RP2040/RP2350 boot mode retention setup (rp2-boot-mode-retention)

Overview This snippet sets up an RP2040/RP2350 based board for retaining the set boot mode via properly configured retained mem in SRAM, enabling the necessary Kconfig symbols for the retained mem drivers and retention system.

RTT Console Snippet (rtt-console)

Overview This snippet enables console output to SEGGER RTT.

Requirements Support for:

- `CONFIG_HAS_SEGGER_RTT`

SystemView RTT Tracing Snippet (rtt-tracing)

```
west build -S rtt-tracing [...]
```

Overview This snippet enables SEGGER SystemView RTT support with the tracing subsystem.

Requirements Hardware support for:

- `CONFIG_HAS_SEGGER_RTT`

Semihost Tracing Snippet (semihost-tracing)

```
west build -S semihost-tracing [...]
```

Overview This snippet enables CTF Tracing using semihosting on a target that supports it.

Using Qemu, you can run the example application and generate a CTF trace file using semihosting. The trace file can then be viewed using Babeltrace[1].

```
(gdb) dump binary memory ram_tracing.bin ram_tracing ram_tracing+8192
```

Using Babeltrace[1], you can view the binary file as a CTF trace:

[1] https://babeltrace.org/

References

UART Console Snippet (uart-console)

Overview This snippet enables console output the chosen UART in `zephyr,console`.

Silicon Labs Packet Trace Interface (silabs-pti)

Overview This snippet allows users to build Zephyr applications for Silicon Labs Series 2 devices where radio packets are emitted over the Packet Trace Interface for use by debugging tools.

```
west build -S silabs-pti [...]
```

Requirements Hardware support for `silabs,pti`.

A pinctrl configuration with nodelabel `pti_default` containing PTI pinout.

Slot1 partition snippet (slot1-partition)

```
west build -S slot1-partition [...]
```

Overview This snippet changes the chosen flash partition to be the `slot1_partition` node, this can be used to build for the alternate slot in MCUboot direct-xip or firmware loader modes.

Requirements Partition mapping correct setup in devicetree, for example:

```
&flash0 {
        partitions {
                ranges;
                #address-cells = <1>;
                #size-cells = <1>;

                boot_partition: partition@0 {
                        compatible = "zephyr,mapped-partition";
                        label = "mcuboot";
                        reg = <0x00000000 0x0000c000>;
                };

                slot0_partition: partition@c000 {
                        compatible = "zephyr,mapped-partition";
                        label = "image-0";
                        reg = <0x0000c000 0x00076000>;
                };
```

(continues on next page)

(continued from previous page)

```
                slot1_partition: partition@82000 {
                        compatible = "zephyr,mapped-partition";
                        label = "image-1";
                        reg = <0x00082000 0x00076000>;
                };

                /*
                 * The flash starting at 0x000f8000 and ending at
                 * 0x000fffff is reserved for use by the application.
                 */

                /*
                 * Storage partition will be used by FCB/LittleFS/NVS
                 * if enabled.
                 */
                storage_partition: partition@f8000 {
                        compatible = "zephyr,mapped-partition";
                        label = "storage";
                        reg = <0x000f8000 0x00008000>;
                };
        };
};
```

SocketCAN on Native Simulator Snippet (socketcan-native-sim)

```
west build -S socketcan-native-sim [...]
```

Overview This snippet enables Linux SocketCAN support on native_sim.

By default, the native simulator expects a SocketCAN network device called `zcan0` (specified in boards/native/native_sim/native_sim.dts). This name can be added as an alternative name for an existing SocketCAN network device (here, a newly created virtual CAN network device `vcan0`) using a command like the following:

```
sudo modprobe vcan
sudo ip link add dev vcan0 type vcan
sudo ip link property add dev vcan0 altname zcan0
```

The SocketCAN device must be configured and brought up before running the native simulator:

```
sudo ip link set vcan0 up
```

Texas Instruments snippets

TI I/O Expander

Overview This snippet enables I/O expander functionality on TI boards

Supported boards

- AM62L EVM

Usage To enable I/O expander functionality, add this snippet to your build:

```
# From the root of the zephyr repository
west build -b am62l_evm/am62l3/a53 --shield ti-io-exp samples/drivers/pwm/capture
```

USB/IP on Native Simulator Snippet (usbip-native-sim)

```
west build -S usbip-native-sim [...]
```

Overview This snippet enables USB/IP support on a native simulator. When building with this snippet, you need to provide DTC overlays using the EXTRA_DTC_OVERLAY_FILE argument.

This snippet is experimental, the behavior may change without notice.

Video Native FIFO Snippet (video-native-fifo)

```
west build -b native_sim/native/64 -S video-native-fifo [...]
```

Overview This snippet instantiates the native_sim host FIFO video source as the `zephyr,camera` *Devicetree* chosen node.

The FIFO path defaults to `/tmp/zephyr-video-fifo-<pid>.fifo`, and is printed when streaming starts. The application selects the resolution and pixel format, 320x240 RGB565 by default.

See the driver documentation for how to set the FIFO path and feed it from a webcam or a test pattern, and for the details of the driver behaviour.

Requirements A native_sim target, and a host process writing raw frames of the selected format to the FIFO. Sufficient memory for the video resolution must be declared by `CONFIG_VIDEO_BUFFER_POOL_HEAP_SIZE`.

Video Software Generator Snippet (video-sw-generator)

```
west build -S video-sw-generator [...]
```

Overview This snippet instantiate a fake video source generating a test pattern continuously for test purpose. It is selected as the `zephyr,camera` *Devicetree* chosen node.

Requirements No hardware support is required besides sufficient memory for the video resolution declared by `CONFIG_VIDEO_BUFFER_POOL_HEAP_SIZE`.

Wi-Fi snippets

Wi-Fi Credentials Snippet (wifi-credentials)

```
west build  -S wifi-credentials [...]
```

Can also be used along with the *Wi-Fi Enterprise Snippet (wifi-enterprise)* snippet.

```
west build  -S "wifi-enterprise,wifi-credentials" [...]
```

Overview This snippet enables Wi-Fi credentials support.

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING
- CONFIG_WIFI_NM_WPA_SUPPLICANT
- CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ENTERPRISE

Wi-Fi Enterprise Snippet (wifi-enterprise)

```
west build  -S wifi-enterprise [...]
```

Can also be used along with the *Wi-Fi IPv4 Snippet (wifi-ipv4)* snippet.

```
west build  -S "wifi-enterprise,wifi-ipv4" [...]
```

Overview This snippet enables enterprise Wi-Fi support.

See *Wi-Fi Management* for more information on the usage.

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING
- CONFIG_WIFI_NM_WPA_SUPPLICANT
- CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ENTERPRISE

Wi-Fi IPv4 and IPv6 Snippet (wifi-ip)

```
west build -S wifi-ip [...]
```

Overview This snippet enables IPv4 and IPv6 Wi-Fi support.

Use Wi-Fi shell to connect to the Wi-Fi network:

```
wifi connect -s <SSID> -k <key_management> -p <passphrase>
```

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING

Wi-Fi IPv4 Snippet (wifi-ipv4)

```
west build -S wifi-ipv4 [...]
```

Overview This snippet enables IPv4 Wi-Fi support.

Use Wi-Fi shell to connect to the Wi-Fi network:

```
wifi connect -s <SSID> -k <key_management> -p <passphrase>
```

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING

Wi-Fi IPv6 Snippet (wifi-ipv6)

```
west build -S wifi-ipv6 [...]
```

Overview This snippet enables IPv6 Wi-Fi support.

