware- based stack overflow protection or userspace is enabled, we additionally create descriptors for the main and double- fault IA tasks, needed for userspace privilege elevation and double-fault handling. If userspace is enabled, we also create flat code/data segments for ring 3 execution.

scripts/build/gen_relocate_app.py

This script will relocate .text, .rodata, .data and .bss sections from required files and places it in the required memory region. This memory region and file are given to this python script in the form of a file. A regular expression filter can be applied to select only the required sections from the file.

Example of content in such an input file would be:

```
SRAM2:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c,.*foo|.*bar
SRAM1:COPY:/home/xyz/zephyr/samples/hello_world/src/main2.c,.*bar
FLASH2:NOCOPY:/home/xyz/zephyr/samples/hello_world/src/main3.c,
```

One can also specify the program header for a given memory region:

SRAM2\ :phdr0:COPY:/home/xyz/zephyr/samples/hello_world/src/main.c,

To invoke this script:

```
python3 gen_relocate_app.py -i input_file -o generated_linker -c generated_code
```

Configuration that needs to be sent to the python script.

- If the memory is like SRAM1/SRAM2/CCD/AON then place full object in the sections
- If the memory type is appended with _DATA / _TEXT/ _RODATA/ _BSS only the selected memory is placed in the required memory region. Others are ignored.
- COPY/NOCOPY defines whether the script should generate the relocation code in code_relocation.c or not
- NOKEEP will suppress the default behavior of marking every relocated symbol with KEEP() in the generated linker script.

Multiple regions can be appended together like SRAM2_DATA_BSS this will place data and bss inside SRAM2.

scripts/build/process_gperf.py

gperf C file post-processor

We use gperf to build up a perfect hashtable of pointer values. The way gperf does this is to create a table 'wordlist' indexed by a string representation of a pointer address, and then doing memcmp() on a string passed in for comparison

We are exclusively working with 4-byte pointer values. This script adjusts the generated code so that we work with pointers directly and not strings. This saves a considerable amount of space.

scripts/build/gen_app_partitions.py

Script to generate a linker script organizing application memory partitions

Applications may declare build-time memory domain partitions with K_APPMEM_PARTITION_DEFINE, and assign globals to them using K_APP_DMEM or K_APP_BMEM macros. For each of these partitions, we need to route all their data into appropriately-sized memory areas which meet the size/alignment constraints of the memory protection hardware.

This linker script is created very early in the build process, before the build attempts to link the kernel binary, as the linker script this tool generates is a necessary pre-condition for kernel linking. We extract the set of memory partitions to generate by looking for variables which have been assigned to input sections that follow a defined naming convention. We also allow entire libraries to be pulled in to assign their globals to a particular memory partition via command line directives.

This script takes as inputs:

- The base directory to look for compiled objects
- key/value pairs mapping static library files to what partitions their globals should end up in.

The output is either a linker script fragment or linker-script generator fragments containing the definition of the app shared memory section, which is further divided, for each partition found, into data and BSS for each partition.

scripts/build/check_init_priorities.py

Checks the initialization priorities

This script parses a Zephyr executable file, creates a list of known devices and their effective initialization priorities and compares that with the device dependencies inferred from the devicetree hierarchy.

This can be used to detect devices that are initialized in the incorrect order, but also devices that are initialized at the same priority but depends on each other, which can potentially break if the linking order is changed.

Optionally, it can also produce a human readable list of the initialization calls for the various init levels.

5.2 CMake Reference

5.2.1 Core Build System & Hardware Modules

arch

Configure arch settings based on Kconfig settings and arch root.

This CMake module will set the following variables in the build system based on board directory and arch root.

If no implementation is available for the current arch, an error will be raised.

Variables The following variables will be defined when this CMake module completes:

- *ARCH*
- *ARCH_DIR*
- *ARCH_ROOT*

boards

Validate board and setup boards target.

This CMake module will validate the *BOARD* argument as well as splitting it into <BOARD> and <BOARD_REVISION>.

If a board implementation is not found for the specified board an error will be raised and list of valid boards will be printed.

If user provided board is a board alias, the board will be adjusted to real board name.

If board name is deprecated, then board will be adjusted to new board name and a deprecation warning will be printed to the user.

Required variables

- *BOARD*

Optional variables

- *BOARD_ROOT*
- *ARCH_ROOT*

Variables The following variables will be defined when this CMake module completes:

- *BOARD*
- *BOARD_REVISION*
- *BOARD_QUALIFIERS*
- *NORMALIZED_BOARD_QUALIFIERS*
- *NORMALIZED_BOARD_TARGET*
- *BOARD_DIR*
- *ARCH_DIR*
- *BOARD_ROOT*

Targets The following targets will be defined when this CMake module completes:

- `boards`

  When invoked, a list of valid boards will be printed.

Optional environment variables *ZEPHYR_BOARD_ALIASES*

Environment setting pointing to a CMake file containing board aliases.

Example usage

```
# BOARD is normally given on the command line, for example:
#   west build -b nrf52840dk/nrf52840
include(boards)

message(STATUS "Building for ${BOARD} (${NORMALIZED_BOARD_TARGET})")
message(STATUS "Board files are in ${BOARD_DIR}")
```

configuration_files

Locate the Kconfig and DT config files that are to be used. Also, locate the appropriate application config directory.

Variables The following variables will be defined when this CMake module completes:

- *CONF_FILE*
- *EXTRA_CONF_FILE*
- *DTC_OVERLAY_FILE*
- *EXTRA_DTC_OVERLAY_FILE*
- *DTS_EXTRA_CPPFLAGS*
- *APPLICATION_CONFIG_DIR*

If any of the above variables are already set when this CMake module is loaded, then no changes to the variable will happen.

Variables set by this module and not mentioned above are considered internal use only and may be removed, renamed, or re-purposed without prior notice.

soc

Configure SoC settings based on Kconfig settings.

This CMake module will set the following variables in the build system based on Kconfig settings for the selected SoC.

Variables The following variables will be defined when this CMake module completes:

- `SOC_FULL_DIR`: Full directory of where the SoC files are located
- `SOC_DIRECTORIES`: List of directories where SoC files which include this SoC are located
- `SOC_TOOLCHAIN_NAME`: Optional toolchain name of the SoC

Variables set by this module and not mentioned above are considered internal use only and may be removed, renamed, or re-purposed without prior notice.

kernel

Main Zephyr Kernel CMake module.

This module is responsible for creating Zephyr libraries and the Zephyr executable. It creates a CMake project named *Zephyr-Kernel* and defines properties used while configuring libraries to be built.

Variables After loading this module, the following global variables are defined:

`ZEPHYR_LIBS`
: Global list of all Zephyr CMake libraries that should be linked in. *`zephyr_library()`* appends libraries to this list.

`ZEPHYR_INTERFACE_LIBS`
: Global list of all Zephyr interface libraries that should be linked in. *`zephyr_interface_library_named()`* appends libraries to this list.

`GENERATED_APP_SOURCE_FILES`
: Source files that are generated after Zephyr has been linked once. May include dev_handles.c etc.

`GENERATED_KERNEL_OBJECT_FILES`
: Object files that are generated after symbol addresses are fixed. May include mmu tables, etc.

`GENERATED_KERNEL_SOURCE_FILES`
: Source files that are generated after symbol addresses are fixed. May include isr_tables.c etc.

Targets

`code_data_relocation_target`
: Custom target for code data relocation.

`app`
: CMake library containing all the application code. Modified by the entry point ${APPLICATION_SOURCE_DIR}/CMakeLists.txt.

Usage This module is not intended for direct loading, but should be loaded through `find_package(Zephyr)`. It won't load any Zephyr CMake modules by itself.

basic_settings

Setup basic settings for a Zephyr project.

Basic settings are:

- Sysbuild defined configuration settings

Details for sysbuild settings:

Sysbuild is a higher level build system used by Zephyr. Sysbuild allows users to build multiple samples for a given system.

For this to work, sysbuild manages other Zephyr CMake build systems by setting dedicated build variables. This CMake module loads the sysbuild cache variables as target properties on a `sysbuild_cache` target.

This ensures that quotes and lists are correctly preserved.

extensions

Zephyr's CMake extension commands.

This module defines the commands that Zephyr applications, Zephyr modules, and the build system itself use to describe what they build.

Many commands come in an `_ifdef` and an `_ifndef` flavour, taking a Kconfig option as their first argument, so that build rules can be made conditional without wrapping them in an `if()` block.

This module is loaded as part of `find_package(Zephyr)`, which means that every command documented below is available in the `CMakeLists.txt` of any Zephyr application or module.

- *Zephyr-aware extensions*
  - *zephyr_**
  - *zephyr_library_**
    - *zephyr_interface_library_**
  - *generate_inc_**
  - *board_**
    - *Zephyr board runners*
    - *Zephyr board revision*
  - *Misc.*
- *Kconfig-aware extensions*
  - *Misc*
- *CMake-generic extensions*
  - *Debugging CMake*
  - *File system management*
  - *Others*
- *Devicetree extensions*
  - *dt_**
  - **_if_dt_node*
  - *zephyr_dt_**

- *Zephyr linker functions*
  - *zephyr_linker**
- *Function helper macros*
- *Linkable loadable extensions (llext)*
  - *Configuration functions*
  - *Build control functions*

Zephyr-aware extensions

zephyr_* The following methods are for modifying the CMake library called zephyr. zephyr is a catch-all CMake library for source files that can be built purely with the include paths, defines, and other compiler flags that all zephyr source files use.

Example usage:

```
zephyr_sources(
  random_esp32.c
  utils.c
)
```

Is short for:

```
target_sources(zephyr PRIVATE
  ${CMAKE_CURRENT_SOURCE_DIR}/random_esp32.c
  ${CMAKE_CURRENT_SOURCE_DIR}/utils.c
)
```

As a very high-level introduction, here are two call graphs that are purposely minimalistic and incomplete.

```
zephyr_library_cc_option()
         |
         v
zephyr_library_compile_options()  -->  target_compile_options()
```

```
zephyr_cc_option()           --->  target_cc_option()
                                        |
                                        v
zephyr_cc_option_fallback()  --->  target_cc_option_fallback()
                                        |
                                        v
zephyr_compile_options()     --->  target_compile_options()
```

zephyr_sources(<sources>...)

Add sources to the zephyr library.

See target_sources for details.

zephyr_include_directories(<dirs>...)

Add include directories to the zephyr library.

See target_include_directories for details.

`zephyr_system_include_directories(<dirs>...)`
: Add system include directories to the `zephyr` library.

  See `target_include_directories` for details.

`zephyr_compile_definitions(<defs>...)`
: Add compile definitions to the `zephyr` library.

  See `target_compile_definitions` for details.

`zephyr_compile_options(<options>...)`
: Add compile options to the `zephyr` library.

  See `target_compile_options` for details.

`zephyr_link_libraries(<item>...)`
: Add link libraries to the `zephyr` library.

  See `target_link_libraries` for details.

`zephyr_libc_link_libraries(<item> ...)`
: Add link libraries to the `zephyr` library's *`LIBC_LINK_LIBRARIES`* property.

  This function allows subsystems to define libraries which get added to the link command after all other libraries and modules. It's useful when using a toolchain library, like libc or libgcc, as those can get added when processing the 'lib' directory, before any module libraries and hence might not get used to resolve symbols from modules.

`zephyr_cc_option(<option>...)`
: Add compiler options to the `zephyr` library, if supported by the compiler.

  This function checks if the compiler supports each option. If supported, it adds the option to the 'zephyr' library.

`zephyr_cc_option_fallback(<option1> <option2>)`
: Add a compiler option to the `zephyr` library, falling back to a second option if the first is not supported.

  This function checks if the compiler supports `<option1>`. If so, it is added. Otherwise, it checks `<option2>` and adds it if supported.

`zephyr_ld_options(<options>...)`
: Add linker options to the `zephyr` library.

  See `target_ld_options()` for details.

`zephyr_get_include_directories_for_lang_as_string(<lang> <var> [STRIP_PREFIX])`
: Get include directories for a specific language as a string.

  Writes the include directories for language `<lang>` to variable `<var>` as a string.

  `<lang>` can be one of `C`, `CXX`, or `ASM`.

  `STRIP_PREFIX` can be specified to omit the prefix from the result.

`zephyr_get_system_include_directories_for_lang_as_string(<lang> <var> [STRIP_PREFIX])`
: Get system include directories for a specific language as a string.

  Writes the system include directories for language `<lang>` to variable `<var>` as a string.

  `<lang>` can be one of `C`, `CXX`, or `ASM`.

  `STRIP_PREFIX` can be specified to omit the prefix from the result.

zephyr_get_compile_definitions_for_lang_as_string(<lang> <var> [STRIP_PREFIX])
Get compile definitions for a specific language as a string.

Writes the compile definitions for language <lang> to variable <var> as a string.

<lang> can be one of C, CXX, or ASM.

STRIP_PREFIX can be specified to omit the prefix from the result.

zephyr_get_compile_options_for_lang_as_string(<lang> <var> [STRIP_PREFIX])
Get compile options for a specific language as a string.

Writes the compile options for language <lang> to variable <var> as a string.

<lang> can be one of C, CXX, or ASM.

STRIP_PREFIX can be specified to omit the prefix from the result.

zephyr_get_include_directories_for_lang(<lang> <var> [STRIP_PREFIX])
Get include directories for a specific language as a list.

Writes the include directories for language <lang> to variable <var> as a list.

<lang> can be one of C, CXX, or ASM.

STRIP_PREFIX can be specified to omit the prefix from the result.

zephyr_get_system_include_directories_for_lang(<lang> <var> [STRIP_PREFIX])
Get system include directories for a specific language as a list.

Writes the system include directories for language <lang> to variable <var> as a list.

<lang> can be one of C, CXX, or ASM.

STRIP_PREFIX can be specified to omit the prefix from the result.

zephyr_get_compile_definitions_for_lang(<lang> <var> [STRIP_PREFIX])
Get compile definitions for a specific language as a list.

Writes the compile definitions for language <lang> to variable <var> as a list.

<lang> can be one of C, CXX, or ASM.

STRIP_PREFIX can be specified to omit the prefix from the result.

zephyr_get_compile_options_for_lang(<lang> <var> [STRIP_PREFIX])
Get compile options for a specific language as a list.

Writes the compile options for language <lang> to variable <var> as a list.

<lang> can be one of C, CXX, or ASM.

STRIP_PREFIX can be specified to omit the prefix from the result.

zephyr_library_* Zephyr libraries use CMake's library concept and a set of assumptions about how zephyr code is organized to cut down on boilerplate code.

A Zephyr library can be constructed by the function *zephyr_library()* or *zephyr_library_named()*. The constructors create a CMake library with a name accessible through the variable *ZEPHYR_CURRENT_LIBRARY*.

The variable *ZEPHYR_CURRENT_LIBRARY* should seldom be needed since the zephyr libraries have methods that modify the libraries. These methods have the signature: zephyr_library_<*target-function*>.

The methods are wrappers around the CMake target_* functions. See manual:cmake-commands(7) for documentation on the underlying target_* functions.

The methods modify the CMake target_* API to reduce boilerplate; PRIVATE is assumed.

The target is assumed to be *ZEPHYR_CURRENT_LIBRARY*

When a flag that is given through the `zephyr_*` API conflicts with the `zephyr_library_*` API then precedence will be given to the `zephyr_library_*` API. In other words, local configuration overrides global configuration.

zephyr_library()

Create a Zephyr library with a directory-inferred name. This sets the *ZEPHYR_CURRENT_LIBRARY* variable to the inferred name.

zephyr_library_named(<name>)

Create a Zephyr library with an explicitly given name. This sets the *ZEPHYR_CURRENT_LIBRARY* variable to the given name.

zephyr_library_amend([<dir>])

Provides amend functionality to a Zephyr library for out-of-tree usage.

When called from a Zephyr module, the corresponding zephyr library defined within Zephyr will be looked up.

<dir>: Use <dir> as out-of-tree base directory from where the Zephyr library name shall be generated. <dir> can be used in cases where the structure for the library is not placed directly at the ZEPHYR_MODULE's root directory or for cases where the module integration file is located in a 'MODULE_EXT_ROOT'.

Note, in order to ensure correct library when amending, the folder structure in the Zephyr module or <dir> base directory must resemble the structure used in Zephyr, as example:

Example: to amend the zephyr library created in `ZEPHYR_BASE/drivers/entropy/CMakeLists.txt`, add a `ZEPHYR_MODULE/drivers/entropy/CMakeLists.txt` file with the following content:

```
zephyr_library_amend()
zephyr_library_sources(...)
```

It is also possible to use generator expression when amending to Zephyr libraries.

For example, in case it is required to expose the Zephyr library's folder as include path then the following is possible:

```
zephyr_library_amend()
zephyr_library_include_directories($<TARGET_PROPERTY:SOURCE_DIR>)
```

See the CMake documentation for more target properties or generator expressions.

zephyr_library_sources(<source> ...)

Add source files to the current Zephyr library.

zephyr_library_include_directories(<include_dir> ...)

Add include directories to the current Zephyr library.

zephyr_library_link_libraries(<item> ...)

Add link libraries to the current Zephyr library.

zephyr_library_compile_definitions(<item> ...)

Add compile definitions to the current Zephyr library.

zephyr_library_compile_options(<item> ...)

Add compile options to the current Zephyr library.

zephyr_library_cc_option(<option> ...)

Add compile options to the current Zephyr library if the C compiler supports them. Unsupported options are ignored.

`zephyr_library_add_dependencies(<item> ...)`
: Add dependencies to the current Zephyr library.

  See `add_dependencies()` for more information.

`zephyr_append_cmake_library(<library>)`
: Add the existing CMake library 'library' to the global list of Zephyr CMake libraries. This is done automatically by the constructor but must be called explicitly on CMake libraries that do not use a zephyr library constructor.

`zephyr_library_import(<library_name> <library_path>)`
: Add the imported library 'library_name', located at 'library_path' to the global list of Zephyr CMake libraries.

`zephyr_library_app_memory(<partition>)`
: Place the current zephyr library in the application memory partition.

  The partition argument is the name of the partition where the library shall be placed.

  Note: Ensure the given partition has been defined using `K_APPMEM_PARTITION_DEFINE` in source code.

`zephyr_interface_library_*` A Zephyr interface library is a thin wrapper over a CMake `INTERFACE` library. The most important responsibility of this abstraction is to ensure that when a user KConfig-enables a library then the header files of this library will be accessible to the 'app' library.

This is done because when a user uses Kconfig to enable a library he expects to be able to include its header files and call its functions out-of-the box.

A Zephyr interface library should be used when there exists some build information (include directories, defines, compiler flags, etc.) that should be applied to a set of Zephyr libraries and 'app' might be one of these libraries.

Zephyr libraries must explicitly call *`zephyr_library_link_libraries(<interface_library>)`* to use this build information. 'app' is treated as a special case for usability reasons; a Kconfig option (CONFIG_APP_LINK_WITH_<interface_library>) should exist for each interface_library and will determine if 'app' links with the interface_library.

This API has a constructor like the zephyr_library API has, but it does not have wrappers over the other cmake target functions.

`zephyr_interface_library_named(<name>)`
: Create a Zephyr interface library with a given name.

`generate_inc_*` These functions are useful if there is a need to generate a file that can be included into the application at build time. The file can also be compressed automatically when embedding it.

See tests/application_development/gen_inc_file for an example of usage.

`generate_inc_file(<source_file> <generated_file> ...)`
: Generate a file that can be included into the application at build time.

  `source_file`
  : The source file to be converted to hex

  `generated_file`
  : The generated file

  `...`
  : Extra arguments are passed to file2hex.py

`board_*` This section is for extensions related to Zephyr board handling.

Zephyr board runners Zephyr board runner extension functions control Zephyr's board runners from the build system. The Zephyr build system has targets for flashing and debugging supported boards. These are wrappers around a "runner" Python subpackage that is part of Zephyr's "west" tool.

This section provides glue between CMake and the Python code that manages the runners.

`board_set_runner(<type> <runner>)`
This function sets the runner for the board unconditionally. It's meant to be used from application's `CMakeLists.txt` files.

> **Note**
> Usually `board_set_xxx_ifnset()` is best in `board.cmake` files. This lets the user set the runner at cmake time, or in their own application's `CMakeLists.txt`.

Example usage:

```
board_set_runner(FLASH pyocd)
```

This would set the board's flash runner to "pyocd".

In general, "type" is FLASH, DEBUG, SIM or ROBOT and "runner" is the name of a runner.

`board_set_runner_ifnset(<type> <runner>)`
This macro is like *board_set_runner()*, but will only make a change if that runner is currently not set.

See also *board_set_flasher_ifnset()* and *board_set_debugger_ifnset()*.

`board_set_flasher(<runner>)`
A convenience macro for *board_set_runner(FLASH ${runner})*.

`board_set_debugger(<runner>)`
A convenience macro for *board_set_runner(DEBUG ${runner})*.

`board_set_flasher_ifnset(<runner>)`
A convenience macro for *board_set_runner_ifnset(FLASH ${runner})*.

`board_set_debugger_ifnset(<runner>)`
A convenience macro for *board_set_runner_ifnset(DEBUG ${runner})*.

`board_set_robot_runner_ifnset(<runner>)`
A convenience macro for *board_set_runner_ifnset(ROBOT ${runner})*.

`board_set_sim_runner_ifnset(<runner>)`
A convenience macro for *board_set_runner_ifnset(SIM ${runner})*.

`board_runner_args(<runner> <args>...)`
This function is intended for board.cmake files and application CMakeLists.txt files.

Usage from board.cmake files:

```
board_runner_args(runner "--some-arg=val1" "--another-arg=val2")
```

The build system will then ensure the command line used to create the runner contains:

```
--some-arg=val1 --another-arg=val2
```

Within application CMakeLists.txt files, ensure that all calls to *board_runner_args()* are part of a macro named `app_set_runner_args()`, like this, which is defined before calling `find_package(Zephyr)`:.

```
macro(app_set_runner_args)
  board_runner_args(runner "--some-app-setting=value")
endmacro()
```

The build system tests for the existence of the macro and will invoke it at the appropriate time if it is defined.

Any explicitly provided settings given by this function override defaults provided by the build system.

`board_set_rimage_target(<target>)`

Set the rimage target for the current board.

Zephyr board revision This section provides a function for revision checking.

`board_check_revision(FORMAT <LETTER | NUMBER | MAJOR.MINOR.PATCH> [EXACT] [DEFAULT_REVISION <revision>] [HIGHEST_REVISION <revision>] [VALID_REVISIONS <revision> ...] )`

Zephyr board extension function.

This function can be used in `boards/board/revision.cmake` to check a user requested revision against available board revisions.

The function will check the revision from `-DBOARD=board@revision` that is provided by the user according to the arguments. When `EXACT` is not specified, this function will set the Zephyr build system variable *ACTIVE_BOARD_REVISION* with the selected revision.

FORMAT <LETTER | NUMBER | MAJOR.MINOR.PATCH>
Specify the revision format.

LETTER
Revision format is a single letter from A - Z.

NUMBER
Revision format is a single integer number.

MAJOR.MINOR.PATCH
Revision format is three numbers, separated by `.`, `x.y.z`. Trailing zeroes may be omitted on the command line, which means that 1.0.0 == 1.0 == 1.

OPTIONAL
Revision specifier is optional.

If revision is not provided the base board will be used. If both `EXACT` and `OPTIONAL` are given, then specifying the revision is optional, but if it is given then the `EXACT` requirements apply. Mutually exclusive with `DEFAULT_REVISION`.

EXACT
Revision is required to be an exact match.

As example, available revisions are: 0.1.0 and 0.3.0, and user provides 0.2.0, then an error is reported when `EXACT` is given. If `EXACT` is not provided, then closest lower revision will be selected as the active revision, which in the example will be 0.1.0.

DEFAULT_REVISION
Provides a default revision to use when user has not selected a revision number.

If no default revision is provided then user will be printed with an error if no revision is given on the command line.

HIGHEST_REVISION
Allows to specify highest valid revision for a board.

This can be used to ensure that a newer board cannot be used with an older Zephyr. As example, if current board supports revisions 0.x.0-0.99.99 and 1.0.0-1.99.99, and it is

expected that current board implementation will not work with board revision 2.0.0, then HIGHEST_REVISION can be set to 1.99.99, and user will be printed with an error if using <*board*>*@2.0.0* or higher. This field is not needed when EXACT is used.

VALID_REVISIONS
A list of valid revisions for this board.

If this argument is not provided, then each Kconfig fragment of the form *board_revision*.conf in the board folder will be used as a valid revision for the board.

Misc.

pow2round(<variable>)

Round number to next power of two.

Example usage:

```
set(test 2)
pow2round(test)
# test is still 2

set(test 5)
pow2round(test)
# test is now 8
```

zephyr_build_string(outvar [BOARD board] [SHORT short_outvar] [BOARD_QUALIFIERS qualifiers] [BOARD_REVISION revision] [MERGE] [REVERSE])

Create a build string based on BOARD, BOARD_REVISION, and BOARD_QUALIFIER. This is a common function to ensure that build strings are always created in a uniform way.

When MERGE is supplied a list of build strings will be returned with the full build string as first item in the list. The full order of build strings returned in the list will be:

- Normalized board target build string, this includes qualifiers and revision ;
- Build string with board variants removed in addition ;
- Build string with cpuset removed in addition ;
- Build string with soc removed in addition.

If REVISION is supplied or obtained as system wide setting a build string with the sanitized revision string will be added in addition to the non-revisioned entry for each entry.

outvar
Output variable where the build string will be returned.

BOARD board
Board name to use when creating the build string.

SHORT short_outvar
Output variable where the shortened build string will be returned.

BOARD_QUALIFIERS qualifiers
Board qualifiers to use.

BOARD_REVISION revision
Board revision to use.

MERGE
Return a list of build strings instead of a single build string.

REVERSE
Reverse the list before returning it.

Example usage:

```
zephyr_build_string(build_string BOARD alpha)
# Returns "alpha" in build_string

zephyr_build_string(build_string BOARD alpha
                                  BOARD_REVISION 1.0.0)
# Returns "alpha_1_0_0" in build_string

zephyr_build_string(build_string BOARD alpha
                                  BOARD_QUALIFIERS /soc/bar)
# Returns "alpha_soc_bar" in build_string

zephyr_build_string(build_string BOARD alpha
                                  BOARD_REVISION 1.0.0
                                  BOARD_QUALIFIERS /soc/bar
                                  MERGE)
# Returns list "alpha_soc_bar_1_0_0;alpha_soc_bar" in build_string

zephyr_build_string(build_string SHORT short_build_string
                                  BOARD alpha
                                  BOARD_REVISION 1.0.0
                                  BOARD_QUALIFIERS /soc/bar
                                  MERGE)
# Returns list "alpha_soc_bar_1_0_0;alpha_soc_bar" in build_string
# Returns list "alpha_bar_1_0_0;alpha_bar" in short_build_string

zephyr_build_string(build_string BOARD_QUALIFIERS /soc/bar/foo)
# Returns "soc_bar_foo" in build_string
```

`zephyr_syscall_include_directories(<directories>...)`

Add one or more directories to the include list passed to the syscall generator.

`<directories>...`
One or more directories to add.

`zephyr_syscall_header(<headers>...)`

Add one or more header files to the list passed to the syscall generator.

`<headers>...`
One or more header files to add.

`zephyr_syscall_header_ifdef(feature_toggle <headers>...)`

Add one or more header files to the list passed to the syscall generator if“feature_toggle“ is true.

`feature_toggle`
The name of the boolean variable to check.

`<headers>...`
One or more header files to add.

`zephyr_blobs_verify(<MODULE module | FILES file [files...]> [REQUIRED])`

Verify blobs fetched using west. If the sha256 checksum isn't valid, a warning/fatal error message is printed (level depends on `REQUIRED` flag).

`MODULE module`
Verify all blobs in the given module.

`FILES file [files...]`
Verify the specified files.

`REQUIRED`
If specified, a fatal error is raised if the verification fails. Otherwise, a warning is

printed.

Example usage:

```
# Verify all blobs in my_module and fail on error
zephyr_blobs_verify(MODULE my_module REQUIRED)

# Verify a single file and print on error
zephyr_blobs_verify(FILES img/file.bin)
```

Kconfig-aware extensions *Kconfig* is a configuration language developed for the Linux kernel. The below functions integrate CMake with Kconfig.

Misc

`import_kconfig(prefix kconfig_fragment [keys] [TARGET target])`

Parse a KConfig fragment (typically with extension .config) and introduce all the symbols that are prefixed with `prefix` into the CMake namespace. List all created variable names in the `keys` output variable if present.

`prefix`
: symbol prefix of settings in the Kconfig fragment.

`kconfig_fragment`
: absolute path to the config fragment file.

`keys`
: output variable which will be populated with variable names loaded from the kconfig fragment.

`TARGET`
: set all symbols on `target` instead of adding them to the CMake namespace.

CMake-generic extensions These functions extend the CMake API in a way that is not particular to Zephyr. Primarily, they work around limitations in the CMake language to allow cleaner build scripts.

`add_subdirectory_ifdef`

This function adds a subdirectory to the build if `feature_toggle` is enabled.

Debugging CMake

`print(arg)`

Print the value of a variable.

Example usage:

```
print(BOARD)
# will print: "BOARD: nrf52dk"
```

`assert(test comment)`

Assert that a condition is true.

This macro will cause a fatal error and print an error message if the first expression is false.

`test`
: The boolean expression to test.

`comment`
: The error message to print if the assertion fails.

Example usage:

```
assert(ZEPHYR_TOOLCHAIN_VARIANT "ZEPHYR_TOOLCHAIN_VARIANT not set.")
```

assert_not(test comment)

Assert that a condition is false.

This macro will cause a fatal error and print an error message if the first expression is true.

test
The boolean expression to test.

comment
The error message to print if the assertion fails.

Example usage:

```
assert_not(OBSOLETE_VAR "OBSOLETE_VAR has been removed; use NEW_VAR instead")
```

assert_exists(var)

Assert that a file or directory exists.

This macro will cause a fatal error if the file or directory pointed to by the variable does not exist.

var
The name of the variable containing the path to check.

Example usage:

```
assert_exists(CMAKE_READELF)
```

File system management

generate_unique_target_name_from_filename(filename target_name)

Generate a unique target name from a filename.

filename
The filename to generate a unique name from.

target_name
The name of the variable to store the generated target name in.

zephyr_file(APPLICATION_ROOT <path> [BASE_DIR <base-dir>])

zephyr_file(CONF_FILES <paths> [DTS <list>] [KCONF <list>] [DEFCONF <list>] [BOARD <board> [BOARD_REVISION <revision>] | NAMES <name> ...] [SUFFIX <suffix>] [REQUIRED])

Zephyr file function extension. This function currently supports the following modes:

APPLICATION_ROOT
Check all paths in provided variable, and convert those paths that are defined with `-D<path>=<val>` to absolute path, relative from `APPLICATION_SOURCE_DIR`. Issue an error for any relative path not specified by user with `-D<path>`.

BASE_DIR <base-dir>
Convert paths relative to `<base-dir>` instead of `APPLICATION_SOURCE_DIR`.

Returns an updated list of absolute paths.

CONF_FILES
Find all configuration files in the list of paths and return them in a list. If paths is empty then no configuration files are returned.

Configuration files will be:

- `DTS`: Overlay files (`.overlay`)
- `Kconfig`: Config fragments (`.conf`)

- defconfig: defconfig files (_defconfig)

The conf file search will return existing configuration files for the current board.

CONF_FILES takes the following additional arguments:

BOARD <board>
Find configuration files for specified board.

BOARD_REVISION <revision>
Find configuration files for specified board revision. Requires BOARD to be specified. If no board is given the current BOARD and BOARD_REVISION will be used, unless NAMES are specified.

NAMES <name1> [name2] ...
List of file names to look for and instead of creating file names based on board settings. Only the first match found in <paths> will be returned in the <list>.

DTS <list>
List to append DTS overlay files in <path> to.

KCONF <list>
List to append Kconfig fragment files in <path> to.

DEFCONF <list>
List to append _defconfig files in <path> to.

SUFFIX <name>
Suffix name to check for instead of the default name but with a fallback to the default name if not found.

For example: SUFFIX fish, will look for <file>_fish.conf and use if found but will use <file>.conf if not found.

REQUIRED
Option to indicate that the <list> specified by DTS or KCONF must contain at least one element, else an error will be raised.

zephyr_file_copy(<oldname> <newname> [ONLY_IF_DIFFERENT])

Zephyr file copy extension.

Deprecated: this function only existed because file(COPY_FILE...) was not available with CMake 3.20; call file(COPY_FILE ...) directly instead.

oldname
Old file name.

newname
New file name.

ONLY_IF_DIFFERENT
Only copy if the files are different.

zephyr_file_suffix(<filename> SUFFIX <suffix>)

Update the filename(s) with the suffix if a file with the suffix exists.

This function checks the provided filename or list of filenames to see if a file with the _<suffix> extension exists. If so, it updates the supplied variable/list with the new path/paths.

<filename>
Variable (singular or list) of absolute path filename(s).

<suffix>
The suffix to test for and append to the end of the provided filename.

Returns an updated variable of absolute path(s).

Others

zephyr_string(ESCAPE <out-var> <input> ...)

zephyr_string(SANITIZE <out-var> <input> ...)

zephyr_string(SANITIZE TOUPPER <out-var> <input> ...)

Zephyr string function extension.

This function extends the CMake `string` function by providing additional manipulation options for the `<mode>` argument, namely:

ESCAPE
: Ensure that every character of the input arguments is considered by CMake as a literal by prefixing the escape character \ where appropriate. This is useful for handling Windows path separators in strings, or when it is desired to write `\n` as an actual string of four characters instead of a single newline. Note that this operation must be performed exactly once during the lifetime of a string, or previous escape characters will be treated as literals and escaped further.

SANITIZE
: Ensure that the output string does not contain any special characters. Special characters, such as -, +, =, $, etc. are converted to underscores _. Multiple arguments are concatenated.

SANITIZE TOUPPER
: Ensure that the output string does not contain any special characters. Special characters, such as -, +, =, $, etc. are converted to underscores _. Multiple arguments are concatenated. The sanitized string will be returned in UPPER case.

Returns the updated string in `<out-var>`.

zephyr_list(TRANSFORM <list> <ACTION> [OUTPUT_VARIABLE <output variable>])

Zephyr list function extension.

Like CMake's `list(TRANSFORM ...)` this is intended as a placeholder for storing current and future Zephyr-related extensions for list processing.

<ACTION>
: This currently must be `NORMALIZE_PATHS`. This action converts the argument list `<list>` to a ;-list with CMake path names, after passing its contents through a `configure_file` transformation. The input list may be whitespace- or semicolon-separated.

OUTPUT_VARIABLE
: the result is normally stored in place, but an alternative variable to store the result can be provided with this.

zephyr_get(<variable> [MERGE [REVERSE]] [SYSBUILD [LOCAL|GLOBAL]] [VAR <var1> ...])

Return the value of `<variable>` as local scoped variable of same name.

If `MERGE` is supplied, will return a list of found items.

If `REVERSE` is supplied together with `MERGE`, the order of the list will be reversed before being returned. Reverse will happen before the list is returned and hence it will not change the order of precedence in which the list itself is constructed.

`VAR` can be used either to store the result in a variable with a different name, or to look for values from multiple variables.

```
zephyr_get(FOO VAR FOO_A FOO_B)
zephyr_get(FOO MERGE VAR FOO_A FOO_B)
```

`zephyr_get()` is a common function to provide a uniform way of supporting build settings that can be set from sysbuild, CMakeLists.txt, CMake cache, or in environment.

The order of precedence for variables defined in multiple scopes:

- Sysbuild defined when sysbuild is used. Sysbuild variables can be defined as global or local to specific image. Examples:
  - BOARD is considered a global sysbuild cache variable
  - blinky_BOARD is considered a local sysbuild cache variable only for the blinky image.

  If no sysbuild scope is specified, GLOBAL is assumed. If using MERGE then SYSBUILD GLOBAL will get both the local and global sysbuild scope variables (in that order, if both exist).
- CMake cache, set by -D<var>=<value> or set(<var> <val> CACHE ...)
- Environment
- Locally in CMakeLists.txt before find_package(Zephyr)

For example, if *ZEPHYR_TOOLCHAIN_VARIANT* is set in environment but locally overridden by setting ZEPHYR_TOOLCHAIN_VARIANT directly in the CMake cache using -DZEPHYR_TOOLCHAIN_VARIANT=<val>, then the value from the cache is returned.

zephyr_create_scope(<scope>)

Create a new scope for the creation of scoped variables.

<scope>
Name of new scope.

zephyr_scope_exists(<result> <scope>)

Check if <scope> exists.

<result>
Variable to set with result. TRUE if scope exists, FALSE otherwise.

<scope>
Name of scope.

zephyr_get_scoped(<output> <scope> <var>)

Get the current value of <var> in a specific <scope>, as defined by a previous *zephyr_set()* call. The value will be stored in the <output> var.

<output>
Variable to store the value in

<scope>
Scope for the variable look up

<var>
Name to look up in the specific scope

zephyr_set(<variable> <value> SCOPE <scope> [APPEND])

Zephyr extension of CMake set which allows a variable to be set in a specific scope.

The scope is used on later *zephyr_get()* invocation for precedence handling when a variable it set in multiple scopes.

<variable>
Name of variable

<value>
Value of variable, multiple values will create a list. The SCOPE argument identifies the end of value list.

SCOPE <scope>
Name of scope for the variable

APPEND
Append values to the already existing variable in <scope>

`zephyr_check_cache(<variable> [REQUIRED] [WATCH])`

Check the current CMake cache for `<variable>` and warn the user if the value is being modified.

This can be used to ensure the user does not accidentally try to change Zephyr build variables, such as:

- `BOARD`
- `SHIELD`

<variable>
Name of `<variable>` to check and set, for example `BOARD`.

REQUIRED
Optional flag. If specified, then an unset `<variable>` will be treated as an error.

WATCH
Optional flag. If specified, watch the variable and print a warning if the variable is later being changed.

Details:

`<variable>` can be set by 3 sources.

- Using CMake argument, `-D<variable>`
- Using an environment variable
- In the project CMakeLists.txt before `find_package(Zephyr)`.

CLI has the highest precedence, then comes environment variables, and then finally CMakeLists.txt.

The value defined on the first CMake invocation will be stored in the CMake cache as `CACHED_<variable>`. This allows the Zephyr build system to detect when a user reconfigures a sticky variable.

A user can ignore all the precedence rules if the same source is always used E.g. always specifies `-D<variable>=` on the command line, always has an environment `<variable>` set, or always has a set(`<variable>` foo) line in his CMakeLists.txt and avoids mixing sources.

The selected `<variable>` can be accessed through the variable '`<variable>`' in following Zephyr CMake code.

If the user tries to change `<variable>` to a new value, then a warning will be printed, and the previously cached value (`CACHED_<variable>`) will be used, as it has precedence.

Together with the warning, user is informed that in order to change `<variable>` the build directory must be cleaned.

`zephyr_get_targets(<directory> <types> <targets>)`

Get build targets for a given directory and sub-directories.

This functions will traverse the build tree, starting from `<directory>`. It will read the `BUILDSYSTEM_TARGETS` for each directory in the build tree and return the build types matching the `<types>` list.

Example of types: `OBJECT_LIBRARY`, `STATIC_LIBRARY`, `INTERFACE_LIBRARY`, `UTILITY`.

Returns a list of targets in `<targets>` matching the required `<types>`.

`target_byproducts(TARGET <target> BYPRODUCTS <file> ...)`

Specify additional `BYPRODUCTS` that this target produces.

This function allows the build system to specify additional byproducts to target created with `add_executable`. When linking an executable the linker may produce additional files, like

map files. Those files are not known to the build system. This function makes it possible to describe such additional byproducts in an easy manner.

`TARGET <target>`
: The target to add byproducts to.

`BYPRODUCTS <file> ...`
: List of byproducts that the target produces.

`topological_sort(TARGETS <target> ... PROPERTY_NAME <property> RESULT_VARIABLE <out-variable>)`

This function performs topological sorting of CMake targets using a specific `<property>`, which dictates target dependencies. A fatal error occurs if the provided dependencies cannot be met, e.g., if they contain cycles.

`TARGETS <target> ...`
: List of target names.

`PROPERTY_NAME <property>`
: Name of the target property to be used when sorting. For every target listed in `TARGETS`, this property must contain a list (possibly empty) of other targets, which this target depends on for a particular purpose. The property must not contain any target which is not also found in `TARGETS`.