Use Wi-Fi shell to connect to the Wi-Fi network:

```
wifi connect -s <SSID> -k <key_management> -p <passphrase>
```

Requirements Hardware support for:

- CONFIG_WIFI
- CONFIG_WIFI_USE_NATIVE_NETWORKING

Xen Dom0: universal snippet for XEN control domain

Overview This snippet allows user to build Zephyr as a Xen initial domain (Dom0). The feature is implemented as configuration snippet to allow support for any compatible platform.

How to add support of a new board

- add board dt overlay to this snippet which deletes UART nodes.
- in application dt overlay add correct memory and hypervisor nodes, based on regions Xen picked for Domain-0 on your setup.

Programming Correct snippet designation for Xen must be entered when you invoke `west build`. For example:

```
west build -b qemu_cortex_a53 -S xen-dom0 samples/synchronization
```

QEMU example with Xen Overlay for qemu_cortex_a53 board, that is present in snippets/xen-dom0/boards/ directory of this snippet is QEMU Xen control domain example.

To run such setup, you need to:

- fetch and build Xen (e.g. RELEASE-4.17.0) for arm64 platform
- take and compile sample device tree from `example/` directory
- build your Zephyr sample/application with `xen-dom0` snippet and start it as Xen control domain

Important notice regarding device tree Xen allocates addresses used for Dom0 image and grant tables/extended regions dynamically so they may differ on specific setups (they depend on memory banks location and size, application image size, hypervisor load address used by boot-loader etc.). Since Zephyr does not parse device tree in runtime and is not a position independent executable, it needs to know exact values on build time. To make it you need to build your final binary, try to boot it with Xen and analyze the hypervisor output to get exact addresses for your setup. They will look as follows:

Grant table region (first reg in hypervisor node):

```
(XEN) Grant table range: 0x00000088080000-0x000000880c0000
```

Extended regions (2nd and further regs in hypervisor node):

```
(XEN) [    0.928173] d0: extended region 2: 0x40000000->0x47e00000
```

Zephyr Dom0 memory:

```
(XEN) Allocating 1:1 mappings for dom0:
(XEN) BANK[0] 0x00000060000000-0x00000070000000 (256MB)
```

Device tree nodes, that should be added by application overlay for provided example (based on R-Car H3ULCB with extended region):

```
hypervisor: hypervisor@88080000 {
    compatible = "xen,xen";
    reg = <0x0 0x88080000 0x0 0x40000 0x0 0x40000000 0x0 0x7e00000>;
    interrupts = <GIC_PPI 0x0 IRQ_TYPE_EDGE IRQ_DEFAULT_PRIORITY>;
    interrupt-parent = <&gic>;
    status = "okay";
};

ram: memory@60000000 {
    device_type = "mmio-sram";
    reg = <0x00 0x60000000 0x00 DT_SIZE_M(256)>;
};
```

Xen extended regions notice By default, support for Xen extended regions is disabled. Therefore, after specifying the extended regions in the hypervisor node in the device tree, it is also required to set the XEN_REGIONS config to 'yes' in the application overlay file.

Start the example For starting you can use QEMU from Zephyr SDK by following command:

```
<path to Zephyr SDK>/sysroots/x86_64-pokysdk-linux/usr/bin/qemu-system-aarch64 -
↪cpu cortex-a53 \
-m 6G -nographic -machine virt,gic-version=3,virtualization=true -chardev␣
↪stdio,id=con,mux=on \
-serial chardev:con -mon chardev=con,mode=readline -pidfile qemu.pid \
-device loader,file=<path to Zephyr app build>/zephyr.bin,addr=0x40600000 \
-dtb <path to DTB>/xen.dtb -kernel <path to Xen build>/xen
```

This will start you a Xen hypervisor with your application as Xen control domain. To make it usable, you can add zephyr-xenlib by Xen-troops library to your project. It'll provide basic domain management functionalities - domain creation and configuration.

XIAO UART/Serial Console Snippet (xiao-serial-console)

Overview This snippet enables console output over the standard XIAO UART pins, setting `zephyr,console` to `&xiao_serial`.

5.5.3 Writing Snippets

- *Basics*
- *Namespacing*
- *Where snippets are located*
- *Processing order*

- *Devicetree overlays (.overlay)*
- *.conf files*
- *Sysbuild .conf files*
- *DTS_EXTRA_CPPFLAGS*
- *Board-specific settings*
  - *By name*
  - *By regular expression*
  - *Board revisions*

Basics

Snippets are defined using YAML files named `snippet.yml`.

A `snippet.yml` file contains the name of the snippet, along with additional build system settings, like this:

```
name: snippet-name
# ... build system settings go here ...
```

Build system settings go in other keys in the file as described later on in this page.

You can combine settings whenever they appear under the same keys. For example, you can combine a snippet-specific devicetree overlay and a `.conf` file like this:

```
name: foo
append:
  EXTRA_DTC_OVERLAY_FILE: foo.overlay
  EXTRA_CONF_FILE: foo.conf
```

In addition, snippets can also be applied to sysbuild configuration like so:

```
name: foo
append:
  SB_EXTRA_CONF_FILE: sb.conf
  EXTRA_CONF_FILE: app.conf
```

Namespacing

When writing devicetree overlays in a snippet, use `snippet_<name>` or `snippet-<name>` as a namespace prefix when choosing names for node labels, node names, etc. This avoids namespace conflicts.

For example, if your snippet is named `foo-bar`, write your devicetree overlays like this:

```
chosen {
        zephyr,baz = &snippet_foo_bar_dev;
};

snippet_foo_bar_dev: device@12345678 {
        /* ... */
};
```

Where snippets are located

The build system looks for snippets in these places:

1. In directories configured by the SNIPPET_ROOT CMake variable. This always includes the zephyr repository (so snippets/ is always a source of snippets).

   Additional directories can be added manually at CMake time.

   The variable is a whitespace- or semicolon-separated list of directories which may contain snippet definitions.

   For each directory in the list, the build system looks for `snippet.yml` files underneath a subdirectory named `snippets/`, if one exists.

   For example, if SNIPPET_ROOT is set to `/foo;/bar`, the build system will look for `snippet.yml` files underneath the following subdirectories:

   - `/foo/snippets/`
   - `/bar/snippets/`

   The `snippet.yml` files can be nested anywhere underneath these locations.

2. In any *module* whose `module.yml` file provides a `snippet_root` setting.

   For example, in a zephyr module named `baz`, you can add this to your `module.yml` file:

   ```
   settings:
     snippet_root: .
   ```

   And then any `snippet.yml` files in `baz/snippets` will automatically be discovered by the build system, just as if the path to `baz` had appeared in SNIPPET_ROOT.

Processing order

Snippets are processed in the order they are listed in the SNIPPET variable, or in the order of the `-S` arguments if using west.

To apply `bar` after `foo`:

```
cmake -Sapp -Bbuild -DSNIPPET="foo;bar" [...]
cmake --build build
```

The same can be achieved with west as follows:

```
west build -S foo -S bar [...] app
```

When multiple snippets set the same configuration, the configuration value set by the last processed snippet ends up in the final configurations.

For instance, if `foo` sets `CONFIG_FOO=1` and `bar` sets `CONFIG_FOO=2` in the above example, the resulting final configuration will be `CONFIG_FOO=2` because `bar` is processed after `foo`.

This principle applies to both Kconfig fragments (`.conf` files) and devicetree overlays (`.overlay` files).

Devicetree overlays (`.overlay`)

This `snippet.yml` adds `foo.overlay` to the build:

```
name: foo
append:
  EXTRA_DTC_OVERLAY_FILE: foo.overlay
```

The path to `foo.overlay` is relative to the directory containing `snippet.yml`. Multiple `.overlay` files can also be provided as a list:

```
name: foo
append:
  EXTRA_DTC_OVERLAY_FILE:
    - foo.overlay
    - bar.overlay
```

`.conf` files

This `snippet.yml` adds `foo.conf` to the build:

```
name: foo
append:
  EXTRA_CONF_FILE: foo.conf
```

The path to `foo.conf` is relative to the directory containing `snippet.yml`. Multiple `.conf` files can also be provided as a list.

Sysbuild `.conf` files

This `snippet.yml` adds `foo.conf` to the sysbuild configuration:

```
name: foo
append:
  SB_EXTRA_CONF_FILE: foo.conf
```

The path to `foo.conf` is relative to the directory containing `snippet.yml`. Multiple sysbuild `.conf` files can also be provided as a list.

`DTS_EXTRA_CPPFLAGS`

This `snippet.yml` adds `DTS_EXTRA_CPPFLAGS` CMake Cache variables to the build:

```
name: foo
append:
  DTS_EXTRA_CPPFLAGS: -DMY_DTS_CONFIGURE
```

Adding these flags enables control over the content of a devicetree file.

Board-specific settings

You can write settings that only apply to some boards.

The settings described here are applied in **addition** to snippet settings that apply to all boards. (This is similar, for example, to the way that an application with both `prj.conf` and `boards/foo.conf` files will use both `.conf` files in the build when building for board `foo`, instead of just `boards/foo.conf`)

By name

```
name: ...
boards:
  bar: # settings for board "bar" go here
    append:
      EXTRA_DTC_OVERLAY_FILE: bar.overlay
  baz: # settings for board "baz" go here
```

(continues on next page)

(continued from previous page)

```
    append:
      EXTRA_DTC_OVERLAY_FILE: baz.overlay
```

The above example uses `bar.overlay` when building for board `bar`, and `baz.overlay` when building for `baz`.

By regular expression You can enclose the board name in slashes (/) to match the name against a regular expression in the CMake syntax. The regular expression must match the entire board name.

For example:

```
name: foo
boards:
  /my_vendor_.*/:
    append:
      EXTRA_DTC_OVERLAY_FILE: my_vendor.overlay
```

The above example uses devicetree overlay `my_vendor.overlay` when building for either board `my_vendor_board1` or `my_vendor_board2`. It would not use the overlay when building for either `another_vendor_board` or `x_my_vendor_board`.

Board revisions Specific configuration for revisions of boards is also supported which will be applied after the common files:

```
name: foo
boards:
  bar:
    append:
      # Base file will be applied first
      EXTRA_DTC_OVERLAY_FILE: first.overlay
    revisions:
      "0.7.0":
        append:
          # Will be applied on top of common board file
          EXTRA_DTC_OVERLAY_FILE: extra_0_7_0.overlay
```

The above example will use `first.overlay` for all revisions of the `bar` board, and will also include `extra_0_7_0.overlay` when building for revision `0.7.0` of the `bar` board (`bar@0.7.0`).

5.5.4 Snippets Design

This page documents design goals for the snippets feature. Further information can be found in Issue #51834.

- **extensible**: for example, it is possible to add board support for an existing built-in snippet without modifying the zephyr repository
- **composable**: it is possible to use multiple snippets at once, for example using:

  ```
  west build -S <snippet1> -S <snippet2> ...
  ```

- **able to combine multiple types of configuration**: snippets make it possible to store multiple different types of build system settings in one place, and apply them all together
- **specializable**: for example, it is possible to customize a snippet's behavior for a particular board, or board revision

- **future-proof and backwards-compatible**: arbitrary future changes to the snippets feature will be possible without breaking backwards compatibility for older snippets
- **applicable to purely "software" changes**: unlike the shields feature, snippets do not assume the presence of a "daughterboard", "shield", "hat", or any other type of external assembly which is connected to the main board
- **DRY** (don't repeat yourself): snippets allow you to skip unnecessary repetition; for example, you can apply the same board-specific configuration to boards `foo` and `bar` by specifying `/(foo|bar)/` as a regular expression for the settings, which will then apply to both boards

5.6 Zephyr CMake Package

The Zephyr CMake package is a convenient way to create a Zephyr-based application.

Note

The *Application types* section introduces the application types used in this page.

The Zephyr CMake package ensures that CMake can automatically select a Zephyr installation to use for building the application, whether it is a *Zephyr repository application*, a *Zephyr workspace application*, or a *Zephyr freestanding application*.

When developing a Zephyr-based application, then a developer simply needs to write `find_package(Zephyr)` in the beginning of the application `CMakeLists.txt` file.

To use the Zephyr CMake package it must first be exported to the CMake user package registry. This means creating a reference to the current Zephyr installation inside the CMake user package registry.

Ubuntu

In Linux, the CMake user package registry is found in:

`~/.cmake/packages/Zephyr`

macOS

In macOS, the CMake user package registry is found in:

`~/.cmake/packages/Zephyr`

Windows

In Windows, the CMake user package registry is found in:

`HKEY_CURRENT_USER\Software\Kitware\CMake\Packages\Zephyr`

The Zephyr CMake package allows CMake to automatically find a Zephyr base. One or more Zephyr installations must be exported. Exporting multiple Zephyr installations may be useful when developing or testing Zephyr freestanding applications, Zephyr workspace application with vendor forks, etc..

5.6.1 Zephyr CMake package export (west)

When installing Zephyr using *west* then it is recommended to export Zephyr using `west zephyr-export`.

5.6.2 Zephyr CMake package export (without west)

Zephyr CMake package is exported to the CMake user package registry using the following commands:

```
cmake -P <PATH-TO-ZEPHYR>/share/zephyr-package/cmake/zephyr_export.cmake
```

This will export the current Zephyr to the CMake user package registry.

5.6.3 Zephyr Base Environment Setting

The Zephyr CMake package search functionality allows for explicitly specifying a Zephyr base using an environment variable.

To do this, use the following `find_package()` syntax:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

This syntax instructs CMake to first search for Zephyr using the Zephyr base environment setting *ZEPHYR_BASE* and then use the normal search paths.

5.6.4 Zephyr CMake Package Search Order

When Zephyr base environment setting is not used for searching, the Zephyr installation matching the following criteria will be used:

- A Zephyr repository application will use the Zephyr in which it is located. For example:

  ```
  <projects>/zephyr-workspace/zephyr
  └── samples
      └── hello_world
  ```

  in this example, `hello_world` will use `<projects>/zephyr-workspace/zephyr`.

- Zephyr workspace application will use the Zephyr that share the same workspace. For example:

  ```
  <projects>/zephyr-workspace
  ├── zephyr
  ├── ...
  └── my_applications
       └── my_first_app
  ```

  in this example, `my_first_app` will use `<projects>/zephyr-workspace/zephyr` as this Zephyr is located in the same workspace as the Zephyr workspace application.

Note

The root of a Zephyr workspace is identical to `west topdir` if the workspace was installed using `west`

- Zephyr freestanding application will use the Zephyr registered in the CMake user package registry. For example:

  ```
  <projects>/zephyr-workspace-1
  └── zephyr                          (Not exported to CMake)

  <projects>/zephyr-workspace-2
  └── zephyr                          (Exported to CMake)
  ```

(continues on next page)

(continued from previous page)

```
<home>/app
├── CMakeLists.txt
├── prj.conf
└── src
    └── main.c
```

in this example, only <projects>/zephyr-workspace-2/zephyr is exported to the CMake package registry and therefore this Zephyr will be used by the Zephyr freestanding application <home>/app.