`RESULT <out-variable>`
: Output variable, where the topologically sorted list of target names will be returned.

`build_info(<tag>... VALUE <value>...)`

`build_info(<tag>... PATH <path>...)`

Populates the `build_info.yml` info file with exchangeable build information related to the current build.

Example usage:

```
# This will update the 'devicetree.files' key in the build info yaml with the list of files
# file1.dts, file2.dts, file3.dts
build_info(devicetree files VALUE file1.dts file2.dts file3.dts)
```

```
# This will place the vendor specific 'foo' key with value 'bar' in the vendor-specific
# section of the build info file.
build_info(vendor-specific foo VALUE bar)
```

`<tag>...`
: One of the pre-defined valid CMake keys supported by build info or vendor-specific. See scripts/schemas/build-schema.yaml, `cmake` section, for valid tags.

`VALUE <value>...`
: Value(s) to place in the build_info.yml file.

`PATH <path>...`
: Path(s) to place in the build_info.yml file. All paths are converted to CMake style. If no conversion is required, for example when paths are already guaranteed to be CMake style, then `VALUE` can also be used.

Devicetree extensions

`dt_*` The following methods are for retrieving devicetree information in CMake.

Notes:

- In CMake, we refer to the nodes using the node's path, therefore there is no `dt_path(...)` function for obtaining a node identifier like there is in the C devicetree.h API.
- As another difference from the C API, you can generally use an alias at the beginning of a path interchangeably with the full path to the aliased node in these functions. The usage comments will make this clear in each case.
- These methods are also available to sysbuild. To retrieve the DT information of some <image>, after its CMake configuration step, the `dt_*` function call must include a `TARGET <image>` argument.

dt_nodelabel(<var> NODELABEL <label> [REQUIRED] [TARGET <target>])

Function for retrieving the node path for the node having nodelabel `<label>`.

The node's path will be returned in the `<var>` parameter. `<var>` will be undefined if node does not exist.

<var>
Return variable where the node path will be stored

NODELABEL <label>
Node label

REQUIRED
Generate a fatal error if the node-label is not found

TARGET <target>
Optional target to retrieve devicetree information from

Example devicetree fragment:

```
/ {
   soc {
       nvic: interrupt-controller@e000e100  { ... };
   };
};
```

Example usage:

```
# Sets 'nvic_path' to "/soc/interrupt-controller@e000e100"
dt_nodelabel(nvic_path NODELABEL "nvic")
```

dt_alias(<var> PROPERTY <prop> [REQUIRED] [TARGET <target>])

Get a node path for an `/aliases` node property.

The node's path will be returned in the `<var>` parameter. The variable will be left undefined if the alias does not exist.

<var>
Return variable where the node path will be stored

PROPERTY <prop>
The alias to check

REQUIRED
Generate a fatal error if the alias is not found

TARGET <target>
Optional target to retrieve devicetree information from

Example usage:

```
# The full path to the 'led0' alias is returned in 'path'.
dt_alias(path PROPERTY "led0")
```

(continues on next page)

(continued from previous page)

```
# The variable 'path' will be left undefined for a nonexistent
# alias "does-not-exist".
dt_alias(path PROPERTY "does-not-exist")
```

`dt_node_exists(<var> PATH <path> [TARGET <target>])`

Tests whether a node with path `<path>` exists in the devicetree.

The `<path>` value may be any of these:

- absolute path to a node, like `/foo/bar`
- a node alias, like `my-alias`
- a node alias followed by a path to a child node, like `my-alias/child-node`

The result of the check, either TRUE or FALSE, will be returned in the `<var>` parameter.

`<var>`
: Return variable where the check result will be returned

`PATH <path>`
: Node path

`TARGET <target>`
: Optional target to retrieve devicetree information from

`dt_node_has_status(<var> PATH <path> STATUS <status> [TARGET <target>])`

Tests whether `<path>` refers to a node which:

- exists in the devicetree, and
- has a status property matching the `<status>` argument (a missing status or an "ok" status is treated as if it were "okay" instead)

The `<path>` value may be any of these:

- absolute path to a node, like '/foo/bar'
- a node alias, like 'my-alias'
- a node alias followed by a path to a child node, like 'my-alias/child-node'

The result of the check, either TRUE or FALSE, will be returned in the `<var>` parameter.

`<var>`
: Return variable where the check result will be returned

`PATH <path>`
: Node path

`STATUS <status>`
: Status to check

`TARGET <target>`
: Optional target to retrieve devicetree information from

`dt_prop(<var> PATH <path> PROPERTY <prop> [INDEX <idx>] [REQUIRED] [TARGET <target>])`

Get a devicetree property value. The value will be returned in the `<var>` parameter.

The `<path>` value may be any of these:

- absolute path to a node, like '/foo/bar'
- a node alias, like 'my-alias'
- a node alias followed by a path to a child node, like 'my-alias/child-node'

This function currently only supports properties with the following devicetree binding types: string, int, boolean, array, uint8-array, string-array, path.

For array valued properties (including uint8-array and string-array), the entire array is returned as a CMake list unless `INDEX` is given. If `INDEX` is given, just the array element at index `<idx>` is returned.

The property value will be returned in the `<var>` parameter if the node exists and has a property `<prop>` with one of the above types. `<var>` will be undefined otherwise.

<var>
Return variable where the property value will be stored

PATH <path>
Node path

PROPERTY <prop>
Property for which a value should be returned, as it appears in the DTS source

INDEX <idx>
Optional index when retrieving a value in an array property

REQUIRED
Generate a fatal error if the property is not found

TARGET <target>
Optional target to retrieve devicetree information from

To test if the property is defined before using it, use `DEFINED` on the return `<var>`, like this:

```
dt_prop(reserved_ranges PATH "/soc/gpio@deadbeef" PROPERTY
↪"gpio-reserved-ranges")
if(DEFINED reserved_ranges)
  # Node exists and has the "gpio-reserved-ranges" property.
endif()
```

To distinguish a missing node from a missing property, combine *dt_prop()* and *dt_node_exists()*, like this:

```
dt_node_exists(node_exists PATH "/soc/gpio@deadbeef")
dt_prop(reserved_ranges    PATH "/soc/gpio@deadbeef" PROPERTY
↪"gpio-reserved-ranges")
if(DEFINED reserved_ranges)
  # Node "/soc/gpio@deadbeef" exists and has the "gpio-reserved-ranges"␣
↪property
elseif(node_exists)
  # Node exists, but doesn't have the property, or the property has an␣
↪unsupported type.
endif()
```

dt_comp_path(<var> COMPATIBLE <compatible> [INDEX <idx>] [TARGET <target>])

Get a list of paths for the nodes with the given compatible. The value will be returned in the `<var>` parameter. `<var>` will be undefined if no such compatible exists.

For details and considerations about the format of `<path>` and the returned parameter refer to *dt_prop()*.

<var>
Return variable where the property value will be stored

COMPATIBLE <compatible>
Compatible for which the list of paths should be returned, as it appears in the DTS source

`INDEX <idx>`
: Optional index when retrieving a value in an array property

`TARGET <target>`
: Optional target to retrieve devicetree information from

`dt_num_regs(<var> PATH <path> [TARGET <target>])`
: Get the number of register blocks in the node's `reg` property; this may be zero.

  The value will be returned in the `<var>` parameter.

  The `<path>` value may be any of these:

  - absolute path to a node, like '/foo/bar'
  - a node alias, like 'my-alias'
  - a node alias followed by a path to a child node, like 'my-alias/child-node'

  `<var>`
  : Return variable where the property value will be stored

  `PATH <path>`
  : Node path

  `TARGET <target>`
  : Optional target to retrieve devicetree information from

`dt_reg_addr(<var> PATH <path> [INDEX <idx>] [NAME <name>] [TARGET <target>])`
: Get the base address of the register block at index `<idx>`, or with name `<name>`. If `<idx>` and `<name>` are both omitted, the value at index 0 will be returned. Do not give both `<idx>` and `<name>`.

  The value will be returned in the `<var>` parameter.

  The `<path>` value may be any of these:

  - absolute path to a node, like '/foo/bar'
  - a node alias, like 'my-alias'
  - a node alias followed by a path to a child node, like 'my-alias/child-node'

  Results can be:

  - The base address of the register block
  - `<var>` will be undefined if node does not exists or does not have a register block at the requested index or with the requested name

  `<var>`
  : Return variable where the address value will be stored

  `PATH <path>`
  : Node path

  `INDEX <idx>`
  : Register block index number

  `NAME <name>`
  : Register block name

  `TARGET <target>`
  : Optional target to retrieve devicetree information from

`dt_reg_size(<var> PATH <path> [INDEX <idx>] [NAME <name>] [TARGET <target>])`

Get the size of the register block at index <idx>, or with name <name>. If <idx> and <name> are both omitted, the value at index 0 will be returned. Do not give both <idx> and <name>.

The value will be returned in the <value> parameter.

The <path> value may be any of these:

- absolute path to a node, like '/foo/bar'
- a node alias, like 'my-alias'
- a node alias followed by a path to a child node, like 'my-alias/child-node'

<var>
Return variable where the size value will be stored

PATH <path>
Node path

INDEX <idx>
Register block index number

NAME <name>
Register block name

TARGET <target>
Optional target to retrieve devicetree information from

`dt_has_chosen(<var> PROPERTY <prop> [TARGET <target>])`

Test if the devicetree's /chosen node has a given property <prop> which contains the path to a node.

The result of the check, either TRUE or FALSE, will be stored in the <var> parameter.

<var>
Return variable

PROPERTY <prop>
Chosen property

TARGET <target>
Optional target to retrieve devicetree information from

Example devicetree fragment:

```
chosen {
        foo = &bar;
};
```

Example usage:

```
# Sets 'result' to TRUE
dt_has_chosen(result PROPERTY "foo")

# Sets 'result' to FALSE
dt_has_chosen(result PROPERTY "baz")
```

`dt_chosen(<var> PROPERTY <prop> [TARGET <target>])`

Get a node path for a /chosen node property.

The node's path will be returned in the <var> parameter. The variable will be left undefined if the chosen node does not exist.

<var>
Return variable where the node path will be stored

PROPERTY <prop>
: Chosen property

TARGET <target>
: Optional target to retrieve devicetree information from

*_if_dt_node This section is similar to the extensions named *_ifdef, except actions are performed if the devicetree contains some node. *_if_dt_node functions may be added as needed, or if they are likely to be useful for user applications.

target_sources_if_dt_node(<path> <target> <scope> <item>...)
: Add item(s) to a target's SOURCES list if a devicetree node exists.

  <path>
  : Path to devicetree node to check

  <target>
  : Build system target whose sources to add to

  <scope>
  : Scope to add items to

  <item>
  : Item (or items) to add to the target

  Example usage:

```
# If the devicetree alias "led0" refers to a node, this
# adds "blink_led.c" to the sources list for the "app" target.
target_sources_if_dt_node("led0" app PRIVATE blink_led.c)

# If the devicetree path "/soc/serial@4000" is a node, this
# adds "uart.c" to the sources list for the "lib" target,
target_sources_if_dt_node("/soc/serial@4000" lib PRIVATE uart.c)
```

zephyr_dt_* The following methods are common code for dealing with devicetree related files in CMake.

Note that functions related to accessing the *contents* of the devicetree belong in section 4.1. This section is just for DT file processing at configuration time.

zephyr_dt_preprocess(CPP <path> [<argument...>] SOURCE_FILES <file...>␣
OUT_FILE <file> [DEPS_FILE <file> [EXTRA_CPPFLAGS <flag...>]␣
[INCLUDE_DIRECTORIES <dir...>] [WORKING_DIRECTORY <dir>])
: Preprocess one or more devicetree source files. The preprocessor symbol __DTS__ will be defined. If the preprocessor command fails, a fatal error occurs.

  Mandatory arguments:

  CPP <path> [<argument...>]
  : path to C preprocessor, followed by any additional arguments

  SOURCE_FILES <file...>
  : The source files to run the preprocessor on. These will, in effect, be concatenated in order and used as the preprocessor input.

  OUT_FILE <file>
  : Where to store the preprocessor output.

  Optional arguments:

  DEPS_FILE <file>
  : If set, generate a dependency file here.

`EXTRA_CPPFLAGS <flag...>`
: Additional flags to pass the preprocessor.

`INCLUDE_DIRECTORIES <dir...>`
: Additional #include file directories.

`WORKING_DIRECTORY <dir>`
: where to run the preprocessor.

`zephyr_dt_import(EDT_PICKLE_FILE <file> TARGET <target>)`
: Parse devicetree information and make it available to CMake, so that it can be accessed by the `dt_*` CMake extensions from section 4.1.

  This requires running a Python script, which can take the output of edtlib and generate a CMake source file from it. If that script fails, a fatal error occurs.

  `EDT_PICKLE_FILE <file>`
  : Input edtlib.EDT object in pickle format

  `TARGET <target>`
  : Target to populate with devicetree properties

Zephyr linker functions

`zephyr_linker*` The following methods are for defining linker structure using CMake functions.

This allows Zephyr developers to define linker sections and their content and have this configuration rendered into an appropriate linker script based on the toolchain in use.

For example:

- ld linker scripts with GNU ld
- ARM scatter files with ARM linker.

Example usage:

```
zephyr_linker_section(
  NAME my_data
  VMA  RAM
  LMA  FLASH
)

# and to configure special input sections for the section
zephyr_linker_section_configure(
  SECTION my_data
  INPUT   "my_custom_data"
  KEEP
)
```

`zephyr_linker([FORMAT <format>] [ENTRY <entry_symbol>])`
: Zephyr linker general settings. This function specifies general settings for the linker script to be generated.

  `FORMAT <format>`
  : The output format of the linked executable.

  `ENTRY <entry_symbol>`
  : The code entry symbol.

`zephyr_linker_memory(NAME <name> START <address> SIZE <size> [FLAGS <flags>])`
: Zephyr linker memory. This function specifies a memory region for the platform in use.

> **Note**
>
> This function should generally be called with values obtained from devicetree or Kconfig.

`NAME <name>`
: Name of the memory region, for example FLASH.

`START <address>`
: Start address of the memory region. Start address can be given as decimal or hex value.

`SIZE <size>`
: Size of the memory region.

  Size can be given as decimal value, hex value, or decimal with postfix k or m. All the following are valid values: `1048576`, `0x10000`, `1024k`, `1024K`, `1m`, and `1M`.

`FLAGS <flags>`
: Flags describing properties of the memory region.

  - `r`: Read-only region
  - `w`: Read-write region
  - `x`: Executable region
  - `a`: Allocatable region
  - `i`: Initialized region
  - `l`: Same as `i`
  - `!`: Invert the sense of any of the attributes that follow

  The flags may be combined like: `rx`, `rx!w`.

`zephyr_linker_memory_ifdef(<setting> NAME <name> START <address> SIZE <size> [FLAGS <flags>])`
: Will create memory region if `<setting>` is enabled.

  `<setting>`
  : Setting to check for True value before invoking *zephyr_linker_memory()*

  See *zephyr_linker_memory()* description for other supported arguments.

`zephyr_linker_dts_section(PATH <path>)`
: Zephyr linker devicetree memory section from path.

  This function specifies an output section for the platform in use based on its devicetree configuration.

  The section will only be defined if the devicetree exists and has status okay.

  `PATH <path>`
  : Devicetree node path.

`zephyr_linker_dts_memory(PATH <path>)`

`zephyr_linker_dts_memory(NODELABEL <nodelabel>)`

`zephyr_linker_dts_memory(CHOSEN <prop>)`
: Zephyr linker devicetree memory.

  This function specifies a memory region for the platform in use based on its devicetree configuration.

  The memory will only be defined if the devicetree node or a devicetree node matching the nodelabel exists and has status okay.

Only one of PATH, NODELABEL, and CHOSEN parameters may be given.

PATH <path>
Devicetree node identifier.

NODELABEL <label>
Node label

CHOSEN <prop>
Chosen property, add memory section described by the /chosen property if it exists.

zephyr_linker_group(NAME <name> [VMA <region|group>] [LMA <region|group>] [GROUP <group>] [SYMBOL <SECTION>])

Zephyr linker group. This function specifies a group inside a memory region or another group.

The group ensures that all section inside the group are located together inside the specified group.

This also allows for section placement inside a given group without the section itself needing the precise knowledge regarding the exact memory region this section will be placed in, as that will be determined by the group setup.

Each group will define the following linker symbols:

- __*name*_start: Start address of the group
- __*name*_end: End address of the group
- __*name*_size: Size of the group

Note: <name> will be converted to lower casing for linker symbols definitions.

NAME <name>
Name of the group.

VMA <region|group>
VMA Memory region or group to be used for this group. If a group is used then the VMA region of that group will be used.

LMA <region|group>
Memory region or group to be used for this group.

GROUP <group>
Place the new group inside the existing group <group>

SYMBOL <SECTION>
Specify that start symbol of the region should be identical to the start address of the first section in the group.

Note: VMA and LMA are mutual exclusive with GROUP

Example:

```
zephyr_linker_memory(NAME memA START ... SIZE ... FLAGS ...)
zephyr_linker_group(NAME groupA LMA memA)
zephyr_linker_group(NAME groupB LMA groupA)
```

will create two groups in same memory region as groupB will inherit the LMA from groupA:

```
+-----------------+
| memory region A |
|                 |
| +-------------+ |
| | groupA      | |
| +-------------+ |
```

(continues on next page)

(continued from previous page)

```
|                 |
| +-------------+ |
| | groupB      | |
| +-------------+ |
|                 |
| +-------------+ |
```

whereas

```
zephyr_linker_memory(NAME memA START ... SIZE ... FLAGS ...)
zephyr_linker_group(NAME groupA LMA memA)
zephyr_linker_group(NAME groupB GROUP groupA)
```

will create groupB inside groupA:

```
+---------------------+
| memory region A     |
|                     |
| +-----------------+ |
| | groupA          | |
| |                 | |
| | +-------------+ | |
| | | groupB      | | |
| | +-------------+ | |
| |                 | |
| +-----------------+ |
|                     |
+---------------------+
```

zephyr_linker_section(NAME <name> [GROUP <group>] [VMA <region|group>]
[LMA <region|group>] [ADDRESS <address>] [ALIGN <alignment>]
[SUBALIGN <alignment>] [FLAGS <flags>] [MIN_SIZE <size>] [MAX_SIZE <size>]
[HIDDEN] [NOINPUT] [NOINIT] [PASS [NOT] <name>...])

Zephyr linker output section. This function specifies an output section for the linker.

When using `zephyr_linker_section(NAME <name>)` an output section with `<name>` will be configured. This section will default include input sections of the same name, unless `NOINPUT` is specified. This means the section named `foo` will default include the sections matching `foo` and `foo.*` Each output section will define the following linker symbols:

- `__name_start`: Start address of the section
- `__name_end`: End address of the section
- `__name_size`: Size of the section
- `__name_load_start`: Load address of the section, if VMA = LMA then this value will be identical to `__name_start`

The location of the output section can be controlled using LMA, VMA, and address parameters

NAME <name>
Name of the output section.

VMA <region|group>
VMA Memory region or group where code / data is located runtime (VMA) If `<group>` is used here it means the section will use the same VMA memory region as `<group>` but will not be placed inside the group itself, see also `GROUP` argument.

KVMA <region|group>
Kernel VMA Memory region or group where code / data is located runtime (VMA) When

MMU is active and Kernel VM base and offset is different from SRAM base and offset, then the region defined by KVMA will be used as VMA. If <group> is used here it means the section will use the same VMA memory region as <group> but will not be placed inside the group itself, see also GROUP argument.

LMA <region|group>
: Memory region or group where code / data is loaded (LMA) If VMA is different from LMA, the code / data will be loaded from LMA into VMA at bootup, this is usually the case for global or static variables that are loaded in rom and copied to ram at boot time. If <group> is used here it means the section will use the same LMA memory region as <group> but will not be placed inside the group itself, see also GROUP argument.

GROUP <group>
: Place this section inside the group <group>

ADDRESS <address>
: Specific address to use for this section.

ALIGN_WITH_INPUT
: The alignment difference between VMA and LMA is kept intact for this section.

ALIGN <alignment>
: Align the execution address with alignment.

SUBALIGN <alignment>
: Align input sections with alignment value.

ENDALIGN <alignment>
: Align the end so that next output section will start aligned. This only has effect on Scatter scripts.

Note: Regarding all alignment attributes. Not all linkers may handle alignment in identical way. For example the Scatter file will align both load and execution address (LMA and VMA) to be aligned when given the ALIGN attribute.

MIN_SIZE <size>
: Pad section so that it at least <size> bytes in size.

MAX_SIZE <size>
: Check that the sections is not larger than <size> bytes.

NOINPUT
: No default input sections will be defined, to setup input sections for section <name>, the corresponding *zephyr_linker_section_configure()* must be used.

PASS [NOT] <name>...
: Linker pass where this section should be active. By default a section will be present during all linker passes.

  PASS <p1> <p2>... makes the section present only in the given passes. Empty list means no passes.

  PASS NOT <p1> <p2>... makes the section present in all but the given passes. Empty list means all passes.

TYPE <type>
: Tag section for special treatment.

  - NOLOAD, BSS - Ensure that the section is NOLOAD
  - LINKER_SCRIPT_FOOTER - One single section to be generated last

Note: VMA and LMA are mutual exclusive with GROUP

```
zephyr_linker_section_ifdef(<setting> NAME <name> [GROUP <group>]␣
[VMA <region|group>] [LMA <region|group>] [ADDRESS <address>] [ALIGN <alignment>]␣
[SUBALIGN <alignment>] [FLAGS <flags>] [MIN_SIZE <size>] [MAX_SIZE <size>]␣
[HIDDEN] [NOINPUT] [NOINIT] [PASS [NOT] <name>...])
```

Will create an output section if <setting> is enabled.

<setting>
Setting to check for True value before invoking *zephyr_linker_section()*

See *zephyr_linker_section()* description for other supported arguments.

zephyr_iterable_section(NAME <name> [GROUP <group>]
[VMA <region|group>] [LMA <region|group>] [ALIGN_WITH_INPUT] [SUBALIGN <alignment>])

Define an output section which will set up an iterable area of equally-sized data structures. For use with STRUCT_SECTION_ITERABLE. Input sections will be sorted by name in lexicographical order.

Each list for an input section will define the following linker symbols:

- _<name>_list_start: Start of the iterable list
- _<name>_list_end: End of the iterable list

The output section will be named <*name*>_*area* and define the following linker symbols:

Symbol	Description
__*name*_area_start	Start address of the section
__*name*_area_end	End address of the section
__*name*_area_size	Size of the section
__*name*_area_load_	Load address of the section, if VMA = LMA then this value will be identical to __*name*_area_start

The options are:

NAME <name>
Name of the struct type, the output section be named accordingly as: <name>_area.

VMA <region|group>
VMA Memory region where code / data is located runtime (VMA)

LMA <region|group>
Memory region where code / data is loaded (LMA) If VMA is different from LMA, the code / data will be loaded from LMA into VMA at bootup, this is usually the case for global or static variables that are loaded in rom and copied to ram at boot time.

GROUP <group>
Place this section inside the group <group>

ADDRESS <address>
Specific address to use for this section.

ALIGN_WITH_INPUT
The alignment difference between VMA and LMA is kept in tact for this section.

NUMERIC
Use numeric sorting.

SUBALIGN <alignment>
Force input alignment with size <alignment>

Note

Regarding all alignment attributes. Not all linkers may handle alignment in identical way. For example the Scatter file will align both load and execution address (LMA and VMA) to be aligned when given the ALIGN attribute.

`zephyr_linker_section_obj_level(SECTION <section> LEVEL <level>)`

Generate a symbol to mark the start of the objects array for the specified object and level, then link all of those objects (sorted by priority). Ensure the objects aren't discarded if there is no direct reference to them.

This is useful content such as struct devices.

For example: `zephyr_linker_section_obj_level(SECTION init LEVEL PRE_KERNEL_1)` will create an input section matching `.z_init_PRE_KERNEL_P_1_SUB_?_`, `.z_init_PRE_KERNEL_P_1_SUB_??_`, and `.z_init_PRE_KERNEL_P_1_SUB_???_`.

`SECTION <section>`
Section in which the objects shall be placed

`LEVEL <level>`
Priority level, all input sections matching the level will be sorted.

`zephyr_linker_section_configure(SECTION <section> [ALIGN <alignment>] [PASS [NOT] <name>] [PRIO <no>] [SORT <sort>] [MIN_SIZE <size>] [MAX_SIZE <size>] [ANY] [FIRST] [KEEP] [INPUT <input>] [SYMBOLS [<start> [<end>]]])`

Configure an output section with additional input sections. An output section can be configured with additional input sections besides its default section. For example, to add the input section `foo` to the output section bar, with `KEEP` attribute, call: `zephyr_linker_section_configure(SECTION bar INPUT foo KEEP)`

`SECTION <section>`
The output section to configure

`ALIGN <alignment>`
Will align the input section placement inside the load region with `<alignment>`

`FIRST`
The first input section in the list should be marked as first section in output.

`SORT <NAME>`
Sort the input sections according to `<type>`. Currently only `NAME` is supported.

`MIN_SIZE <size>`
Pad section so that it at least `<size>` bytes in size.

`MAX_SIZE <size>`
Check that the sections is not larger than `<size>` bytes.

`KEEP`
Do not eliminate input section during linking

`PRIO`
The priority of the input section. Per default, input sections order is not guaranteed by all linkers, but using priority Zephyr CMake linker will create sections such that order can be guaranteed. All unprioritized sections will internally be given a CMake process order priority counting from 100, so first unprioritized section is handled internal prio 100, next 101, and so on. To ensure a specific input section come before those, you may use `PRIO 50`, `PRIO 20` and so on. To ensure an input section is at the end, it is advised to use `PRIO 200` and above.

`PASS [NOT] <pass>...`
Control in which linker passes this piece is present See *zephyr_linker_section()* PASS for details.

`FLAGS <flags>`
Special section flags such as "+RO", +XO, "+ZI". The FLAGS and ANY arguments only has effect for scatter files.

`ANY`
ANY section flag in scatter file. The FLAGS and ANY arguments only has effect for scatter files.

`INPUT <input>`
: Input section name or list of input section names. `<input>` is either just a section name ".data*" or `<file-pattern>(<section-patterns>... )` `<file-pattern>` is `[library.a:]file` e.g. `foo.a:bar.o(.data*)`

`SYMBOLS <start> <end>`
: Generate start and end symbols for the input section.

`zephyr_linker_symbol(SYMBOL <name> EXPR <expr>)`
: Add additional user defined symbol to the generated linker script.

`SYMBOL <name>`
: Symbol name to be available.

`EXPR <expr>`
: Expression that defines the symbol. Due to linker limitations all expressions should only contain simple math, such as `+`, `-`, `*` and similar. The expression will go directly into the linker, and all `@<symbol>@` will be replaced with the referred symbol.

Example:
: To create a new symbol `bar` pointing to the start VMA address of section `foo` + 1024, one can write:

```
zephyr_linker_symbol(SYMBOL bar EXPR "(@foo@ + 1024)")
```

`zephyr_linker_include_generated((CMAKE | KCONFIG | HEADER) <name> [PASS [NOT] <pass>...])`
: Add file that is generated at build-time to be included when running the linker script generator.

`CMAKE <name>`
: includes the given cmake file

`KCONFIG <name>`
: import_kconfig() the given Kconfig file. gives `@variable@` access to all the CONFIG_FOO settings

`HEADER <name>`
: finds all #define FOO value in name. Plain regex, no proper preprocessing.

`PASS [NOT] <pass>...`
: Rule for which PASSES to include file. see *zephyr_linker_section()* PASS

`zephyr_linker_include_var(VAR <name> [VALUE <value>] [PASS [NOT] <pass>...])`
: Save the value of `<name>` for when the generator is running at build-time. If `VALUE` isn't set, the current value of the variable is used.

`VAR <name>`
: Variable to be set

`VALUE <value>`
: The value

`PASS [NOT] <pass>...`
: Rule for which PASSES to include variable see *zephyr_linker_section()* PASS for details.

`zephyr_linker_generate_linker_settings_file(<file_name>)`
: Generate a file for the settings to the linker file generator script.

`<file_name>`
: File to be created

Function helper macros Set of CMake macros to facilitate argument processing when defining functions.

`zephyr_check_arguments_required(<function_name> <prefix> <arg1> [<arg2> ...])`

Helper macro for verifying that at least one of the required arguments has been provided by the caller.

A `FATAL_ERROR` will be raised if not one of the required arguments has been passed by the caller.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<prefix>`
Prefix used in `cmake_parse_arguments`, usually `arg` or the function name in uppercase.

`<arg>`
One or more arguments to check.

`zephyr_check_arguments_required_allow_empty(<function_name> <prefix> <arg1> [<arg2> ...])`

Helper macro for verifying that at least one of the required arguments has been provided by the caller. Arguments with empty values are allowed.

A `FATAL_ERROR` will be raised if not one of the required arguments has been passed by the caller.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<prefix>`
Prefix used in `cmake_parse_arguments`, usually `arg` or the function name in uppercase.

`<arg>`
One or more arguments to check.

`zephyr_check_flags_required(<function_name> <prefix> <flag1> [<flag2> ...])`

Helper macro for verifying that at least one of the required flags has been provided by the caller.

A `FATAL_ERROR` will be raised if not one of the required arguments has been passed by the caller.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<prefix>`
Prefix used in `cmake_parse_arguments`, usually `arg` or the function name in uppercase.

`<flag>`
One or more flags to check.

`zephyr_check_arguments_required_all(<function_name> <prefix> <arg1> [<arg2> ...])`

Helper macro for verifying that all the required arguments have been provided by the caller.

A `FATAL_ERROR` will be raised if one of the required arguments is missing.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<prefix>`
Prefix used in `cmake_parse_arguments`, usually `arg` or the function name in uppercase.

`<arg>`
One or more arguments to check.

`zephyr_check_arguments_exclusive(<function_name> <prefix> <arg1> <arg2> [<arg3> ...])`

Helper macro for verifying that none of the mutual exclusive arguments are provided together.

A `FATAL_ERROR` will be raised if any of the arguments are given together.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<prefix>`
Prefix used in `cmake_parse_arguments`, usually `arg` or the function name in uppercase.

`<arg>`
One or more arguments to check.

`zephyr_check_flags_exclusive(<function_name> <prefix> <flag1> <flag2> [<flag3> ...])`

Helper macro for verifying that none of the mutual exclusive flags are provided together.

A `FATAL_ERROR` will be raised if any of the flags are given together.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<prefix>`
Prefix used in `cmake_parse_arguments`, usually `arg` or the function name in uppercase.

`<flag>`
One or more flags to check.

`zephyr_check_no_arguments(<function_name> <arg1> [<arg2> ...])`

Helper macro for verifying that no unexpected arguments are provided.

A `FATAL_ERROR` will be raised if any unexpected argument is given.

`<function_name>`
Name of the function the check is performed for. Used in error message generation.

`<arg>`
One or more arguments to check.

Linkable loadable extensions (llext) These functions simplify the creation and management of *Linkable Loadable Extensions (LLEXT)*.

Configuration functions The following functions simplify access to the compilation/link stage properties of an llext using the same API as CMake's `target_*` functions.

`llext_compile_definitions(target_name <defs>...)`

Add compile definitions to the llext target.

`target_name`
Name of the llext target.

`<defs>`
Arguments passed to `target_compile_definitions`.

`llext_compile_features(target_name <features>...)`

Add compile features to the llext target.

`target_name`
Name of the llext target.

`<features>`
Arguments passed to `target_compile_features`.

`llext_compile_options(target_name <options>...)`

Add compile options to the llext target.

`target_name`
Name of the llext target.

`<options>`
Arguments passed to `target_compile_options`.

`llext_include_directories(target_name <dirs>...)`

Add include directories to the llext target.

`target_name`
Name of the llext target.

`<dirs>`
Arguments passed to `target_include_directories`.

`llext_link_options(target_name <options>...)`

Add link options to the llext target.

`target_name`
Name of the llext target.

`<options>`
Arguments passed to `target_link_options`.

Build control functions The following functions add targets and subcommands to the build system to compile and link an llext.

`add_llext_target(target_name OUTPUT <output_file> SOURCES <source_files>)`

Add a custom target that compiles a set of source files to a .llext file.

Output and source files must be specified using the `OUTPUT` and `SOURCES` arguments. Only one source file is supported when `CONFIG_LLEXT_TYPE_ELF_OBJECT` is selected, since there is no linking step in that case.

The llext code will be compiled with mostly the same C compiler flags used in the Zephyr build, but with some important modifications. The list of flags to remove and flags to append is controlled respectively by the *`LLEXT_REMOVE_FLAGS`* and *`LLEXT_APPEND_FLAGS`* global variables.

The following custom properties of `target_name` are defined and can be retrieved using the `get_target_property` function:

- `lib_target`: Target name for the source compilation and/or link step.
- `lib_output`: The binary file resulting from compilation and/or linking steps.
- `pkg_input`: The file to be used as input for the packaging step.
- `pkg_output`: The final .llext file.

Example usage:

```
add_llext_target(hello_world
  OUTPUT  ${PROJECT_BINARY_DIR}/hello_world.llext
  SOURCES ${PROJECT_SOURCE_DIR}/src/llext/hello_world.c
)
```

This will compile the source file `src/llext/hello_world.c` to a file named *`$PROJECT_BINARY_DIR`*`/hello_world.llext`.

`add_llext_command(TARGET <target_name> PRE_BUILD <command> [...])`

`add_llext_command(TARGET <target_name> POST_BUILD <command> [...])`

`add_llext_command(TARGET <target_name> POST_PKG <command> [...])`

Add a custom command to an llext target that will be executed during the build. The command will be executed at the specified build step and can refer to `<target>`'s properties for build-specific details.

The different build steps are:

`PRE_BUILD`
: Before the llext code is linked, if the architecture uses dynamic libraries. This step can access `lib_target` and its own properties.

`POST_BUILD`
: After the llext code is built, but before packaging it in an .llext file. This step is expected to create a `pkg_input` file by reading the contents of `lib_output`.

`POST_PKG`
: After the .llext file has been created. This can operate on the final llext file `pkg_output`.

Anything else after `COMMAND` will be passed to `add_custom_command` as-is (including multiple commands and other options).

kconfig

This module contains the Kconfig configuration logic.

It provides the following targets:

- `menuconfig`: Run the Kconfig menuconfig tool.
- `guiconfig`: Run the Kconfig guiconfig tool.
- `hardenconfig`: Run the Kconfig hardenconfig tool.
- `traceconfig`: Run the Kconfig traceconfig tool.

Variables After loading this module, the following global variables are defined:

`KCONFIG_ROOT`
: Path to the Kconfig root file. Default: `${ZEPHYR_BASE}/Kconfig`.

`AUTOCONF_H`
: Path to the generated autoconf header file. Default: `${PROJECT_BINARY_DIR}/include/generated/zephyr/autoconf.h`.

`DOTCONFIG`
: Path to the generated .config file. Default: `${PROJECT_BINARY_DIR}/.config`.

`EXTRA_KCONFIG_TARGETS`
: List of extra Kconfig targets to add.

`EXTRA_KCONFIG_TARGET_COMMAND_FOR_<target>`
: Command to run for the extra Kconfig target.

The Kconfig fragments this module reads are selected by *CONF_FILE* and *EXTRA_CONF_FILE*, which are resolved by the *configuration_files* module.

5.2.2 Sysbuild Modules

sysbuild_extensions

Sysbuild's CMake extension commands.

This module defines the commands used to describe a *sysbuild* configuration: which images take part in the build, how they are configured, and in which order they are configured and flashed.

The commands documented below are available in the `sysbuild.cmake` file of any application or Zephyr module that participates in a sysbuild build.

Commands not documented here are used by sysbuild itself and may be removed, renamed, or re-purposed without prior notice.

- *Setting Kconfig values on an image*

sysbuild_get(<variable> IMAGE <image> [VAR <image-variable>] <KCONFIG|CACHE>)

Read a CMake cache variable or Kconfig setting from an image.

Sysbuild can only read an image once that image has been configured, for example from the post-CMake hook of a *sysbuild module*.

If `VAR` is provided, the name given as parameter will be looked up, but if `VAR` is not given, the `<variable>` name provided will be used both for lookup and value return.

The result will be returned in `<variable>`.

<variable>
Variable used for returning the value. Also used as lookup variable if `VAR` is not provided.

IMAGE <image>
Name of the image to read the variable from.

VAR <image-variable>
Name of the variable to look up.

KCONFIG
Flag indicating that a Kconfig setting should be fetched.

CACHE
Flag indicating that a CMake cache variable should be fetched.

Example usage:

```
# Look up PROJECT_NAME from the CMake cache of `my_sample` and return it
# in the local variable `PROJECT_NAME`.
sysbuild_get(PROJECT_NAME IMAGE my_sample CACHE)

# Same lookup, but returned in `my_sample_PROJECT_NAME`.
sysbuild_get(my_sample_PROJECT_NAME IMAGE my_sample VAR PROJECT_NAME CACHE)

# Look up the Kconfig setting CONFIG_FOO of `my_sample`.
sysbuild_get(my_sample_CONFIG_FOO IMAGE my_sample VAR CONFIG_FOO KCONFIG)
```

ExternalZephyrProject_Add(APPLICATION <name> SOURCE_DIR <dir>␣
[BOARD <board> [BOARD_REVISION <revision>]]␣
[APP_TYPE <MAIN|BOOTLOADER|FIRMWARE_LOADER>] [BUILD_ONLY <bool>])

Include a Zephyr based build system into the multi-image build system.

APPLICATION <name>
Name of the application. The name will also be used for the build folder of the application.

SOURCE_DIR <dir>
Source directory of the application.

BOARD <board>
Use `<board>` for the application build instead of the user defined *BOARD*.

`BOARD_REVISION <revision>`
: Use `<revision>` of `<board>` for the application. Only valid if `BOARD` is also supplied.

`APP_TYPE <MAIN|BOOTLOADER|FIRMWARE_LOADER>`
: Application type.

  `MAIN` indicates this application is the main application, and where user defined settings should be passed on as-is except for multi image build flags. For example, `-DCONF_FILE=<files>` will be passed on to the main application unmodified.

  `BOOTLOADER` indicates this application is a bootloader.

  `FIRMWARE_LOADER` indicates this application is a firmware loader image for MCUboot.

`BUILD_ONLY <bool>`
: Mark the application as build-only. If `<bool>` evaluates to true, then this application will be excluded from flashing and debugging.

See *Adding Zephyr applications to sysbuild* for a worked example.

`ExternalZephyrVariantProject_Add(APPLICATION <name> SOURCE_APP <name> [SNIPPET <snippet>] [EXTRA_DTC_OVERLAY_FILE <file>] [EXTRA_CONF_FILE <file>] [BUILD_ONLY <bool>] )`

Duplicate an existing Zephyr based build system into the multi-image build system with a specified modification.

This will not create the extra build targets that *`ExternalZephyrProject_Add()`* adds, for example `<app>_menuconfig`.

> **Note**
>
> The variant image must have a *`CONF_FILE`*, *`EXTRA_CONF_FILE`*, *`EXTRA_DTC_OVERLAY_FILE`* or `SNIPPET` added to it, or it will be invalid and image configuration will result in a fatal error.

`APPLICATION <name>`
: Name of the application. The name will also be used for the build folder of the application.

`SOURCE_APP <name>`
: Name of the existing image to use for duplication.

`SNIPPET <snippet>`
: List of default snippets to apply for the variant image.

`EXTRA_DTC_OVERLAY_FILE <file>`
: List of default extra devicetree overlay files to apply for the variant image.

`EXTRA_CONF_FILE <file>`
: List of default extra Kconfig fragments to apply for the variant image.

`BUILD_ONLY <bool>`
: Mark the application as build-only. If `<bool>` evaluates to true, then this application will be excluded from flashing and debugging.

`sysbuild_cache_set(VAR <variable> [APPEND [REMOVE_DUPLICATES]] <value>)`

Set a sysbuild cache variable, which can then be accessed by images.

The result will be returned in `<variable>`.

`VAR <variable>`
: Name of the variable in the CMake cache.

`APPEND`
: If specified, append the supplied data to the existing value as a list.

REMOVE_DUPLICATES
: If specified, remove duplicate entries contained within the list before saving to the cache.

<value>
: Value to set or update.