If user wants to test the application with <projects>/zephyr-workspace-1/zephyr, this can be done by using the Zephyr Base environment setting, meaning set ZEPHYR_BASE=<projects>/zephyr-workspace-1/zephyr, before running CMake.

Note

The Zephyr package selected on the first CMake invocation will be used for all subsequent builds. To change the Zephyr package, for example to test the application using Zephyr base environment setting, then it is necessary to do a pristine build first (See *Rebuilding an Application*).

5.6.5 Zephyr CMake Package Version

When writing an application then it is possible to specify a Zephyr version number x.y.z that must be used in order to build the application.

Specifying a version is especially useful for a Zephyr freestanding application as it ensures the application is built with a minimal Zephyr version.

It also helps CMake to select the correct Zephyr to use for building, when there are multiple Zephyr installations in the system.

For example:

```
find_package(Zephyr 2.2.0)
project(app)
```

will require app to be built with Zephyr 2.2.0 as minimum. CMake will search all exported candidates to find a Zephyr installation which matches this version criteria.

Thus it is possible to have multiple Zephyr installations and have CMake automatically select between them based on the version number provided, see CMake package version for details.

For example:

```
<projects>/zephyr-workspace-2.a
└── zephyr                      (Exported to CMake)

<projects>/zephyr-workspace-2.b
└── zephyr                      (Exported to CMake)

<home>/app
├── CMakeLists.txt
├── prj.conf
└── src
    └── main.c
```

in this case, there are two released versions of Zephyr installed at their own workspaces. Workspace 2.a and 2.b, corresponding to the Zephyr version.

To ensure app is built with minimum version `2.a` the following `find_package` syntax may be used:

```
find_package(Zephyr 2.a)
project(app)
```

Note that both `2.a` and `2.b` fulfill this requirement.

CMake also supports the keyword `EXACT`, to ensure an exact version is used, if that is required. In this case, the application CMakeLists.txt could be written as:

```
find_package(Zephyr 2.a EXACT)
project(app)
```

In case no Zephyr is found which satisfies the version required, as example, the application specifies

```
find_package(Zephyr 2.z)
project(app)
```

then an error similar to below will be printed:

```
Could not find a configuration file for package "Zephyr" that is compatible
with requested version "2.z".

The following configuration files were considered but not accepted:

↪<projects>/zephyr-workspace-2.a/zephyr/share/zephyr-package/cmake/ZephyrConfig.cmake,␣
↪version: 2.a.0

↪<projects>/zephyr-workspace-2.b/zephyr/share/zephyr-package/cmake/ZephyrConfig.cmake,␣
↪version: 2.b.0
```

Note

It can also be beneficial to specify a version number for Zephyr repository applications and Zephyr workspace applications. Specifying a version in those cases ensures the application will only build if the Zephyr repository or workspace is matching. This can be useful to avoid accidental builds when only part of a workspace has been updated.

5.6.6 Multiple Zephyr Installations (Zephyr workspace)

Testing out a new Zephyr version, while at the same time keeping the existing Zephyr in the workspace untouched is sometimes beneficial.

Or having both an upstream Zephyr, Vendor specific, and a custom Zephyr in same workspace.

For example:

```
<projects>/zephyr-workspace
├── zephyr
├── zephyr-vendor
├── zephyr-custom
├── ...
```

(continues on next page)

(continued from previous page)

```
└── my_applications
    └── my_first_app
```

in this setup, `find_package(Zephyr)` has the following order of precedence for selecting which Zephyr to use:

- Project name: `zephyr`
- First project, when Zephyr projects are ordered lexicographical, in this case.
  - `zephyr-custom`
  - `zephyr-vendor`

This means that `my_first_app` will use `<projects>/zephyr-workspace/zephyr`.

It is possible to specify a Zephyr preference list in the application.

A Zephyr preference list can be specified as:

```
set(ZEPHYR_PREFER "zephyr-custom" "zephyr-vendor")
find_package(Zephyr)

project(my_first_app)
```

the `ZEPHYR_PREFER` is a list, allowing for multiple Zephyrs. If a Zephyr is specified in the list, but not found in the system, it is simply ignored and `find_package(Zephyr)` will continue to the next candidate.

This allows for temporary creation of a new Zephyr release to be tested, without touching current Zephyr. When testing is done, the `zephyr-test` folder can simply be removed. Such a CMakeLists.txt could look as:

```
set(ZEPHYR_PREFER "zephyr-test")
find_package(Zephyr)

project(my_first_app)
```

5.6.7 Zephyr Build Configuration CMake packages

There are two Zephyr Build configuration packages which provide control over the build settings in Zephyr in a more generic way. These packages are:

- **ZephyrBuildConfiguration**: Applies to all Zephyr applications in the workspace
- **ZephyrAppConfiguration**: Applies only to the application you are currently building

They are similar to the per-user `.zephyrrc` file that can be used to set *Environment Variables*, but they set CMake variables instead. They also allow you to automatically share the build configuration among all users through the project repository. They also allow more advanced use cases, such as loading of additional CMake boilerplate code.

The Zephyr Build Configuration CMake packages will be loaded in the Zephyr boilerplate code after initial properties and `ZEPHYR_BASE` has been defined, but before CMake code execution. The ZephyrBuildConfiguration is included first and ZephyrAppConfiguration afterwards. That means the application-specific package could override the workspace settings, if needed. This allows the Zephyr Build Configuration CMake packages to setup or extend properties such as: `DTS_ROOT`, `BOARD_ROOT`, `TOOLCHAIN_ROOT` / other toolchain setup, fixed overlays, and any other property that can be controlled. It also allows inclusion of additional boilerplate code.

To provide a ZephyrBuildConfiguration or ZephyrAppConfiguration, create `ZephyrBuildConfig.cmake` and/or `ZephyrAppConfig.cmake` respectively and place them in the appropriate location.

The CMake `find_package` mechanism will search for these files with the steps below. Other default CMake package search paths and hints are disabled and there is no version checking implemented for these packages. This also means that these packages cannot be installed in the CMake package registry. The search steps are:

1. If `ZephyrBuildConfiguration_ROOT`, or `ZephyrAppConfiguration_ROOT` respectively, is set, search within this prefix path. If a matching file is found, execute this file. If no matching file is found, go to step 2.
2. Search within `${ZEPHYR_BASE}/../*`, or `${APPLICATION_SOURCE_DIR}` respectively. If a matching file is found, execute this file. If no matching file is found, abort the search.

It is recommended to place the files in the default paths from step 2, but with the `<PackageName>_ROOT` variables you have the flexibility to place them anywhere. This is especially necessary for freestanding applications, for which the default path to ZephyrBuildConfiguration usually does not work. In this case the `<PackageName>_ROOT` variables can be set on the CMake command line, **before** `find_package(Zephyr ...)`, as environment variable or from a CMake cache initialization file with the `-C` command line option.

Note

The `<PackageName>_ROOT` variables, as well as the default paths, are just the prefixes to the search path. These prefixes get combined with additional path suffixes, which together form the actual search path. Any combination that honors the CMake package search procedure is valid and will work.

If you want to completely disable the search for these packages, you can use the special CMake `CMAKE_DISABLE_FIND_PACKAGE_<PackageName>` variable for that. Just set `CMAKE_DISABLE_FIND_PACKAGE_ZephyrBuildConfiguration` or `CMAKE_DISABLE_FIND_PACKAGE_ZephyrAppConfiguration` to `TRUE` to disable the package.

An example folder structure could look like this:

```
<projects>/zephyr-workspace
├── zephyr
├── ...
├── manifest repo (can be named anything)
│    └── cmake/ZephyrBuildConfig.cmake
├── ...
└── zephyr application
     └── share/zephyrapp-package/cmake/ZephyrAppConfig.cmake
```

A sample `ZephyrBuildConfig.cmake` can be seen below.

```
# ZephyrBuildConfig.cmake sample code

# To ensure final path is absolute and does not contain ../.. in variable.
get_filename_component(APPLICATION_PROJECT_DIR
                       ${CMAKE_CURRENT_LIST_DIR}/../../..
                       ABSOLUTE
)

# Add this project to list of board roots
list(APPEND BOARD_ROOT ${APPLICATION_PROJECT_DIR})

# Default to GNU Arm Embedded toolchain if no toolchain is set
if(NOT ENV{ZEPHYR_TOOLCHAIN_VARIANT})
    set(ZEPHYR_TOOLCHAIN_VARIANT gnuarmemb)
    find_program(GNU_ARM_GCC arm-none-eabi-gcc)
```

(continues on next page)

(continued from previous page)

```
    if(NOT ${GNU_ARM_GCC} STREQUAL GNU_ARM_GCC-NOTFOUND)
        # The toolchain root is located above the path to the compiler.
        get_filename_component(GNUARMEMB_TOOLCHAIN_PATH ${GNU_ARM_GCC}/../..␣
↪ABSOLUTE)
    endif()
endif()
```

5.6.8 Zephyr CMake package source code

The Zephyr CMake package source code in share/zephyr-package/cmake contains the CMake config package which is used by the CMake `find_package` function.

It also contains code for exporting Zephyr as a CMake config package.

The following is an overview of the files in this directory:

`ZephyrConfigVersion.cmake`
: The Zephyr package version file. This file is called by CMake to determine if this installation fulfils the requirements specified by user when calling `find_package(Zephyr ...)`. It is also responsible for detection of Zephyr repository or workspace only installations.

`ZephyrConfig.cmake`
: The Zephyr package file. This file is called by CMake to for the package meeting which fulfils the requirements specified by user when calling `find_package(Zephyr ...)`. This file is responsible for sourcing of boilerplate code.

`zephyr_package_search.cmake`
: Common file used for detection of Zephyr repository and workspace candidates. Used by `ZephyrConfigVersion.cmake` and `ZephyrConfig.cmake` for common code.

`zephyr_export.cmake`
: See *Zephyr CMake package export (without west)*.

5.7 Sysbuild (System build)

Sysbuild is a higher-level build system that can be used to combine multiple other build systems together. It is a higher-level layer that combines one or more Zephyr build systems and optional additional build systems into a hierarchical build system.

For example, you can use sysbuild to build a Zephyr application together with the MCUboot bootloader, flash them both onto your device, and debug the results.

Sysbuild works by configuring and building at least a Zephyr application and, optionally, as many additional projects as you want. The additional projects can be either Zephyr applications or other types of builds you want to run.

Like Zephyr's *build system*, sysbuild is written in CMake and uses *Kconfig*.

5.7.1 Definitions

The following are some key concepts used in this document:

Single-image build
: When sysbuild is used to create and manage just one Zephyr application's build system.

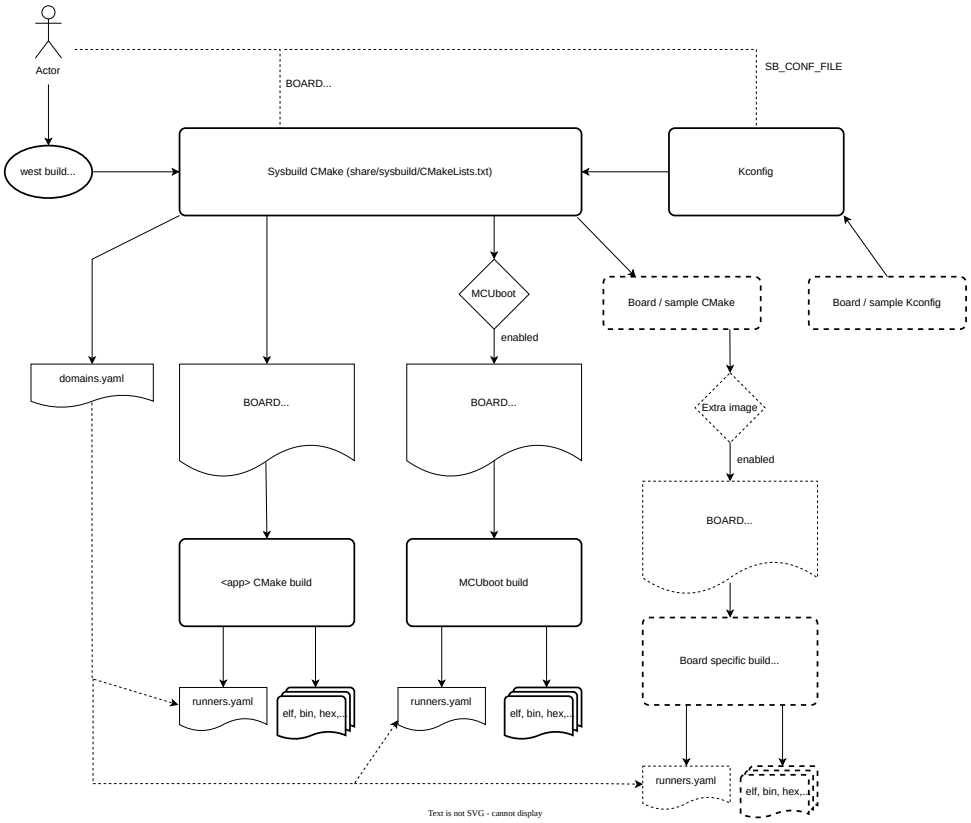
Multi-image build
: When sysbuild is used to manage multiple build systems. The word "image" is used because your main goal is usually to generate the binaries of the firmware application images from each build system.

Domain
: Every Zephyr CMake build system managed by sysbuild.

Multi-domain
: When more than one Zephyr CMake build system (domain) is managed by sysbuild.

5.7.2 Architectural Overview

This figure is an overview of sysbuild's inputs, outputs, and user interfaces:



The following are some key sysbuild features indicated in this figure:

- You can run sysbuild either with *west build* or directly via `cmake`.
- You can use sysbuild to generate application images from each build system, shown above as ELF, BIN, and HEX files.
- You can configure sysbuild or any of the build systems it manages using various configuration variables. These variables are namespaced so that sysbuild can direct them to the right build system. In some cases, such as the `BOARD` variable, these are shared among multiple build systems.
- Sysbuild itself is also configured using Kconfig. For example, you can instruct sysbuild to build the MCUboot bootloader, as well as to build and link your main Zephyr application as an MCUboot-bootable image, using sysbuild's Kconfig files.
- Sysbuild integrates with west's *Building, Flashing and Debugging* commands. It does this by managing the *Configuration Options*, and specifically the `runners.yaml` files that each Zephyr build system will contain. These are packaged into a global view of how to flash and debug each build system in a `domains.yaml` file generated and managed by sysbuild.
- Build names are prefixed with the target name and an underscore, for example the sysbuild target is prefixed with `sysbuild_` and if MCUboot is enabled as part of sysbuild, it will be prefixed with `mcuboot_`. This also allows for running things like menuconfig with the prefix,

for example (if using ninja) `ninja sysbuild_menuconfig` to configure sysbuild or (if using make) `make mcuboot_menuconfig`.

5.7.3 Building with sysbuild

As mentioned above, you can run sysbuild via `west build` or `cmake`.