Example usage:

```
# Add `battery` to the `ATTRIBUTES` list in the CMake cache, removing
# any duplicates from the list.
sysbuild_cache_set(VAR ATTRIBUTES APPEND REMOVE_DUPLICATES battery)
```

Setting Kconfig values on an image The following commands add a Kconfig fragment line to <image>. They are the supported way for a sysbuild.cmake file to configure an image it has added.

The collected fragment is passed to the image as a forced input configuration, so it is applied last and takes precedence over the image's own Kconfig fragments. See *Kconfig namespacing* for how these relate to SB_CONFIG_ options.

set_config_bool(<image> <setting> <value>)
: Set a boolean Kconfig option to y if <value> evaluates to true, and to n otherwise.

set_config_string(<image> <setting> <value>)
: Set a string Kconfig option to <value>.

set_config_int(<image> <setting> <value>)
: Set an int or hex Kconfig option to <value>.

Example usage:

```
set_config_bool(${DEFAULT_IMAGE} CONFIG_BOOTLOADER_MCUBOOT y)
set_config_string(${DEFAULT_IMAGE} CONFIG_MCUBOOT_SIGNATURE_KEY_FILE "$
↪{keyfile}")
set_config_int(mcuboot CONFIG_LOG_MAX_LEVEL 2)
```

sysbuild_add_subdirectory(<source_dir> [<binary_dir>])
: Add a subdirectory, and recursively process the sysbuild images it adds.

  This command extends add_subdirectory with additional, recursive processing of the sysbuild images added via <source_dir>.

  After exiting <source_dir>, this command will take every image added so far and include() its sysbuild.cmake file, if found. If more images get added at this stage, their sysbuild.cmake files will be included as well, and so on. This continues until all expected images have been added, before returning.

sysbuild_add_dependencies(<CONFIGURE | FLASH> <image> [<image-dependency> ...])
: Make an image depend on other images in the configuration or flashing order.

  Each image named <image-dependency> will be ordered before the image named <image>.

  CONFIGURE
  : Add CMake configuration dependencies. This will determine the order in which images are configured.

  FLASH
  : Add flashing dependencies. This will determine the order in which all images will appear in domains.yaml.

  See *Adding dependencies among Zephyr applications* for a worked example.

`sysbuild_images_order(<variable> <CONFIGURE | FLASH> IMAGES <images>)`

Sort the provided <images> to satisfy the dependencies specified using *sysbuild_add_dependencies()*.

The result will be returned in <variable>.

sysbuild_kconfig

Sysbuild's own Kconfig configuration.

Sysbuild has a Kconfig tree of its own, rooted at the application's `Kconfig.sysbuild` file and namespaced under `SB_CONFIG_` so that it cannot collide with an image's own `CONFIG_` options. See *Kconfig namespacing*.

This module locates the sysbuild configuration files and runs Kconfig over them. It also defines the `sysbuild_menuconfig` and `sysbuild_guiconfig` build targets, which edit sysbuild's own configuration rather than that of any image.

Configuration input files are looked up in *SB_APPLICATION_CONFIG_DIR*, falling back to *APPLICATION_CONFIG_DIR*, and are controlled by:

- *SB_CONF_FILE*
- *SB_EXTRA_CONF_FILE*

sysbuild_root

Convert Zephyr roots to absolute paths to be used by sysbuild.

This module converts all relative paths in the following root lists to absolute paths, relative from *APP_DIR*:

- *ARCH_ROOT*
- *BOARD_ROOT*
- *MODULE_EXT_ROOT*
- *SCA_ROOT*
- *SNIPPET_ROOT*
- *SOC_ROOT*

If a root is defined, this module checks the list of paths in the root, converts any relative path to an absolute path, and updates the root list. If a root is undefined, it is still undefined once this module has loaded.

Converted paths are placed in the CMake cache so that they are propagated correctly to image builds.

native_simulator_sb_extensions

Sysbuild extension commands for native_sim based targets.

These commands are used by the `sysbuild.cmake` file of a board or application that builds several images into a single native simulator executable. They are no-ops unless the board target is a native simulator or bsim based one.

`native_simulator_set_final_executable(<final_image>)`

Add a build target which copies the executable produced by `<final_image>` to the top level, as `zephyr/zephyr.exe`.

`<final_image>` is expected to have been set to assemble other dependent images into itself if necessary, by calling *native_simulator_set_child_images()*.

This allows other tools, like twister or the bsim test scripts, as well as users, to find this final executable in the same place as for non-sysbuild builds.

`native_simulator_set_child_images(<final_image> <child_image>)`
: Set `<child_image>` as a dependency of `<final_image>`, and configure the final image to assemble the child image into its final executable.

`native_simulator_set_primary_mcu_index(<image> [<image2> ...])`
: Propagate the `SB_CONFIG_NATIVE_SIMULATOR_PRIMARY_MCU_INDEX` setting, if it is set, to the `CONFIG_NATIVE_SIMULATOR_PRIMARY_MCU_INDEX` of each given image.

5.2.3 Utility & Tooling Modules

doc

This CMake module will load all Zephyr CMake modules required for a documentation build.

The following CMake modules will be loaded:

- *extensions*
- *python*
- *west*
- root
- zephyr_module

Outcome: The Zephyr package required for documentation build setup.

python

Configure Python for use in Zephyr build system.

This module finds and configures Python for use in the Zephyr build system. It ensures a compatible Python version is available and sets up necessary environment variables and CMake variables.

Variables The *PYTHON_MINIMUM_REQUIRED* variable is used to specify the minimum required Python version.

The following variables will be defined when this CMake module completes:

- *PYTHON_EXECUTABLE*

Search Process The module searches for Python in the following order:

1. Using the `Python3_EXECUTABLE` if already defined
2. Using the `WEST_PYTHON` if defined
3. Searching for “python” or “python3” in the system PATH and virtual environment
4. Using CMake’s `find_package(Python3)` mechanism

The module verifies that any found Python meets the minimum version requirement.

Windows-Specific Configuration On Windows systems, the module sets the `PYTHONIOENCODING` environment variable to “utf-8” to ensure consistent encoding behavior when Python is invoked from CMake.

Example Usage

```
include(python)

# Now PYTHON_EXECUTABLE can be used to invoke Python scripts
execute_process(COMMAND ${PYTHON_EXECUTABLE} my_script.py)
```

west

This module finds and configures the `west` meta-tool for use in the Zephyr build system. It ensures that west is available and correctly configured.

Variables The following variables will be defined when this CMake module completes:

- *WEST*
- *WEST_TOPDIR*

git

Provides Git-related functionality for the Zephyr build system.

This module provides functions for interacting with Git repositories within the Zephyr build system.

Commands

git_describe

Get a short Git description associated with a directory or file.

```
git_describe(<file|dir> OUTPUT)
```

This function runs `git describe --abbrev=12 --always` on the provided directory, or if provided a file, the directory containing that file. In both cases, the result is stored in the provided output variable.

file|dir
: The directory or file to run the git command for.

OUTPUT
: The variable name where the git description will be stored. If the git command fails or Git is not found, this variable will not be set.

The function will output status messages if:

- The **git** command fails (error message)
- The **git** command produces warnings (warning message)

Example Usage

```
include(git)

git_describe(${CMAKE_CURRENT_SOURCE_DIR} GIT_DESCRIPTION)
if(DEFINED GIT_DESCRIPTION)
  message(STATUS "Git description: ${GIT_DESCRIPTION}")
endif()
```

yaml

Provides YAML file handling functionality for the Zephyr build system.

This module offers support for reading, writing, and manipulating YAML files within the Zephyr build system. It supports basic key-value pairs, nested objects, lists, and lists of maps.

Supported YAML Features The module supports the following YAML constructs:

Basic key-value pairs

```
foo: bar
```

Nested objects

```
foo:
  bar: baz
```

Simple lists

```
foos:
  - foo1
  - foo2
  - foo3
```

Lists of maps

```
foo:
  - bar: val1
    baz: val1
  - bar: val2
    baz: val2
```

Example Usage

```
include(yaml)

# Create a new YAML context
yaml_create(NAME my_yaml FILE my_file.yaml)

# Set some values
yaml_set(NAME my_yaml KEY foo VALUE bar)
yaml_set(NAME my_yaml KEY list LIST item1 item2 item3)

# Append a map to a list
yaml_set(NAME my_yaml KEY list APPEND LIST MAP "name: test, value: 42")

# Save the context to file
yaml_save(NAME my_yaml)

# my_file.yaml now contains:
#
# foo: bar
# list:
#   - item1
#   - item2
#   - item3
#   - name: test
#     value: 42
```

Commands

yaml_context

Query the status of a YAML context.

```
yaml_context(EXISTS NAME <name> <result>)
```

EXISTS
Check if the YAML context exists in the current scope. If the context exists, then TRUE is returned in `<result>`.

NAME <name>
Name of the YAML context.

<result>
Variable to store the result of the query.

yaml_create

Create a new empty YAML context.

```
yaml_create(NAME <name> [FILE <file>])
```

NAME <name>
Name of the YAML context.

FILE <file>
Path to file to be used together with this YAML context. This file will be used when *yaml_save()* is called.

yaml_load

Load an existing YAML file into a YAML context.

```
yaml_load(FILE <file> NAME <name>)
```

FILE <file>
Path to file to load.

NAME <name>
Name of the YAML context.

yaml_get

Get the value of a key from a YAML context.

```
yaml_get(<out-var> NAME <name> KEY <key>...)
```

NAME <name>
Name of the YAML context.

KEY <key>...
Name of key(s) to retrieve. Multiple keys can be specified for nested access.

<out-var>
Variable to store the retrieved value.

If the key represents a list, the list is returned. Behavior is undefined if the key points to a complex object.

yaml_length

Get the length of an array defined by a key.

```
yaml_length(<out-var> NAME <name> KEY <key>...)
```

NAME <name>
Name of the YAML context.

KEY <key>...
Name of key defining the list.

<out-var>
Variable to store the length.

Returns -1 if the key does not define an array.

yaml_set

Set a value or list of values in a YAML context.

```
yaml_set(NAME <name> KEY <key>... [GENEX] VALUE <value>)
yaml_set(NAME <name> KEY <key>... [APPEND] [GENEX] LIST <value>...)
yaml_set(NAME <name> KEY <key>... [APPEND] LIST MAP <map1> MAP <map2> MAP ...)
```

NAME <name>
Name of the YAML context.

KEY <key>...
Name of key(s) to set.

VALUE <value>
New value for the key.

LIST <values>
New list of values for the key.

APPEND
Append the list of values to the existing list.

GENEX
The value(s) contain generator expressions.

MAP <map>
Map with key-value pairs where pairs are separated by ';' and key-value by ':'. Format: "<key1>: <value1>, <key2>: <value2>, ...". Multiple MAP arguments can be given to separate maps when adding to a list. Cannot be used with GENEX.

Note: If a map value contains commas, the value must be quoted in single quotes and commas must be double escaped: `'A \\,string'`

yaml_remove

Remove a key from a YAML context.

```
yaml_remove(NAME <name> KEY <key>...)
```

NAME <name>
Name of the YAML context.

KEY <key>...
Name of key(s) to remove. Multiple keys can be specified for nested access.

yaml_save

Write a YAML context to a file.

```
yaml_save(NAME <name> [FILE <file>])
```

`NAME <name>`
: Name of the YAML context.

`FILE <file>`
: Path to file to write the context. If not given, uses the FILE property of the YAML context.

If the context uses generator expressions, keys containing them will initially be written as comments. The full contents will be available at build time. Build steps depending on the file being complete must depend on the *name*`_yaml_saved` target.

5.2.4 Target properties

LIBC_LINK_LIBRARIES

A list of libraries that are linked to the C standard library when it is built. This property is used to define additional dependencies that the C standard library may have on other libraries.

See also: *zephyr_libc_link_libraries()*.

5.2.5 Variables

ACTIVE_BOARD_REVISION

The revision of the active board.

See *boards*.

APPLICATION_CONFIG_DIR

Root folder for application configuration.

See *configuration_files*.

APP_BUILD_VERSION

This variable is used in all contexts as the build version of the application.

By default, if the application is in a Git repository, its contents are generated from the output of the command `git describe --abbrev=12 --always` run in the application folder. This results in a string which contains the most recent tag, the number of commits since that tag, and the abbreviated commit hash.

This default behavior can also be overridden by setting the CMake variable `APP_BUILD_VERSION` to the desired string value. This can either be done in the `CMakeLists.txt` file, or on the command line when invoking CMake, e.g. via `cmake -DAPP_BUILD_VERSION="v3.3.0-18-g2c85d92" ...`

Input to `version` Custom application build version to use for this build, if set externally.

Output from `version` Final value of the build version of the application: either the value of `APP_BUILD_VERSION`, if set, or the value generated from the Git repository.

See *Application version management* for details; see also *BUILD_VERSION*.

APP_DIR

Source directory of the main application in a sysbuild build.

Set from the `-DAPP_DIR=<path>` build option or the matching environment variable. Sysbuild resolves the sysbuild configuration files and root lists relative to this directory.

See *Sysbuild (System build)*.

ARCH

Name of the architecture in use.

See *arch*.

ARCH_DIR

Directory containing the architecture implementation.

See *arch*.

ARCH_ROOT

List of directories containing architecture implementations. This variable is updated to include *ZEPHYR_BASE* appended.

See *arch*.

BOARD

Input to *boards* Board name, including any optional revision field, for example: `foo` or `foo@1.0.0`.

Output from *boards* Board name, without revision field.

See *boards*.

BOARD_DIR

Board directory with the implementation for selected board.

See *boards*.

BOARD_QUALIFIERS

Board qualifiers.

See *boards*.

BOARD_REVISION

Board revision.

See *boards*.

BOARD_ROOT

Input to *boards* List of directories containing board implementations.

Output from *boards* List of directories containing board implementations. This variable is updated to include *ZEPHYR_BASE* appended.

See *boards*.

BSIM_COMPONENTS_PATH

Path to the BabbleSim components source folder.

See *BabbleSim*.

BSIM_OUT_PATH

Path to the BabbleSim build output root path (under which libraries and binaries are kept).

See *BabbleSim*.

BUILD_VERSION

This variable is used in all contexts as the build version of the Zephyr kernel.

By default, if the Zephyr project is in a Git repository and the `git` tool is available, its contents are generated from the output of the command `git describe --abbrev=12 --always` run in the Zephyr folder. This results in a string which contains the most recent tag, the number of commits since that tag, and the abbreviated commit hash.

This default behavior can also be overridden by setting the CMake variable `BUILD_VERSION` to the desired string value. This can either be done in the `CMakeLists.txt` file, or on the command line when invoking CMake, e.g. via `cmake -DBUILD_VERSION="v3.3.0-18-g2c85d92" ...`

Input to `version` Custom Zephyr build version to use for this build, if set externally.

Output from `version` Final value of the build version of the Zephyr project: either the value of `BUILD_VERSION`, if already set, or the value generated from the Git repository.

See also *APP_BUILD_VERSION*.

CONF_FILE

List of Kconfig fragments.

See *configuration_files*.

DEFAULT_IMAGE

Name of the main application image in a sysbuild build.

This is the image added with `APP_TYPE MAIN`, and the one reported as the default domain in `domains.yaml`. Use it from a `sysbuild.cmake` file to refer to the main image without hardcoding its name.

See *ExternalZephyrProject_Add()*.

DTC_OVERLAY_FILE

List of devicetree overlay files.

See *configuration_files*.

DTS_EXTRA_CPPFLAGS

List of additional devicetree preprocessor defines.

See *configuration_files*.

EXTRA_CONF_FILE

List of additional Kconfig fragments.

See *configuration_files*.

EXTRA_DTC_OVERLAY_FILE

List of additional devicetree overlay files.

See *configuration_files*.

LLEXT_APPEND_FLAGS

Global list of compiler flags to be added to compiler invocations when compiling extensions. Target and compiler dependent, usually set in toolchain files.

See *add_llext_target()*.

LLEXT_REMOVE_FLAGS

Global list of regular expressions describing compiler flags to be removed from compiler invocations when compiling extensions. Target and compiler dependent, usually set in toolchain files.

See *add_llext_target()*.

MODULE_EXT_ROOT

List of directories containing module external roots, which hold the CMake and Kconfig glue code for Zephyr modules that do not carry it themselves.

See *sysbuild_root* for how sysbuild resolves this variable for image builds.

NORMALIZED_BOARD_QUALIFIERS

Board qualifiers in lower-case format where slashes have been replaced with underscores.

See *boards*.

NORMALIZED_BOARD_TARGET

Board target in lower-case format where slashes have been replaced with underscores.

See *boards*.

PYTHON_EXECUTABLE

Path to the Python executable that will be used by Zephyr. This is an alias to `Python3_EXECUTABLE` for backward compatibility.

See *python*.

PYTHON_MINIMUM_REQUIRED

The minimum required Python version (currently 3.12).

See *python*.

SB_APPLICATION_CONFIG_DIR

Directory searched for sysbuild's own configuration files.

When set, it takes precedence over *APPLICATION_CONFIG_DIR* for locating *SB_CONF_FILE*.

See *sysbuild_kconfig*.

SB_CONF_FILE

Sysbuild Kconfig configuration file, or list of files.

Defaults to `sysbuild.conf` in *APPLICATION_CONFIG_DIR*, if that file exists. Sysbuild is an opt-in feature, so the file is optional.

Settings in these files override the defaults of sysbuild's own Kconfig tree. Paths are resolved relative to *APP_DIR*.

See *sysbuild_kconfig*.

SB_EXTRA_CONF_FILE

Additional sysbuild Kconfig fragment files, applied on top of *SB_CONF_FILE*.

Paths are resolved relative to *APP_DIR*.

See *sysbuild_kconfig*.

SB_SNIPPET

List of snippets to apply to the sysbuild build itself.

Defaults to the value of `SNIPPET` when that is set and `SB_SNIPPET` is not.

See *Snippets*.

SCA_ROOT

List of directories containing static code analysis tool integrations.

See *sysbuild_root* for how sysbuild resolves this variable for image builds.

SNIPPET_ROOT

List of directories searched for snippet definitions.

See *sysbuild_root* for how sysbuild resolves this variable for image builds.

SOC_ROOT

List of directories containing SoC implementations.

See *sysbuild_root* for how sysbuild resolves this variable for image builds.

USE_CCACHE

This variable can be set to `0` to explicitly disable the use of ccache, even if it is installed on the system. If set to any other value (or unset) and ccache is found on the system, it will be used for compilation and linking.

WEST

Path to the west executable.

See *west*.

WEST_PYTHON

Path to the Python interpreter used by west.

See *west*.

WEST_TOPDIR

Top-level directory of the west workspace.

See *west*.

ZEPHYR_CURRENT_LIBRARY

The name of the current Zephyr library.

5.3 Devicetree

A *devicetree* is a hierarchical data structure primarily used to describe hardware. Zephyr uses devicetree in two main ways:

- to describe hardware to the *Device Driver Model*
- to provide that hardware's initial configuration

This page links to a high level guide on devicetree as well as reference material.

5.3.1 Devicetree Guide

The pages in this section are a high-level guide to using devicetree for Zephyr development.

Introduction to devicetree

> **Tip**
>
> This is a conceptual overview of devicetree and how Zephyr uses it. For step-by-step guides and examples, see *Devicetree HOWTOs*.

The following pages introduce general devicetree concepts and how they apply to Zephyr.

Scope and purpose A *devicetree* is primarily a hierarchical data structure that describes hardware. The Devicetree specification defines its source and binary representations.

Zephyr uses devicetree to describe:

- the hardware available on its boards
- that hardware's initial configuration

As such, devicetree is both a hardware description language and a configuration language for Zephyr. See *Devicetree versus Kconfig* for some comparisons between devicetree and Zephyr's other main configuration language, Kconfig.

There are two types of devicetree input files: *devicetree sources* and *devicetree bindings*. The sources contain the devicetree itself. The bindings describe its contents, including data types. The *build system* uses devicetree sources and bindings to produce a generated C header. The generated header's contents are abstracted by the `devicetree.h` API, which you can use to get information from your devicetree.

Here is a simplified view of the process:

All Zephyr and application source code files can include and use `devicetree.h`. This includes *device drivers*, *applications*, *tests*, the kernel, etc.

The API itself is based on C macros. The macro names all start with `DT_`. In general, if you see a macro that starts with `DT_` in a Zephyr source file, it's probably a `devicetree.h` macro. The generated C header contains macros that start with `DT_` as well; you might see those in compiler

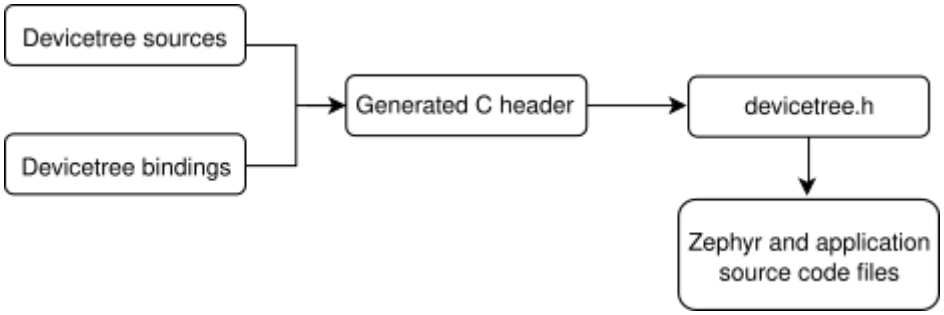


Fig. 1: Devicetree build flow

error messages. You always can tell a generated- from a non-generated macro: generated macros have some lowercased letters, while the `devicetree.h` macro names have all capital letters.

Syntax and structure As the name indicates, a devicetree is a tree. The human-readable text format for this tree is called DTS (for devicetree source), and is defined in the Devicetree specification.

This page's purpose is to introduce devicetree in a more gradual way than the specification. However, you may still need to refer to the specification to understand some detailed cases.

Contents

- *Example*
- *Nodes*
- *Properties*
- *Devicetrees reflect hardware*
- *Properties in practice*
- *Unit addresses*
- *Important properties*
- *Writing property values*
- *Aliases and chosen nodes*

Example Here is an example DTS file:

```
/dts-v1/;

/ {
        a-node {
                subnode_nodelabel: a-sub-node {
                        foo = <3>;
                };
        };
};
```

The `/dts-v1/;` line means the file's contents are in version 1 of the DTS syntax, which has replaced a now-obsolete "version 0".

Nodes Like any tree data structure, a devicetree has a hierarchy of *nodes*. The above tree has three nodes:

1. A root node: `/`
2. A node named `a-node`, which is a child of the root node
3. A node named `a-sub-node`, which is a child of `a-node`

Nodes can be assigned *node labels*, which are unique shorthands that refer to the labeled node. Above, `a-sub-node` has the node label `subnode_nodelabel`. A node can have zero, one, or multiple node labels. You can use node labels to refer to the node elsewhere in the devicetree.

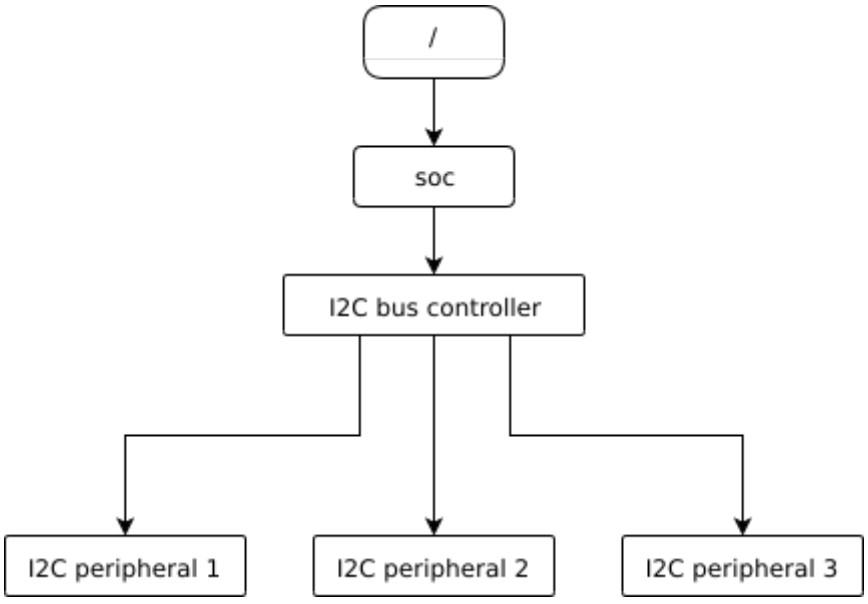
Devicetree nodes have *paths* identifying their locations in the tree. Like Unix file system paths, devicetree paths are strings separated by slashes (`/`), and the root node's path is a single slash: `/`. Otherwise, each node's path is formed by concatenating the node's ancestors' names with the node's own name, separated by slashes. For example, the full path to `a-sub-node` is `/a-node/a-sub-node`.

Properties Devicetree nodes can also have *properties*. Properties are name/value pairs. Property values can be any sequence of bytes. In some cases, the values are an array of what are called *cells*. A cell is just a 32-bit unsigned integer.

Node `a-sub-node` has a property named `foo`, whose value is a cell with value 3. The size and type of `foo`'s value are implied by the enclosing angle brackets (< and >) in the DTS.

See *Writing property values* below for more example property values.

Devicetrees reflect hardware In practice, devicetree nodes usually correspond to some hardware, and the node hierarchy reflects the hardware's physical layout. For example, let's consider a board with three I2C peripherals connected to an I2C bus controller on an SoC, like this:



Nodes corresponding to the I2C bus controller and each I2C peripheral would be present in the devicetree. Reflecting the hardware layout, the I2C peripheral nodes would be children of the bus controller node. Similar conventions exist for representing other types of hardware.

The DTS would look something like this:

```
/dts-v1/;

/ {
```

(continues on next page)

(continued from previous page)

```
        soc {
                i2c-bus-controller {
                        i2c-peripheral-1 {
                        };
                        i2c-peripheral-2 {
                        };
                        i2c-peripheral-3 {
                        };
                };
        };
};
```

Properties in practice In practice, properties usually describe or configure the hardware the node represents. For example, an I2C peripheral's node has a property whose value is the peripheral's address on the bus.

Here's a tree representing the same example, but with real-world node names and properties you might see when working with I2C devices.

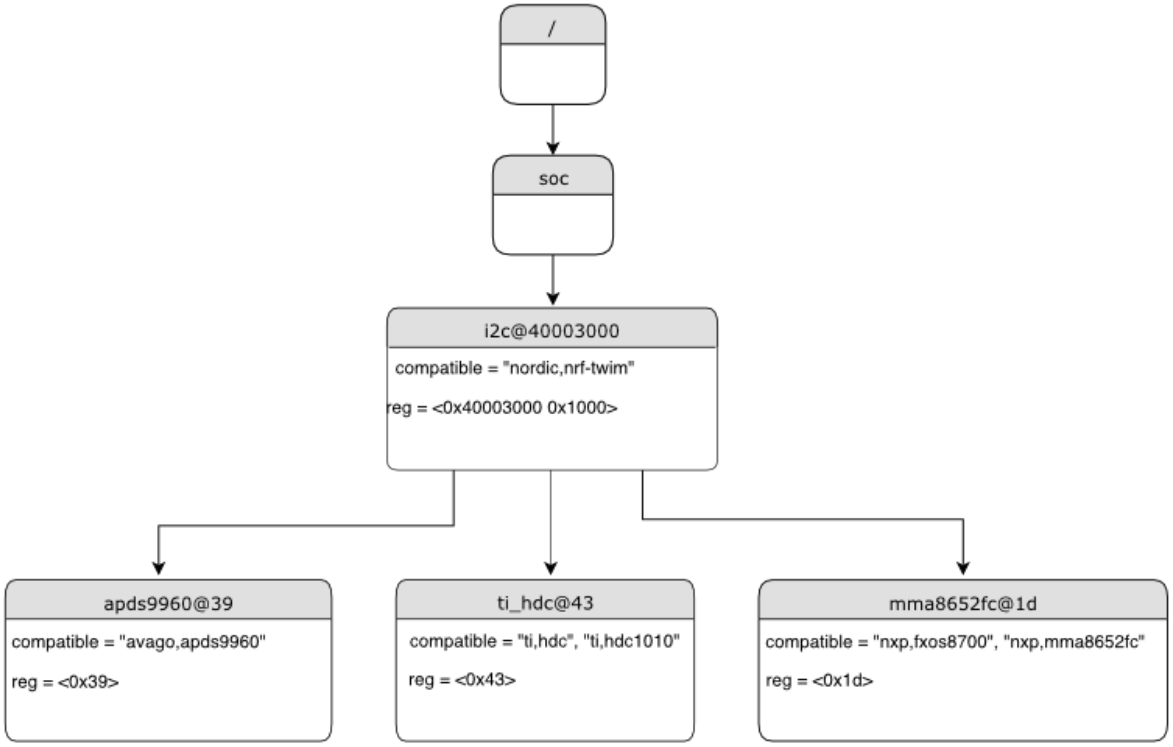


Fig. 2: I2C devicetree example with real-world names and properties. Node names are at the top of each node with a gray background. Properties are shown as "name=value" lines.

This is the corresponding DTS:

```
/dts-v1/;

/ {
        soc {
                i2c@40003000 {
                        compatible = "nordic,nrf-twim";
                        reg = <0x40003000 0x1000>;
```

(continues on next page)

(continued from previous page)

```
                        apds9960@39 {
                                compatible = "avago,apds9960";
                                reg = <0x39>;
                        };
                        ti_hdc@43 {
                                compatible = "ti,hdc", "ti,hdc1010";
                                reg = <0x43>;
                        };
                        mma8652fc@1d {
                                compatible = "nxp,fxos8700", "nxp,mma8652fc";
                                reg = <0x1d>;
                        };
                };
        };
};
```

Unit addresses In addition to showing more real-world names and properties, the above example introduces a new devicetree concept: unit addresses. Unit addresses are the parts of node names after an "at" sign (`@`), like `40003000` in `i2c@40003000`, or `39` in `apds9960@39`. Unit addresses are optional: the `soc` node does not have one.

In devicetree, unit addresses give a node's address in the address space of its parent node. Here are some example unit addresses for different types of hardware.

Memory-mapped peripherals
: The peripheral's register map base address. For example, the node named `i2c@40003000` represents an I2C controller whose register map base address is 0x40003000.

I2C peripherals
: The peripheral's address on the I2C bus. For example, the child node `apds9960@39` of the I2C controller in the previous section has I2C address 0x39.

SPI peripherals
: An index representing the peripheral's chip select line number. (If there is no chip select line, 0 is used.)

Memory
: The physical start address. For example, a node named `memory@2000000` represents RAM starting at physical address 0x2000000.

Memory-mapped flash
: Like RAM, the physical start address. For example, a node named `flash@8000000` represents a flash device whose physical start address is 0x8000000.

Fixed flash partitions
: This applies when the devicetree is used to store a flash partition table. The unit address is the partition's start offset within the flash memory. For example, take this flash device and its partitions:

```
flash@8000000 {
    /* ... */
    partitions {
            partition@0 { /* ... */ };
            partition@20000 {  /* ... */ };
            /* ... */
    };
};
```

The node named `partition@0` has offset 0 from the start of its flash device, so its base address is 0x8000000. Similarly, the base address of the node named `partition@20000` is 0x8020000.

Important properties The devicetree specification defines several standard properties. Some of the most important ones are:

compatible
The name of the hardware device the node represents.

The recommended format is `"vendor,device"`, like `"avago,apds9960"`, or a sequence of these, like `"ti,hdc", "ti,hdc1010"`. The `vendor` part is an abbreviated name of the vendor. The file dts/bindings/vendor-prefixes.txt contains a list of commonly accepted `vendor` names. The `device` part is usually taken from the datasheet.

It is also sometimes a value like `gpio-keys`, `mmio-sram`, or `fixed-clock` when the hardware's behavior is generic.

The build system uses the compatible property to find the right *bindings* for the node. Device drivers use `devicetree.h` to find nodes with relevant compatibles, in order to determine the available hardware to manage.

The `compatible` property can have multiple values. Additional values are useful when the device is a specific instance of a more general family, to allow the system to match from most- to least-specific device drivers.

Within Zephyr's bindings syntax, this property has type `string-array`.

reg
Information used to address the device. The value is specific to the device (i.e. is different depending on the compatible property).

The `reg` property is a sequence of `(address, length)` pairs. Each pair is called a "register block". Values are conventionally written in hex.

Here are some common patterns:

- Devices accessed via memory-mapped I/O registers (like `i2c@40003000`): `address` is usually the base address of the I/O register space, and `length` is the number of bytes occupied by the registers.
- I2C devices (like `apds9960@39` and its siblings): `address` is a slave address on the I2C bus. There is no `length` value.
- SPI devices: `address` is a chip select line number; there is no `length`.

You may notice some similarities between the `reg` property and common unit addresses described above. This is not a coincidence. The `reg` property can be seen as a more detailed view of the addressable resources within a device than its unit address.

status
A string which describes whether the node is enabled.

The devicetree specification allows this property to have values `"okay"`, `"disabled"`, `"reserved"`, `"fail"`, and `"fail-sss"`. Zephyr treats any value other than `"okay"` as disabled. In particular, `"reserved"` is used to document that a node exists but is enabled elsewhere (e.g. by another core or domain in a multi-domain application); it is handled the same as `"disabled"` by `edtlib`. Use of the remaining values (`"fail"` and `"fail-sss"`) is not currently used by Zephyr.

A node is considered enabled if its status property is either `"okay"` or not defined (i.e. does not exist in the devicetree source). Nodes with status `"disabled"` are explicitly disabled. Devicetree nodes which correspond to physical devices must be enabled for the corresponding `struct device` in the Zephyr driver model to be allocated and initialized.

Note that a child node is not implicitly disabled when its parent node is disabled, i.e. child nodes should be disabled explicitly if desired.

interrupts
Information about interrupts generated by the device, encoded as an array of one or more *interrupt specifiers*. Each interrupt specifier has some number of cells. See section 2.4, *Interrupts and Interrupt Mapping*, in the Devicetree Specification release v0.3 for more details.

Zephyr's devicetree bindings language lets you give a name to each cell in an interrupt specifier.

Note

Earlier versions of Zephyr made frequent use of the `label` property, which is distinct from the standard *node label*. Use of the label *property* in new devicetree bindings, as well as use of the `DT_LABEL` macro in new code, are actively discouraged. Label properties continue to persist for historical reasons in some existing bindings and overlays, but should not be used in new bindings or device implementations.

Writing property values This section describes how to write property values in DTS format. The property types in the table below are described in detail in *Devicetree bindings*.

Some specifics are skipped in the interest of keeping things simple; if you're curious about details, see the devicetree specification.

Property type	How to write	Example
string	Double quoted	`a-string = "hello, world!";`
int	between angle brackets (< and >)	`an-int = <1>;`
boolean	for `true`, with no value (for `false`, use `/delete-property/`)	`my-true-boolean;`
array	between angle brackets (< and >), separated by spaces	`foo = <0xdeadbeef 1234 0>;`
uint8-array	in hexadecimal *without* leading `0x`, between square brackets ([and]).	`a-byte-array = [00 01 ab];`
string-array	separated by commas	`a-string-array = "string one", "string two", "string three";`
phandle	between angle brackets (< and >)	`a-phandle = <&mynode>;`
phandles	between angle brackets (< and >), separated by spaces	`some-phandles = <&mynode0 &mynode1 &mynode2>;`
phandle-array	between angle brackets (< and >), separated by spaces	`a-phandle-array = <&mynode0 1 2>, <&mynode1 3 4>;`

Additional notes on the above:

- The values in the `phandle`, `phandles`, and `phandle-array` types are described further in *Phandles*
- Boolean properties are true if present. They should not have a value. A boolean property is only false if it is completely missing in the DTS.
- The `foo` property value above has three *cells* with values 0xdeadbeef, 1234, and 0, in that order. Note that hexadecimal and decimal numbers are allowed and can be intermixed. Since Zephyr transforms DTS to C sources, it is not necessary to specify the endianness of an individual cell here.

- 64-bit integers are written as two 32-bit cells in big-endian order. The value 0xaaaa0000bbbb1111 would be written `<0xaaaa0000 0xbbbb1111>`.
- The `a-byte-array` property value is the three bytes 0x00, 0x01, and 0xab, in that order.
- Parentheses, arithmetic operators, and bitwise operators are allowed. The `bar` property contains a single cell with value 64:

```
bar = <(2 * (1 << 5))>;
```

  Note that the entire expression must be parenthesized.

- A cell whose parenthesized expression evaluates to a negative value, such as `<(-1)>` or `<(4 - 6)>`, is preserved as a signed value for `int` and `array` typed properties. Cells written as positive decimal or hexadecimal literals (including `0xffffffff`), or whose expression evaluates to a non-negative value, remain unsigned.
- Property values refer to other nodes in the devicetree by their *phandles*. You can write a phandle using `&foo`, where `foo` is a *node label*. Here is an example devicetree fragment:

```
foo: device@0 { };
device@1 {
        sibling = <&foo 1 2>;
};
```

  The `sibling` property of node `device@1` contains three cells, in this order:

  1. The `device@0` node's phandle, which is written here as `&foo` since the `device@0` node has a node label `foo`
  2. The value 1
  3. The value 2

  In the devicetree, a phandle value is a cell – which again is just a 32-bit unsigned int. However, the Zephyr devicetree API generally exposes these values as *node identifiers*. Node identifiers are covered in more detail in *Devicetree access from C/C++*.

- Array and similar type property values can be split into several <> blocks, like this:

```
foo = <1 2>, <3 4>;                          // Okay for 'type: array'
foo = <&label1 &label2>, <&label3 &label4>; // Okay for 'type: phandles'
foo = <&label1 1 2>, <&label2 3 4>;          // Okay for 'type: phandle-array'
```

  This is recommended for readability when possible if the value can be logically grouped into blocks of sub-values.

Aliases and chosen nodes There are two additional ways beyond *node labels* to refer to a particular node without specifying its entire path: by alias, or by chosen node.

Here is an example devicetree which uses both:

```
/dts-v1/;

/ {
    chosen {
            zephyr,console = &uart0;
    };

    aliases {
            my-uart = &uart0;
    };
```

(continues on next page)

(continued from previous page)

```
    soc {
            uart0: serial@12340000 {
                    ...
            };
    };
};
```

The `/aliases` and `/chosen` nodes do not refer to an actual hardware device. Their purpose is to specify other nodes in the devicetree.

Above, `my-uart` is an alias for the node with path `/soc/serial@12340000`. Using its node label `uart0`, the same node is set as the value of the chosen `zephyr,console` node.

Zephyr sample applications sometimes use aliases to allow overriding the particular hardware device used by the application in a generic way. For example, blinky uses this to abstract the LED to blink via the `led0` alias.

The `/chosen` node's properties are used to configure system- or subsystem-wide values. See *Chosen nodes* for more information.

Input and output files This section describes the input and output files shown in the figure in *Scope and purpose* in more detail.

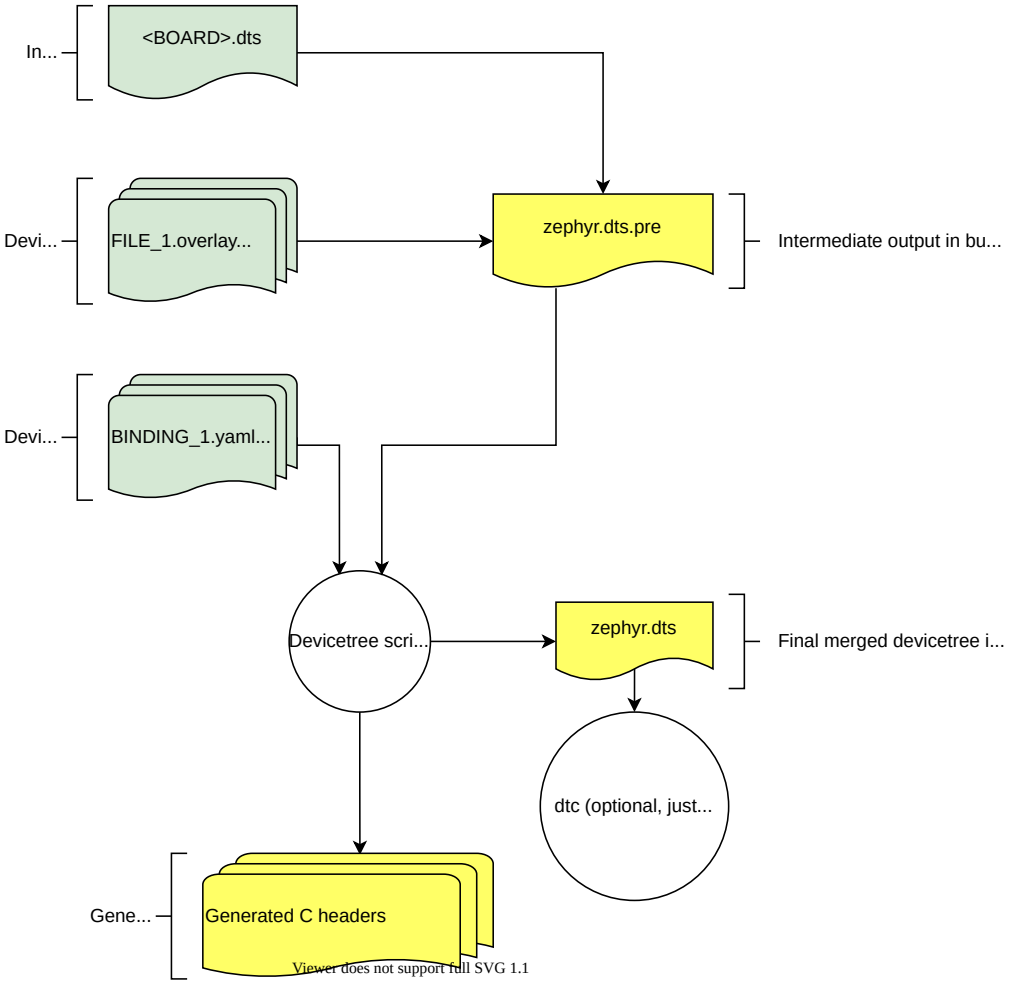

Fig. 3: Devicetree input (green) and output (yellow) files

Input files There are four types of devicetree input files:

- sources (`.dts`)
- includes (`.dtsi`)
- overlays (`.overlay`)
- bindings (`.yaml`)

The devicetree files inside the `zephyr` directory look like this:

```
boards/<ARCH>/<BOARD>/<BOARD>.dts
dts/common/skeleton.dtsi
dts/<ARCH>/.../<SOC>.dtsi
dts/bindings/.../binding.yaml
```

Generally speaking, every supported board has a `BOARD.dts` file describing its hardware. For example, the `reel_board` has boards/phytec/reel_board/reel_board.dts.

`BOARD.dts` includes one or more `.dtsi` files. These `.dtsi` files describe the CPU or system-on-chip Zephyr runs on, perhaps by including other `.dtsi` files. They can also describe other common hardware features shared by multiple boards. In addition to these includes, `BOARD.dts` also describes the board's specific hardware.

The `dts/common` directory contains `skeleton.dtsi`, a minimal include file for defining a complete devicetree. Architecture-specific subdirectories (`dts/<ARCH>`) contain `.dtsi` files for CPUs or SoCs which extend `skeleton.dtsi`.

The C preprocessor is run on all devicetree files to expand macro references, and includes are generally done with `#include <filename>` directives, even though DTS has a `/include/ "<filename>"` syntax.

`BOARD.dts` can be extended or modified using *overlays*. Overlays are also DTS files; the `.overlay` extension is just a convention which makes their purpose clear. Overlays adapt the base devicetree for different purposes:

- Zephyr applications can use overlays to enable a peripheral that is disabled by default, select a sensor on the board for an application specific purpose, etc. Along with *Configuration System (Kconfig)*, this makes it possible to reconfigure the kernel and device drivers without modifying source code.
- Overlays are also used when defining *Shields*.

The build system automatically picks up `.overlay` files stored in certain locations. It is also possible to explicitly list the overlays to include, via the `DTC_OVERLAY_FILE` CMake variable. See *Set devicetree overlays* for details.

The build system combines `BOARD.dts` and any `.overlay` files by concatenating them, with the overlays put last. This relies on DTS syntax which allows merging overlapping definitions of nodes in the devicetree. See *Example: FRDM-K64F and Hexiwear K64* for an example of how this works (in the context of `.dtsi` files, but the principle is the same for overlays). Putting the contents of the `.overlay` files last allows them to override `BOARD.dts`.

Devicetree bindings (which are YAML files) are essentially glue. They describe the contents of devicetree sources, includes, and overlays in a way that allows the build system to generate C macros usable by device drivers and applications. The `dts/bindings` directory contains bindings.

Scripts and tools The following libraries and scripts, located in scripts/dts/, create output files from input files. Their sources have extensive documentation.

dtlib.py
: A low-level DTS parsing library.

edtlib.py
: A library layered on top of dtlib that uses bindings to interpret properties and give a higher-level view of the devicetree. Uses dtlib to do the DTS parsing.

gen_defines.py
: A script that uses edtlib to generate C preprocessor macros from the devicetree and bindings.

In addition to these, the standard `dtc` (devicetree compiler) tool is run on the final devicetree if it is installed on your system. This is just to catch errors or warnings. The output is unused. Boards may need to pass `dtc` additional flags, e.g. for warning suppression. Board directories can contain a file named `pre_dt_board.cmake` which configures these extra flags, like this:

```
list(APPEND EXTRA_DTC_FLAGS "-Wno-simple_bus_reg")
```

Shield directories can contain a file named `pre_dt_shield.cmake` which has the same functionality as the aforementioned `pre_dt_board.cmake`.

Output files These are created in your application's build directory.

> **Warning**
>
> Don't include the header files directly. *Devicetree access from C/C++* explains what to do instead.

<build>/zephyr/zephyr.dts.pre
: The preprocessed DTS source. This is an intermediate output file, which is input to `gen_defines.py` and used to create `zephyr.dts` and `devicetree_generated.h`.

<build>/zephyr/include/generated/zephyr/devicetree_generated.h
: The generated macros and additional comments describing the devicetree. Included by `devicetree.h`.

<build>/zephyr/zephyr.dts
: The final merged devicetree. This file is output by `gen_defines.py`. It is useful for debugging any issues. If the devicetree compiler `dtc` is installed, it is also run on this file, to catch any additional warnings or errors.

Design goals

Zephyr's use of devicetree has evolved significantly over time, and further changes are expected. The following are the general design goals, along with specific examples about how they impact Zephyr's source code, and areas where more work remains to be done.

Single source for hardware information Zephyr's built-in device drivers and sample applications shall obtain configurable hardware descriptions from devicetree.

Examples

- New device drivers shall use devicetree APIs to determine which *devices to create*.
- In-tree sample applications shall use *aliases* to determine which of multiple possible generic devices of a given type will be used in the current build. For example, the blinky sample uses this to determine the LED to blink.
- Boot-time pin muxing and pin control for new SoCs shall be accomplished via a devicetree-based pinctrl driver

Example remaining work

- Zephyr's *Test Runner (Twister)* currently use `board.yaml` files to determine the hardware supported by a board. This should be obtained from devicetree instead.

- Legacy device drivers currently use Kconfig to determine which instances of a particular compatible are enabled. This can and should be done with devicetree overlays instead.
- Board-level documentation still contains tables of hardware support which are generated and maintained by hand. This can and should be obtained from the board level devicetree instead.
- Runtime determination of `struct device` relationships should be done using information obtained from devicetree, e.g. for device power management.

Source compatibility with other operating systems Zephyr's devicetree tooling is based on a generic layer which is interoperable with other devicetree users, such as the Linux kernel.

Zephyr's binding language *semantics* can support Zephyr-specific attributes, but shall not express Zephyr-specific relationships.

Examples

- Zephyr's devicetree source parser, *dtlib.py*, is source-compatible with other tools like dtc in both directions: `dtlib.py` can parse `dtc` output, and `dtc` can parse `dtlib.py` output.
- Zephyr's "extended dtlib" library, `edtlib.py`, shall not include Zephyr-specific features. Its purpose is to provide a higher-level view of the devicetree for common elements like interrupts and buses.

  Only the high-level `gen_defines.py` script, which is built on top of `edtlib.py`, contains Zephyr-specific knowledge and features.

Example remaining work

- Zephyr has a custom *Devicetree bindings* language *syntax*. While Linux's dtschema does not yet meet Zephyr's needs, we should try to follow what it is capable of representing in Zephyr's own bindings.
- Due to inflexibility in the bindings language, Zephyr cannot support the full set of bindings supported by Linux.
- Devicetree source sharing between Zephyr and Linux is not done.

Modeling hardware exposed through multiple Zephyr APIs When a hardware block can be used through different Zephyr APIs, devicetree should keep hardware identity separate from the way software drivers and subsystems use each hardware instance.

Guidelines

- Keep the `compatible` property focused on the device programming model. Avoid changing it only to route software API selection. A different `compatible` is appropriate when the hardware interfaces are architecturally distinct, for example because they use separate register blocks.
- Use `/chosen` for singleton system-wide selection. If the system must select exactly one instance for a global function, such as the system timer, console, or entropy source, represent that choice with a platform-agnostic chosen property, even if other identical hardware instances are used by other APIs. See also *Zephyr-specific chosen nodes*.
- Place the selection at the right integration level. If it is a silicon-level fixed attribute, describe it in the SoC `.dtsi`. If it varies by board, product, or application, describe it in the board `.dts` or an overlay.

If different uses of the hardware device have different required properties, child nodes, or bus semantics, then they do not have to share one binding schema. In that case, use different `compatible` values or model the device as a multifunction one.

Examples **Singleton selection with** `/chosen`

The system timer is a singleton function. The `zephyr,system-timer` chosen property selects which hardware timer instance provides it, while other identical instances remain available for other APIs.

For example, two identical LPTMR timer instances can share the same `compatible` in the hardware description:

```
lptmr1: timer@44300000 {
    compatible = "nxp,lptmr";
    reg = <0x44300000 0x1000>;
    /* ... */
};

lptmr2: timer@424d0000 {
    compatible = "nxp,lptmr";
    reg = <0x424d0000 0x1000>;
    /* ... */
};
```

An integration layer can then select which one provides the singleton system timer function:

```
/ {
    chosen {
        zephyr,system-timer = &lptmr1;
    };
};
```

The system-timer driver binds to the `/chosen` node. The counter driver skips that instance and uses the remaining one.

Devicetree bindings

A devicetree on its own is only half the story for describing hardware, as it is a relatively unstructured format. *Devicetree bindings* provide the other half.

A devicetree binding declares requirements on the contents of nodes, and provides semantic information about the contents of valid nodes. Zephyr devicetree bindings are YAML files in a custom format (Zephyr does not use the dt-schema tools used by the Linux kernel).

These pages introduce bindings, describe what they do, note where they are found, and explain their data format.

Note

See the *Bindings index* for reference information on bindings built in to Zephyr.

Note

For a detailed syntax reference, see *Devicetree bindings syntax*.

Introduction to Devicetree Bindings Devicetree nodes are matched to bindings using their *compatible properties*.

During the *Configuration Phase*, the build system tries to match each node in the devicetree to a binding file. When this succeeds, the build system uses the information in the binding file both when validating the node's contents and when generating macros for the node.

A simple example Here is an example devicetree node:

```
/* Node in a DTS file */
bar-device {
     compatible = "foo-company,bar-device";
     num-foos = <3>;
};
```

Here is a minimal binding file which matches the node:

```
# A YAML binding matching the node

compatible: "foo-company,bar-device"

properties:
  num-foos:
    type: int
    required: true
```

The build system matches the `bar-device` node to its YAML binding because the node's `compatible` property matches the binding's `compatible:` line.

What the build system does with bindings The build system uses bindings both to validate devicetree nodes and to convert the devicetree's contents into the generated *devicetree_generated.h* header file.

For example, the build system would use the above binding to check that the required `num-foos` property is present in the `bar-device` node, and that its value, `<3>`, has the correct type.

The build system will then generate a macro for the `bar-device` node's `num-foos` property, which will expand to the integer literal `3`. This macro lets you get the value of the property in C code using the API which is discussed later in this guide in *Devicetree access from C/C++*.

For another example, the following node would cause a build error, because it has no `num-foos` property, and this property is marked required in the binding:

```
bad-node {
     compatible = "foo-company,bar-device";
};
```

Other ways nodes are matched to bindings If a node has more than one string in its `compatible` property, the build system looks for compatible bindings in the listed order and uses the first match.

Take this node as an example:

```
baz-device {
     compatible = "foo-company,baz-device", "generic-baz-device";
};
```

The `baz-device` node would get matched to a binding with a `compatible: "generic-baz-device"` line if the build system can't find a binding with a `compatible: "foo-company,baz-device"` line.

Nodes without compatible properties can be matched to bindings associated with their parent nodes. These are called "child bindings". If a node describes hardware on a bus, like I2C or SPI, then the bus type is also taken into account when matching nodes to bindings. (See *On-bus* for details).

See *The /zephyr,user node* for information about a special node that doesn't require any binding.

Where bindings are located Binding file names usually match their `compatible:` lines. For example, the above example binding would be named `foo-company,bar-device.yaml` by convention.

The build system looks for bindings in `dts/bindings` subdirectories of the following places:

- the zephyr repository
- your *application source directory*
- your *board directory*
- any *shield directories*
- any directories manually included in the *DTS_ROOT* CMake variable
- any *module* that defines a `dts_root` in its *Build settings*

The build system will consider any YAML file in any of these, including in any subdirectories, when matching nodes to bindings. A file is considered YAML if its name ends with `.yaml` or `.yml`.

Warning

The binding files must be located somewhere inside the `dts/bindings` subdirectory of the above places.

For example, if `my-app` is your application directory, then you must place application-specific bindings inside `my-app/dts/bindings`. So `my-app/dts/bindings/serial/my-company,my-serial-port.yaml` would be found, but `my-app/my-company,my-serial-port.yaml` would be ignored.

Devicetree bindings syntax This page documents the syntax of Zephyr's bindings format. Zephyr bindings files are YAML files. A *simple example* was given in the introduction page.

Top level keys The top level of a bindings file maps keys to values. The top-level keys look like this:

```
# When the description text is too long, this field can
# be used to improve readability, e.g.:
#
# title: Binding the device's hardware model.
#
# description |
#   A piece of content with 20 lines.
#   ...
title: Concise title for the long description [optional]

# A high level description of the device the binding applies to:
description: |
   This is the Vendomatic company's foo-device.

   Descriptions which span multiple lines (like this) are OK,
   and are encouraged for complex bindings.

   See https://yaml-multiline.info/ for formatting help.

# You can include definitions from other bindings using this syntax:
include: other.yaml

# Used to match nodes to this binding:
compatible: "manufacturer,foo-device"

properties:
  # Requirements for and descriptions of the properties that this
  # binding's nodes need to satisfy go here.

child-binding:
  # You can constrain the children of the nodes matching this binding
  # using this key.
```

(continues on next page)

(continued from previous page)

```
# If the node describes bus hardware, like an SPI bus controller
# on an SoC, use 'bus:' to say which one, like this:
bus: spi

# If the node instead appears as a device on a bus, like an external
# SPI memory chip, use 'on-bus:' to say what type of bus, like this.
# Like 'compatible', this key also influences the way nodes match
# bindings.
on-bus: spi

examples:
  # You can put a sample node here showing how to use the binding.
  # - |
  #  ...
  # or
  # - ...

foo-cells:
  # "Specifier" cell names for the 'foo' domain go here; example 'foo'
  # values are 'gpio', 'pwm', and 'dma'. See below for more information.
```

These keys are explained in the following sections.

Title An *optional*, short description of the bound device, typically the hardware model. It should typically be of the format “Vendor Family Model”. If acronyms are used, they should be spelled out in parentheses. The naming should stay as close to the vendor datasheet as possible.

Titles should not exceed 100 characters. The description field should be used for longer descriptions. The words “binding”, “schema” or “driver” should not be used in the title, everything is a binding.

```
title: Acme Foo UART (Universal Asynchronous Receiver/Transmitter)
```

Description A free-form description of node hardware goes here. You can put links to datasheets or example nodes or properties as well.

Compatible This key is used to match nodes to this binding as described in *Introduction to Devicetree Bindings*. It should look like this in a binding file:

```
# Note the comma-separated vendor prefix and device name
compatible: "manufacturer,device"
```

This devicetree node would match the above binding:

```
device {
     compatible = "manufacturer,device";
};
```

Assuming no binding has `compatible: "manufacturer,device-v2"`, it would also match this node:

```
device-2 {
    compatible = "manufacturer,device-v2", "manufacturer,device";
};
```

Each node's `compatible` property is tried in order. The *bindings* are uniquely identified by a pair of (*compatible*, *on-bus*), where the *on-bus* may be unspecified. A specified *on-bus* takes precedence over unspecified. The first matching binding is used.

For the following device:

```
spi-bus {
        device-3 {
                compatible = "manufacturer,device";
        };
};
```

The following two bindings can coexist and would match in the following order:

`manufacturer,device-spi.yaml`

```
compatible: "manufacturer,device"
on-bus: spi
```

`manufacturer,device.yaml`

```
compatible: "manufacturer,device"
```

The following binding can coexist but would not match.

`manufacturer,device-i2c.yaml`

```
compatible: "manufacturer,device"
on-bus: i2c
```

If more than one matching binding for a compatible is found, an error is raised.

The `manufacturer` prefix identifies the device vendor. See dts/bindings/vendor-prefixes.txt for a list of accepted vendor prefixes. The `device` part is usually from the datasheet.

Some bindings apply to a generic class of devices which do not have a specific vendor. In these cases, there is no vendor prefix. One example is the `gpio-leds` compatible which is commonly used to describe board LEDs connected to GPIOs.

Properties The `properties:` key describes properties that nodes which match the binding contain. For example, a binding for a UART peripheral might look something like this:

```
compatible: "manufacturer,serial"

properties:
  reg:
    type: array
    description: UART peripheral MMIO register space
    required: true
  current-speed:
    type: int
    description: current baud rate
    required: true
```

In this example, a node with compatible `"manufacturer,serial"` must contain a property named `current-speed`. The property's value must be a single integer. Similarly, the node must contain a `reg` property.

The build system uses bindings to generate C macros for devicetree properties that appear in DTS files. You can read more about how to get property values in source code from these macros in *Devicetree access from C/C++*. Generally speaking, the build system only generates macros for

properties listed in the `properties:` key for the matching binding. Properties not mentioned in the binding are generally ignored by the build system.

The one exception is that the build system will always generate macros for standard properties, like *reg*, whose meaning is defined by the devicetree specification. This happens regardless of whether the node has a matching binding or not.

Property entry syntax Property entries in `properties:` are written in this syntax:

```
<property name>:
  required: <true | false>
  type: <string | int | boolean | array | uint8-array | string-array |
         phandle | phandles | phandle-array | path | compound>
  deprecated: <true | false>
  default: <default>
  description: <description of the property>
  enum:
    - <item1>
    - <item2>
    ...
    - <itemN>
  const: <string | int | array | uint8-array | string-array>
  min: <int>
  max: <int>
  min-len: <int>
  max-len: <int>
  specifier-space: <space-name>
  dependency-mode: <normal | reverse | ignore | child-ignore>
```

Example property definitions Here are some more examples.

```
properties:
    # Describes a property like 'current-speed = <115200>;'. We pretend that
    # it's obligatory for the example node and set 'required: true'.
    current-speed:
        type: int
        required: true
        description: Initial baud rate for bar-device

    # Describes an optional property like 'keys = "foo", "bar";'
    keys:
        type: string-array
        description: Keys for bar-device

    # Describes an optional property like 'maximum-speed = "full-speed";'
    # the enum specifies known values that the string property may take
    maximum-speed:
        type: string
        description: Configures USB controllers to work up to a specific speed.
        enum:
           - "low-speed"
           - "full-speed"
           - "high-speed"
           - "super-speed"

    # Describes an optional property like 'resolution = <16>;'
    # the enum specifies known values that the int property may take
```

(continues on next page)

(continued from previous page)

```
    resolution:
      type: int
      enum:
       - 8
       - 16
       - 24
       - 32

    # Describes a required property '#address-cells = <1>';  the const
    # specifies that the value for the property is expected to be the value 1
    "#address-cells":
        type: int
        required: true
        const: 1

    int-with-default:
        type: int
        default: 123
        description: Value for int register, default is power-up configuration.

    array-with-default:
        type: array
        default: [1, 2, 3] # Same as 'array-with-default = <1 2 3>'

    string-with-default:
        type: string
        default: "foo"

    string-array-with-default:
        type: string-array
        default: ["foo", "bar"] # Same as 'string-array-with-default = "foo",
↪"bar"'

    uint8-array-with-default:
        type: uint8-array
        default: [0x12, 0x34] # Same as 'uint8-array-with-default = [12 34]'
```

required Adding `required: true` to a property definition will fail the build if a node matches the binding, but does not contain the property.

The default setting is `required: false`; that is, properties are optional by default. Using `required: false` is therefore redundant and strongly discouraged.

type The type of a property constrains its values. The following types are available. See *Writing property values* for more details about writing values of each type in a DTS file. See *Phandles* for more information about the `phandle*` type properties.

Type	Description	Example in DTS
`string`	exactly one string	`status = "disabled";`
`int`	exactly one 32-bit value (cell)	`current-speed = <115200>;`
`boolean`	flags that don't take a value when true, and are absent if false	`hw-flow-control;`
`array`	zero or more 32-bit values (cells)	`offsets = <0x100 0x200 0x300>;`
`uint8-array`	zero or more bytes, in hex ('bytestring' in the Devicetree specification)	`local-mac-address = [de ad be ef 12 34];`
`string-array`	zero or more strings	`dma-names = "tx", "rx";`
`phandle`	exactly one phandle	`interrupt-parent = <&gic>;`
`phandles`	zero or more phandles	`pinctrl-0 = <&usart2_tx_pd5 &usart2_rx_pd6>;`
`phandle-array`	a list of phandles and 32-bit cells (usually specifiers)	`dmas = <&dma0 2>, <&dma0 3>;`
`path`	a path to a node as a phandle path reference or path string	`zephyr,bt-c2h-uart = &uart0;` or `foo = "/path/to/some/node";`
`compound`	a catch-all for more complex types (no macros will be generated)	`foo = <&label>, [01 02];`

deprecated A property with `deprecated: true` indicates to both the user and the tooling that the property is meant to be phased out.

The tooling will report a warning if the devicetree includes the property that is flagged as deprecated. (This warning is upgraded to an error in the *Test Runner (Twister)* for upstream pull requests.)

The default setting is `deprecated: false`. Using `deprecated: false` is therefore redundant and strongly discouraged.

default The optional `default:` setting gives a value that will be used if the property is missing from the devicetree node.

For example, with this binding fragment:

```
properties:
  foo:
    type: int
    default: 3
```

If property `foo` is missing in a matching node, then the output will be as if `foo = <3>;` had appeared in the DTS (except YAML data types are used for the default value).

Note that a binding which declares both `default:` and `required: true` for the same property will produce a warning, since the two settings are redundant: `required: true` already fails the build when the property is missing, so the default can never apply. A binding may still override an inherited `default:` with `required: true` to force an explicit value; this is well defined and is not reported. A binding which is only ever reached through `include:` is not loaded on its own during a build, so the warning for it is seen when the documentation is generated rather than when an application is built.

For rules related to `default` in upstream Zephyr bindings, see *Rules for default values*.

See *Example property definitions* for examples. Putting `default:` on any property type besides those used in *Example property definitions* will raise an error.

enum The `enum:` line is followed by a list of values the property may contain. If a property value in DTS is not in the `enum:` list in the binding, an error is raised. See *Example property definitions* for examples.

min and max The `min:` and `max:` keys constrain the range of valid values for properties with `type: int` or `type: array`. If a property value in DTS is outside the `[min, max]` range, an error is raised.

Both keys are optional and independent; you may specify just `min:`, just `max:`, or both. They cannot be combined with `enum:` on the same property.

For `type: array`, each element of the array is checked against the range.

Example:

```
properties:
  # A brightness percentage between 0 and 100
  brightness:
    type: int
    min: 0
    max: 100
    description: LED brightness as a percentage

  # A timeout in milliseconds, with a minimum of 1 ms (no upper bound)
  timeout-ms:
    type: int
    min: 1
    description: Timeout in milliseconds
```

min-len and max-len The `min-len:` and `max-len:` keys constrain the number of elements (length) for array-type properties (`array`, `uint8-array`, `string-array`, `phandles`, and `phandle-array`). If the length of a property value in DTS is outside the `[min-len, max-len]` range, an error is raised.

Both keys are optional and independent; you may specify just `min-len:`, just `max-len:`, or both.

Example:

```
properties:
  # An array of exactly 3 integers
  coordinates:
    type: array
    min-len: 3
    max-len: 3
    description: 3D coordinates

  # A list of up to 4 GPIO phandles
  gpios:
    type: phandle-array
    max-len: 4
    description: Up to 4 GPIOs
```

const This specifies a constant value the property must take. It is mainly useful for constraining the values of common properties for a particular piece of hardware.

Warning

It is an abuse of this feature to use it to name properties in unconventional ways.

For example, this feature is not meant for cases like naming a property `my-pin`, then assigning it to the "gpio" specifier space using this feature. Properties which refer to GPIOs should use conventional names, i.e. end in `-gpios` or `-gpio`.

specifier-space This property, if present, manually sets the specifier space associated with a property with type `phandle-array`.

Normally, the specifier space is encoded implicitly in the property name. A property named `foos` with type `phandle-array` implicitly has specifier space `foo`. As a special case, `*-gpios` properties have specifier space "gpio", so that `foo-gpios` will have specifier space "gpio" rather than "foo-gpio".

You can use `specifier-space` to manually provide a space if using this convention would result in an awkward or unconventional name.

For example:

```
compatible: ...
properties:
  bar:
    type: phandle-array
    specifier-space: my-custom-space
```

Above, the `bar` property's specifier space is set to "my-custom-space".

You could then use the property in a devicetree like this:

```
controller1: custom-controller@1000 {
        #my-custom-space-cells = <2>;
};

controller2: custom-controller@2000 {
        #my-custom-space-cells = <1>;
};

my-node {
        bar = <&controller1 10 20>, <&controller2 30>;
};
```

Generally speaking, you should reserve this feature for cases where the implicit specifier space naming convention doesn't work. One appropriate example is an `mboxes` property with specifier space "mbox", not "mboxe". You can write this property as follows:

```
properties:
  mboxes:
    type: phandle-array
    specifier-space: mbox
```

dependency-mode The `dependency-mode` setting controls how phandle properties are treated when calculating the dependency graph in Zephyr.

By default, any *phandle property* creates a dependency between the node containing the property and the node it references. The `dependency-mode` setting allows you to override this behavior.

Possible values The `dependency-mode` setting accepts the following values:

`normal` **or unspecified**
: The default behavior. The referencing node depends on the referenced node (the node pointed to by the phandle).

`reverse`
: Reverses the dependency direction. Instead of the referencing node depending on the referenced node, the referenced node depends on the referencing node.

`ignore`
: The phandle property does not create a dependency.

`child-ignore`
: Similar to `ignore`, but the dependency is only ignored if the referenced node is a child of the referencing node. If the referenced node is not a child, a normal dependency is created.

  Use this when a phandle may reference either a child node (no dependency needed) or an external node (dependency required).

Using dependency-mode The `dependency-mode` setting is specified within a property definition in a binding file. Here's an example:

```
compatible: "vendor,ethernet-controller"

properties:
  phy-handle:
    type: phandle
    description: |
      Specifies a reference to a node representing a PHY device.
    dependency-mode: ignore
```

Another example using `child-ignore`:

```
compatible: "vendor,node-with-optional-phandle"

properties:
  optional-ref:
    type: phandle
    description: |
      References either a child node or an external device.
      Child node references create no dependency, but external
      device references do.
    dependency-mode: child-ignore
```

Example DTS using that binding:

```
root {
        external_dev: external-device@2000 {
                compatible = "vendor,external-device";
                reg = <0x2000 0x100>;
        };

        parent_dev: parent-device@1000 {
                compatible = "vendor,node-with-optional-phandle";
                reg = <0x1000 0x100>;
                optional-ref = <&internal_child>; /* child: ignored dependency */

                internal_child: internal-device {
                        compatible = "vendor,internal-device";
                };
        };
```

(continues on next page)

(continued from previous page)

```
        peer_dev: peer-device@3000 {
                compatible = "vendor,node-with-optional-phandle";
                reg = <0x3000 0x100>;
                optional-ref = <&external_dev>; /* external: normal dependency */
        };
};
```

Default behavior If `dependency-mode` is not specified, the default value is `normal`, which means the referencing node depends on the referenced node.

Child-binding `child-binding` can be used when a node has children that all share the same properties. Each child gets the contents of `child-binding` as its binding, though an explicit `compatible = ...` on the child node takes precedence, if a binding is found for it.

Consider a binding for a PWM LED node like this one, where the child nodes are required to have a `pwms` property:

```
pwmleds {
        compatible = "pwm-leds";

        red_pwm_led {
                pwms = <&pwm3 4 15625000>;
        };
        green_pwm_led {
                pwms = <&pwm3 0 15625000>;
        };
        /* ... */
};
```

The binding would look like this:

```
compatible: "pwm-leds"

child-binding:
  description: LED that uses PWM

  properties:
    pwms:
      type: phandle-array
      required: true
```

`child-binding` also works recursively. For example, this binding:

```
compatible: foo

child-binding:
  child-binding:
    properties:
      my-property:
        type: int
        required: true
```

will apply to the `grandchild` node in this DTS:

```
parent {
        compatible = "foo";
        child {
                grandchild {
                        my-property = <123>;
                };
        };
};
```

Bus If the node is a bus controller, use `bus:` in the binding to say what type of bus. For example, a binding for a SPI peripheral on an SoC would look like this:

```
compatible: "manufacturer,spi-peripheral"
bus: spi
# ...
```

The presence of this key in the binding informs the build system that the children of any node matching this binding appear on this type of bus.

This in turn influences the way `on-bus:` is used to match bindings for the child nodes.

For a single bus supporting multiple protocols, e.g. I3C and I2C, the `bus:` in the binding can have a list as value:

```
compatible: "manufacturer,i3c-controller"
bus: [i3c, i2c]
# ...
```

On-bus If the node appears as a device on a bus, use `on-bus:` in the binding to say what type of bus.

For example, a binding for an external SPI memory chip should include this line:

```
on-bus: spi
```

And a binding for an I2C based temperature sensor should include this line:

```
on-bus: i2c
```

When looking for a binding for a node, the build system checks if the binding for the parent node contains `bus: <bus type>`. If it does, then only bindings with a matching `on-bus: <bus type>` and bindings without an explicit `on-bus` are considered. Bindings with an explicit `on-bus: <bus type>` are searched for first, before bindings without an explicit `on-bus`. The search repeats for each item in the node's `compatible` property, in order.

This feature allows the same device to have different bindings depending on what bus it appears on. For example, consider a sensor device with compatible `manufacturer,sensor` which can be used via either I2C or SPI.

The sensor node may therefore appear in the devicetree as a child node of either an SPI or an I2C controller, like this:

```
spi-bus@0 {
   /* ... some compatible with 'bus: spi', etc. ... */

   sensor@0 {
       compatible = "manufacturer,sensor";
       reg = <0>;
       /* ... */
```

(continues on next page)

(continued from previous page)

```
    };
};

i2c-bus@0 {
    /* ... some compatible with 'bus: i2c', etc. ... */

    sensor@79 {
        compatible = "manufacturer,sensor";
        reg = <79>;
        /* ... */
    };
};
```

You can write two separate binding files which match these individual sensor nodes, even though they have the same compatible:

```
# manufacturer,sensor-spi.yaml, which matches sensor@0 on the SPI bus:
compatible: "manufacturer,sensor"
on-bus: spi

# manufacturer,sensor-i2c.yaml, which matches sensor@79 on the I2C bus:
compatible: "manufacturer,sensor"
properties:
  uses-clock-stretching:
    type: boolean
on-bus: i2c
```

Only `sensor@79` can have a `use-clock-stretching` property. The bus-sensitive logic ignores `manufacturer,sensor-i2c.yaml` when searching for a binding for `sensor@0`.

Class If nodes matching the binding can be used as devices of one or more Zephyr device classes, use `class:` to declare those classes:

```
compatible: "manufacturer,adc"
class: adc
```

The value is a device class name or a list of names. Names use lowercase letters, digits, `-` and `_`; malformed or duplicate names are rejected. Each name should match a device API class registered with `DEVICE_API` (like adc); lowercase-and-hyphens names are converted to lowercase-and-underscores C tokens the same way compatibles are.

The key declares which device API class(es) the node's drivers *can* implement; which driver and API are actually built for a node remains a Kconfig decision. A list value covers hardware whose drivers can implement more than one API depending on configuration:

```
compatible: "manufacturer,rtc"
class: [rtc, counter]
```

`class:` is normally declared once in a device class base binding (for example dts/bindings/adc/adc-controller.yaml) so that every binding including it inherits the class. When a binding and its included files declare classes, the values are unioned: a binding that includes several class base bindings belongs to all of their classes.

Class membership can be queried at build time with `DT_NODE_HAS_CLASS`, iterated with `DT_FOREACH_CLASS_STATUS_OKAY`, counted with `DT_NUM_CLASS_STATUS_OKAY`, and tested from Kconfig with `$(dt_class_enabled,<class name>)`.

To add a class to a device whose binding cannot be changed, for example to classify an upstream device from a downstream module, define a more specific compatible whose binding includes

the original binding and declares the class, and list both compatibles on the node:

```
# vnd,foo-classed.yaml
compatible: "vnd,foo-classed"
include: vnd,foo.yaml
class: xyz
```

```
compatible = "vnd,foo-classed", "vnd,foo";
```

The node's binding, and with it its classes, comes from the first compatible that has a binding; drivers match on any of the node's compatibles, so the original driver still binds. Two bindings for the same compatible are an error, so an existing binding cannot be shadowed.

Examples If you feel you want to provide a minimal example for your binding, you can use it like this:

```
description: ...

properties:
 ...

examples:
  - |
    leds {
      compatible = "gpio-leds";

      uled: led {
      gpios = <&gpioe 12 GPIO_ACTIVE_HIGH>;
      };
    };
```

Specifier cell names (*-cells) This section documents how to name the cells in a specifier within a binding. These concepts are discussed in detail later in this guide in *phandle-array properties*.

Consider a binding for a node whose phandle may appear in a `phandle-array` property, like the PWM controllers `pwm1` and `pwm2` in this example:

```
pwm1: pwm@deadbeef {
    compatible = "foo,pwm";
    #pwm-cells = <2>;
};

pwm2: pwm@deadbeef {
    compatible = "bar,pwm";
    #pwm-cells = <1>;
};

my-node {
    pwms = <&pwm1 1 2000>, <&pwm2 3000>;
};
```

The bindings for compatible `"foo,pwm"` and `"bar,pwm"` must give a name to the cells that appear in a PWM specifier using `pwm-cells:`, like this:

```
# foo,pwm.yaml
compatible: "foo,pwm"
```

(continues on next page)

(continued from previous page)

```
...
pwm-cells:
  - channel
  - period

# bar,pwm.yaml
compatible: "bar,pwm"
...
pwm-cells:
  - period
```

A `*-names` (e.g. `pwm-names`) property can appear on the node as well, giving a name to each entry.

This allows the cells in the specifiers to be accessed by name, e.g. using APIs like `DT_PWMS_CHANNEL_BY_NAME`.

If the specifier is empty (e.g. `#clock-cells = <0>`), then `*-cells` can either be omitted (recommended) or set to an empty array. Note that an empty array is specified as e.g. `clock-cells: []` in YAML.

Include Bindings can include other files, which can be used to share common property definitions between bindings. Use the `include:` key for this. Its value is either a string or a list.

In the simplest case, you can include another file by giving its name as a string, like this:

```
include: foo.yaml
```

If any file named `foo.yaml` is found (see *Where bindings are located* for the search process), it will be included into this binding.

Included files are merged into bindings with a simple recursive dictionary merge. The build system will check that the resulting merged binding is well-formed. It is allowed to include at any level, including `child-binding`, like this:

```
# foo.yaml will be merged with content at this level
include: foo.yaml

child-binding:
  # bar.yaml will be merged with content at this level
  include: bar.yaml
```

It is an error if a key appears with a different value in a binding and in a file it includes, with two exceptions: a binding can have `required: true` for a *property definition* for which the included file has `required: false` (the `required: true` takes precedence, allowing bindings to strengthen requirements from included files), and `class:` values are unioned as described in *Class*.

Note that weakening requirements by having `required: false` where the included file has `required: true` is an error. This is meant to keep the organization clean.

The file base.yaml contains definitions for many common properties. When writing a new binding, it is a good idea to check if `base.yaml` already defines some of the needed properties, and include it if it does.

Note that you can make a property defined in base.yaml obligatory like this, taking *reg* as an example:

```
reg:
  required: true
```

This relies on the dictionary merge to fill in the other keys for `reg`, like `type`.

To include multiple files, you can use a list of strings:

```
include:
  - foo.yaml
  - bar.yaml
```

This includes the files `foo.yaml` and `bar.yaml`. (You can write this list in a single line of YAML as `include: [foo.yaml, bar.yaml]`.)

When including multiple files, any overlapping `required` keys on properties in the included files are ORed together. This makes sure that a `required: true` is always respected.

In some cases, you may want to include some property definitions from a file, but not all of them. In this case, `include:` should be a list, and you can filter out just the definitions you want by putting a mapping in the list, like this:

```
include:
  - name: foo.yaml
    property-allowlist:
      - i-want-this-one
      - and-this-one
  - name: bar.yaml
    property-blocklist:
      - do-not-include-this-one
      - or-this-one
```

Each map element must have a `name` key which is the filename to include, and may have `property-allowlist` and `property-blocklist` keys that filter which properties are included.

You cannot have a single map element with both `property-allowlist` and `property-blocklist` keys. A map element with neither `property-allowlist` nor `property-blocklist` is valid; no additional filtering is done.

You can freely intermix strings and mappings in a single `include:` list:

```
include:
  - foo.yaml
  - name: bar.yaml
    property-blocklist:
      - do-not-include-this-one
      - or-this-one
```

Finally, you can filter from a child binding like this:

```
include:
  - name: bar.yaml
    child-binding:
      property-allowlist:
        - child-prop-to-allow
```

Nexus nodes and maps All `phandle-array` type properties support mapping through `*-map` properties, e.g. `gpio-map`, as defined by the Devicetree specification.

This is used, for example, to define connector nodes for common breakout headers, such as the `arduino_header` nodes that are conventionally defined in the devicetrees for boards with Arduino compatible expansion headers.

Rules for upstream bindings This section includes general rules for writing bindings that you want to submit to the upstream Zephyr Project. (You don't need to follow these rules for bindings you don't intend to contribute to the Zephyr Project, but it's a good idea.)

Decisions made by the Zephyr devicetree maintainer override the contents of this section. If that happens, though, please let them know so they can update this page, or you can send a patch yourself.

Contents

- *Always check for existing bindings*
- *General rules*
  - *File names*
  - *Recommendations are requirements*
  - *Descriptions*
  - *Naming conventions*
- *Rules for vendor prefixes*
- *Rules for default values*
- *The `zephyr,` prefix*

Always check for existing bindings Zephyr aims for devicetree *Source compatibility with other operating systems*. Therefore, if there is an existing binding for your device in an authoritative location, you should try to replicate its properties when writing a Zephyr binding, and you must justify any Zephyr-specific divergences.

In particular, this rule applies if:

- There is an existing binding in the mainline Linux kernel. See `Documentation/devicetree/bindings` in Linus's tree for existing bindings and the Linux devicetree documentation for more information.
- Your hardware vendor provides an official binding outside of the Linux kernel.

General rules Wherever possible, when writing Devicetree bindings for Zephyr, try to follow the same design guidelines laid out by Linux.

File names Bindings which match a compatible must have file names based on the compatible.

- For example, a binding for compatible `vnd,foo` must be named `vnd,foo.yaml`.
- If the binding is bus-specific, you can append the bus to the file name; for example, if the binding YAML has `on-bus: bar`, you may name the file `vnd,foo-bar.yaml`.

Recommendations are requirements All recommendations in *default* are requirements when submitting the binding.

In particular, if you use the `default:` feature, you must justify the value in the property's description.

Descriptions There are only two acceptable ways to write property `description:` strings.