`west build`

Here is an example. For details, see *Sysbuild (multi-domain builds)* in the `west build` documentation.

```
west build -b reel_board --sysbuild samples/hello_world
```

Tip

To configure `west build` to use `--sysbuild` by default from now on, run:

```
west config build.sysbuild True
```

Since sysbuild supports both single- and multi-image builds, this lets you use sysbuild all the time, without worrying about what type of build you are running.

To turn this off, run this before generating your build system:

```
west config build.sysbuild False
```

To turn this off for just one `west build` command, run:

```
west build --no-sysbuild ...
```

`cmake`

Here is an example using CMake and Ninja.

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world␣
↪share/sysbuild
ninja -Cbuild
```

To use sysbuild directly with CMake, you must specify the sysbuild project as the source folder, and give `-DAPP_DIR=<path-to-sample>` as an extra CMake argument or set APP_DIR as environment variable. `APP_DIR` is the path to the main Zephyr application managed by sysbuild.

Tip

The environment variables `CMAKE_BUILD_PARALLEL_LEVEL` and `VERBOSE` can be used to control the build process when using sysbuild with CMake and ninja.

To set number of jobs for ninja for all sysbuild images, set the `CMAKE_BUILD_PARALLEL_LEVEL` environment variable and invoke the build with `cmake --build`, for example:

```
CMAKE_BUILD_PARALLEL_LEVEL=<n> cmake --build .
```

For verbose output of all images, use:

```
VERBOSE=1 cmake --build .
```

5.7.4 Configuration namespacing

When building a single Zephyr application without sysbuild, all CMake cache settings and Kconfig build options given on the command line as `-D<var>=<value>` or `-DCONFIG_<var>=<value>`

are handled by the Zephyr build system.

However, when sysbuild combines multiple Zephyr build systems, there could be Kconfig settings exclusive to sysbuild (and not used by any of the applications). To handle this, sysbuild has namespaces for configuration variables. You can use these namespaces to direct settings either to sysbuild itself or to a specific Zephyr application managed by sysbuild using the information in these sections.

The following example shows how to build hello_world with MCUboot enabled, applying to both images debug optimizations:

west build

```
west build -b reel_board --sysbuild samples/hello_world -- -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -DCONFIG_DEBUG_OPTIMIZATIONS=y -
↪Dmcuboot_CONFIG_DEBUG_OPTIMIZATIONS=y
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -DCONFIG_DEBUG_OPTIMIZATIONS=y -
↪Dmcuboot_CONFIG_DEBUG_OPTIMIZATIONS=y share/sysbuild
ninja -Cbuild
```

See the following subsections for more information.

CMake variable namespacing

CMake variable settings can be passed to CMake using `-D<var>=<value>` on the command line. You can also set Kconfig options via CMake as `-DCONFIG_<var>=<value>` or `-D<namespace>_CONFIG_<var>=<value>`.

Since sysbuild is the entry point for the build system, and sysbuild is written in CMake, all CMake variables are first processed by sysbuild.

Sysbuild creates a namespace for each domain. The namespace prefix is the domain's application name. See *Adding Zephyr applications to sysbuild* for more information.

To set the variable `<var>` in the namespace `<namespace>`, use this syntax:

```
-D<namespace>_<var>=<value>
```

For example, to set the CMake variable `FOO` in the `my_sample` application build system to the value `BAR`, run the following commands:

west build

```
west build --sysbuild ... -- -Dmy_sample_FOO=BAR
```

cmake

```
cmake -Dmy_sample_FOO=BAR ...
```

Kconfig namespacing

To set the sysbuild Kconfig option `<var>` to the value `<value>`, use this syntax:

```
-DSB_CONFIG_<var>=<value>
```

In the previous example, `SB_CONFIG` is the namespace prefix for sysbuild's Kconfig options.

To set a Zephyr application's Kconfig option instead, use this syntax:

```
-D<namespace>_CONFIG_<var>=<value>
```

In the previous example, <namespace> is the application name discussed above in *CMake variable namespacing*.

For example, to set the Kconfig option FOO in the my_sample application build system to the value BAR, run the following commands:

west build

```
west build --sysbuild ... -- -Dmy_sample_CONFIG_FOO=BAR
```

cmake

```
cmake -Dmy_sample_CONFIG_FOO=BAR ...
```

Tip

When no <namespace> is used, the Kconfig setting is passed to the main Zephyr application my_sample.

This means that passing -DCONFIG_<var>=<value> and -Dmy_sample_CONFIG_<var>=<value> are equivalent.

This allows you to build the same application with or without sysbuild using the same syntax for setting Kconfig values at CMake time. For example, the following commands will work in the same way:

```
west build -b <board> my_sample -- -DCONFIG_FOO=BAR
```

```
west build -b <board> --sysbuild my_sample -- -DCONFIG_FOO=BAR
```

5.7.5 Sysbuild flashing using west flash

You can use *west flash* to flash applications with sysbuild.

When invoking west flash on a build consisting of multiple images, each image is flashed in sequence. Extra arguments such as --runner jlink are passed to each invocation.

For more details, see *Multi-domain flashing*.

5.7.6 Sysbuild debugging using west debug

You can use west debug to debug the main application, whether you are using sysbuild or not. Just follow the existing *west debug* guide to debug the main sample.

To debug a different domain (Zephyr application), such as mcuboot, use the --domain argument, as follows:

```
west debug --domain mcuboot
```

For more details, see *Multi-domain debugging*.

5.7.7 Building a sample with MCUboot

Sysbuild supports MCUboot natively.

To build a sample like hello_world with MCUboot, enable MCUboot and build and flash the sample as follows:

west build

```
west build -b reel_board --sysbuild samples/hello_world -- -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y share/sysbuild
ninja -Cbuild
```

This builds `hello_world` and `mcuboot` for the `reel_board`, and then flashes both the `mcuboot` and `hello_world` application images to the board.

More detailed information regarding the use of MCUboot with Zephyr can be found in the MCUboot with Zephyr documentation page on the MCUboot website.

Note

The deprecated MCUBoot Kconfig option `CONFIG_ZEPHYR_TRY_MASS_ERASE` will perform a full chip erase when flashed. If this option is enabled, then flashing only MCUBoot, for example using `west flash --domain mcuboot`, may erase the entire flash, including the main application image.

5.7.8 Sysbuild Kconfig file

You can set sysbuild's Kconfig options for a single application using configuration files. By default, sysbuild looks for a configuration file named `sysbuild.conf` in the application top-level directory.

In the following example, there is a `sysbuild.conf` file that enables building and flashing with MCUboot whenever sysbuild is used:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
└── sysbuild.conf
```

```
SB_CONFIG_BOOTLOADER_MCUBOOT=y
```

You can set a configuration file to use with the `-DSB_CONF_FILE=<sysbuild-conf-file>` CMake build setting.

For example, you can create `sysbuild-mcuboot.conf` and then specify this file when building with sysbuild, as follows:

`west build`

```
west build -b reel_board --sysbuild samples/hello_world -- -
↪DSB_CONF_FILE=sysbuild-mcuboot.conf
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=samples/hello_world -
↪DSB_CONF_FILE=sysbuild-mcuboot.conf share/sysbuild
ninja -Cbuild
```

5.7.9 Sysbuild targets

Sysbuild creates build targets for each image (including sysbuild itself) for the following modes:

- menuconfig
- hardenconfig
- guiconfig

For the main application (as is the same without using sysbuild) these can be ran normally without any prefix. For other images (including sysbuild), these are ran with a prefix of the image name and an underscore e.g. `sysbuild_` or `mcuboot_`, using ninja or make - for details on how to run image build targets that do not have mapped build targets in sysbuild, see the *Dedicated image build targets* section.