If your description is short, it's fine to use this style:

```
description: my short string
```

If your description is long or spans multiple lines, you must use this style:

```
title: I'm sure you need a short title.

description: |
  My very long string
  goes here.
  Look at all these lines!
```

This | style prevents YAML parsers from removing the newlines in multi-line descriptions. This in turn makes these long strings display properly in the *Bindings index*.

If using the binding's properties gets complicated, you can use examples to provide a minimal node. e.g.:

```
description: ...

properties:
 ...

examples:
  - |
    leds {
      compatible = "gpio-leds";

      uled: led {
      gpios = <&gpioe 12 GPIO_ACTIVE_HIGH>;
      };
    };
```

Naming conventions Do not use uppercase letters (`A` through `Z`) or underscores (`_`) in property names. Use lowercase letters (a through z) instead of uppercase. Use dashes (`-`) instead of underscores. (The one exception to this rule is if you are replicating a well-established binding from somewhere like Linux.)

Rules for vendor prefixes The following general rules apply to vendor prefixes in *compatible* properties.

- If your device is manufactured by a specific vendor, then its compatible should have a vendor prefix.

  If your binding describes hardware with a well known vendor from the list in dts/bindings/vendor-prefixes.txt, you must use that vendor prefix.

- If your device is not manufactured by a specific hardware vendor, do **not** invent a vendor prefix. Vendor prefixes are not mandatory parts of compatible properties, and compatibles should not include them unless they refer to an actual vendor. There are some exceptions to this rule, but the practice is strongly discouraged.

- Do not submit additions to Zephyr's `dts/bindings/vendor-prefixes.txt` file unless you also include users of the new prefix. This means at least a binding and a devicetree using the vendor prefix, and should ideally include a device driver handling that compatible.

  For custom bindings, you can add a custom `dts/bindings/vendor-prefixes.txt` file to any directory in your *DTS_ROOT*. The devicetree tooling will respect these prefixes, and will not generate warnings or errors if you use them in your own bindings or devicetrees.

- We sometimes synchronize Zephyr's vendor-prefixes.txt file with the Linux kernel's equivalent file; this process is exempt from the previous rule.
- If your binding is describing an abstract class of hardware with Zephyr specific drivers handling the nodes, it's usually best to use `zephyr` as the vendor prefix. See *Zephyr Project (zephyr)* for examples.

Rules for default values In any case where `default:` is used in a devicetree binding, the `description:` for that property **must** explain *why* the value was selected and any conditions that would make it necessary to provide a different value. Additionally, if changing one property would require changing another to create a consistent configuration, then those properties should be made required.

There is no need to document the default value itself; this is already present in the *Bindings index* output.

There is a risk in using `default:` when the value in the binding may be incorrect for a particular board or hardware configuration. For example, defaulting the capacity of the connected power cell in a charging IC binding is likely to be incorrect. For such properties it's better to make the property `required: true`, forcing the user to make an explicit choice.

Driver developers should use their best judgment as to whether a value can be safely defaulted. Candidates for default values include:

- delays that would be different only under unusual conditions (such as intervening hardware)
- configuration for devices that have a standard initial configuration (such as a USB audio headset)
- defaults which match the vendor-specified power-on reset value (as long as they are independent from other properties)

Default values for `status`, `#address-cells` and `#size-cells` cannot be defined in the bindings. The default behavior for these properties is already defined in the devicetree specification §2.3.4 and §2.3.5.

Examples of how to write descriptions according to these rules:

```
properties:
  cs-interval:
    type: int
    default: 0
    description: |
      Minimum interval between chip select deassertion and assertion.
      The default corresponds to the reset value of the register field.
  hold-time-ms:
    type: int
    default: 20
    description: |
      Amount of time to hold the power enable GPIO asserted before
      initiating communication. The default was recommended in the
      manufacturer datasheet, and would only change under very
      cold temperatures.
```

Some examples of what **not** to do, and why:

```
properties:
  # Description doesn't mention anything about the default
  foo:
    type: int
    default: 1
```

(continues on next page)

(continued from previous page)

```
    description: number of foos

  # Description mentions the default value instead of why it
  # was chosen
  bar:
    type: int
    default: 2
    description: bar size; default is 2

  # Explanation of the default value is in a comment instead
  # of the description. This won't be shown in the bindings index.
  baz:
    type: int
    # This is the recommended value chosen by the manufacturer.
    default: 2
    description: baz time in milliseconds
```

The `zephyr,` prefix You must add this prefix to property names in the following cases:

- Zephyr-specific extensions to bindings we share with upstream Linux. One example is the `zephyr,vref-mv` ADC channel property which is common to ADC controllers defined in dts/bindings/adc/adc-controller.yaml. This channel binding is partially shared with an analogous Linux binding, and Zephyr-specific extensions are marked as such with the prefix.
- Configuration values that are specific to a Zephyr device driver. One example is the `zephyr,lazy-load` property in the `ti,bq274xx` binding. Though devicetree in general is a hardware description and configuration language, it is Zephyr's only mechanism for configuring driver behavior for an individual `struct device`. Therefore, as a compromise, we do allow some software configuration in Zephyr's devicetree bindings, as long as they use this prefix to show that they are Zephyr specific.

You may use the `zephyr,` prefix when naming a devicetree compatible that is specific to Zephyr. One example is `zephyr,ipc-openamp-static-vrings`. In this case, it's permitted but not required to add the `zephyr,` prefix to properties defined in the binding.

Devicetree access from C/C++

This guide describes Zephyr's `<zephyr/devicetree.h>` API for reading the devicetree from C source files. It assumes you're familiar with the concepts in *Introduction to devicetree* and *Devicetree bindings*. See *Devicetree Reference* for reference material.

A note for Linux developers Linux developers familiar with devicetree should be warned that the API described here differs significantly from how devicetree is used on Linux.

Instead of generating a C header with all the devicetree data which is then abstracted behind a macro API, the Linux kernel would instead read the devicetree data structure in its binary form. The binary representation is parsed at runtime, for example to load and initialize device drivers.

Zephyr does not work this way because the size of the devicetree binary and associated handling code would be too large to fit comfortably on the relatively constrained devices Zephyr supports.

Node identifiers To get information about a particular devicetree node, you need a *node identifier* for it. This is a just a C macro that refers to the node.

These are the main ways to get a node identifier:

By path
Use `DT_PATH()` along with the node's full path in the devicetree, starting from the root node. This is mostly useful if you happen to know the exact node you're looking for.

By node label
Use `DT_NODELABEL()` to get a node identifier from a *node label*. Node labels are often provided by SoC `.dtsi` files to give nodes names that match the SoC datasheet, like `i2c1`, `spi2`, etc.

By alias
Use `DT_ALIAS()` to get a node identifier for a property of the special `/aliases` node. This is sometimes done by applications (like blinky, which uses the `led0` alias) that need to refer to *some* device of a particular type ("the board's user LED") but don't care which one is used. You may also use `DT_HAS_ALIAS()` to verify whether an alias node exists.

By instance number
This is done primarily by device drivers, as instance numbers are a way to refer to individual nodes based on a matching compatible. Get these with `DT_INST()`, but be careful doing so. See below.

By chosen node
Use `DT_CHOSEN()` to get a node identifier for `/chosen` node properties.

By parent/child
Use `DT_PARENT()` and `DT_CHILD()` to get a node identifier for a parent or child node, starting from a node identifier you already have.

Two node identifiers which refer to the same node are identical and can be used interchangeably.

Here's a DTS fragment for some imaginary hardware we'll return to throughout this file for examples:

```
/dts-v1/;

/ {
        aliases {
                sensor-controller = &i2c1;
        };

        soc {
                i2c1: i2c@40002000 {
                        compatible = "vnd,soc-i2c";
                        label = "I2C_1";
                        reg = <0x40002000 0x1000>;
                        status = "okay";
                        clock-frequency = <100000>;
                };
        };
};
```

Here are a few ways to get node identifiers for the `i2c@40002000` node:

- `DT_PATH(soc, i2c_40002000)`
- `DT_NODELABEL(i2c1)`
- `DT_ALIAS(sensor_controller)`
- `DT_INST(x, vnd_soc_i2c)` for some unknown number `x`. See the `DT_INST()` documentation for details.

Important

Non-alphanumeric characters like dash (-) and the at sign (@) in devicetree names are converted to underscores (_). The names in a DTS are also converted to lowercase.

Node identifiers are not values There is no way to store one in a variable. You cannot write:

```
/* These will give you compiler errors: */

void *i2c_0 = DT_INST(0, vnd_soc_i2c);
unsigned int i2c_1 = DT_INST(1, vnd_soc_i2c);
long my_i2c = DT_NODELABEL(i2c1);
```

If you want something short to save typing, use C macros:

```
/* Use something like this instead: */

#define MY_I2C DT_NODELABEL(i2c1)

#define INST(i) DT_INST(i, vnd_soc_i2c)
#define I2C_0 INST(0)
#define I2C_1 INST(1)
```

Property access The right API to use to read property values depends on the node and property.

- *Checking properties and values*
- *Simple properties*
- *reg properties*
- *interrupts properties*
- *phandle properties*

Checking properties and values You can use `DT_NODE_HAS_PROP()` to check if a node has a property. For the *example devicetree* above:

```
DT_NODE_HAS_PROP(DT_NODELABEL(i2c1), clock_frequency)  /* expands to 1 */
DT_NODE_HAS_PROP(DT_NODELABEL(i2c1), not_a_property)   /* expands to 0 */
```

Simple properties Use `DT_PROP(node_id, property)` to read basic integer, boolean, string, numeric array, and string array properties.

For example, to read the `clock-frequency` property's value in the *above example*:

```
DT_PROP(DT_PATH(soc, i2c_40002000), clock_frequency)  /* This is 100000, */
DT_PROP(DT_NODELABEL(i2c1), clock_frequency)          /* and so is this, */
DT_PROP(DT_ALIAS(sensor_controller), clock_frequency) /* and this. */
```

Important

The DTS property `clock-frequency` is spelled `clock_frequency` in C. That is, properties also need special characters converted to underscores. Their names are also forced to lowercase.

Properties with `string` and `boolean` types work the exact same way. The `DT_PROP()` macro expands to a string literal in the case of strings, and the number 0 or 1 in the case of booleans. For example:

```
#define I2C1 DT_NODELABEL(i2c1)

DT_PROP(I2C1, status)  /* expands to the string literal "okay" */
```

Note

Don't use DT_NODE_HAS_PROP() for boolean properties. Use DT_PROP() instead as shown above. It will expand to either 0 or 1 depending on if the property is present or absent.

Properties with type `array`, `uint8-array`, and `string-array` work similarly, except `DT_PROP()` expands to an array initializer in these cases. Here is an example devicetree fragment:

```
foo: foo@1234 {
        a = <1000 2000 3000>; /* array */
        b = [aa bb cc dd];    /* uint8-array */
        c = "bar", "baz";     /* string-array */
};
```

Its properties can be accessed like this:

```
#define FOO DT_NODELABEL(foo)

int a[] = DT_PROP(FOO, a);           /* {1000, 2000, 3000} */
unsigned char b[] = DT_PROP(FOO, b); /* {0xaa, 0xbb, 0xcc, 0xdd} */
char* c[] = DT_PROP(FOO, c);         /* {"bar", "baz"} */
```

You can use `DT_PROP_LEN()` to get logical array lengths in number of elements.

```
size_t a_len = DT_PROP_LEN(FOO, a); /* 3 */
size_t b_len = DT_PROP_LEN(FOO, b); /* 4 */
size_t c_len = DT_PROP_LEN(FOO, c); /* 2 */
```

`DT_PROP_LEN()` cannot be used with the special `reg` or `interrupts` properties. These have alternative macros which are described next.

reg properties See *Important properties* for an introduction to `reg`.

Given a node identifier `node_id`, `DT_NUM_REGS(node_id)` is the total number of register blocks in the node's `reg` property.

You **cannot** read register block addresses and lengths with `DT_PROP(node, reg)`. Instead, if a node only has one register block, use `DT_REG_ADDR` or `DT_REG_SIZE`:

- `DT_REG_ADDR(node_id)`: the given node's register block address
- `DT_REG_SIZE(node_id)`: its size

Use `DT_REG_ADDR_BY_IDX` or `DT_REG_SIZE_BY_IDX` instead if the node has multiple register blocks:

- `DT_REG_ADDR_BY_IDX(node_id, idx)`: address of register block at index `idx`
- `DT_REG_SIZE_BY_IDX(node_id, idx)`: size of block at index `idx`

The `idx` argument to these must be an integer literal or a macro that expands to one without requiring any arithmetic. In particular, `idx` cannot be a variable. This won't work:

```
/* This will cause a compiler error. */

for (size_t i = 0; i < DT_NUM_REGS(node_id); i++) {
        size_t addr = DT_REG_ADDR_BY_IDX(node_id, i);
}
```

interrupts properties See *Important properties* for a brief introduction to `interrupts`.

Given a node identifier `node_id`, `DT_NUM_IRQS(node_id)` is the total number of interrupt specifiers in the node's `interrupts` property.

The most general purpose API macro for accessing these is `DT_IRQ_BY_IDX`:

```
DT_IRQ_BY_IDX(node_id, idx, val)
```

Here, `idx` is the logical index into the `interrupts` array, i.e. it is the index of an individual interrupt specifier in the property. The `val` argument is the name of a cell within the interrupt specifier. To use this macro, check the bindings file for the node you are interested in to find the `val` names.

Most Zephyr devicetree bindings have a cell named `irq`, which is the interrupt number. You can use `DT_IRQN` as a convenient way to get a processed view of this value.

Warning

Here, "processed" reflects Zephyr's devicetree *Scripts and tools*, which change the `irq` number in *zephyr.dts* to handle hardware constraints on some SoCs and in accordance with Zephyr's multilevel interrupt numbering.

This is currently not very well documented, and you'll need to read the scripts' source code and existing drivers for more details if you are writing a device driver.

Note

See *Phandles* for a detailed guide to phandles.

phandle properties Property values can refer to other nodes using the `&another-node` phandle syntax introduced in *Writing property values*. Properties which contain phandles have type `phandle`, `phandles`, or `phandle-array` in their bindings. We'll call these "phandle properties" for short.

You can convert a phandle to a node identifier using `DT_PHANDLE`, `DT_PHANDLE_BY_IDX`, or `DT_PHANDLE_BY_NAME`, depending on the type of property you are working with.

One common use case for phandle properties is referring to other hardware in the tree. In this case, you usually want to convert the devicetree-level phandle to a Zephyr driver-level *struct device*. See *Get a struct device from a devicetree node* for ways to do that.

Another common use case is accessing specifier values in a phandle array. The general purpose APIs for this are `DT_PHA_BY_IDX` and `DT_PHA`. There are also hardware-specific shorthands like `DT_GPIO_CTLR_BY_IDX`, `DT_GPIO_CTLR`, `DT_GPIO_PIN_BY_IDX`, `DT_GPIO_PIN`, `DT_GPIO_FLAGS_BY_IDX`, and `DT_GPIO_FLAGS`.

See `DT_PHA_HAS_CELL_AT_IDX` and `DT_PROP_HAS_IDX` for ways to check if a specifier value is present in a phandle property.

Other APIs Here are pointers to some other available APIs.

- DT_CHOSEN, DT_HAS_CHOSEN: for properties of the special /chosen node
- DT_HAS_COMPAT_STATUS_OKAY, DT_NODE_HAS_COMPAT: global- and node-specific tests related to the compatible property
- DT_BUS: get a node's bus controller, if there is one
- DT_ENUM_IDX: for properties whose values are among a fixed list of choices
- *Fixed and mapped flash partitions*: APIs for managing fixed flash partitions and mapped flash partitions. Also see *Flash map*, which wraps this in a more user-friendly API.

Device driver conveniences Special purpose macros are available for writing device drivers, which usually rely on *instance identifiers*.

To use these, you must define DT_DRV_COMPAT to the compat value your driver implements support for. This compat value is what you would pass to DT_INST.

If you do that, you can access the properties of individual instances of your compatible with less typing, like this:

```
#include <zephyr/devicetree.h>

#define DT_DRV_COMPAT my_driver_compat

/* This is same thing as DT_INST(0, my_driver_compat): */
DT_DRV_INST(0)

/*
 * This is the same thing as
 * DT_PROP(DT_INST(0, my_driver_compat), clock_frequency)
 */
DT_INST_PROP(0, clock_frequency)
```

See *Instance-based APIs* for a generic API reference.

Hardware specific APIs Convenience macros built on top of the above APIs are also defined to help readability for hardware specific code. See *Hardware specific APIs* for details.

Generated macros While the zephyr/devicetree.h API is not generated, it does rely on a generated C header which is put into every application build directory: *devicetree_generated.h*. This file contains macros with devicetree data.

These macros have tricky naming conventions which the *Devicetree API* API abstracts away. They should be considered an implementation detail, but it's useful to understand them since they will frequently be seen in compiler error messages.

This section contains an Augmented Backus-Naur Form grammar for these generated macros, with examples and more details in comments. See **RFC 7405** (which extends **RFC 5234**) for a syntax specification.

```
; An RFC 7405 ABNF grammar for devicetree macros.
;
; This does *not* cover macros pulled out of DT via Kconfig,
; like CONFIG_SRAM_BASE_ADDRESS, etc. It only describes the
; ones that start with DT_ and are directly generated.

; ---------------------------------------------------------------------

;
; This in "lowercase-and-underscores" form. I.e. it is
; the node's devicetree path converted to a C token by changing:
;
; - each slash (/) to _S_
; - all letters to lowercase
; - non-alphanumerics characters to underscores
;
; For example, the leaf node "bar-BAZ" in this devicetree:
;
;   / {
;           foo@123 {
;                   bar-BAZ {};
;           };
;   };
;
; has path-id "_S_foo_123_S_bar_baz".
path-id = 1*( %s"_S_" dt-name )

; ------------------------------------------------------------------------
; prop-id: a property identifier
;
; A property name converted to a C token by changing:
;
; - all letters to lowercase
; - non-alphanumeric characters to underscores
;
; Example node:
;
;   chosen {
;       zephyr,console = &uart1;
;       WHY,AM_I_SHOUTING = "unclear";
;   };
;
; The 'zephyr,console' property has prop-id 'zephyr_console'.
; 'WHY,AM_I_SHOUTING' has prop-id 'why_am_i_shouting'.
prop-id = dt-name
```

; ------------------------------------------------------------------------
; prop-suf: a property-specific macro suffix
;
; Extra macros are generated for properties:
;
; - that are special to the specification ("reg", "interrupts", etc.)
; - with array types (uint8-array, phandle-array, etc.)
; - with "enum:" in their bindings
; - that have zephyr device API specific macros for phandle-arrays
; - related to phandle specifier names ("foo-names")
;
; Here are some examples:
;
; - _EXISTS: property, index or name existence flag
; - _SIZE: logical property length
; - _IDX_<i>: values of individual array elements
; - _IDX_<DIGIT>_VAL_<dt-name>: values of individual specifier
;   cells within a phandle array
; - _ADDR_<i>: for reg properties, the i-th register block address
; - _LEN_<i>: for reg properties, the i-th register block length
;
; The different cases are not exhaustively documented here to avoid
; this file going stale. Please see devicetree.h if you need to know
; the details.
prop-suf = 1*( "_" gen-name ["_" dt-name] )

; ------------------------------------------------------------------------
; other-macro: grab bag for everything that isn't a node-macro.

; See examples below.
other-macro =  %s"DT_N_" alternate-id
; Total count of enabled instances of a compatible.
other-macro =/ %s"DT_N_INST_" dt-name %s"_NUM_OKAY"
; These are used internally by DT_FOREACH_NODE and

(continued from previous page)

```
;   #define DT_COMPAT_HAS_OKAY_vnd_dev 1
other-macro =/ %s"DT_COMPAT_HAS_OKAY_" dt-name
; Declares that a device class has at least one status "okay" node,
; and the count of such nodes.
; Example:
;
;   #define DT_CLASS_HAS_OKAY_adc 1
;   #define DT_N_CLASS_adc_NUM_OKAY 2
other-macro =/ %s"DT_CLASS_HAS_OKAY_" dt-name
other-macro =/ %s"DT_N_CLASS_" dt-name %s"_NUM_OKAY"
; These are used internally by DT_FOREACH_CLASS_STATUS_OKAY,
; which iterates over each enabled node of a device class.
other-macro =/ %s"DT_FOREACH_OKAY_CLASS_" dt-name
other-macro =/ %s"DT_FOREACH_OKAY_VARGS_CLASS_" dt-name
; Currently used to allow mapping a lowercase-and-underscores "label"
; property to a fixed-partitions node. See the flash map API docs
; for an example.
other-macro =/ %s"DT_COMPAT_" dt-name %s"_LABEL_" dt-name
; Get the node label of the phandle
other-macro =/ %s"DT_N_NODELABEL_" %s"DT_N" path-id "_IDX_" DIGIT "_C_TOKEN"

; ------------------------------------------------------------------
; alternate-id: another way to specify a node besides a path-id
;
; Example devicetree:
;
;   / {
;           aliases {
;                   dev = &dev_1;
;           };
;
;           soc {
;               dev_1: device@123 {
;                   compatible = "vnd,device";
;               };
;           };
;   };
;
; Node device@123 has these alternate-id values:
;
; - ALIAS_dev
; - NODELABEL_dev_1
; - INST_0_vnd_device
;
; The full alternate-id macros are:
;
;   #define DT_N_INST_0_vnd_device     DT_N_S_soc_S_device_123
;   #define DT_N_ALIAS_dev             DT_N_S_soc_S_device_123
;   #define DT_N_NODELABEL_dev_1       DT_N_S_soc_S_device_123
;
; These mainly exist to allow pasting an alternate-id macro onto a
; "_P_<prop-id>" to access node properties given a node's alias, etc.
;
; Notice that "inst"-type IDs have a leading instance identifier,
; which is generated by the devicetree scripts. The other types of
; alternate-id begin immediately with names taken from the devicetree.
```

(continues on next page)

```
alternate-id =  ( %s"ALIAS" / %s"NODELABEL" ) dt-name
alternate-id =/ %s"INST_" 1*DIGIT "_" dt-name

; ------------------------------------------------------------------------
; miscellaneous helper definitions

; A dt-name is one or more:
; - lowercase ASCII letters (a-z)
; - numbers (0-9)
; - underscores ("_")
;
; They are the result of converting names or combinations of names
; from devicetree to a valid component of a C identifier by
; lowercasing letters (in practice, this is a no-op) and converting
; non-alphanumeric characters to underscores.
;
; You'll see these referred to as "lowercase-and-underscores" forms of
; various devicetree identifiers throughout the documentation.
dt-name = 1*( lower / DIGIT / "_" )

; gen-name is used as a stand-in for a component of a generated macro
; name which does not come from devicetree (dt-name covers that case).
;
; - uppercase ASCII letters (a-z)
; - numbers (0-9)
; - underscores ("_")
gen-name = upper 1*( upper / DIGIT / "_" )

; "lowercase ASCII letter" turns out to be pretty annoying to specify
; in RFC-7405 syntax.
;
; This is just ASCII letters a (0x61) through z (0x7a).
lower = %x61-7A

; "uppercase ASCII letter" in RFC-7405 syntax
upper = %x41-5A
```

Phandles

The devicetree concept of a *phandle* is very similar to pointers in C. You can use phandles to refer to nodes in devicetree similarly to the way you can use pointers to refer to structures in C.

Getting phandles The usual way to get a phandle for a devicetree node is from one of its node labels. For example, with this devicetree:

```
/ {
        lbl_a: node-1 {};
        lbl_b: lbl_c: node-2 {};
};
```

You can write the phandle for:

- `/node-1` as `&lbl_a`
- `/node-2` as either `&lbl_b` or `&lbl_c`

Notice how the `&nodelabel` devicetree syntax is similar to the "address of" C syntax.

Note

"Type" in this section refers to one of the type names documented in *Properties* in the devicetree bindings documentation.

Using phandles Here are the main ways you will use phandles.

One node: phandle type You can use phandles to refer to `node-b` from `node-a`, where `node-b` is related to `node-a` in some way.

One common example is when `node-a` represents some hardware that generates an interrupt, and `node-b` represents the interrupt controller that receives the asserted interrupt. In this case, you could write:

```
node_b: node-b {
        interrupt-controller;
};

node-a {
        interrupt-parent = <&node_b>;
};
```

This uses the standard `interrupt-parent` property defined in the devicetree specification to capture the relationship between the two nodes.

These properties have type `phandle`.

Zero or more nodes: phandles type You can use phandles to make an array of references to other nodes.

One common example occurs in *pin control*. Pin control properties like `pinctrl-0`, `pinctrl-1` etc. may contain multiple phandles, each of which "points" to a node containing information related to pin configuration for that hardware peripheral. Here's an example of six phandles in a single property:

```
pinctrl-0 = <&quadspi_clk_pe10 &quadspi_ncs_pe11
             &quadspi_bk1_io0_pe12 &quadspi_bk1_io1_pe13
             &quadspi_bk1_io2_pe14 &quadspi_bk1_io3_pe15>;
```

These properties have type `phandles`.

Zero or more nodes with metadata: phandle-array type You can use phandles to refer to and configure one or more resources that are "owned" by some other node.

This is the most complex case. There are examples and more details in the next section.

These properties have type `phandle-array`.

phandle-array properties These properties are commonly used to specify a resource that is owned by another node along with additional metadata about the resource.

High level description Usually, properties with this type are written like `phandle-array-prop` in this example:

```
node {
        phandle-array-prop = <&foo 1 2>, <&bar 3>, <&baz 4 5>;
};
```

That is, the property's value is written as a comma-separated sequence of "groups", where each "group" is written inside of angle brackets (`< ... >`). Each "group" starts with a phandle (`&foo`, `&bar`, `&baz`). The values that follow the phandle in each "group" are called *specifiers*. There are three specifiers in the above example:

1. `1 2`
2. `3`
3. `4 5`

The phandle in each "group" is used to "point" to the hardware that controls the resource you are interested in. The specifier describes the resource itself, along with any additional necessary metadata.

The rest of this section describes a common example. Subsequent sections document more rules about how to use phandle-array properties in practice.

Example phandle-arrays: GPIOs Perhaps the most common use case for phandle-array properties is specifying one or more GPIOs on your SoC that another chip on your board connects to. For that reason, we'll focus on that use case here. However, there are **many other use cases** that are handled in devicetree with phandle-array properties.

For example, consider an external chip with an interrupt pin that is connected to a GPIO on your SoC. You will typically need to provide that GPIO's information (GPIO controller and pin number) to the *device driver* for that chip. You usually also need to provide other metadata about the GPIO, like whether it is active low or high, what kind of internal pull resistor within the SoC should be enabled in order to communicate with the device, etc., to the driver.

In the devicetree, there will be a node that represents the GPIO controller that controls a group of pins. This reflects the way GPIO IP blocks are usually developed in hardware. Therefore, there is no single node in the devicetree that represents a GPIO pin, and you can't use a single phandle to represent it.

Instead, you would use a phandle-array property, like this:

```
my-external-ic {
        irq-gpios = <&gpioX pin flags>;
};
```

In this example, `irq-gpios` is a phandle-array property with just one "group" in its value. `&gpioX` is the phandle for the GPIO controller node that controls the pin. `pin` is the pin number (0, 1, 2, ...). `flags` is a bit mask describing pin metadata (for example `(GPIO_ACTIVE_LOW | GPIO_PULL_UP)`); see include/zephyr/dt-bindings/gpio/gpio.h for more details.

The device driver handling the `my-external-ic` node can then use the `irq-gpios` property's value to set up interrupt handling for the chip as it is used on your board. This lets you configure the device driver in devicetree, without changing the driver's source code.

Such properties can contain multiple values as well:

```
my-other-external-ic {
        handshake-gpios = <&gpioX pinX flagsX>, <&gpioY pinY flagsY>;
};
```

The above example specifies two pins:

- `pinX` on the GPIO controller with phandle `&gpioX`, flags `flagsX`
- `pinY` on `&gpioY`, flags `flagsY`

You may be wondering how the "pin and flags" convention is established and enforced. To answer this question, we'll need to introduce a concept called specifier spaces before moving on to some information about devicetree bindings.

Specifier spaces *Specifier spaces* are a way to allow nodes to describe how you should use them in phandle-array properties.

We'll start with an abstract, high level description of how specifier spaces work in DTS files, before moving on to a concrete example and providing references to further reading for how this all works in practice using DTS files and bindings files.

High level description As described above, a phandle-array property is a sequence of "groups" of phandles followed by some number of cells:

```
node {
        phandle-array-prop = <&foo 1 2>, <&bar 3>;
};
```

The cells that follow each phandle are called a *specifier*. In this example, there are two specifiers:

1. `1 2`: two cells
2. `3`: one cell

Every phandle-array property has an associated *specifier space*. This sounds complex, but it's really just a way to assign a meaning to the cells that follow each phandle in a hardware specific way. Every specifier space has a unique name. There are a few "standard" names for commonly used hardware, but you can create your own as well.

Devicetree nodes encode the number of cells that must appear in a specifier, by name, using the `#SPACE_NAME-cells` property. For example, let's assume that `phandle-array-prop`'s specifier

space is named baz. Then we would need the foo and bar nodes to have the following #baz-cells properties:

```
foo: node@1000 {
        #baz-cells = <2>;
};

bar: node@2000 {
        #baz-cells = <1>;
};
```

Without the #baz-cells property, the devicetree tooling would not be able to validate the number of cells in each specifier in phandle-array-prop.

This flexibility allows you to write down an array of hardware resources in a single devicetree property, even though the amount of metadata you need to describe each resource might be different for different nodes.

A single node can also have different numbers of cells in different specifier spaces. For example, we might have:

```
foo: node@1000 {
        #baz-cells = <2>;
        #bob-cells = <1>;
};
```

With that, if phandle-array-prop-2 has specifier space bob, we could write:

```
node {
        phandle-array-prop = <&foo 1 2>, <&bar 3>;
        phandle-array-prop-2 = <&foo 4>;
};
```

This flexibility allows you to have a node that manages multiple different kinds of resources at the same time. The node describes the amount of metadata needed to describe each kind of resource (how many cells are needed in each case) using different #SPACE_NAME-cells properties.

Example specifier space: gpio From the above example, you're already familiar with how one specifier space works: in the "gpio" space, specifiers almost always have two cells:

1. a pin number
2. a bit mask of flags related to the pin

Therefore, almost all GPIO controller nodes you will see in practice will look like this:

```
gpioX: gpio-controller@deadbeef {
        gpio-controller;
        #gpio-cells = <2>;
};
```

Associating properties with specifier spaces Above, we have described that:

- each phandle-array property has an associated specifier space
- specifier spaces are identified by name
- devicetree nodes use #SPECIFIER_NAME-cells properties to configure the number of cells which must appear in a specifier

In this section, we explain how phandle-array properties get their specifier spaces.

High level description In general, a `phandle-array` property named `foos` implicitly has specifier space `foo`. For example:

```
properties:
  dmas:
    type: phandle-array
  pwms:
    type: phandle-array
```

The `dmas` property's specifier space is "dma". The `pwms` property's specifier space is `pwm`.

Special case: GPIOs and IO channels `*-gpios` and `*-io-channels` properties are special-cased so that e.g. `foo-gpios` and `bar-io-channels` resolve to `#gpio-cells` and `#io-channel-cells` respectively, rather than `#foo-gpio-cells` and `#bar-io-channel-cells`.

Manually specifying a space You can manually specify the specifier space for any `phandle-array` property. See *specifier-space*.

Naming the cells in a specifier You should name the cells in each specifier space your hardware supports when writing bindings. For details on how to do this, see *Specifier cell names (*-cells)*.

This allows C code to query information about and retrieve the values of cells in a specifier by name using devicetree APIs like these:

- `DT_PHA_BY_IDX`
- `DT_PHA_BY_NAME`

This feature and these macros are used internally by numerous hardware-specific APIs. Here are a few examples:

- `DT_GPIO_PIN_BY_IDX`
- `DT_PWMS_CHANNEL_BY_IDX`
- `DT_DMAS_CELL_BY_NAME`
- `DT_IO_CHANNELS_INPUT_BY_IDX`
- `DT_CLOCKS_CELL_BY_NAME`

- *specifier-space*: how to manually specify a phandle-array property's specifier space
- *dependency-mode*: how to control node dependencies using phandle properties

The `/zephyr,user` node

Zephyr's devicetree scripts handle the `/zephyr,user` node as a special case: you can put essentially arbitrary properties inside it and retrieve their values without having to write a binding. It is meant as a convenient container when only a few simple properties are needed. The type is inferred from the values assigned to the property.

Note

This node is meant for sample code and user applications. It should not be used in the upstream Zephyr source code for device drivers, subsystems, etc.

Simple values You can store numeric or array values in `/zephyr,user` if you want them to be configurable at build time via devicetree.

For example, with this devicetree overlay:

```
/ {
    zephyr,user {
            boolean;
            bytes = [81 82 83];
            number = <23>;
            numbers = <1>, <2>, <3>;
            string = "text";
            strings = "a", "b", "c";
    };
};
```

You can get the above property values in C/C++ code like this:

```
#define ZEPHYR_USER_NODE DT_PATH(zephyr_user)

DT_PROP(ZEPHYR_USER_NODE, boolean) // 1
DT_PROP(ZEPHYR_USER_NODE, bytes)   // {0x81, 0x82, 0x83}
DT_PROP(ZEPHYR_USER_NODE, number)  // 23
DT_PROP(ZEPHYR_USER_NODE, numbers) // {1, 2, 3}
DT_PROP(ZEPHYR_USER_NODE, string)  // "text"
DT_PROP(ZEPHYR_USER_NODE, strings) // {"a", "b", "c"}
```

Devices You can store *phandles* in `/zephyr,user` if you want to be able to reconfigure which devices your application uses in simple cases using devicetree overlays.

For example, with this devicetree overlay:

```
/ {
    zephyr,user {
            handle = <&gpio0>;
            handles = <&gpio0>, <&gpio1>;
    };
};
```

You can convert the phandles in the `handle` and `handles` properties to device pointers like this:

```
/*
 * Same thing as:
 *
 * ... my_dev = DEVICE_DT_GET(DT_NODELABEL(gpio0));
 */
const struct device *my_device =
    DEVICE_DT_GET(DT_PROP(ZEPHYR_USER_NODE, handle));

/*
 * Same thing as:
 *
```

(continues on next page)

(continued from previous page)

```
 * ... *my_devices[] = {
 *         DEVICE_DT_GET(DT_NODELABEL(gpio0)),
 *         DEVICE_DT_GET(DT_NODELABEL(gpio1))
 * };
 */
const struct device *my_devices[] = {
    DT_FOREACH_PROP_ELEM_SEP(ZEPHYR_USER_NODE, handles, DEVICE_DT_GET_BY_IDX, (,))
};
```

GPIOs The `/zephyr,user` node is a convenient place to store application-specific GPIOs that you want to be able to reconfigure with a devicetree overlay.

> **Note**
>
> All properties with a value containing at least one phandle and a number will be inferred as a phandle-array. example `<&adc0 1>`.

For example, with this devicetree overlay:

```
#include <zephyr/dt-bindings/gpio/gpio.h>

/ {
    zephyr,user {
            signal-gpios = <&gpio0 1 GPIO_ACTIVE_HIGH>;
    };
};
```

You can convert the pin defined in `signal-gpios` to a `struct gpio_dt_spec` in your source code, then use it like this:

```
#include <zephyr/drivers/gpio.h>

#define ZEPHYR_USER_NODE DT_PATH(zephyr_user)

const struct gpio_dt_spec signal =
        GPIO_DT_SPEC_GET(ZEPHYR_USER_NODE, signal_gpios);

/* Configure the pin */
gpio_pin_configure_dt(&signal, GPIO_OUTPUT_INACTIVE);

/* Set the pin to its active level */
gpio_pin_set_dt(&signal, 1);
```

(See `gpio_dt_spec`, `GPIO_DT_SPEC_GET`, and `gpio_pin_configure_dt()` for details on these APIs.)

Devicetree HOWTOs

This page has step-by-step advice for getting things done with devicetree.

> **Tip**
>
> See *Troubleshooting devicetree* for troubleshooting advice.

Get your devicetree and generated header A board's devicetree (*BOARD.dts*) pulls in common node definitions via `#include` preprocessor directives. This at least includes the SoC's `.dtsi`. One way to figure out the devicetree's contents is by opening these files, e.g. by looking in `dts/<ARCH>/<vendor>/<soc>.dtsi`, but this can be time consuming.

If you just want to see the "final" devicetree for your board, build an application and open the `zephyr.dts` file in the build directory.

> **Tip**
>
> You can build hello_world to see the "base" devicetree for your board without any additional changes from *overlay files*.

For example, using the qemu_cortex_m3 board to build hello_world:

```
# --cmake-only here just forces CMake to run, skipping the
# build process to save time.
west build -b qemu_cortex_m3 samples/hello_world --cmake-only
```

You can change `qemu_cortex_m3` to match your board.

CMake prints the input and output file locations like this:

```
-- Found BOARD.dts: .../zephyr/boards/arm/qemu_cortex_m3/qemu_cortex_m3.dts
-- Generated zephyr.dts: .../zephyr/build/zephyr/zephyr.dts
-- Generated devicetree_generated.h: .../
↪zephyr/build/zephyr/include/generated/zephyr/devicetree_generated.h
```

The `zephyr.dts` file is the final devicetree in DTS format.

The `devicetree_generated.h` file is the corresponding generated header.

See *Input and output files* for details about these files.

Get a struct device from a devicetree node When writing Zephyr applications, you'll often want to get a driver-level *struct device* corresponding to a devicetree node.

For example, with this devicetree fragment, you might want the struct device for `serial@40002000`:

```
/ {
        soc {
                serial0: serial@40002000 {
                        status = "okay";
                        current-speed = <115200>;
                        /* ... */
                };
        };

        aliases {
                my-serial = &serial0;
        };

        chosen {
                zephyr,console = &serial0;
        };
};
```

Start by making a *node identifier* for the device you are interested in. There are different ways to do this; pick whichever one works best for your requirements. Here are some examples:

```
/* Option 1: by node label */
#define MY_SERIAL DT_NODELABEL(serial0)

/* Option 2: by alias */
#define MY_SERIAL DT_ALIAS(my_serial)

/* Option 3: by chosen node */
#define MY_SERIAL DT_CHOSEN(zephyr_console)

/* Option 4: by path */
#define MY_SERIAL DT_PATH(soc, serial_40002000)
```

Once you have a node identifier there are two ways to proceed. One way to get a device is to use DEVICE_DT_GET:

```
const struct device *const uart_dev = DEVICE_DT_GET(MY_SERIAL);

if (!device_is_ready(uart_dev)) {
        /* Not ready, do not use */
        return -ENODEV;
}
```

There are variants of DEVICE_DT_GET such as DEVICE_DT_GET_OR_NULL, DEVICE_DT_GET_ONE or DEVICE_DT_GET_ANY. This idiom fetches the device pointer at build-time, which means there is no runtime penalty. This method is useful if you want to store the device pointer as configuration data. But because the device may not be initialized, or may have failed to initialize, you must verify that the device is ready to be used before passing it to any API functions. (This check is done for you by device_get_binding().)

In some situations the device cannot be known at build-time, e.g., if it depends on user input like in a shell application. In this case you can get the `struct device` by combining device_get_binding() with the device name:

```
const char *dev_name = /* TODO: insert device name from user */;
const struct device *uart_dev = device_get_binding(dev_name);
```

You can then use `uart_dev` with *Universal Asynchronous Receiver-Transmitter (UART)* API functions like uart_configure(). Similar code will work for other device types; just make sure you use the correct API for the device.

If you're having trouble, see *Troubleshooting devicetree*. The first thing to check is that the node has `status = "okay"`, like this:

```
#define MY_SERIAL DT_NODELABEL(my_serial)

#if DT_NODE_HAS_STATUS(MY_SERIAL, okay)
const struct device *const uart_dev = DEVICE_DT_GET(MY_SERIAL);
#else
#error "Node is disabled"
#endif
```

If you see the `#error` output, make sure to enable the node in your devicetree. In some situations your code will compile but it will fail to link with a message similar to:

```
...undefined reference to `__device_dts_ord_N'
collect2: error: ld returned 1 exit status
```

This likely means there's a Kconfig issue preventing the device driver from being built, resulting in a reference that does not exist. If your code compiles successfully, the last thing to check is if the device is ready, like this:

```
if (!device_is_ready(uart_dev)) {
     printk("Device not ready\n");
}
```

If you find that the device is not ready, it likely means that the device's initialization function failed. Enabling logging or debugging driver code may help in such situations. Note that you can also use `device_get_binding()` to obtain a reference at runtime. If it returns `NULL` it can either mean that device's driver failed to initialize or that it does not exist.

Find a devicetree binding *Devicetree bindings* are YAML files which declare what you can do with the nodes they describe, so it's critical to be able to find them for the nodes you are using.

If you don't have them already, *Get your devicetree and generated header*. To find a node's binding, open the generated header file, which starts with a list of nodes in a block comment:

```
/*
 * [...]
 * Nodes in dependency order (ordinal and path):
 *   0   /
 *   1   /aliases
 *   2   /chosen
 *   3   /flash@0
 *   4   /memory@20000000
 *          (etc.)
 * [...]
 */
```

Make note of the path to the node you want to find, like `/flash@0`. Search for the node's output in the file, which starts with something like this if the node has a matching binding:

```
/*
 * Devicetree node:
 *   /flash@0
 *
 * Binding (compatible = soc-nv-flash):
 *   $ZEPHYR_BASE/dts/bindings/mtd/soc-nv-flash.yaml
 * [...]
 */
```

See *Check for missing bindings* for troubleshooting.

Set devicetree overlays Devicetree overlays are explained in *Introduction to devicetree*. The CMake variable **DTC_OVERLAY_FILE** contains a space- or semicolon-separated list of overlay files to use. If **DTC_OVERLAY_FILE** specifies multiple files, they are included in that order by the C preprocessor. A file in a Zephyr module can be referred to by escaping the Zephyr module dir variable like `\${ZEPHYR_<module>_MODULE_DIR}/<path-to>/dts.overlay` when setting the DTC_OVERLAY_FILE variable.

You can set **DTC_OVERLAY_FILE** to contain exactly the files you want to use. Here is an *example* using `west build`.

If you don't set **DTC_OVERLAY_FILE**, the build system will follow these steps, looking for files in your application configuration directory to use as devicetree overlays:

1. If the file `socs/<SOC>_<BOARD_QUALIFIERS>.overlay` exists, it will be used.
2. If the file `boards/<BOARD>.overlay` exists, it will be used in addition to the above.
3. If the current board has *multiple revisions* and `boards/<BOARD>_<revision>.overlay` exists, it will be used in addition to the above.

4. If one or more files have been found in the previous steps, the build system stops looking and just uses those files.
5. Otherwise, if `<BOARD>.overlay` exists, it will be used, and the build system will stop looking for more files.
6. Otherwise, if `app.overlay` exists, it will be used.

Extra devicetree overlays may be provided using `EXTRA_DTC_OVERLAY_FILE` which will still allow the build system to automatically use devicetree overlays described in the above steps.

The build system appends overlays specified in `EXTRA_DTC_OVERLAY_FILE` to the overlays in `DTC_OVERLAY_FILE` when processing devicetree overlays. This means that changes made via `EXTRA_DTC_OVERLAY_FILE` have higher precedence than those made via `DTC_OVERLAY_FILE`.

All configuration files will be taken from the application's configuration directory except for files with an absolute path that are given with the `DTC_OVERLAY_FILE` or `EXTRA_DTC_OVERLAY_FILE` argument.

See *Application Configuration Directory* on how the application configuration directory is defined.

Using *Shields* will also add devicetree overlay files.

The **DTC_OVERLAY_FILE** value is stored in the CMake cache and used in successive builds.

The *build system* prints all the devicetree overlays it finds in the configuration phase, like this:

```
-- Found devicetree overlay: .../some/file.overlay
```

Use devicetree overlays See *Set devicetree overlays* for how to add an overlay to the build.

Overlays can override node property values in multiple ways. For example, if your BOARD.dts contains this node:

```
/ {
        soc {
                serial0: serial@40002000 {
                        status = "okay";
                        current-speed = <115200>;
                        /* ... */
                };
        };
};
```

These are equivalent ways to override the `current-speed` value in an overlay:

```
/* Option 1 */
&serial0 {
     current-speed = <9600>;
};

/* Option 2 */
&{/soc/serial@40002000} {
     current-speed = <9600>;
};
```

We'll use the `&serial0` style for the rest of these examples.

You can add aliases to your devicetree using overlays: an alias is just a property of the `/aliases` node. For example:

```
/ {
    aliases {
            my-serial = &serial0;
    };
};
```

Chosen nodes work the same way. For example:

```
/ {
    chosen {
            zephyr,console = &serial0;
    };
};
```

To delete a property (in addition to deleting properties in general, this is how to set a boolean property to false if it's true in BOARD.dts):

```
&serial0 {
    /delete-property/ some-unwanted-property;
};
```

You can add subnodes using overlays. For example, to configure a SPI or I2C child device on an existing bus node, do something like this:

```
/* SPI device example */
&spi1 {
    my_spi_device: temp-sensor@0 {
            compatible = "...";
            label = "TEMP_SENSOR_0";
            /* reg is the chip select number, if needed;
             * If present, it must match the node's unit address. */
            reg = <0>;

            /* Configure other SPI device properties as needed.
             * Find your device's DT binding for details. */
            spi-max-frequency = <DT_FREQ_M(4)>;
    };
};

/* I2C device example */
&i2c2 {
    my_i2c_device: touchscreen@76 {
            compatible = "...";
            label = "TOUCHSCREEN";
            /* reg is the I2C device address.
             * It must match the node's unit address. */
            reg = <76>;

            /* Configure other I2C device properties as needed.
             * Find your device's DT binding for details. */
    };
};
```

Other bus devices can be configured similarly:

- create the device as a subnode of the parent bus
- set its properties according to its binding

Assuming you have a suitable device driver associated with the `my_spi_device` and

my_i2c_device compatibles, you should now be able to enable the driver via Kconfig and *get the struct device* for your newly added bus node, then use it with that driver API.

Write device drivers using devicetree APIs "Devicetree-aware" *device drivers* should create a struct device for each status = "okay" devicetree node with a particular *compatible* (or related set of compatibles) supported by the driver.

Writing a devicetree-aware driver begins by defining a *devicetree binding* for the devices supported by the driver. Use existing bindings from similar drivers as a starting point. A skeletal binding to get started needs nothing more than this:

```
description: <Human-readable description of your binding>
compatible: "foo-company,bar-device"
include: base.yaml
```

See *Find a devicetree binding* for more advice on locating existing bindings.

After writing your binding, your driver C file can then use the devicetree API to find status = "okay" nodes with the desired compatible, and instantiate a struct device for each one. There are two options for instantiating each struct device: using instance numbers, and using node labels.

In either case:

- Each struct device's name should be set to its devicetree node's label property. This allows the driver's users to *Get a struct device from a devicetree node* in the usual way.
- Each device's initial configuration should use values from devicetree properties whenever practical. This allows users to configure the driver using *devicetree overlays*.

Examples for how to do this follow. They assume you've already implemented the device-specific configuration and data structures and API functions, like this:

```
/* my_driver.c */
#include <zephyr/drivers/some_api.h>

/* Define data (RAM) and configuration (ROM) structures: */
struct my_dev_data {
     /* per-device values to store in RAM */
};
struct my_dev_cfg {
     uint32_t freq; /* Just an example: initial clock frequency in Hz */
     /* other configuration to store in ROM */
};

/* Implement driver API functions (drivers/some_api.h callbacks): */
static int my_driver_api_func1(const struct device *dev, uint32_t *foo) { /* ...␣
↪*/ }
static int my_driver_api_func2(const struct device *dev, uint64_t bar) { /* ... */␣
↪}
static struct some_api my_api_funcs = {
     .func1 = my_driver_api_func1,
     .func2 = my_driver_api_func2,
};
```

Option 1: create devices using instance numbers Use this option, which uses *Instance-based APIs*, if possible. However, they only work when devicetree nodes for your driver's compatible are all equivalent, and you do not need to be able to distinguish between them.

To use instance-based APIs, begin by defining DT_DRV_COMPAT to the lowercase-and-underscores version of the compatible that the device driver supports. For example, if your driver's compati-

ble is "vnd,my-device" in devicetree, you would define DT_DRV_COMPAT to vnd_my_device in your driver C file:

```
/*
 * Put this near the top of the file. After the includes is a good place.
 * (Note that you can therefore run "git grep DT_DRV_COMPAT drivers" in
 * the zephyr Git repository to look for example drivers using this style).
 */
#define DT_DRV_COMPAT vnd_my_device
```

Important

As shown, the DT_DRV_COMPAT macro should have neither quotes nor special characters. Remove quotes and convert special characters to underscores when creating DT_DRV_COMPAT from the compatible property.

Finally, define an instantiation macro, which creates each `struct device` using instance numbers. Do this after defining my_api_funcs.

```
/*
 * This instantiation macro is named "CREATE_MY_DEVICE".
 * Its "inst" argument is an arbitrary instance number.
 *
 * Put this near the end of the file, e.g. after defining "my_api_funcs".
 */
#define CREATE_MY_DEVICE(inst)                                          \
    static struct my_dev_data my_data_##inst = {                        \
            /* initialize RAM values as needed, e.g.: */                \
            .freq = DT_INST_PROP(inst, clock_frequency),                \
    };                                                                  \
    static const struct my_dev_cfg my_cfg_##inst = {                    \
            /* initialize ROM values as needed. */                      \
    };                                                                  \
    DEVICE_DT_INST_DEFINE(inst,                                         \
                          my_dev_init_function,                         \
                          NULL,                                         \
                          &my_data_##inst,                              \
                          &my_cfg_##inst,                               \
                          MY_DEV_INIT_LEVEL, MY_DEV_INIT_PRIORITY,      \
                          &my_api_funcs);
```

Notice the use of APIs like DT_INST_PROP and DEVICE_DT_INST_DEFINE to access devicetree node data. These APIs retrieve data from the devicetree for instance number `inst` of the node with compatible determined by DT_DRV_COMPAT.

Finally, pass the instantiation macro to DT_INST_FOREACH_STATUS_OKAY:

```
/* Call the device creation macro for each instance: */
DT_INST_FOREACH_STATUS_OKAY(CREATE_MY_DEVICE)
```

DT_INST_FOREACH_STATUS_OKAY expands to code which calls CREATE_MY_DEVICE once for each enabled node with the compatible determined by DT_DRV_COMPAT. It does not append a semicolon to the end of the expansion of CREATE_MY_DEVICE, so the macro's expansion must end in a semicolon or function definition to support multiple devices.

Option 2: create devices using node labels Some device drivers cannot use instance numbers. One example is an SoC peripheral driver which relies on vendor HAL APIs specialized for individual IP blocks to implement Zephyr driver callbacks. Cases like this should use

DT_NODELABEL to refer to individual nodes in the devicetree representing the supported peripherals on the SoC. The devicetree.h *Generic APIs* can then be used to access node data.

For this to work, your *SoC's dtsi file* must define node labels like mydevice0, mydevice1, etc. appropriately for the IP blocks your driver supports. The resulting devicetree usually looks something like this:

```
/ {
        soc {
                mydevice0: dev@0 {
                        compatible = "vnd,my-device";
                };
                mydevice1: dev@1 {
                        compatible = "vnd,my-device";
                };
        };
};
```

The driver can use the mydevice0 and mydevice1 node labels in the devicetree to operate on specific device nodes:

```
/*
 * This is a convenience macro for creating a node identifier for
 * the relevant devices. An example use is MYDEV(0) to refer to
 * the node with label "mydevice0".
 */
#define MYDEV(idx) DT_NODELABEL(mydevice ## idx)

/*
 * Define your instantiation macro; "idx" is a number like 0 for mydevice0
 * or 1 for mydevice1. It uses MYDEV() to create the node label from the
 * index.
 */
#define CREATE_MY_DEVICE(idx)                                          \
     static struct my_dev_data my_data_##idx = {                       \
             /* initialize RAM values as needed, e.g.: */              \
             .freq = DT_PROP(MYDEV(idx), clock_frequency),             \
     };                                                                \
     static const struct my_dev_cfg my_cfg_##idx = { /* ... */ };      \
     DEVICE_DT_DEFINE(MYDEV(idx),                                      \
                      my_dev_init_function,                            \
                      NULL,                                            \
                      &my_data_##idx,                                  \
                      &my_cfg_##idx,                                   \
                      MY_DEV_INIT_LEVEL, MY_DEV_INIT_PRIORITY,         \
                      &my_api_funcs)
```

Notice the use of APIs like DT_PROP and DEVICE_DT_DEFINE to access devicetree node data.

Finally, manually detect each enabled devicetree node and use CREATE_MY_DEVICE to instantiate each struct device:

```
#if DT_NODE_HAS_STATUS(DT_NODELABEL(mydevice0), okay)
CREATE_MY_DEVICE(0)
#endif

#if DT_NODE_HAS_STATUS(DT_NODELABEL(mydevice1), okay)
CREATE_MY_DEVICE(1)
#endif
```

Since this style does not use `DT_INST_FOREACH_STATUS_OKAY()`, the driver author is responsible for calling `CREATE_MY_DEVICE()` for every possible node, e.g. using knowledge about the peripherals available on supported SoCs.

Device drivers that depend on other devices At times, one `struct device` depends on another `struct device` and requires a pointer to it. For example, a sensor device might need a pointer to its SPI bus controller device. Some advice:

- Write your devicetree binding in a way that permits use of *Hardware specific APIs* from devicetree.h if possible.
- In particular, for bus devices, your driver's binding should include a file like dts/bindings/spi/spi-device.yaml which provides common definitions for devices addressable via a specific bus. This enables use of APIs like `DT_BUS` to obtain a node identifier for the bus node. You can then *Get a struct device from a devicetree node* for the bus in the usual way.

Search existing bindings and device drivers for examples.

Applications that depend on board-specific devices One way to allow application code to run unmodified on multiple boards is by supporting a devicetree alias to specify the hardware specific portions, as is done in the blinky sample. The application can then be configured in *BOARD.dts* files or via *devicetree overlays*.

Troubleshooting devicetree

Here are some tips for fixing misbehaving devicetree related code.

See *Devicetree HOWTOs* for other "HOWTO" style information.

> **Important**
>
> Try this first, before doing anything else.

Try again with a pristine build directory See *Pristine Builds* for examples, or just delete the build directory completely and retry.

This is general advice which is especially applicable to debugging devicetree issues, because the outputs are created during the CMake configuration phase, and are not always regenerated when one of their inputs changes.

Use Devicetree diagnostics tool (DT Doctor) An optional Devicetree diagnostics tool is available to help diagnose Devicetree issues. It can be enabled by passing the `-DZEPHYR_SCA_VARIANT=dtdoctor` argument to *west build*.

See *Devicetree diagnostics (dtdoctor)* for more information.

Make sure <devicetree.h> is included Unlike Kconfig symbols, the `devicetree.h` header must be included explicitly.

Many Zephyr header files rely on information from devicetree, so including some other API may transitively include `devicetree.h`, but that's not guaranteed.

undefined reference to `__device_dts_ord_<N>` This usually happens on a line like this:

```
const struct device *dev = DEVICE_DT_GET(NODE_ID);
```

where NODE_ID is a valid *node identifier*, but no device driver has allocated a `struct device` for this devicetree node. You thus get a linker error, because you're asking for a pointer to a device that isn't defined.

To fix it, you need to make sure that:

1. The node is enabled: the node must have `status = "okay";`.

   (Recall that a missing `status` property means the same thing as `status = "okay";`; see *Important properties* for more information about `status`).

2. A device driver responsible for allocating the `struct device` is enabled. That is, the Kconfig option which makes the build system compile the driver sources into your application needs to be set to `y`.

   (See *Setting Kconfig configuration values* for more information on setting Kconfig options.)

Below, <build> means your build directory.

Making sure the node is enabled:

To find the devicetree node you need to check, use the number <N> from the linker error. Look for this number in the list of nodes at the top of <build>/zephyr/include/generated/zephyr/devicetree_generated.h. For example, if <N> is 15, and your devicetree_generated.h file looks like this, the node you are interested in is /soc/i2c@deadbeef:

```
/*
 * Generated by gen_defines.py
 *
 * DTS input file:
 *   zephyr.dts.pre
 *
 * Directories with bindings:
 *   $ZEPHYR_BASE/dts/bindings
 *
 * Node dependency ordering (ordinal and path):
 *   0   /
 *   1   /aliases
[...]
 *   15  /soc/i2c@deadbeef
[...]
```

Now look for this node in <build>/zephyr/zephyr.dts, which is the final devicetree for your application build. (See *Get your devicetree and generated header* for information and examples.)

If the node has `status = "disabled";` in zephyr.dts, then you need to enable it by setting `status = "okay";`, probably by using a devicetree *overlay*. For example, if zephyr.dts looks like this:

```
i2c0: i2c@deadbeef {
        status = "disabled";
};
```

Then you should put this into your devicetree overlay and *Try again with a pristine build directory*:

```
&i2c0 {
        status = "okay";
};
```

Make sure that you see `status = "okay";` in zephyr.dts after you rebuild.

Making sure the device driver is enabled:

The first step is to figure out which device driver is responsible for handling your devicetree node and allocating devices for it. To do this, you need to start with the `compatible` property in your devicetree node, and find the driver that allocates `struct device` instances for that compatible.

If you're not familiar with how devices are allocated from devicetree nodes based on compatible properties, the ZDS 2021 talk A deep dive into the Zephyr 2.5 device model may be a useful place to start, along with the *Device Driver Model* pages. See *Important properties* and the Devicetree specification for more information about `compatible`.

There is currently no documentation for what device drivers exist and which devicetree compatibles they are associated with. You will have to figure this out by reading the source code:

- Look in drivers for the appropriate subdirectory that corresponds to the API your device implements
- Look inside that directory for relevant files until you figure out what the driver is, or realize there is no such driver.

Often, but not always, you can find the driver by looking for a file that sets the `DT_DRV_COMPAT` macro to match your node's `compatible` property, except lowercased and with special characters converted to underscores. For example, if your node's compatible is `vnd,foo-device`, look for a file with this line:

```
#define DT_DRV_COMPAT vnd_foo_device
```

Important

This **does not always work** since not all drivers use `DT_DRV_COMPAT`.

If you find a driver, you next need to make sure the Kconfig option that compiles it is enabled. (If you don't find a driver, and you are sure the compatible property is correct, then you need to write a driver. Writing drivers is outside the scope of this documentation page.)

Continuing the above example, if your devicetree node looks like this now:

```
i2c0: i2c@deadbeef {
        compatible = "nordic,nrf-twim";
        status = "okay";
};
```

Then you would look inside of drivers/i2c for the driver file that handles the compatible `nordic,nrf-twim`. In this case, that is drivers/i2c/i2c_nrfx_twim.c. Notice how even in cases where `DT_DRV_COMPAT` is not set, you can use information like driver file names as clues.

Once you know the driver you want to enable, you need to make sure its Kconfig option is set to `y`. You can figure out which Kconfig option is needed by looking for a line similar to this one in the `CMakeLists.txt` file in the drivers subdirectory. Continuing the above example, drivers/i2c/CMakeLists.txt has a line that looks like this:

```
zephyr_library_sources_ifdef(CONFIG_NRFX_TWIM       i2c_nrfx_twim.c)
```

This means that `CONFIG_NRFX_TWIM` must be set to `y` in `<build>/zephyr/.config` file.

If your driver's Kconfig is not set to `y`, you need to figure out what you need to do to make that happen. Often, this will happen automatically as soon as you enable the devicetree node. Otherwise, it is sometimes as simple as adding a line like this to your application's `prj.conf` file and then making sure to *Try again with a pristine build directory*:

```
CONFIG_FOO=y
```

where `CONFIG_FOO` is the option that `CMakeLists.txt` uses to decide whether or not to compile the driver.

However, there may be other problems in your way, such as unmet Kconfig dependencies that you also have to enable before you can enable your driver.

Consult the Kconfig file that defines `CONFIG_FOO` (for your value of `FOO`) for more information.

Make sure you're using the right names Remember that:

- In C/C++, devicetree names must be lowercased and special characters must be converted to underscores. Zephyr's generated devicetree header has DTS names converted in this way into the C tokens used by the preprocessor-based `<devicetree.h>` API.
- In overlays, use devicetree node and property names the same way they would appear in any DTS file. Zephyr overlays are just DTS fragments.

For example, if you're trying to **get** the `clock-frequency` property of a node with path `/soc/i2c@12340000` in a C/C++ file:

```
/*
 * foo.c: lowercase-and-underscores names
 */

/* Don't do this: */
#define MY_CLOCK_FREQ DT_PROP(DT_PATH(soc, i2c@1234000), clock-frequency)
/*                                          ^               ^
 *                                       @ should be _     - should be _  */

/* Do this instead: */
#define MY_CLOCK_FREQ DT_PROP(DT_PATH(soc, i2c_1234000), clock_frequency)
/*                                          ^               ^           */
```

And if you're trying to **set** that property in a devicetree overlay:

```
/*
 * foo.overlay: DTS names with special characters, etc.
 */

/* Don't do this; you'll get devicetree errors. */
&{/soc/i2c_12340000/} {
     clock_frequency = <115200>;
};

/* Do this instead. Overlays are just DTS fragments. */
&{/soc/i2c@12340000/} {
     clock-frequency = <115200>;
};
```

Look at the preprocessor output To save preprocessor output files, enable the `CONFIG_COMPILER_SAVE_TEMPS` option. For example, to build hello_world with west with this option set, use:

```
west build -b BOARD samples/hello_world -- -DCONFIG_COMPILER_SAVE_TEMPS=y
```

This will create a preprocessor output file named `foo.c.i` in the build directory for each source file `foo.c`.

You can then search for the file in the build directory to see what your devicetree macros expanded to. For example, on macOS and Linux, using `find` to find `main.c.i`:

```
$ find build -name main.c.i
build/CMakeFiles/app.dir/src/main.c.i
```

It's usually easiest to run a style formatter on the results before opening them. For example, to use `clang-format` to reformat the file in place:

```
clang-format -i build/CMakeFiles/app.dir/src/main.c.i
```

You can then open the file in your favorite editor to view the final C results after preprocessing.

Do not track macro expansion Compiler messages for devicetree errors can sometimes be very long. This typically happens when the compiler prints a message for every step of a complex macro expansion that has several intermediate expansion steps.

To prevent the compiler from doing this, you can disable the `CONFIG_COMPILER_TRACK_MACRO_EXPANSION` option. This typically reduces the output to one message per error.

For example, to build hello_world with west and this option disabled, use:

```
west build -b BOARD samples/hello_world -- -
↪DCONFIG_COMPILER_TRACK_MACRO_EXPANSION=n
```

Validate properties If you're getting a compile error reading a node property, check your node identifier and property. For example, if you get a build error on a line that looks like this:

```
int baud_rate = DT_PROP(DT_NODELABEL(my_serial), current_speed);
```

Try checking the node by adding this to the file and recompiling:

```
#if !DT_NODE_EXISTS(DT_NODELABEL(my_serial))
#error "whoops"
#endif
```

If you see the "whoops" error message when you rebuild, the node identifier isn't referring to a valid node. *Get your devicetree and generated header* and debug from there.

Some hints for what to check next if you don't see the "whoops" error message:

- did you *Make sure you're using the right names*?
- does the *property exist*?
- does the node have a *matching binding*?
- does the binding define the property?

Check for missing bindings See *Devicetree bindings* for information about bindings, and *Bindings index* for information on bindings built into Zephyr.

If the build fails to *Find a devicetree binding* for a node, then either the node's `compatible` property is not defined, or its value has no matching binding. If the property is set, check for typos in its name. In a devicetree source file, `compatible` should look like `"vnd,some-device"` – *Make sure you're using the right names*.

If your binding file is not under `zephyr/dts`, you may need to set *DTS_ROOT*; see *Where bindings are located*.

Errors with DT_INST_() APIs If you're using an API like `DT_INST_PROP()`, you must define `DT_DRV_COMPAT` to the lowercase-and-underscores version of the compatible you are interested in. See *Option 1: create devices using instance numbers*.

Devicetree versus Kconfig

Along with devicetree, Zephyr also uses the Kconfig language to configure the source code. Whether to use devicetree or Kconfig for a particular purpose can sometimes be confusing. This section should help you decide which one to use.

In short:

- Use devicetree to describe **hardware** and its **boot-time configuration**. Examples include peripherals on a board, boot-time clock frequencies, interrupt lines, etc.
- Use Kconfig to configure **software support** to build into the final image. Examples include whether to add networking support, which drivers are needed by the application, etc.

In other words, devicetree mainly deals with hardware, and Kconfig with software.

For example, consider a board containing a SoC with 2 UART, or serial port, instances.

- The fact that the board has this UART **hardware** is described with two UART nodes in the devicetree. These provide the UART type (via the `compatible` property) and certain settings such as the address range of the hardware peripheral registers in memory (via the `reg` property).
- Additionally, the UART **boot-time configuration** is also described with devicetree. This could include configuration such as the RX IRQ line's priority and the UART baud rate. These may be modifiable at runtime, but their boot-time configuration is described in devicetree.
- From the application code, both UART are interchangeable and using one or the other has no impact, it is only a matter of board design. It is pure **hardware configuration** and should be done with devicetree.
- Whether or not to include **software support** for UART in the build is controlled via Kconfig. Applications which do not need to use the UARTs can remove the driver source code from the build using Kconfig, even though the board's devicetree still includes UART nodes.

As another example, consider a device with a 2.4GHz, multi-protocol radio supporting both the Bluetooth Low Energy and 802.15.4 wireless technologies.

- Devicetree should be used to describe the presence of the radio **hardware**, what driver or drivers it's compatible with, etc.
- **Boot-time configuration** for the radio, such as TX power in dBm, should also be specified using devicetree.
- On the application, using one or the other protocol will not get the same code into play, but the same hardware will be used. This is relevant to **software configuration**.
- Kconfig should determine which **software features** should be built for the radio, such as selecting a BLE or 802.15.4 protocol stack.

As another example, Kconfig options that formerly enabled a particular instance of a driver (that is itself enabled by Kconfig) have been removed. The devices are selected individually using devicetree's *status* keyword on the corresponding hardware instance.

There are **exceptions** to these rules:

- Because Kconfig is unable to flexibly control some instance-specific driver configuration parameters, such as the size of an internal buffer, these options may be defined in devicetree. However, to make clear that they are specific to Zephyr drivers and not hardware description or configuration these properties should be prefixed with `zephyr,`, e.g. `zephyr,random-mac-address` in the common Ethernet devicetree properties.
- Devicetree's `chosen` keyword, which allows the user to select a specific instance of a hardware device to be used for a particular purpose. An example of this is selecting a particular UART for use as the system's console.

Automatic Kconfig symbols from devicetree During the devicetree processing step, CMake runs scripts/dts/gen_driver_kconfig_dts.py, which scans all *DTS root* directories, including dts/bindings and writes `Kconfig.dts` into the build's `KCONFIG_BINARY_DIR` (for example `<build>/zephyr` or `<build>/<image>/zephyr` in case of *Sysbuild (System build)*). For each `compatible = "vendor,chip"` that appears in a binding, the generated file contains:

```
DT_COMPAT_VENDOR_CHIP := vendor,chip

config DT_HAS_VENDOR_CHIP_ENABLED
        def_bool $(dt_compat_enabled,$(DT_COMPAT_VENDOR_CHIP))
```

The assignment keeps the literal `compatible` string available to the preprocessor functions described in *Custom Kconfig Preprocessor Functions*, so that Kconfig files can call helpers such as `$(dt_compat_on_bus,$(DT_COMPAT_<compatible>),i2c)`. Characters like `-`, `,` and `@` are converted to underscores when the symbol names are created.

The hidden boolean symbol becomes `CONFIG_DT_HAS_<compatible>_ENABLED` after Kconfig runs. Its value tracks whether the current devicetree contains at least one node with that `compatible` whose *status* is `okay`. Symbols for enabling drivers should almost certainly be `default y` and have `depends on CONFIG_DT_HAS_<compatible>_ENABLED`, for example:

```
config SENSOR_VENDOR_CHIP
        bool "Vendor Chip sensor"
        default y
        depends on DT_HAS_VENDOR_CHIP_ENABLED
```

Because these symbols are generated automatically, adding a new binding with a `compatible` property is all that is required to make the corresponding `DT_HAS_<compatible>_ENABLED` and `DT_COMPAT_<compatible>` constructs available to Kconfig.

5.3.2 Devicetree Reference

These pages contain reference material for Zephyr's devicetree APIs and built-in bindings.

For the platform-independent details, see the Devicetree specification.

Devicetree API

This is a reference page for the `<zephyr/devicetree.h>` API. The API is macro based. Use of these macros has no impact on scheduling. They can be used from any calling context and at file scope.

Some of these – the ones beginning with `DT_INST_` – require a special macro named `DT_DRV_COMPAT` to be defined before they can be used; these are discussed individually below. These macros are generally meant for use within *device drivers*, though they can be used outside of drivers with appropriate care.

Contents

  - *SPI*
- *Chosen nodes*
- *Zephyr-specific chosen nodes*

Generic APIs The APIs in this section can be used anywhere and do not require `DT_DRV_COMPAT` to be defined.

Node identifiers and helpers A *node identifier* is a way to refer to a devicetree node at C preprocessor time. While node identifiers are not C values, you can use them to access devicetree data in C rvalue form using, for example, the *Property access* API.

The root node `/` has node identifier `DT_ROOT`. You can create node identifiers for other devicetree nodes using `DT_PATH`, `DT_NODELABEL`, `DT_ALIAS`, and `DT_INST`.

There are also `DT_PARENT` and `DT_CHILD` macros which can be used to create node identifiers for a given node's parent node or a particular child node, respectively.

The following macros create or operate on node identifiers.

Node identifiers and helpers

Related code samples

- GPIO with custom Devicetree bindingUse custom Devicetree binding to control a GPIO.

Property access The following general-purpose macros can be used to access node properties. There are special-purpose APIs for accessing the *ranges property*, *reg property* and *interrupts property*.

Property values can be read using these macros even if the node is disabled, as long as it has a matching binding.

Property accessors

`ranges` property Use these APIs instead of *Property access* to access the `ranges` property. Because this property's semantics are defined by the devicetree specification, these macros can be used even for nodes without matching bindings. However, they take on special semantics when the node's binding indicates it is a PCIe bus node, as defined in the PCI Bus Binding to: IEEE Std 1275-1994 Standard for Boot (Initialization Configuration) Firmware

ranges property

`reg` property Use these APIs instead of *Property access* to access the `reg` property. Because this property's semantics are defined by the devicetree specification, these macros can be used even for nodes without matching bindings.

reg property

`interrupts` property Use these APIs instead of *Property access* to access the `interrupts` property.

Because this property's semantics are defined by the devicetree specification, some of these macros can be used even for nodes without matching bindings. This does not apply to macros which take cell names as arguments.

interrupts property

For-each macros The `DT_FOREACH_ANCESTOR` macro allows iterating over the ancestor node of a devicetree node. Additionally, the `DT_FOREACH_CHILD` macro allows iterating over the children of a devicetree node.

There are special-purpose for-each macros, like `DT_INST_FOREACH_STATUS_OKAY`, but these require `DT_DRV_COMPAT` to be defined before use.

"For-each" macros

Existence checks This section documents miscellaneous macros that can be used to test if a node exists, how many nodes of a certain type exist, whether a node has certain properties, etc. Some macros used for special purposes (such as `DT_IRQ_HAS_IDX` and all macros which require `DT_DRV_COMPAT`) are documented elsewhere on this page.

Existence checks

Related code samples

- GPIO with custom Devicetree bindingUse custom Devicetree binding to control a GPIO.

Inter-node dependencies The `devicetree.h` API has some support for tracking dependencies between nodes. Dependency tracking relies on a binary "depends on" relation between devicetree nodes, which is defined as the transitive closure of the following "directly depends on" relation:

- every non-root node directly depends on its parent node

- a node directly depends on any nodes its properties refer to by phandle, this can be changed with *dependency-mode* in the node's binding
- a node directly depends on its `interrupt-parent` if it has an `interrupts` property
- a parent node inherits all dependencies from its child nodes

A *dependency ordering* of a devicetree is a list of its nodes, where each node `n` appears earlier in the list than any nodes that depend on `n`. A node's *dependency ordinal* is then its zero-based index in that list. Thus, for two distinct devicetree nodes `n1` and `n2` with dependency ordinals `d1` and `d2`, we have:

- `d1 != d2`
- if `n1` depends on `n2`, then `d1 > d2`
- `d1 > d2` does **not** necessarily imply that `n1` depends on `n2`

The Zephyr build system chooses a dependency ordering of the final devicetree and assigns a dependency ordinal to each node. Dependency related information can be accessed using the following macros. The exact dependency ordering chosen is an implementation detail, but cyclic dependencies are detected and cause errors, so it's safe to assume there are none when using these macros.

There are instance number-based conveniences as well; see `DT_INST_DEP_ORD` and subsequent documentation.

Dependency tracking

Bus helpers Zephyr's devicetree bindings language supports a `bus:` key which allows bindings to declare that nodes with a given compatible describe system buses. In this case, child nodes are considered to be on a bus of the given type, and the following APIs may be used.

Bus helpers

Instance-based APIs These are recommended for use within device drivers. To use them, define `DT_DRV_COMPAT` to the lowercase-and-underscores compatible the device driver implements support for. Here is an example devicetree fragment:

```
serial@40001000 {
        compatible = "vnd,serial";
        status = "okay";
        current-speed = <115200>;
};
```

Example usage, assuming `serial@40001000` is the only enabled node with compatible `vnd,serial`:

```
#define DT_DRV_COMPAT vnd_serial
DT_DRV_INST(0)                  // node identifier for serial@40001000
DT_INST_PROP(0, current_speed)  // 115200
```

Warning

Be careful making assumptions about instance numbers. See `DT_INST` for the API guarantees.

As shown above, the `DT_INST_*` APIs are conveniences for addressing nodes by instance number. They are almost all defined in terms of one of the *Generic APIs*. The equivalent generic API can be found by removing `INST_` from the macro name. For example, `DT_INST_PROP(inst, prop)` is equivalent to `DT_PROP(DT_DRV_INST(inst), prop)`. Similarly, `DT_INST_REG_ADDR(inst)` is equivalent to `DT_REG_ADDR(DT_DRV_INST(inst))`, and so on. There

are some exceptions: DT_ANY_INST_ON_BUS_STATUS_OKAY and DT_INST_FOREACH_STATUS_OKAY are special-purpose helpers without straightforward generic equivalents.

Since DT_DRV_INST() requires DT_DRV_COMPAT to be defined, it's an error to use any of these without that macro defined.

Note that there are also helpers available for specific hardware; these are documented in *Hardware specific APIs*.

Instance-based devicetree APIs

Hardware specific APIs The following APIs can also be used by including <devicetree.h>; no additional include is needed.

CAN These conveniences may be used for nodes which describe CAN controllers/transceivers, and properties related to them.

Devicetree CAN API

Clocks These conveniences may be used for nodes which describe clock sources, and properties related to them.

Devicetree Clocks API

DMA These conveniences may be used for nodes which describe direct memory access controllers or channels, and properties related to them.

Devicetree DMA API

Display These conveniences may be used for nodes which describe display controllers, and properties related to them.

Devicetree Display API

Fixed and mapped flash partitions These conveniences may be used for the special-purpose fixed-partitions and zephyr,mapped-partition compatibles used to encode information about flash memory partitions in the device tree. See fixed-partitions and zephyr,mapped-partition for more details.

Devicetree Fixed Partition API

GPIO These conveniences may be used for nodes which describe GPIO controllers/pins, and properties related to them.

Devicetree GPIO API

HWSpinlock These conveniences may be used for nodes which describe hardware spinlock, and properties related to them.

Devicetree HW spinlock API

IO channels These are commonly used by device drivers which need to use IO channels (e.g. ADC or DAC channels) for conversion.

Devicetree IO Channels API

MBOX These conveniences may be used for nodes which describe MBOX controllers/users, and properties related to them.

Devicetree MBOX API

MUX These conveniences may be used for nodes which describe MUX controllers/consumers, and properties related to them.

Devicetree MUX API

NVMEM These conveniences may be used for nodes which describe Non-Volatile Memory, and properties related to them.

NVMEM Devicetree Helpers

Ordinals These conveniences may be used for nodes which describe Dependency tracking, and properties related to them.

Dependency tracking

Pinctrl (pin control) These are used to access pin control properties by name or index.

Devicetree nodes may have properties which specify pin control (sometimes known as pin mux) settings. These are expressed using `pinctrl-<index>` properties within the node, where the `<index>` values are contiguous integers starting from 0. These may also be named using the `pinctrl-names` property.

Here is an example:

```
node {
    ...
    pinctrl-0 = <&foo &bar ...>;
    pinctrl-1 = <&baz ...>;
    pinctrl-names = "default", "sleep";
};
```

Above, `pinctrl-0` has name `"default"`, and `pinctrl-1` has name `"sleep"`. The `pinctrl-<index>` property values contain phandles. The `&foo`, `&bar`, etc. phandles within the properties point to nodes whose contents vary by platform, and which describe a pin configuration for the node.

Pin control

PWM These conveniences may be used for nodes which describe PWM controllers and properties related to them.

Devicetree PWMs API

Reset Controller These conveniences may be used for nodes which describe reset controllers and properties related to them.

Devicetree Reset Controller API

SPI These conveniences may be used for nodes which describe either SPI controllers or devices, depending on the case.

Devicetree SPI API

Chosen nodes The special `/chosen` node contains properties whose values describe system-wide settings. The `DT_CHOSEN()` macro can be used to get a node identifier for a chosen node.

Chosen nodes

Zephyr-specific chosen nodes The following table documents some commonly used Zephyr-specific chosen nodes.

Sometimes, a chosen node's label property will be used to set the default value of a Kconfig option which in turn configures a hardware-specific device. This is usually for backwards compatibility in cases when the Kconfig option predates devicetree support in Zephyr. In other cases, there is no Kconfig option, and the devicetree node is used directly in the source code to select a device.