5.7.10 Dedicated image build targets

Not all build targets for images are given equivalent prefixed build targets when sysbuild is used, for example build targets like `ram_report`, `rom_report`, `footprint`, `puncover` and `pahole` are not exposed. When using *Trusted Firmware*, the build targets prefixed with `tfm_` and `bl2_` are also not exposed, for example: `tfm_rom_report` and `bl2_ram_report`. To run these build targets, the build directory of the image can be provided to west/ninja/make along with the name of the build target to execute and it will run.

`west`

Assuming that a project has been configured and built using `west` using sysbuild with mcuboot enabled in the default `build` folder location, the `rom_report` build target for `mcuboot` can be ran with:

```
west build -d build/mcuboot -t rom_report
```

For TF-M projects using TF-M targets, the application build directory is used like so:

```
west build -d build/<app_name> -t tfm_rom_report
```

`ninja`

Assuming that a project has been configured using `cmake` and built using `ninja` using sysbuild with mcuboot enabled, the `rom_report` build target for `mcuboot` can be ran with:

```
ninja -C mcuboot rom_report
```

For TF-M projects using TF-M targets, the application build directory is used like so:

```
ninja -C <app_name> -t tfm_rom_report
```

`make`

Assuming that a project has been configured using `cmake` and built using `make` using sysbuild with mcuboot enabled, the `rom_report` build target for `mcuboot` can be ran with:

```
make -C mcuboot rom_report
```

For TF-M projects using TF-M targets, the application build directory is used like so:

```
make -C <app_name> -t tfm_rom_report
```

5.7.11 Adding Zephyr applications to sysbuild

You can use the *`ExternalZephyrProject_Add()`* function to add Zephyr applications as sysbuild domains. Call this CMake function from your application's `sysbuild.cmake` file, or any other CMake file you know will run as part sysbuild CMake invocation.

A variant image can also added using the *ExternalZephyrVariantProject_Add()* function which will duplicate an existing image in the sysbuild project, and allows for slight differences in configuration. An example use case for this feature is to change the chosen flash node of an image but having the rest of the configuration identical to the base image. When this is used, neither sysbuild itself nor the image will have the extra Kconfig targets made for it such as menuconfig, guiconfig, hardenconfig or traceconfig, as the base image can be used for viewing/adjusting these instead.

Targeting the same board

To include `my_sample` as another sysbuild domain, targeting the same board as the main image, use this example:

```
ExternalZephyrProject_Add(
  APPLICATION my_sample
  SOURCE_DIR <path-to>/my_sample
)
```

This could be useful, for example, if your board requires you to build and flash an SoC-specific bootloader along with your main application.

Targeting a different board

In sysbuild and Zephyr CMake build system a board may refer to:

- A physical board with a single core SoC.
- A specific core on a physical board with a multi-core SoC, such as nrf5340dk.
- A specific SoC on a physical board with multiple SoCs, such as nrf9160dk_nrf9160 and nrf9160dk_nrf52840.

If your main application, for example, is built for `mps2/an521/cpu0`, and your helper application must target the `mps2/an521/cpu1` board target, add a CMake function call that is structured as follows:

```
ExternalZephyrProject_Add(
  APPLICATION my_sample
  SOURCE_DIR <path-to>/my_sample
  BOARD mps2/an521/cpu1
)
```

This could be useful, for example, if your main application requires another helper Zephyr application to be built and flashed alongside it, but the helper runs on another core in your SoC.

Targeting conditionally using Kconfig

You can control whether extra applications are included as sysbuild domains using Kconfig.

If the extra application image is specific to the board or an application, you can create two additional files: `sysbuild.cmake` and `Kconfig.sysbuild`.

For an application, this would look like this:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
├── Kconfig.sysbuild
└── sysbuild.cmake
```

In the previous example, `sysbuild.cmake` would be structured as follows:

```
if(SB_CONFIG_SECOND_SAMPLE)
  ExternalZephyrProject_Add(
    APPLICATION second_sample
    SOURCE_DIR <path-to>/second_sample
  )
endif()
```

`Kconfig.sysbuild` would be structured as follows:

```
source "sysbuild/Kconfig"

config SECOND_SAMPLE
        bool "Second sample"
        default y
```

This will include `second_sample` by default, while still allowing you to disable it using the Kconfig option `SECOND_SAMPLE`.

For more information on setting sysbuild Kconfig options, see *Kconfig namespacing*.

Building without flashing

You can mark `my_sample` as a build-only application in this manner:

```
ExternalZephyrProject_Add(
  APPLICATION my_sample
  SOURCE_DIR <path-to>/my_sample
  BUILD_ONLY TRUE
)
```

As a result, `my_sample` will be built as part of the sysbuild build invocation, but it will be excluded from the default image sequence used by `west flash`. Instead, you may use the outputs of this domain for other purposes - for example, to produce a secondary image for DFU, or to merge multiple images together.

You can also replace `TRUE` with another boolean constant in CMake, such as a Kconfig option, which would make `my_sample` conditionally build-only.

Note

Applications marked as build-only can still be flashed manually, using `west flash --domain my_sample`. As such, the `BUILD_ONLY` option only controls the default behavior of `west flash`.

Zephyr application configuration

When adding a Zephyr application to sysbuild, such as MCUboot, then the configuration files from the application (MCUboot) itself will be used.

When integrating multiple applications with each other, then it is often necessary to make adjustments to the configuration of extra images.

Sysbuild gives users the ability of creating Kconfig fragments or devicetree overlays that will be used together with the application's default configuration. Sysbuild also allows users to change *Application Configuration Directory* in order to give users full control of an image's configuration.

Zephyr application Kconfig fragment and devicetree overlay In the folder of the main application, create a Kconfig fragment or a devicetree overlay under a sysbuild folder, where the

name of the file is <image>.conf or <image>.overlay, for example if your main application includes my_sample then create a sysbuild/my_sample.conf file or a devicetree overlay sysbuild/my_sample.overlay.

A Kconfig fragment could look as:

```
# sysbuild/my_sample.conf
CONFIG_FOO=n
```

Zephyr application configuration directory In the folder of the main application, create a new folder under sysbuild/<image>/. This folder will then be used as APPLICATION_CONFIG_DIR when building <image>. As an example, if your main application includes my_sample then create a sysbuild/my_sample/ folder and place any configuration files in there as you would normally do:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
└── sysbuild
    └── my_sample
        ├── prj.conf
        ├── app.overlay
        └── boards
            ├── <board_A>.conf
            ├── <board_A>.overlay
            ├── <board_B>.conf
            └── <board_B>.overlay
```

All configuration files under the sysbuild/my_sample/ folder will now be used when my_sample is included in the build, and the default configuration files for my_sample will be ignored.

This give you full control on how images are configured when integrating those with application.

Sysbuild file suffix support File suffix support through the FILE_SUFFIX is supported in sysbuild (see *File Suffixes* for details on this feature in applications). For sysbuild, a globally provided option will be passed down to all images. In addition, the image configuration file will have this value applied and used (instead of the build type) if the file exists.

Given the example project:

```
<home>/application
├── CMakeLists.txt
├── prj.conf
├── sysbuild.conf
├── sysbuild_test_key.conf
└── sysbuild
    ├── mcuboot.conf
    ├── mcuboot_max_log.conf
    └── my_sample.conf
```

- If FILE_SUFFIX is not defined and both mcuboot and my_sample images are included, mcuboot will use the mcuboot.conf Kconfig fragment file and my_sample will use the my_sample.conf Kconfig fragment file. Sysbuild itself will use the sysbuild.conf Kconfig fragment file.
- If FILE_SUFFIX is set to max_log and both mcuboot and my_sample images are included, mcuboot will use the mcuboot_max_log.conf Kconfig fragment file and my_sample will use the my_sample.conf Kconfig fragment file (as it will fallback to the file without the suffix). Sysbuild itself will use the sysbuild.conf Kconfig fragment file (as it will fallback to the file without the suffix).