Table 1: Zephyr-specific chosen properties

Property	Purpose
mcuboot,ram-load-dev	When a Zephyr application is built to be loaded to RAM by MCUboot, with `CONFIG_MCUBOOT_BOOTLOADER_MODE_SINGLE_APP_RAM_LOAD`, this property is used to tell MCUboot the load address of the image, which will be the `reg` of the chosen node.
zephyr,boot-mode	Used for *Boot mode* selection, part of *Retention System*, which specifies what image on a device should be booted.
zephyr,bootloader-info	Selects the *Retention System* area used to share information with the bootloader.
zephyr,bt-c2h-uart	Selects the UART used for host communication in the bluetooth_hci_uart
zephyr,bt-hci	Selects the HCI device used by the Bluetooth host stack
zephyr,bt-hci-ipc	Selects the IPC device used to expose a Bluetooth controller to another device or CPU in the bluetooth_hci_ipc sample.
zephyr,bt-mon-uart	Sets UART device used for the Bluetooth monitor logging
zephyr,camera	Video input device, typically a camera.
zephyr,canbus	Sets the default CAN controller
zephyr,code-partition	Flash partition that the Zephyr image's text section should be linked into
zephyr,console	Sets UART device used by console driver
zephyr,cpu-load-counter	Selects the *Counter* device used to track CPU idle time.
zephyr,crc	Selects the CRC device used as an accelerator by the CRC subsystem
zephyr,display	Sets the default display controller
zephyr,dtcm	Data Tightly Coupled Memory node on some Arm SoCs
zephyr,edac	Selects the *Error Detection And Correction (EDAC)* device used by the EDAC subsystem.
zephyr,entropy	A device which can be used as a system-wide entropy source
zephyr,flash	A node whose `reg` is sometimes used to set the defaults for `CONFIG_FLASH_BASE_ADDRESS` and `CONFIG_FLASH_SIZE`
zephyr,flash-controller	The node corresponding to the flash controller device for the `zephyr,flash` node
zephyr,gdbstub-uart	Sets UART device used by the *GDB stub* subsystem
zephyr,hdlc-rcp-if	Selects the radio device used by the OpenThread HDLC RCP interface. This device must have `hdlc_api` as its `api`.
zephyr,host-cmd-espi-backend	Refer to *EC Host Command* API documentation.
zephyr,host-cmd-shi-backend	Refer to *EC Host Command* API documentation.
zephyr,host-cmd-spi-backend	Refer to *EC Host Command* API documentation.

continues on next page

Table 1 – continued from previous page

Property	Purpose
zephyr,host-cmd-uart-backend	Refer to *EC Host Command* API documentation.
zephyr,ieee802154	Used by the networking subsystem to set the IEEE 802.15.4 device
zephyr,ipc	Used by the OpenAMP subsystem to specify the inter-process communication (IPC) device
zephyr,ipc_rsc_table	Specifies a memory region that will be used for the OpenAMP resource table. Only needed if `CONFIG_OPENAMP_COPY_RSC_TABLE` is enabled.
zephyr,ipc_rx	Alternative to `zephyr,ipc`. Selects the IPC device to use for reception when separate devices are used for TX and RX. `zephyr,ipc_tx` must also be provided alongside this chosen, and selects the IPC device to use for transmission. When this chosen and `zephyr,ipc_tx` are provided, the single-device `zephyr,ipc` compatible **must not** be provided.
zephyr,ipc_shm	A node whose `reg` is used by the OpenAMP subsystem to determine the base address and size of the shared memory (SHM) usable for interprocess-communication (IPC)
zephyr,ipc_tx	See description of `zephyr,ipc_rx`.
zephyr,itcm	Instruction Tightly Coupled Memory node on some Arm SoCs
zephyr,led-strip	A LED-strip node which is used to determine the timings of the WS2812 GPIO driver
zephyr,log-ipc	Selects the IPC device used by the logging subsystem's IPC service backend.
zephyr,log-uart	Sets the UART device(s) used by the logging subsystem's UART backend. If defined, the UART log backend would output to the devices listed in this node.
zephyr,modem-uart	Selects the modem UART used by the at_client sample.
zephyr,ocm	On-chip memory node on Xilinx Zynq-7000 and ZynqMP SoCs
zephyr,openthread-counter	Selects the counter device used by the OpenThread platform for microsecond alarm timers when `CONFIG_OPENTHREAD_ALARM_COUNTER` is enabled.
zephyr,osdp-uart	Sets UART device used by OSDP subsystem
zephyr,ot-uart	Used by the OpenThread to specify UART device for Spinel protocol
zephyr,pcie-controller	The node corresponding to the PCIe Controller
zephyr,ppp-uart	Sets UART device used by PPP
zephyr,ram-console	Selects the `RAM section` in which the console subsystem's RAM backend should place its buffer.
zephyr,rtc	Sets the default RTC device (used for example by the *SNTP library* to set the system time when `CONFIG_NET_CONFIG_CLOCK_SNTP_SET_RTC` is enabled)
zephyr,rtk-serial	Selects the *Universal Asynchronous Receiver-Transmitter (UART)* device used by the Serial GNSS RTK client.
zephyr,secure-storage-its-partition	Fixed partition node. This selects the partition used by the Secure Storage ZMS backend.
zephyr,sensor-clock	Selects the *Counter* device used as sensor time source.
zephyr,settings-partition	Fixed partition node. If defined this selects the partition used by the NVS and FCB settings backends.
zephyr,shell-uart	Sets UART device used by serial shell backend
zephyr,sram	A node whose `reg` sets the base address and size of SRAM memory available to the Zephyr image, used during linking

continues on next page

Table 1 – continued from previous page

Property	Purpose
zephyr,system-timer	Selects the hardware timer instance used as the Zephyr system timer, which is a singleton system-wide function. This chosen is needed when the selected system timer driver corresponds to timer hardware for which multiple instances may exist: it selects one instance as the system timer and allows using the other instances with other APIs. This chosen is ignored when the selected system timer driver corresponds to timer hardware for which only one instance may ever exist, such as the Cortex-M SysTick timer; otherwise, it must corresponds to a node that the selected system timer driver can operate. (Note: the Zephyr system timer *driver* is selected using Kconfig options such as `CONFIG_CORTEX_M_SYSTICK` - not Devicetree!)
zephyr,system-timer-companion	Selects the device used to keep time while the primary system timer is inactive in low-power states. It must implement the *Counter* API.
zephyr,tflm-storage	Selects the `memory region` used by the tflite-ethosu sample.
zephyr,touch	Touchscreen controller device node. When LVGL is used, if `CONFIG_LV_Z_POINTER_FROM_CHOSEN_TOUCH` is enabled, an LVGL pointer input device is created using the touchscreen controller as its input source.
zephyr,tracing-uart	Sets UART device used by tracing subsystem
zephyr,uart-mcumgr	UART used for *Device Management*
zephyr,uart-pipe	Sets UART device used by serial pipe driver
zephyr,videoenc	Video encoder device, typically an H264 or MJPEG video encoder.

Bindings index

This page documents the available devicetree bindings. See *Devicetree bindings* for an introduction to the Zephyr bindings file format.

The bindings are grouped both by **type** and by **vendor**. Within each group, bindings are listed by the "compatible" property they apply to, like this:

- <compatible-A>
- <compatible-B> (on <bus-name> bus)
- <compatible-C>
- ...

The text "(on <bus-name> bus)" appears when bindings may behave differently depending on the bus the node appears on. For example, this applies to some sensor device nodes, which may appear as children of either I2C or SPI bus nodes.

Type index This section contains an index of bindings by type. Click on a type's name to go to the list of bindings for that type.

- *1-Wire*

Vendor index This section contains an index of hardware vendors. Click on a vendor's name to go to the list of bindings for that vendor.

- *Generic or vendor-independent*
- *AD Semiconductor Co., Ltd. (adsemi)*
- *Adafruit Industries, LLC (adafruit)*
- *ADH Technology Co. Ltd. (adh-tech)*
- *Advanced Micro Devices (AMD), Inc. (amd)*
- *Aesc Silicon (aesc)*
- *Alibaba Xuantie (xuantie)*
- *Alif Semiconductor (alif)*
- *Allegro DVT (allegro)*
- *Allwinner Technology Co., Ltd. (allwinner)*
- *Altera Corp. (altr)*
- *Ambiq Micro, Inc. (ambiq)*
- *AMS AG (ams)*
- *Analog Devices, Inc. (adi)*
- *Andes Technology Corporation (andestech)*
- *Angst+Pfister (ap)*
- *Apa Electronic Co., Ltd (apa)*
- *Aptina Imaging (aptina)*
- *Arducam Technology Co., Limited (arducam)*
- *Arduino (arduino)*
- *ARM Ltd. (arm)*
- *Asahi Kasei Corp. (asahi-kasei)*
- *ASMedia Technology Inc. (asmedia)*
- *ASPEED Technology Inc. (aspeed)*
- *Atmel Corporation (atmel)*
- *Avago Technologies (avago)*

- *avia semiconductor (avia)*
- *Beijing Phosense Electronic Technology Co., Ltd. (phosense)*
- *Bosch Sensortec GmbH (bosch)*
- *Bouffalo Lab (Nanjing) Co., Ltd. (bflb)*
- *Broadcom Corporation (brcm)*
- *Cadence Design Systems Inc. (cdns)*
- *Centre for Development of Advanced Computing (C-DAC) (cdac)*
- *CFSensor Co., Ltd (cfsensor)*
- *Chip Wealth Technology Ltd. (chipwealth)*
- *ChipOne (chipone)*
- *Chipsemi Corp. (chipsemi)*
- *Cirque Corporation (cirque)*
- *Cirrus Logic, Inc. (cirrus)*
- *Cirrus Logic, Inc. (formerly Wolfson Microelectronics plc) (wolfson)*
- *Cypress Semiconductor Corporation (cypress)*
- *DAVICOM Semiconductor, Inc. (davicom)*
- *DFRobot (dfrobot)*
- *Dialog Semiconductor (dlg)*
- *Digilent, Inc. (digilent)*
- *Diodes Incorporated (diodes)*
- *E Ink Corporation (eink)*
- *Efinix Inc (efinix)*
- *Egis Technology Inc (egis)*
- *Elan Microelectronic Corp. (elan)*
- *ENE Technology, Inc. (ene)*
- *EPCOS AG (epcos)*
- *Espressif Systems (espressif)*
- *Everlight Electronics Co. Ltd. (everlight)*
- *Fairchild Semiconductor (fcs)*
- *Feature Integration Technology Inc. (fintek)*
- *Festo SE & Co. KG (festo)*
- *Fibocom Wireless Inc. (fibocom)*
- *Fitipower Integrated Technology Inc. (fitipower)*
- *FoBE Studio (fobe)*
- *FocalTech Systems Co.,Ltd (focaltech)*
- *Freescale Semiconductor (fsl)*
- *Fujitsu Ltd. (fujitsu)*
- *Futaba Corporation (futaba)*
- *Future Technology Devices International Ltd. (ftdi)*

- *Fuzhou Rockchip Electronics Co., Ltd (rockchip)*
- *Gaisler (gaisler)*
- *Galaxycore, Inc. (galaxycore)*
- *Gas Sensing Solutions Ltd. (gss)*
- *GigaDevice Semiconductor (gd)*
- *GlobalTop Technology, Inc. (globaltop)*
- *GreeLed Electronic Ltd. (greeled)*
- *Guangzhou Aosong Electronic Co., Ltd. (aosong)*
- *Hamamatsu Photonics K.K. (hamamatsu)*
- *Hangzhou Grow Technology Co., Ltd. (hzgrow)*
- *Hangzhou Zhian Technology Co., Ltd. (zhiantec)*
- *Hazard3 by Luke Wren (hazard3)*
- *Himax Technologies, Inc. (himax)*
- *Hitachi Ltd. (hit)*
- *Holtek Semiconductor, Inc. (holtek)*
- *Honeywell (honeywell)*
- *HOPERF Microelectronics Co. Ltd (hoperf)*
- *Hycon Technology Corp. (hycon)*
- *Hynitron (hynitron)*
- *Iclegend Microelectronics Co., Ltd. (iclegend)*
- *ILI Technology Corporation (ILITEK) (ilitek)*
- *Imagination Technologies Ltd. (formerly MIPS Technologies Inc.) (mti)*
- *Infineon Technologies (infineon)*
- *Innovative Sensor Technology IST AG (ist)*
- *Integrated Silicon Solutions Inc. (issi)*
- *Integrated Solutions Technology Inc. (istech)*
- *Intel Corporation (intel)*
- *Intersil (isil)*
- *InvenSense Inc. (invensense)*
- *Inventek Systems (inventek)*
- *Isentek Inc. (isentek)*
- *ITE Tech. Inc. (ite)*
- *Japan Display Inc. (jdi)*
- *JEDEC Solid State Technology Association (jedec)*
- *Koninklijke Philips N.V. (philips)*
- *Kvaser (kvaser)*
- *Lattice Semiconductor (lattice)*
- *LeveTop Semiconductor (levetop)*
- *Linaro Limited (linaro)*

- *Linear Technology Corporation (lltc)*
- *LiteOn OptoElectronics (liteon)*
- *LiteX SoC builder (litex)*
- *lowRISC Community Interest Company (lowrisc)*
- *LuatOS Team (luatos)*
- *M5Stack (m5stack)*
- *Macronix International Co., Ltd. (mxicy)*
- *MaxBotix Inc. (maxbotix)*
- *Maxim Integrated Products (maxim)*
- *Maxlinear, Inc. (maxlinear)*
- *Measurement Specialties (meas)*
- *MediaTek Inc. (mediatek)*
- *Melexis N.V. (melexis)*
- *MEMSIC Inc. (memsic)*
- *Micro Crystal AG (microcrystal)*
- *Micro:bit Educational Foundation (microbit)*
- *Microchip Technology Inc. (microchip)*
- *Micron Technology Inc. (micron)*
- *Monolithic Power Systems Inc. (mps)*
- *Motorcomm Electronic Technology Co., Ltd. (motorcomm)*
- *Motorola, Inc. (motorola)*
- *Murata Manufacturing Co., Ltd. (murata)*
- *National Semiconductor (national)*
- *NEORV32 RISC-V Processor (neorv32)*
- *Netsol, CO., LTD (netsol)*
- *Ningbo Peacefair Electronic Technology Co., Ltd (peacefair)*
- *Nintendo (nintendo)*
- *Nordic Semiconductor (nordic)*
- *Noritake Co., Inc. Electronics Division (noritake)*
- *Nuclei System Technology (nuclei)*
- *Nuvoton Technology Corporation (nuvoton)*
- *NXP Semiconductors (nxp)*
- *OmniVision Technologies Inc. (ovti)*
- *OMRON Corporation (omron)*
- *ON Semiconductor Corp. (onnn)*
- *open-isa.org (openisa)*
- *OpenCores.org (opencores)*
- *OpenHW Group (openhwgroup)*
- *OpenThread.io (openthread)*

- *Orise Technology (orisetech)*
- *Panasonic Corporation (panasonic)*
- *Parade Technologies Inc. (parade)*
- *PixArt Imaging Inc. (pixart)*
- *Plantower Co., Ltd (plantower)*
- *PNI Sensor Corporation (pni)*
- *Princeton Technology Corp. (ptc)*
- *QEMU, a generic and open source machine emulator and virtualizer (qemu)*
- *Qorvo, Inc (formerly Decawave) (decawave)*
- *QST Corporation (qst)*
- *Qualcomm Atheros, Inc. (qca)*
- *Qualcomm Technologies, Inc (qcom)*
- *Quectel Wireless Solutions Co., Ltd. (quectel)*
- *QuickLogic Corp. (quicklogic)*
- *Raspberry Pi Foundation (raspberrypi)*
- *Raydium Semiconductor Corp. (raydium)*
- *Realtek Semiconductor Corp. (realtek)*
- *Renesas Electronics Corporation (renesas)*
- *Reyax Technology Co., Ltd. (reyax)*
- *Richtek Technology Corporation (richtek)*
- *RISC-V Foundation (riscv)*
- *ROCKTECH DISPLAYS LIMITED (rocktech)*
- *ROHM Semiconductor Co., Ltd (rohm)*
- *Sciosense B.V. (sciosense)*
- *Seeed Technology Co., Ltd (seeed)*
- *SEGGER Microcontroller GmbH (segger)*
- *Seiko Epson Corp. (epson)*
- *Semtech Corporation (semtech)*
- *Sensirion AG (sensirion)*
- *sensry.io (sensry)*
- *Sensylink Inc. (sensylink)*
- *Sequans Communications (sqn)*
- *SHAKTI Processor Program (shakti)*
- *Shanghai Awinic Technology Co., Ltd. (awinic)*
- *Sharp Corporation (sharp)*
- *Shenzhen Frida LCD Co., Ltd. (frida)*
- *Shenzhen Huiding Technology Co., Ltd. (goodix)*
- *Shenzhen Jinghua Displays Electronics Co., Ltd. (jhd)*
- *Shenzhen Titan Micro Electronics Co., Ltd. (titanmec)*

- *Shenzhen Xptek Technology Co., Ltd (xptek)*
- *Siemens AG (siemens)*
- *Sierra Wireless (swir)*
- *SiFive, Inc. (sifive)*
- *SiFli Technologies (sifli)*
- *Silergy Corp. (silergy)*
- *Silicon Laboratories (silabs)*
- *SIMCom Wireless Solutions Co., LTD (simcom)*
- *Sino Wealth Electronic Ltd (sinowealth)*
- *Sitronix Technology Corporation (sitronix)*
- *Skyworks Solutions, Inc. (skyworks)*
- *Smart Battery System (sbs)*
- *Socionext Inc. (socionext)*
- *Soldered Electronics (solderedelectronics)*
- *Solomon Systech Limited (solomon)*
- *Sony Corporation (sony)*
- *SparkFun Electronics (sparkfun)*
- *SpinalHDL (spinalhdl)*
- *Standard Microsystems Corporation (smsc)*
- *StarChips Technology Inc. (sct)*
- *STMicroelectronics (st)*
- *Synaptics Inc. (syna)*
- *Synopsys, Inc. (snps)*
- *Synopsys, Inc. (formerly ARC International PLC) (arc)*
- *TBS Technologies (tbs)*
- *TDK Corporation. (tdk)*
- *Telink Semiconductor (telink)*
- *Telit Cinterion (telit)*
- *Texas Instruments (ti)*
- *Trasna (trasna)*
- *u-blox (u-blox)*
- *UltraChip Inc. (ultrachip)*
- *Virtual I/O Device Specification, developed by the OASIS consortium (virtio)*
- *Vishay Intertechnology, Inc (vishay)*
- *Waveshare Electronics (waveshare)*
- *WeAct Studio (weact)*
- *Winbond Electronics corp. (winbond)*
- *WinChipHead (wch)*
- *Wistron NeWeb Corporation (wnc)*

- *WIZnet Co., Ltd. (wiznet)*
- *Worldsemi Co., Limited (worldsemi)*
- *Würth Elektronik GmbH. (we)*
- *X-Powers (x-powers)*
- *Xen Hypervisor (xen)*
- *Xilinx (xlnx)*
- *Zephyr Project (zephyr)*
- *Zhengzhou Winsen Electronics Technology Co., Ltd. (winsen)*
- *Unknown vendor*

5.4 Configuration System (Kconfig)

The Zephyr kernel and subsystems can be configured at build time to adapt them for specific application and platform needs. Configuration is handled through Kconfig, which is the same configuration system used by the Linux kernel. The goal is to support configuration without having to change any source code.

Configuration options (often called *symbols*) are defined in `Kconfig` files, which also specify dependencies between symbols that determine what configurations are valid. Symbols can be grouped into menus and sub-menus to keep the interactive configuration interfaces organized.

The output from Kconfig is a header file `autoconf.h` with macros that can be tested at build time. Code for unused features can be compiled out to save space.

The following sections explain how to set Kconfig configuration options, go into detail on how Kconfig is used within the Zephyr project, and have some tips and best practices for writing `Kconfig` files.

5.4.1 Interactive Kconfig interfaces

There are two interactive configuration interfaces available for exploring the available Kconfig options and making temporary changes: `menuconfig` and `guiconfig`. `menuconfig` is a curses-based interface that runs in the terminal, while `guiconfig` is a graphical configuration interface.

Note

The configuration can also be changed by editing `zephyr/.config` in the application build directory by hand. Using one of the configuration interfaces is often handier, as they correctly handle dependencies between configuration symbols.

If you try to enable a symbol with unsatisfied dependencies in `zephyr/.config`, the assignment will be ignored and overwritten when re-configuring.

To make a setting permanent, you should set it in a `*.conf` file, as described in *Setting Kconfig configuration values*.

Tip

Saving a minimal configuration file (with e.g. `D` in menuconfig) and inspecting it can be handy when making settings permanent. The minimal configuration file only lists symbols that differ from their default value.

To run one of the configuration interfaces, do this:

1. Build your application as usual using either `west` or `cmake`:

   Using west:

   ```
   west build -b <board>
   ```

   Using CMake and ninja:

   ```
   mkdir build && cd build
   cmake -GNinja -DBOARD=<board> ..
   ninja
   ```

2. To run the terminal-based `menuconfig` interface, use either of these commands:

   ```
   west build -t menuconfig
   ```

   ```
   ninja menuconfig
   ```

   To run the graphical `guiconfig`, use either of these commands:

   ```
   west build -t guiconfig
   ```

   ```
   ninja guiconfig
   ```

   Note

   If you get an import error for `tkinter` when trying to run `guiconfig`, you are missing required packages. See *Install Linux Host Dependencies*. The package you need is usually called something like `python3-tk`/`python3-tkinter`.

   `tkinter` is not included by default in many Python installations, despite being part of the standard library.

   The two interfaces are shown below:

   `guiconfig` always shows the help text and other information related to the currently selected item in the bottom window pane. In the terminal interface, press ? to view the same

Kconfig definition, with propagated dependencies
Modified

information.

> **Note**
>
> If you prefer to work in the `guiconfig` interface, then it's a good idea to check any changes to Kconfig files you make in *single-menu mode*, which is toggled via a checkbox at the top. Unlike full-tree mode, single-menu mode will distinguish between symbols defined with `config` and symbols defined with `menuconfig`, showing you what things would look like in the `menuconfig` interface.

3. Change configuration values in the `menuconfig` interface as follows:

   - Navigate the menu with the arrow keys. Common Vim key bindings are supported as well.
   - Use `Space` and `Enter` to enter menus and toggle values. Menus appear with `--->` next to them. Press `ESC` to return to the parent menu.

     Boolean configuration options are shown with *[ ]* brackets, while numeric and string-valued configuration symbols are shown with *( )* brackets. Symbol values that can't be changed are shown as `- -` or `-*-`.

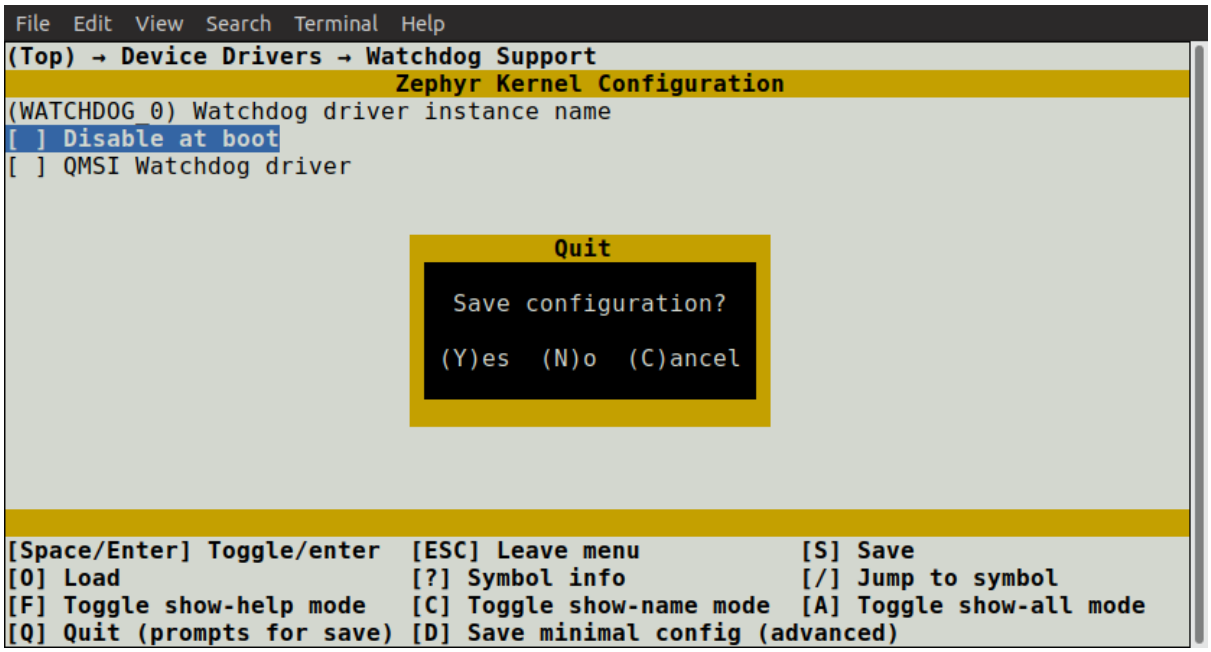
     > **Note**
     >
     > You can also press `Y` or `N` to set a boolean configuration symbol to the corresponding value.

   - Press `?` to display information about the currently selected symbol, including its help text. Press `ESC` or `Q` to return from the information display to the menu.

   In the `guiconfig` interface, either click on the image next to the symbol to change its value, or double-click on the row with the symbol (this only works if the symbol has no children, as double-clicking a symbol with children open/closes its menu instead).

   `guiconfig` also supports keyboard controls, which are similar to `menuconfig`.

4. Pressing `Q` in the `menuconfig` interface will bring up the save-and-quit dialog (if there are changes to save):

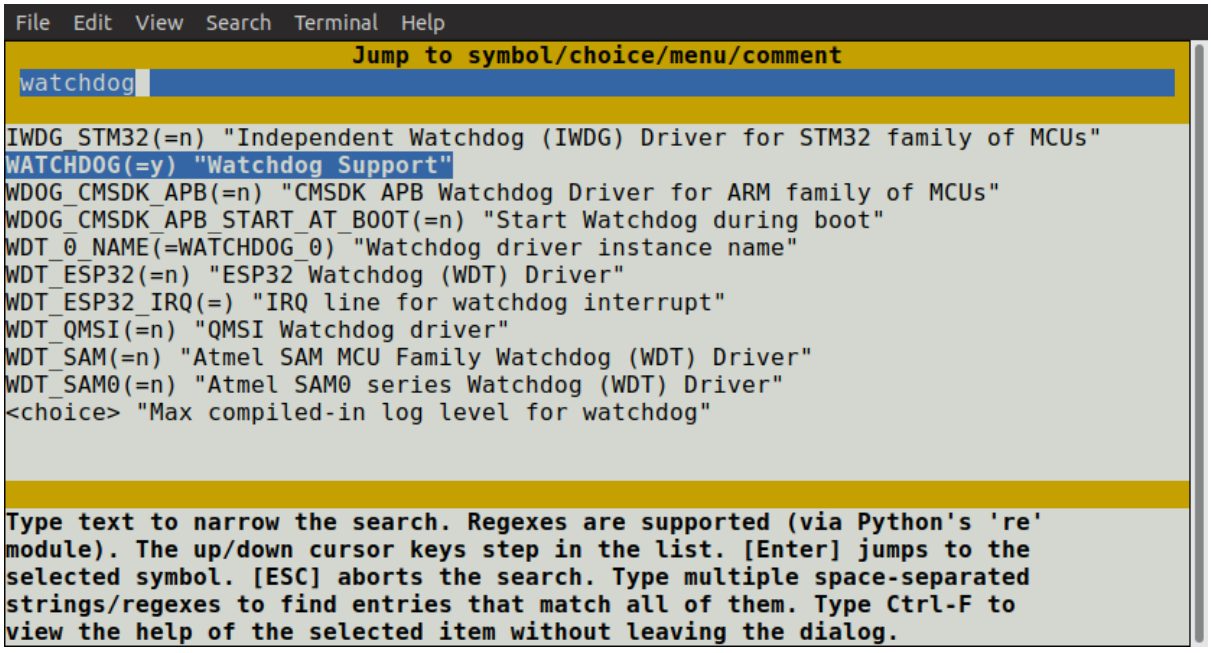


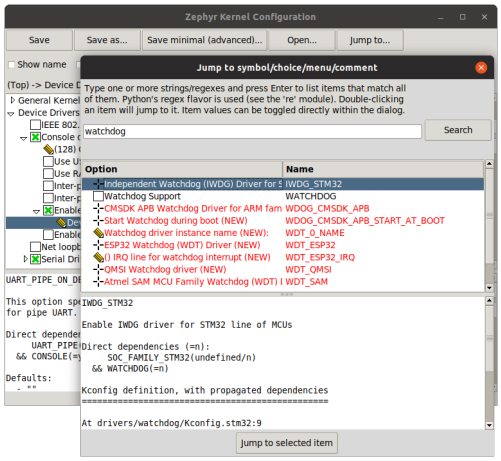
Press `Y` to save the kernel configuration options to the default filename (`zephyr/.config`). You will typically save to the default filename unless you are experimenting with different configurations.

The `guiconfig` interface will also prompt for saving the configuration on exit if it has been modified.

> **Note**
>
> The configuration file used during the build is always `zephyr/.config`. If you have another saved configuration that you want to build with, copy it to `zephyr/.config`. Make sure to back up your original configuration file.
>
> Also note that filenames starting with `.` are not listed by `ls` by default on Linux and macOS. Use the `-a` flag to see them.

Finding a symbol in the menu tree and navigating to it can be tedious. To jump directly to a symbol, press the `/` key (this also works in `guiconfig`). This brings up the following dialog, where you can search for symbols by name and jump to them. In `guiconfig`, you can also change symbol values directly within the dialog.





If you jump to a symbol that isn't currently visible (e.g., due to having unsatisfied dependencies),

then *show-all mode* will be enabled. In show-all mode, all symbols are displayed, including currently invisible symbols. To turn off show-all mode, press `A` in `menuconfig` or `Ctrl-A` in `guiconfig`.

Note

Show-all mode can't be turned off if there are no visible items in the current menu.

To figure out why a symbol you jumped to isn't visible, inspect its dependencies, either by pressing `?` in `menuconfig` or in the information pane at the bottom in `guiconfig`. If you discover that the symbol depends on another symbol that isn't enabled, you can jump to that symbol in turn to see if it can be enabled.

Note

In `menuconfig`, you can press `Ctrl-F` to view the help of the currently selected item in the jump-to dialog without leaving the dialog.

For more information on `menuconfig` and `guiconfig`, see the Python docstrings at the top of menuconfig.py and guiconfig.py.

5.4.2 Tracing values to their source

The merged configuration saved to `zephyr/.config` contains the result of applying the user configuration file to the whole tree of Kconfig files. This process can be hard to follow, especially when invisible symbols are being implicitly selected from anywhere in the tree. To help with this, the `traceconfig` target can be used to generate a file in the build directory that details how each symbol got its final value.

After building the Zephyr project as usual, the Kconfig trace can be generated with either of these commands:

```
west build -t traceconfig
```

```
ninja traceconfig
```

Note

The generated information is only useful on a clean build, because otherwise the `.config` file "pins" all settings to a specific value (as described in *Stuck symbols*). Therefore, it is recommended to run a *pristine build* before generating the trace.

The output will be in the `zephyr/kconfig-trace.md` file in the build directory. This file is best viewed within IDEs to take advantage of Markdown elements (tables, highlighting, clickable links), but can easily be understood even when opened directly with any text editor.

The report is divided in three sections:

1. Visible symbols
2. Invisible symbols
3. Unset symbols

For sections 1 and 2, a table is presented where each symbol is shown with its type, name, and current value. The fourth column details the kind of statement that resulted in the value being applied, and can be one of the following:

- *assigned*, when an explicit assignment, of the form `CONFIG_xxx=y`, is read from a config file;

- *default*, when there was no user assignment, but an applicable default value was read from Kconfig tree;
- *selected* or *implied*, when a `select` or `imply` statement from a separate symbol caused the symbol to be set.

The fifth column details the location for the source statement. For the first two kinds of statements, the exact location (file name and line number) is provided; in the latter cases, it contains the expressions that resulted in the symbol being set.

Finally, section 3 simply lists all undefined symbols. These have no additional information since they never received a value by any of the above means.

5.4.3 Setting Kconfig configuration values

The *menuconfig and guiconfig interfaces* can be used to test out configurations during application development. This page explains how to make settings permanent.

All Kconfig options can be searched in the Kconfig search page.

> **Note**
>
> Before making changes to Kconfig files, it's a good idea to also go through the *Kconfig - Tips and Best Practices* page.

Visible and invisible Kconfig symbols

When making Kconfig changes, it's important to understand the difference between *visible* and *invisible* symbols.

- A visible symbol is a symbol defined with a prompt. Visible symbols show up in the interactive configuration interfaces (hence *visible*), and can be set in configuration files.

  Here's an example of a visible symbol:

  ```
  config FPU
     bool "Support floating point operations"
     depends on HAS_FPU
  ```

  The symbol is shown like this in `menuconfig`, where it can be toggled:

  ```
  [ ] Support floating point operations
  ```

- An *invisible* symbol is a symbol without a prompt. Invisible symbols are not shown in the interactive configuration interfaces, and users have no direct control over their value. They instead get their value from defaults or from other symbols.

  Here's an example of an invisible symbol:

  ```
  config CPU_HAS_FPU
     bool
     help
       This symbol is y if the CPU has a hardware floating point unit.
  ```

  In this case, `CPU_HAS_FPU` is enabled through other symbols having `select CPU_HAS_FPU`.

Setting symbols in configuration files

Visible symbols can be configured by setting them in configuration files. The initial configuration is produced by merging a `*_defconfig` file for the board with application settings, usually from `prj.conf`. See *The Initial Configuration* below for more details.

Assignments in configuration files use this syntax:

```
CONFIG_<symbol name>=<value>
```

There should be no spaces around the equals sign.

`bool` symbols can be enabled or disabled by setting them to `y` or `n`, respectively. The `FPU` symbol from the example above could be enabled like this:

```
CONFIG_FPU=y
```

Note

A boolean symbol can also be set to `n` with a comment formatted like this:

```
# CONFIG_SOME_OTHER_BOOL is not set
```

This is the format you will see in the merged configuration saved to `zephyr/.config` in the build directory.

This style is accepted for historical reasons: Kconfig configuration files can be parsed as makefiles (though Zephyr doesn't use this). Having `n`-valued symbols correspond to unset variables simplifies tests in Make.

Other symbol types are assigned like this:

```
CONFIG_SOME_STRING="cool value"
CONFIG_SOME_INT=123
```

Comments use a #:

```
# This is a comment
```

Assignments in configuration files are only respected if the dependencies for the symbol are satisfied. A warning is printed otherwise. To figure out what the dependencies of a symbol are, use one of the *interactive configuration interfaces* (you can jump directly to a symbol with /), or look up the symbol in the Kconfig search page.

The Initial Configuration

The initial configuration for an application comes from merging configuration settings from three sources:

1. A `BOARD`-specific configuration file stored in `boards/<VENDOR>/<BOARD>/<BOARD>_defconfig`
2. Any CMake cache entries prefix with `CONFIG_`
3. The application configuration

The application configuration can come from the sources below (each file is known as a Kconfig fragment, which are then merged to get the final configuration used for a particular build). By default, `prj.conf` is used.

1. If `CONF_FILE` is set, the configuration file(s) specified in it are merged and used as the application configuration. `CONF_FILE` can be set in various ways:
    1. In `CMakeLists.txt`, before calling `find_package(Zephyr)`
    2. By passing `-DCONF_FILE=<conf file(s)>`, either directly or via `west`
    3. From the CMake variable cache
2. Otherwise, if `boards/<BOARD>.conf` exists in the application configuration directory, the result of merging it with `prj.conf` is used.

3. Otherwise, if board revisions are used and `boards/<BOARD>_<revision>.conf` exists in the application configuration directory, the result of merging it with `prj.conf` and `boards/<BOARD>.conf` is used.
4. Otherwise, `prj.conf` is used from the application configuration directory. If it does not exist then a fatal error will be emitted.

Furthermore, applications can have SoC Kconfig fragments added to the configuration, the file `socs/<SOC>_<BOARD_QUALIFIERS>.conf` will be applied if it exists, after the main project configuration has been applied and before any board Kconfig fragments files have been applied.

All configuration files will be taken from the application's configuration directory except for files with an absolute path that are given with the `CONF_FILE`, `EXTRA_CONF_FILE`, `DTC_OVERLAY_FILE`, and `EXTRA_DTC_OVERLAY_FILE` arguments. For these, a file in a Zephyr module can be referred by escaping the Zephyr module dir variable like this `\${ZEPHYR_<module>_MODULE_DIR}/<path-to>/<file>` when setting any of said variables in the application's `CMakeLists.txt`.

See *Application Configuration Directory* on how the application configuration directory is defined.

If a symbol is assigned both in `<BOARD>_defconfig` and in the application configuration, the value set in the application configuration takes precedence.

The merged configuration is saved to `zephyr/.config` in the build directory.

As long as `zephyr/.config` exists and is up-to-date (is newer than any `BOARD` and application configuration files), it will be used in preference to producing a new merged configuration. `zephyr/.config` is also the configuration that gets modified when making changes in the *interactive configuration interfaces*.

Treating Kconfig warnings as errors

Some Kconfig warnings abort the build by default, for example assignments to undefined symbols. Others are only printed, for example when a symbol is set more than once, or when an assignment is ignored because the dependencies of the symbol are not satisfied.

Set the **KCONFIG_WARNING_AS_ERROR** CMake variable to treat *every* Kconfig warning as an error:

```
west build -b <board> <app> -- -DKCONFIG_WARNING_AS_ERROR=y
```

This is useful in CI, where a silently ignored configuration setting is likely to be a mistake. It is read with `zephyr_get()`, so it can also be given as an *environment variable* or through a *Zephyr Build Configuration CMake packages*.

Tracking Kconfig symbols

It is possible to create Kconfig symbols which takes the default value of another Kconfig symbol.

This is valuable when you want a symbol specific to an application or subsystem but do not want to rely directly on the common symbol. For example, you might want to decouple the settings so they can be independently configured, or to ensure you always have a locally named setting, even if the external setting name changes. is later changed.

For example, consider the common `FOO_STRING` setting where a subsystem wants to have a `SUB_FOO_STRING` but still allow for customization.

This can be done like this:

```
config FOO_STRING
        string "Foo"
        default "foo"

config SUB_FOO_STRING
```

(continues on next page)

(continued from previous page)

```
        string "Sub-foo"
        default FOO_STRING
```

This ensures that the default value of SUB_FOO_STRING is identical to FOO_STRING while still allows users to configure both settings independently.

It is also possible to make SUB_FOO_STRING invisible and thereby keep the two symbols in sync, unless the value of the tracking symbol is changed in a defconfig file.

```
config FOO_STRING
        string "Foo"
        default "foo"

config SUB_FOO_STRING
        string
        default FOO_STRING
        help
          Hidden symbol which follows FOO_STRING
          Can be changed through *.defconfig files.
```

Configuring invisible Kconfig symbols

When making changes to the default configuration for a board, you might have to configure invisible symbols. This is done in boards/<VENDOR>/<BOARD>/Kconfig.defconfig, which is a regular Kconfig file.

> **Note**
>
> Assignments in .config files have no effect on invisible symbols, so this scheme is not just an organizational issue.

Assigning values in Kconfig.defconfig relies on defining a Kconfig symbol in multiple locations. As an example, say we want to set FOO_WIDTH below to 32:

```
config FOO_WIDTH
    int
```

To do this, we extend the definition of FOO_WIDTH as follows, in Kconfig.defconfig:

```
if BOARD_MY_BOARD

config FOO_WIDTH
    default 32

endif
```

> **Note**
>
> Since the type of the symbol (int) has already been given at the first definition location, it does not need to be repeated here. Only giving the type once at the "base" definition of the symbol is a good idea for reasons explained in *Common Kconfig shorthands*.

default values in Kconfig.defconfig files have priority over default values given on the "base" definition of a symbol. Internally, this is implemented by including the Kconfig.defconfig files

first. Kconfig uses the first `default` with a satisfied condition, where an empty condition corresponds to `if y` (is always satisfied).

Note that conditions from surrounding top-level `if`s are propagated to symbol properties, so the above `default` is equivalent to `default 32 if BOARD_MY_BOARD`.

Multiple symbol definitions When a symbol is defined in multiple locations, each definition acts as an independent symbol that happens to share the same name. This means that properties are not appended to previous definitions. If the conditions for **ANY** definition result in the symbol resolving to `y`, the symbol will be `y`. It is therefore not possible to make the dependencies of a symbol more restrictive by defining it in multiple locations.

For example, the dependencies of the symbol `FOO` below are satisfied if either `DEP1` **OR** `DEP2` are true, it does not require both:

```
config FOO
   ...
   depends on DEP1

config FOO
   ...
   depends on DEP2
```

Warning

Symbols without explicit dependencies still follow the above rule. A symbol without any dependencies will result in the symbol always being assignable. The definition below will result in `FOO` always being enabled by default, regardless of the value of `DEP1`.

```
config FOO
   bool "FOO"
   depends on DEP1

config FOO
   default y
```

This dependency weakening can be avoided with the *configdefault* extension if the desire is only to add a new default without modifying any other behaviour of the symbol.

Note

When making changes to `Kconfig.defconfig` files, always check the symbol's direct dependencies in one of the *interactive configuration interfaces* afterwards. It is often necessary to repeat dependencies from the base definition of the symbol to avoid weakening a symbol's dependencies.

Motivation for Kconfig.defconfig files One motivation for this configuration scheme is to avoid making fixed `BOARD`-specific settings configurable in the interactive configuration interfaces. If all board configuration were done via `<BOARD>_defconfig`, all symbols would have to be visible, as values given in `<BOARD>_defconfig` have no effect on invisible symbols.

Having fixed settings be user-configurable would clutter up the configuration interfaces and make them harder to understand, and would make it easier to accidentally create broken configurations.

When dealing with fixed board-specific settings, also consider whether they should be handled via *devicetree* instead.

Configuring choices There are two ways to configure a Kconfig `choice`:

1. By setting one of the choice symbols to `y` in a configuration file.

   Setting one choice symbol to `y` automatically gives all other choice symbols the value `n`.

   If multiple choice symbols are set to `y`, only the last one set to `y` will be honored (the rest will get the value `n`). This allows a choice selection from a board `defconfig` file to be overridden from an application `prj.conf` file.

2. By changing the `default` of the choice in `Kconfig.defconfig`.

   As with symbols, changing the default for a choice is done by defining the choice in multiple locations. For this to work, the choice must have a name.

   As an example, assume that a choice has the following base definition (here, the name of the choice is `FOO`):

   ```
   choice FOO
       bool "Foo choice"
       default B

   config A
       bool "A"

   config B
       bool "B"

   endchoice
   ```

   To change the default symbol of `FOO` to `A`, you would add the following definition to `Kconfig.defconfig`:

   ```
   choice FOO
       default A
   endchoice
   ```

The `Kconfig.defconfig` method should be used when the dependencies of the choice might not be satisfied. In that case, you're setting the default selection whenever the user makes the choice visible.

More Kconfig resources The *Kconfig - Tips and Best Practices* page has some tips for writing Kconfig files.

The kconfiglib.py docstring (at the top of the file) goes over how symbol values are calculated in detail.

5.4.4 Kconfig - Tips and Best Practices

This page covers some Kconfig best practices and explains some Kconfig behaviors and features that might be cryptic or that are easily overlooked.

Note

What to turn into Kconfig options

When deciding whether something belongs in Kconfig, it helps to distinguish between symbols that have prompts and symbols that don't.

If a symbol has a prompt (e.g. `bool "Enable foo"`), then the user can change the symbol's value in the `menuconfig` or `guiconfig` interface (see *Interactive Kconfig interfaces*), or by manually editing configuration files. Conversely, a symbol without a prompt can never be changed directly by the user, not even by manually editing configuration files.

Only put a prompt on a symbol if it makes sense for the user to change its value.

Symbols without prompts are called *hidden* or *invisible* symbols, because they don't show up in `menuconfig` and `guiconfig`. Symbols that have prompts can also be invisible, when their dependencies are not satisfied.

Symbols without prompts can't be configured directly by the user (they derive their value from other symbols), so less restrictions apply to them. If some derived setting is easier to calculate in Kconfig than e.g. during the build, then do it in Kconfig, but keep the distinction between symbols with and without prompts in mind.

See the *optional prompts* section for a way to deal with settings that are fixed on some machines and configurable on other machines.

What not to turn into Kconfig options

In Zephyr, Kconfig configuration is done after selecting a target board. In general, it does not make sense to use Kconfig for a value that corresponds to a fixed machine-specific setting. Usually, such settings should be handled via *devicetree* instead.

In particular, avoid adding new Kconfig options of the following types:

Options that specify a device in the system by name For example, if you are writing an I2C device driver, avoid creating an option named `MY_DEVICE_I2C_BUS_NAME` for specifying the bus node your device is controlled by. See *Device drivers that depend on other devices* for alternatives.

Similarly, if your application depends on a hardware-specific PWM device to control an RGB LED, avoid creating an option like `MY_PWM_DEVICE_NAME`. See *Applications that depend on board-specific devices* for alternatives.

Options that specify fixed hardware configuration For example, avoid Kconfig options specifying a GPIO pin.

An alternative applicable to device drivers is to define a GPIO specifier with type phandle-array in the device binding, and using the *GPIO* devicetree API from C. Similar advice applies to other cases where devicetree.h provides *Hardware specific APIs* for referring to other nodes in the system. Search the source code for drivers using these APIs for examples.

An application-specific devicetree *binding* to identify board specific properties may be appropriate. See tests/drivers/gpio/gpio_basic_api for an example.

For applications, see blinky for a devicetree-based alternative.

`select` statements

The `select` statement is used to force one symbol to `y` whenever another symbol is `y`. For example, the following code forces `CONSOLE` to `y` whenever `USB_CONSOLE` is `y`:

```
config CONSOLE
     bool "Console support"

...

config USB_CONSOLE
     bool "USB console support"
     select CONSOLE
```

This section covers some pitfalls and good uses for `select`.

`select` pitfalls `select` might seem like a generally useful feature at first, but can cause configuration issues if overused.

For example, say that a new dependency is added to the `CONSOLE` symbol above, by a developer who is unaware of the `USB_CONSOLE` symbol (or simply forgot about it):

```
config CONSOLE
     bool "Console support"
     depends on STRING_ROUTINES
```

Enabling USB_CONSOLE now forces CONSOLE to y, even if STRING_ROUTINES is n.

To fix the problem, the STRING_ROUTINES dependency needs to be added to USB_CONSOLE as well:

```
config USB_CONSOLE
     bool "USB console support"
     select CONSOLE
     depends on STRING_ROUTINES

...

config STRING_ROUTINES
     bool "Include string routines"
```

More insidious cases with dependencies inherited from `if` and `menu` statements are common.

An alternative attempt to solve the issue might be to turn the `depends on` into another `select`:

```
config CONSOLE
     bool "Console support"
     select STRING_ROUTINES

...

config USB_CONSOLE
     bool "USB console support"
     select CONSOLE
```

In practice, this often amplifies the problem, because any dependencies added to STRING_ROUTINES now need to be copied to both CONSOLE and USB_CONSOLE.

In general, whenever the dependencies of a symbol are updated, the dependencies of all symbols that (directly or indirectly) select it have to be updated as well. This is very often overlooked in practice, even for the simplest case above.

Chains of symbols selecting each other should be avoided in particular, except for simple helper symbols, as covered below in *Using select for helper symbols*.

Liberal use of `select` also tends to make Kconfig files harder to read, both due to the extra dependencies and due to the non-local nature of `select`, which hides ways in which a symbol might get enabled.

Alternatives to `select` For the example in the previous section, a better solution is usually to turn the `select` into a `depends on`:

```
config CONSOLE
     bool "Console support"

...

config USB_CONSOLE
     bool "USB console support"
     depends on CONSOLE
```

This makes it impossible to generate an invalid configuration, and means that dependencies only ever have to be updated in a single spot.

An objection to using `depends on` here might be that configuration files that enable `USB_CONSOLE` now also need to enable `CONSOLE`:

```
CONFIG_CONSOLE=y
CONFIG_USB_CONSOLE=y
```

This comes down to a trade-off, but if enabling `CONSOLE` is the norm, then a mitigation is to make `CONSOLE` default to `y`:

```
config CONSOLE
     bool "Console support"
     default y
```

This gives just a single assignment in configuration files:

```
CONFIG_USB_CONSOLE=y
```

Note that configuration files that do not want `CONSOLE` enabled now have to explicitly disable it:

```
CONFIG_CONSOLE=n
```

Using `select` for helper symbols A good and safe use of `select` is for setting "helper" symbols that capture some condition. Such helper symbols should preferably have no prompt or dependencies.

For example, a helper symbol for indicating that a particular CPU/SoC has an FPU could be defined as follows:

```
config CPU_HAS_FPU
     bool
     help
       If y, the CPU has an FPU

...

config SOC_FOO
    bool
    select CPU_HAS_FPU

...

config SOC_BAR
    bool
    select CPU_HAS_FPU
```

This makes it possible for other symbols to check for FPU support in a generic way, without having to look for particular architectures:

```
config FPU
     bool "Support floating point operations"
     depends on CPU_HAS_FPU
```

The alternative would be to have dependencies like the following, possibly duplicated in several spots:

```
config FPU
     bool "Support floating point operations"
     depends on SOC_FOO || SOC_BAR || ...
```

Invisible helper symbols can also be useful without `select`. For example, the following code defines a helper symbol that has the value `y` if the machine has some arbitrarily-defined "large" amount of memory:

```
config LARGE_MEM
     def_bool MEM_SIZE >= 64
```

Note

This is short for the following:

```
config LARGE_MEM
  bool
  default MEM_SIZE >= 64
```

`select` recommendations In summary, here are some recommended practices for `select`:

- Avoid selecting symbols with prompts or dependencies. Prefer `depends on`. If `depends on` causes annoying bloat in configuration files, consider adding a Kconfig default for the most common value.

  Rare exceptions might include cases where you're sure that the dependencies of the selecting and selected symbol will never drift out of sync, e.g. when dealing with two simple symbols defined close to one another within the same `if`.

  Common sense applies, but be aware that `select` often causes issues in practice. `depends on` is usually a cleaner and safer solution.

- Select simple helper symbols without prompts and dependencies however much you like. They're a great tool for simplifying Kconfig files.

- An exemption are buses like I2C and SPI, and following the same thought process things like MFD as well. Drivers on these buses should use `select` to allow the automatic activation of the necessary bus drivers when devices on the bus are enabled in the devicetree.

```
config ADC_FOO
   bool "external SPI ADC foo driver"
   select SPI
```

(Lack of) conditional includes

`if` blocks add dependencies to each item within the `if`, as if `depends on` was used.

A common misunderstanding related to `if` is to think that the following code conditionally includes the file `Kconfig.other`:

```
if DEP

source "Kconfig.other"

endif
```

In reality, there are no conditional includes in Kconfig. `if` has no special meaning around a `source`.

Note

Conditional includes would be impossible to implement, because `if` conditions may contain (either directly or indirectly) forward references to symbols that haven't been defined yet.

Say that `Kconfig.other` above contains this definition:

```
config FOO
	bool "Support foo"
```

In this case, `FOO` will end up with this definition:

```
config FOO
	bool "Support foo"
	depends on DEP
```

Note that it is redundant to add `depends on DEP` to the definition of `FOO` in `Kconfig.other`, because the `DEP` dependency has already been added by `if DEP`.

In general, try to avoid adding redundant dependencies. They can make the structure of the Kconfig files harder to understand, and also make changes more error-prone, since it can be hard to spot that the same dependency is added twice.

"Stuck" symbols in menuconfig and guiconfig

There is a common subtle gotcha related to interdependent configuration symbols with prompts. Consider these symbols:

```
config FOO
	bool "Foo"

config STACK_SIZE
	hex "Stack size"
	default 0x200 if FOO
	default 0x100
```

Assume that the intention here is to use a larger stack whenever `FOO` is enabled, and that the configuration initially has `FOO` disabled. Also, remember that Zephyr creates an initial configuration in `zephyr/.config` in the build directory by merging configuration files (including e.g. `prj.conf`). This configuration file exists before `menuconfig` or `guiconfig` is run.

When first entering the configuration interface, the value of `STACK_SIZE` is 0x100, as expected. After enabling `FOO`, you might reasonably expect the value of `STACK_SIZE` to change to 0x200, but it stays as 0x100.

To understand what's going on, remember that `STACK_SIZE` has a prompt, meaning it is user-configurable, and consider that all Kconfig has to go on from the initial configuration is this:

```
CONFIG_STACK_SIZE=0x100
```

Since Kconfig can't know if the 0x100 value came from a `default` or was typed in by the user, it has to assume that it came from the user. Since `STACK_SIZE` is user-configurable, the value from the configuration file is respected, and any symbol defaults are ignored. This is why the value of `STACK_SIZE` appears to be "frozen" at 0x100 when toggling `FOO`.

The right fix depends on what the intention is. Here's some different scenarios with suggestions:

- If `STACK_SIZE` can always be derived automatically and does not need to be user-configurable, then just remove the prompt:

```
config STACK_SIZE
   hex
   default 0x200 if FOO
   default 0x100
```

Symbols without prompts ignore any value from the saved configuration.

- If `STACK_SIZE` should usually be user-configurable, but needs to be set to 0x200 when `FOO` is enabled, then disable its prompt when `FOO` is enabled, as described in *optional prompts*:

```
config STACK_SIZE
   hex "Stack size" if !FOO
   default 0x200 if FOO
   default 0x100
```

- If `STACK_SIZE` should usually be derived automatically, but needs to be set to a custom value in rare circumstances, then add another option for making `STACK_SIZE` user-configurable:

```
config CUSTOM_STACK_SIZE
   bool "Use a custom stack size"
   help
     Enable this if you need to use a custom stack size. When disabled, a
     suitable stack size is calculated automatically.

config STACK_SIZE
   hex "Stack size" if CUSTOM_STACK_SIZE
   default 0x200 if FOO
   default 0x100
```

As long as `CUSTOM_STACK_SIZE` is disabled, `STACK_SIZE` will ignore the value from the saved configuration.

It is a good idea to try out changes in the `menuconfig` or `guiconfig` interface, to make sure that things behave the way you expect. This is especially true when making moderately complex changes like these.

Assignments to promptless symbols in configuration files

Assignments to hidden (promptless, also called *invisible*) symbols in configuration files are always ignored. Hidden symbols get their value indirectly from other symbols, via e.g. `default` and `select`.

A common source of confusion is opening the output configuration file (`zephyr/.config`), seeing a bunch of assignments to hidden symbols, and assuming that those assignments must be respected when the configuration is read back in by Kconfig. In reality, all assignments to hidden symbols in `zephyr/.config` are ignored by Kconfig, like for other configuration files.

To understand why `zephyr/.config` still includes assignments to hidden symbols, it helps to realize that `zephyr/.config` serves two separate purposes:

1. It holds the saved configuration, and
2. it holds configuration output. `zephyr/.config` is parsed by the CMake files to let them query configuration settings, for example.

The assignments to hidden symbols in `zephyr/.config` are just configuration output. Kconfig itself ignores assignments to hidden symbols when calculating symbol values.

> **Note**
>
> A *minimal configuration*, which can be generated from within the *menuconfig and guiconfig interfaces*, could be considered closer to just a saved configuration, without the full configuration output.

`depends on` and `string`/`int`/`hex` symbols

`depends on` works not just for `bool` symbols, but also for `string`, `int`, and `hex` symbols (and for choices).

The Kconfig definitions below will hide the `FOO_DEVICE_FREQUENCY` symbol and disable any configuration output for it when `FOO_DEVICE` is disabled.

```
config FOO_DEVICE
     bool "Foo device"

config FOO_DEVICE_FREQUENCY
     int "Foo device frequency"
     depends on FOO_DEVICE
```

In general, it's a good idea to check that only relevant symbols are ever shown in the `menuconfig`/`guiconfig` interface. Having `FOO_DEVICE_FREQUENCY` show up when `FOO_DEVICE` is disabled (and possibly hidden) makes the relationship between the symbols harder to understand, even if code never looks at `FOO_DEVICE_FREQUENCY` when `FOO_DEVICE` is disabled.

`menuconfig` symbols

If the definition of a symbol `FOO` is immediately followed by other symbols that depend on `FOO`, then those symbols become children of `FOO`. If `FOO` is defined with `config FOO`, then the children are shown indented relative to `FOO`. Defining `FOO` with `menuconfig FOO` instead puts the children in a separate menu rooted at `FOO`.

`menuconfig` has no effect on evaluation. It's just a display option.

`menuconfig` can cut down on the number of menus and make the menu structure easier to navigate. For example, say you have the following definitions:

```
menu "Foo subsystem"

config FOO_SUBSYSTEM
     bool "Foo subsystem"

if FOO_SUBSYSTEM

config FOO_FEATURE_1
     bool "Foo feature 1"

config FOO_FEATURE_2
     bool "Foo feature 2"

config FOO_FREQUENCY
     int "Foo frequency"

... lots of other FOO-related symbols

endif # FOO_SUBSYSTEM
```

(continues on next page)

(continued from previous page)

```
endmenu
```

In this case, it's probably better to get rid of the `menu` and turn `FOO_SUBSYSTEM` into a `menuconfig` symbol:

```
menuconfig FOO_SUBSYSTEM
     bool "Foo subsystem"

if FOO_SUBSYSTEM

config FOO_FEATURE_1
     bool "Foo feature 1"

config FOO_FEATURE_2
     bool "Foo feature 2"

config FOO_FREQUENCY
     int "Foo frequency"

... lots of other FOO-related symbols

endif # FOO_SUBSYSTEM
```

In the `menuconfig` interface, this will be displayed as follows:

```
[*] Foo subsystem  --->
```

Note that making a symbol without children a `menuconfig` is meaningless. It should be avoided, because it looks identical to a symbol with all children invisible:

```
[*] I have no children  ----
[*] All my children are invisible  ----
```

Commas in macro arguments

Kconfig uses commas to separate macro arguments. This means a construct like this will fail:

```
config FOO
    bool
    default y if $(dt_chosen_enabled,"zephyr,bar")
```

To solve this problem, create a variable with the text and use this variable as argument, as follows:

```
DT_CHOSEN_ZEPHYR_BAR := zephyr,bar

config FOO
    bool
    default y if $(dt_chosen_enabled,$(DT_CHOSEN_ZEPHYR_BAR))
```

Note

A variable `DT_COMPAT_VND_MY_DEVICE := vnd,my-device` is automatically created by Zephyr for every `compatible` found in Devicetree bindings; there is no need to define such variables. See *Automatic Kconfig symbols from devicetree* for details.

Checking changes in menuconfig/guiconfig

When adding new symbols or making other changes to Kconfig files, it is a good idea to look up the symbols in *menuconfig or guiconfig* afterwards. To get to a symbol quickly, use the jump-to feature (press /).

Here are some things to check:

- Are the symbols placed in a good spot? Check that they appear in a menu where they make sense, close to related symbols.

  If one symbol depends on another, then it's often a good idea to place it right after the symbol it depends on. It will then be shown indented relative to the symbol it depends on in the `menuconfig` interface, and in a separate menu rooted at the symbol in `guiconfig`. This also works if several symbols are placed after the symbol they depend on.

- Is it easy to guess what the symbols do from their prompts?
- If many symbols are added, do all combinations of values they can be set to make sense?

  For example, if two symbols `FOO_SUPPORT` and `NO_FOO_SUPPORT` are added, and both can be enabled at the same time, then that makes a nonsensical configuration. In this case, it's probably better to have a single `FOO_SUPPORT` symbol.

- Are there any duplicated dependencies?

  This can be checked by selecting a symbol and pressing ? to view the symbol information. If there are duplicated dependencies, then use the `Included via ...` path shown in the symbol information to figure out where they come from.

Checking changes with `scripts/kconfig/lint.py`

After you make Kconfig changes, you can use the scripts/kconfig/lint.py script to check for some potential issues, like unused symbols and symbols that are impossible to enable. Use `--help` to see available options.

Some checks are necessarily a bit heuristic, so a symbol being flagged by a check does not necessarily mean there's a problem. If a check returns a false positive e.g. due to token pasting in C (`CONFIG_FOO_##index##_BAR`), just ignore it.

When investigating an unknown symbol `FOO_BAR`, it is a good idea to run `git grep FOO_BAR` to look for references. It is also a good idea to search for some components of the symbol name with e.g. `git grep FOO` and `git grep BAR`, as it can help uncover token pasting.

Style recommendations and shorthands

This section gives some style recommendations and explains some common Kconfig shorthands.

Factoring out common dependencies If a sequence of symbols/choices share a common dependency, the dependency can be factored out with an `if`.

As an example, consider the following code:

```
config FOO
     bool "Foo"
     depends on DEP

config BAR
     bool "Bar"
     depends on DEP

choice
     prompt "Choice"
```

(continues on next page)

(continued from previous page)

```
     depends on DEP

config BAZ
     bool "Baz"

config QAZ
     bool "Qaz"

endchoice
```

Here, the DEP dependency can be factored out like this:

```
if DEP

config FOO
     bool "Foo"

config BAR
     bool "Bar"

choice
     prompt "Choice"

config BAZ
     bool "Baz"

config QAZ
     bool "Qaz"

endchoice

endif # DEP
```

Note

Internally, the second version of the code is transformed into the first.

If a sequence of symbols/choices with shared dependencies are all in the same menu, the dependency can be put on the menu itself:

```
menu "Foo features"
     depends on FOO_SUPPORT

config FOO_FEATURE_1
     bool "Foo feature 1"

config FOO_FEATURE_2
     bool "Foo feature 2"

endmenu
```

If FOO_SUPPORT is n, the entire menu disappears.

Redundant defaults bool symbols implicitly default to n, and string symbols implicitly default to the empty string. Therefore, `default n` and `default ""` are (almost) always redundant.

The recommended style in Zephyr is to skip redundant defaults for `bool` and `string` symbols. That also generates clearer documentation: (*Implicitly defaults to n* instead of *n if <dependencies, possibly inherited>*).

Defaults *should* always be given for `int` and `hex` symbols, however, as they implicitly default to the empty string. This is partly for compatibility with the C Kconfig tools, though an implicit 0 default might be less likely to be what was intended compared to other symbol types as well.

The one case where `default n`/`default ""` is not redundant is when defining a symbol in multiple locations and wanting to override e.g. a `default y` on a later definition. Note that a `default n` does not override a previously defined `default y`.

That is, FOO will be set to `n` in the example below. If the `default n` was omitted in the first definition, FOO would have been set to `y`.

```
config FOO
   bool "foo"
   default n

config FOO
   bool "foo"
   default y
```

In the following example FOO will get the value `y`.

```
config FOO
   bool "foo"
   default y

config FOO
   bool "foo"
   default n
```

Common Kconfig shorthands Kconfig has two shorthands that deal with prompts and defaults.

- `<type> "prompt"` is a shorthand for giving a symbol/choice a type and a prompt at the same time. These two definitions are equal:

  ```
  config FOO
     bool "foo"
  ```

  ```
  config FOO
     bool
     prompt "foo"
  ```

  The first style, with the shorthand, is preferred in Zephyr.

- `def_<type> <value>` is a shorthand for giving a type and a value at the same time. These two definitions are equal:

  ```
  config FOO
     def_bool BAR && BAZ
  ```

  ```
  config FOO
     bool
     default BAR && BAZ
  ```

Using both the `<type> "prompt"` and the `def_<type> <value>` shorthand in the same definition is redundant, since it gives the type twice.

The `def_<type> <value>` shorthand is generally only useful for symbols without prompts, and somewhat obscure.

> **Note**
>
> For a symbol defined in multiple locations (e.g., in a `Kconfig.defconfig` file in Zephyr), it is best to only give the symbol type for the "base" definition of the symbol, and to use `default` (instead of `def_<type> value`) for the remaining definitions. That way, if the base definition of the symbol is removed, the symbol ends up without a type, which generates a warning that points to the other definitions. That makes the extra definitions easier to discover and remove.

Prompt strings For a Kconfig symbol that enables a driver/subsystem FOO, consider having just "Foo" as the prompt, instead of "Enable Foo support" or the like. It will usually be clear in the context of an option that can be toggled on/off, and makes things consistent.

Style See *Coding Style Guidelines* for style guidelines.

Lesser-known/used Kconfig features

This section lists some more obscure Kconfig behaviors and features that might still come in handy.

The `imply` statement The `imply` statement is similar to `select`, but respects dependencies and doesn't force a value. For example, the following code could be used to enable USB keyboard support by default on the FOO SoC, while still allowing the user to turn it off:

```
config SOC_FOO
    bool
    imply USB_KEYBOARD

...

config USB_KEYBOARD
     bool "USB keyboard support"
```

`imply` acts like a suggestion, whereas `select` forces a value.

Optional prompts A condition can be put on a symbol's prompt to make it optionally configurable by the user. For example, a value `MASK` that's hardcoded to 0xFF on some boards and configurable on others could be expressed as follows:

```
config MASK
     hex "Bitmask" if HAS_CONFIGURABLE_MASK
     default 0xFF
```

> **Note**
>
> This is short for the following:
>
> ```
> config MASK
>   hex
>   prompt "Bitmask" if HAS_CONFIGURABLE_MASK
>   default 0xFF
> ```

The HAS_CONFIGURABLE_MASK helper symbol would get selected by boards to indicate that MASK is configurable. When MASK is configurable, it will also default to 0xFF.

Optional choices Defining a choice with the optional keyword allows the whole choice to be toggled off to select none of the symbols:

```
choice
     prompt "Use legacy protocol"
     optional

config LEGACY_PROTOCOL_1
     bool "Legacy protocol 1"

config LEGACY_PROTOCOL_2
     bool "Legacy protocol 2"

endchoice
```

In the menuconfig interface, this will be displayed e.g. as [*] Use legacy protocol (Legacy protocol 1) --->, where the choice can be toggled off to enable neither of the symbols.

visible if conditions Putting a visible if condition on a menu hides the menu and all the symbols within it, while still allowing symbol default values to kick in.

As a motivating example, consider the following code:

```
menu "Foo subsystem"
     depends on HAS_CONFIGURABLE_FOO

config FOO_SETTING_1
     int "Foo setting 1"
     default 1

config FOO_SETTING_2
     int "Foo setting 2"
     default 2

endmenu
```

When HAS_CONFIGURABLE_FOO is n, no configuration output is generated for FOO_SETTING_1 and FOO_SETTING_2, as the code above is logically equivalent to the following code:

```
config FOO_SETTING_1
     int "Foo setting 1"
     default 1
     depends on HAS_CONFIGURABLE_FOO

config FOO_SETTING_2
     int "Foo setting 2"
     default 2
     depends on HAS_CONFIGURABLE_FOO
```

If we want the symbols to still get their default values even when HAS_CONFIGURABLE_FOO is n, but not be configurable by the user, then we can use visible if instead:

```
menu "Foo subsystem"
     visible if HAS_CONFIGURABLE_FOO
```

(continues on next page)

(continued from previous page)

```
config FOO_SETTING_1
     int "Foo setting 1"
     default 1

config FOO_SETTING_2
     int "Foo setting 2"
     default 2

endmenu
```

This is logically equivalent to the following:

```
config FOO_SETTING_1
     int "Foo setting 1" if HAS_CONFIGURABLE_FOO
     default 1

config FOO_SETTING_2
     int "Foo setting 2" if HAS_CONFIGURABLE_FOO
     default 2
```

Note

See the *optional prompts* section for the meaning of the conditions on the prompts.

When `HAS_CONFIGURABLE_FOO` is `n`, we now get the following configuration output for the symbols, instead of no output:

```
...
CONFIG_FOO_SETTING_1=1
CONFIG_FOO_SETTING_2=2
...
```

Other resources

The *Intro to symbol values* section in the Kconfiglib docstring goes over how symbols values are calculated in more detail.

5.4.5 Custom Kconfig Preprocessor Functions

Kconfiglib supports custom Kconfig preprocessor functions written in Python. These functions are defined in scripts/kconfig/kconfigfunctions.py.

Note

The official Kconfig preprocessor documentation can be found here.

See the Python docstrings in scripts/kconfig/kconfigfunctions.py for detailed documentation. Most of the custom preprocessor functions are used to get devicetree information into Kconfig. For example, the default value of a Kconfig symbol can be fetched from a devicetree `reg` property.

Devicetree-related Functions

The functions listed below are used to get devicetree information into Kconfig. The `*_int` version of each function returns the value as a decimal integer, while the `*_hex` version returns a hexadecimal value starting with `0x`.

```
$(dt_alias_enabled,<node alias>)
$(dt_chosen_bool_prop, <property in /chosen>, <prop>)
$(dt_chosen_enabled,<property in /chosen>)
$(dt_chosen_has_compat,<property in /chosen>,<compatible string>)
$(dt_chosen_label,<property in /chosen>)
$(dt_chosen_partition,addr_hex,<chosen>[,<index>,<unit>])
$(dt_chosen_partition,addr_int,<chosen>[,<index>,<unit>])
$(dt_chosen_path,<property in /chosen>)
$(dt_chosen_reg_addr_hex,<property in /chosen>[,<index>,<unit>])
$(dt_chosen_reg_addr_int,<property in /chosen>[,<index>,<unit>])
$(dt_chosen_reg_size_hex,<property in /chosen>[,<index>,<unit>])
$(dt_chosen_reg_size_int,<property in /chosen>[,<index>,<unit>])
$(dt_class_enabled,<class name>)

```
$(dt_partition_mtd,<node path>)
```

Integer functions

The functions listed below can be used to do arithmetic operations on integer variables, such as addition, subtraction and more. Functions with and without the `_hex` suffix in their names return hexadecimal and decimal values respectively.

```
$(add,<value>[,value]...)
$(add_hex,<value>[,value]...)
$(dec,<value>[,value]...)
$(dec_hex,<value>[,value]...)
$(div,<value>[,value]...)
$(div_hex,<value>[,value]...)
$(inc,<value>[,value]...)
$(inc_hex,<value>[,value]...)
$(max,<value>[,value]...)
$(max_hex,<value>[,value]...)
$(min,<value>[,value]...)
$(min_hex,<value>[,value]...)
$(mod,<value>[,value]...)
$(mod_hex,<value>[,value]...)
$(mul,<value>[,value]...)
$(mul_hex,<value>[,value]...)
$(sub,<value>[,value]...)
$(sub_hex,<value>[,value]...)
```

String functions

The functions listed below can be used to modify string variables.

```
$(normalize_upper,<string>)
$(substring,<string>,<start>[,<stop>])
```

Other functions

Functions to perform specific operations, currently only a check if a shield name is specified.

```
$(shields_list_contains,<shield name>)
```

Shield names cannot contain whitespace. A space after the comma, as in `$(shields_list_contains, foo)`, is stripped and a warning is printed so the lookup still matches `foo`.

Example Usage Assume that the devicetree for some board looks like this:

```
{
     soc {
             #address-cells = <1>;
             #size-cells = <1>;

             spi0: spi@10014000 {
                     compatible = "sifive,spi0";
                     reg = <0x10014000 0x1000 0x20010000 0x3c0900>;
                     reg-names = "control", "mem";
```

(continues on next page)

(continued from previous page)

```
                    ...
            };
};
```

The second entry in `reg` in `spi@1001400` (`<0x20010000 0x3c0900>`) corresponds to `mem`, and has the address `0x20010000`. This address can be inserted into Kconfig as follows:

```
config FLASH_BASE_ADDRESS
     default $(dt_node_reg_addr_hex,/soc/spi@1001400,1)
```

After preprocessor expansion, this turns into the definition below:

```
config FLASH_BASE_ADDRESS
     default 0x20010000
```

5.4.6 Kconfig extensions

Zephyr uses the Kconfiglib implementation of Kconfig, which includes some Kconfig extensions:

- Default values can be applied to existing symbols without *weakening* the symbols dependencies through the use of `configdefault`.

  ```
  config FOO
      bool "FOO"
      depends on BAR

  configdefault FOO
      default y if FIZZ
  ```

  The statement above is equivalent to:

  ```
  config FOO
      bool "Foo"
      default y if FIZZ
      depends on BAR
  ```

  `configdefault` symbols cannot contain any fields other than `default`, however they can be wrapped in `if` statements. The two statements below are equivalent:

  ```
  configdefault FOO
      default y if BAR

  if BAR
  configdefault FOO
      default y
  endif # BAR
  ```

- Environment variables in `source` statements are expanded directly, meaning no "bounce" symbols with `option env="ENV_VAR"` need to be defined.

  Note

  `option env` has been removed from the C tools as of Linux 4.18 as well.

  The recommended syntax for referencing environment variables is `$(FOO)` rather than `$FOO`. This uses the new Kconfig preprocessor. The `$FOO` syntax for expanding environment variables is only supported for backwards compatibility.

- The `source` statement supports glob patterns and includes each matching file. A pattern is required to match at least one file.

  Consider the following example:

  ```
  source "foo/bar/*/Kconfig"
  ```

  If the pattern `foo/bar/*/Kconfig` matches the files `foo/bar/baz/Kconfig` and `foo/bar/qaz/Kconfig`, the statement above is equivalent to the following two `source` statements:

  ```
  source "foo/bar/baz/Kconfig"
  source "foo/bar/qaz/Kconfig"
  ```

  If no files match the pattern, an error is generated.

  The wildcard patterns accepted are the same as for the Python glob module.

  For cases where it's okay for a pattern to match no files (or for a plain filename to not exist), a separate `osource` (*optional source*) statement is available. `osource` is a no-op if no file matches.

  Note

  `source` and `osource` are analogous to `include` and `-include` in Make.

- An `rsource` statement is available for including files specified with a relative path. The path is relative to the directory of the `Kconfig` file that contains the `rsource` statement.

  As an example, assume that `foo/Kconfig` is the top-level `Kconfig` file, and that `foo/bar/Kconfig` has the following statements:

  ```
  source "qaz/Kconfig1"
  rsource "qaz/Kconfig2"
  ```

  This will include the two files `foo/qaz/Kconfig1` and `foo/bar/qaz/Kconfig2`.

  `rsource` can be used to create `Kconfig` "subtrees" that can be moved around freely.

  `rsource` also supports glob patterns.

  A drawback of `rsource` is that it can make it harder to figure out where a file gets included, so only use it if you need it.

- An `orsource` statement is available that combines `osource` and `rsource`.

  For example, the following statement will include `Kconfig1` and `Kconfig2` from the current directory (if they exist):

  ```
  orsource "Kconfig[12]"
  ```

- `def_int`, `def_hex`, and `def_string` keywords are available, analogous to `def_bool`. These set the type and add a `default` at the same time.

- A symbol name can be associated to `choice` groups using the `choice <symbol>` syntax. Such choices, called *named choices*, can be modified from places other than their initial definition. For example, the following statements define the named choice `FOOBAR`:

  ```
  choice FOOBAR
          prompt "Example choice"
          default BAR

  config FOO
  ```

(continues on next page)

(continued from previous page)

```
        bool "Foo"

config BAR
        bool "Bar"

endchoice
```

The following statements could then be used, in a `Kconfig.defconfig` file for example, to override the default option of choice `FOOBAR`:

```
# Note how "prompt" is not present here
choice FOOBAR
    default FOO
endchoice
```

Note

The *named choices* feature originates from Linux, but it is no longer supported in Linux since kernel release 6.9, and has thus become a Kconfiglib language extension.

Users interested in optimizing their configuration for security should refer to the Zephyr Security Guide's section on the *Hardening Tool*.

5.5 Snippets

Snippets are a way to save build system settings in one place, and then use those settings when you build any Zephyr application. This lets you save common configuration separately when it applies to multiple different applications.

Some example use cases for snippets are:

- changing your board's console backend from a "real" UART to a USB CDC-ACM UART
- enabling frequently-used debugging options
- applying interrelated configuration settings to your "main" CPU and a co-processor core on an AMP SoC

The following pages document this feature.

5.5.1 Using Snippets

Tip

See *Built-in snippets* for a list of snippets that are provided by Zephyr.

Snippets have names. You use snippets by giving their names to the build system.

With west build

To use a snippet named `foo` when building an application `app`:

```
west build -S foo app
```

To use multiple snippets:

```
west build -S snippet1 -S snippet2 [...] app
```

With cmake

If you are running CMake directly instead of using `west build`, use the `SNIPPET` variable. This is a whitespace- or semicolon-separated list of snippet names you want to use. For example:

```
cmake -Sapp -Bbuild -DSNIPPET="snippet1;snippet2" [...]
cmake --build build
```

5.5.2 Built-in snippets

Zephyr Bluetooth LE Controller (bt-ll-sw-split)

You can build with this snippet by following the instructions in *the snippets usage page*. When building with `west`, you can do:

```
west build -S bt-ll-sw-split [...]
```

Overview This selects the Zephyr Bluetooth LE Controller.

Requirements Hardware support for:

- `CONFIG_BT`

CDC-ACM Console Snippet (cdc-acm-console)

```
west build -S cdc-acm-console [...]
```

Overview This snippet redirects serial console output to a CDC ACM UART. The USB device which should be used is configured using *Devicetree*.

Requirements Hardware support for:

- `CONFIG_USB_DEVICE_STACK`
- `CONFIG_SERIAL`
- `CONFIG_CONSOLE`
- `CONFIG_UART_CONSOLE`
- `CONFIG_UART_LINE_CTRL`

A devicetree node with node label `zephyr_udc0` that points to an enabled USB device node with driver support. This should look roughly like this in *your devicetree*:

```
zephyr_udc0: usbd@deadbeef {
     compatible = "vnd,usb-device";
     /* ... */
};
```

Espressif snippets

Espressif Flash 128MB

Overview This snippet allows users to select the 128MB SPI flash variant of the ESP32 chips.

Espressif Flash 16MB

Overview This snippet allows users to select the 16MB SPI flash variant of the ESP32 chips.

Espressif Flash 2MB

Overview This snippet allows users to select the 2MB SPI flash variant of the ESP32 chips.

Espressif Flash 32MB

Overview This snippet allows users to select the 32MB SPI flash variant of the ESP32 chips.

Espressif Flash 4MB

Overview This snippet allows users to select the 4MB SPI flash variant of the ESP32 chips.

Espressif Flash 64MB

Overview This snippet allows users to select the 64MB SPI flash variant of the ESP32 chips.

Espressif Flash 8MB

Overview This snippet allows users to select the 8MB SPI flash variant of the ESP32 chips.

Espressif PSRAM 2MB

Overview This snippet allows users to select the 2MB SPI PSRAM variant of the ESP32 chips.

Espressif PSRAM 4MB

Overview This snippet allows users to select the 4MB SPI PSRAM variant of the ESP32 chips.

Espressif PSRAM 8MB

Overview This snippet allows users to select the 8MB SPI PSRAM variant of the ESP32 chips.

Espressif PSRAM relocations

Overview This snippet allows users to enable the flash sections to be relocated to PSRAM.

Espressif PSRAM Wi-Fi buffers

Overview This snippet allows users to configure Wi-Fi buffers to use PSRAM.

Native Simulator support for hci_uart Snippet (hci-uart-native-sim)

```
west build -S hci-uart-native-sim [...]
```

Overview This snippet allows to use hci_uart connected to the host computer with the Native Simulator. It is useful for testing with a real Bluetooth controller, such as a device running Zephyr.

Nordic snippets

Nordic FLPR snippet with execution in place (nordic-flpr-xip)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic FLPR (Fast Lightweight Peripheral Processor) from application core. FLPR code is to be executed from RRAM, so the FLPR image must be built for the `xip` board variant, or with `CONFIG_XIP` enabled.

Nordic FLPR snippet with execution from SRAM (nordic-flpr)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic FLPR (Fast Lightweight Peripheral Processor) from application core. FLPR code is to be executed from SRAM, so the FLPR image must be built without the `xip` board variant, or with `CONFIG_XIP` disabled.

Nordic Dictionary-based STM logging snippet (nordic-log-stm-dict)

Overview This snippet allows users to build Zephyr with the dictionary-based logging to the Coresight STM stimulus ports. Data is collected in ETR buffer. Data from ETR buffer is output on UART.

Nordic Dictionary-based STM to TPIU logging snippet (nordic-log-stm-tpiu-dict)

Overview This snippet allows users to build Zephyr with the dictionary-based logging to the Coresight STM stimulus ports. Data is written to the TPIU interface and can be captured with nrfutil trace to translate into a human-readable format.

Nordic Standalone STM logging snippet (nordic-log-stm)

Overview This snippet allows users to build Zephyr with the logging to the Coresight STM stimulus ports. Data is collected in ETR buffer. Data from ETR buffer is decoded and human-readable data is output on the UART.

Nordic boot PPR snippet with execution in place (nordic-ppr-xip)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic PPR (Peripheral Processor) from another core. PPR code is to be executed from MRAM, so the PPR image must be built for the `xip` board variant, or with `CONFIG_XIP` enabled.

Nordic PPR snippet (nordic-ppr)

Overview This snippet allows users to build Zephyr with the capability to boot Nordic PPR (Peripheral Processor) from another core.

NUS Console Snippet (nus-console)

```
west build -S nus-console [...]
```

Overview This snippet redirects serial console output to a UART over NUS (Bluetooth LE) instance. The Bluetooth Serial device used shall be configured using *Devicetree*.

Requirements Hardware support for:

- CONFIG_BT
- CONFIG_BT_PERIPHERAL
- CONFIG_BT_ZEPHYR_NUS
- CONFIG_SERIAL
- CONFIG_CONSOLE
- CONFIG_UART_CONSOLE

RAM Console Snippet (ram-console)

```
west build -S ram-console [...]
```

Overview This snippet redirects console output to a RAM buffer. The RAM console buffer is a global array located in RAM region by default, whose address is unknown before building. The RAM console driver also supports using a dedicated section for the RAM console buffer with prefined address.

How to enable RAM console buffer section Add board dts overlay to this snippet to add property `zephyr,ram-console` in the chosen node and memory-region node with compatible string `zephyr,memory-region` as the following:

```
/ {
    chosen {
        zephyr,ram-console = &snippet_ram_console;
    };

   snippet_ram_console: memory@93d00000 {
        compatible = "zephyr,memory-region";
        reg = <0x93d00000 DT_SIZE_K(4)>;
        zephyr,memory-region = "RAM_CONSOLE";
   };
};
```

RAM Tracing Snippet (ram-tracing)

```
west build -S ram-tracing [...]
```

Overview This snippet enables CTF Tracing using the RAM backend.

After connecting to the target in GDB, you can dump the RAM tracing data to a binary file:

```
(gdb) dump binary memory ram_tracing.bin ram_tracing ram_tracing+8192
```

Using Babeltrace[1], you can view the binary file as a CTF trace:

[1] https://babeltrace.org/