- If FILE_SUFFIX is set to test_key and both mcuboot and my_sample images are included, mcuboot will use the mcuboot.conf Kconfig fragment file and my_sample will use the my_sample.conf Kconfig fragment file (as it will fallback to the files without the suffix). Sysbuild itself will use the sysbuild_test_key.conf Kconfig fragment file. This can be used to apply a different sysbuild configuration, for example to use a different signing key in MCUboot and when signing the main application.

The FILE_SUFFIX can also be applied only to single images by prefixing the variable with the image name:

west build

```
west build -b reel_board --sysbuild file_suffix_example -- -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -Dmcuboot_FILE_SUFFIX="max_log"
```

cmake

```
cmake -Bbuild -GNinja -DBOARD=reel_board -DAPP_DIR=<app_dir> -
↪DSB_CONFIG_BOOTLOADER_MCUBOOT=y -Dmcuboot_FILE_SUFFIX="max_log" share/sysbuild
ninja -Cbuild
```

Adding dependencies among Zephyr applications

Sometimes, in a multi-image build, you may want certain Zephyr applications to be configured or flashed in a specific order. For example, if you need some information from one application's build system to be available to another's, then the first thing to do is to add a configuration dependency between them. Separately, you can also add flashing dependencies to control the sequence of images used by west flash; this could be used if a specific flashing order is required by an SoC, a _runner_, or something else.

By default, sysbuild will configure and flash applications in the order that they are added, as *ExternalZephyrProject_Add()* calls are processed by CMake. You can use the *sysbuild_add_dependencies()* function to make adjustments to this order, according to your needs. Its usage is similar to the standard add_dependencies() function in CMake.

Here is an example of adding configuration dependencies for my_sample:

```
sysbuild_add_dependencies(IMAGE CONFIGURE my_sample sample_a sample_b)
```

This will ensure that sysbuild will run CMake for sample_a and sample_b (in some order) before doing the same for my_sample, when building these domains in a single invocation.

If you want to add flashing dependencies instead, then do it like this:

```
sysbuild_add_dependencies(IMAGE FLASH my_sample sample_a sample_b)
```

As a result, my_sample will be flashed after sample_a and sample_b (in some order), when flashing these domains in a single invocation.

Note

Adding flashing dependencies is not allowed for build-only applications. If my_sample had been created with BUILD_ONLY TRUE, then the above call to sysbuild_add_dependencies() would have produced an error.

5.7.12 Merged hex files

Sysbuild supports creating merged hex files, which will be created one per unique board target in a sysbuild project and can be enabled with SB_CONFIG_MERGED_HEX_FILES. The output filename format will be merged_<NORMALIZED_BOARD_TARGET>.hex. This is ideal for creating production

images for deployment, it requires that all images output hex files. If a sysbuild project builds multiple images for the same board target but for **different** devices (e.g. 3 images for 3 different boards as part of a test), then this option should remain disabled. Hex files will be merged as per the flashing order they have been configured in, any overlapping data from previous addresses that conflicts with later merged hex files will be overwritten with the later hex file data - see *Adding dependencies among Zephyr applications* for how to configure the flashing order of sysbuild images.

5.7.13 Adding non-Zephyr applications to sysbuild

You can include non-Zephyr applications in a multi-image build using the standard CMake module `ExternalProject`. Please refer to the CMake documentation for usage details.

When using `ExternalProject`, the non-Zephyr application will be built as part of the sysbuild build invocation, but `west flash` or `west debug` will not be aware of the application. Instead, you must manually flash and debug the application.

5.7.14 Configuring sysbuild internal state

Because sysbuild is a CMake project in it's own right, it runs and sets up itself similar to a Zephyr application but using it's own CMake code. This means that some features, for example specifying variables in an application `CMakeLists.txt` (such as `BOARD_ROOT`) will not work, instead these must be set by using a *a module* or by using a custom sysbuild project file as `<application>/sysbuild/CMakeLists.txt`, for example:

```
# Place pre-sysbuild configuration items here

# For changing configuration that sysbuild itself uses:
# set(<var> <value>)
# list(APPEND <list> <value>)

# For changing configuration of other images:
# set(<image>_<var> <value> CACHE INTERNAL "<description>")

# Finds the sysbuild project and includes it with the new configuration
find_package(Sysbuild REQUIRED HINTS $ENV{ZEPHYR_BASE})

project(sysbuild LANGUAGES)
```

An example of adding a `BOARD_ROOT`:

```
list(APPEND BOARD_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/../<extra-board-root>)

find_package(Sysbuild REQUIRED HINTS $ENV{ZEPHYR_BASE})

project(sysbuild LANGUAGES)
```

This will pass the board root on to all images as part of a project, it does not need to be repeated in each image's `CMakeLists.txt` file.

5.7.15 Extending sysbuild

Sysbuild can be extended by other modules to give it additional functionality or include other configuration or images, an example could be to add support for another bootloader or external signing method.

Modules can be extended by adding custom CMake or Kconfig files as normal *modules* do, this will cause the files to be included in each image that is part of a project. Alternatively, there are *sysbuild-specific module extension* files which can be used to include CMake and Kconfig files for

the overall sysbuild image itself, this is where e.g. a custom image for a particular board or SoC can be added.

Sysbuild images

Sysbuild can be used to add additional images to builds, these can be added by projects or boards though at present must be Zephyr applications.

Methods of adding images Images can be added to project or projects in various ways, multiple ways can be used simultaneously, they can be added in the following ways:

Applications Applications can add sysbuild images using the `sysbuild.cmake` file in the application directory, the inclusion of images can be controlled with a `Kconfig.sysbuild` file in the application directory.

Boards Boards can add sysbuild images by using the `sysbuild.cmake` file in the board directory, the inclusion of images can be controlled with a `Kconfig.sysbuild` file in the board directory.

SoCs SoCs can add sysbuild images by using the `sysbuild.cmake` file in the soc directory.

Modules *Modules (External projects)* can add sysbuild images with the `sysbuild-cmake` and `sysbuild-kconfig` options in a `module.yml` file, see *Sysbuild integration* for details.

Adding images Images can be added in one of two ways:

Single unchangeable image With this setup, the image to be added is fixed to a specific application and cannot be changed (although it cannot be changed to another image, the version of the image itself can be changed by use of a west manifest bringing in a different version of the application repo or from an alternate source, assuming that the image is in it's own repository).

> **Note**
>
> This method should only be used if the image is locked to a specific interface and has no extensibility.

An example of how to create such an image, this assumes that a *Zephyr application has been created*:

`Kconfig.sysbuild`

```
config MY_IMAGE
        bool "Include my amazing image"
        help
          If enabled, will include my amazing image in the build which does...
```

> **Note**
>
> Remember to have `source "share/sysbuild/Kconfig"` in the file if this is being applied in an application `Kconfig.sysbuild` file.

`sysbuild.cmake`

```
if(SB_CONFIG_MY_IMAGE)
  ExternalZephyrProject_Add(
    APPLICATION my_image
    SOURCE_DIR ${ZEPHYR_MY_IMAGE_MODULE_DIR}/path/to/my_image
  )
endif()
```

Additional dependency ordering can be set here if needed, see *Adding dependencies among Zephyr applications* for details, image configuration can also be set here, see *Image configuration* for details.

This image can be enabled when building with west like so:

```
west build -b nrf52840dk/nrf52840 --sysbuild <app> -- -DSB_CONFIG_MY_IMAGE=y
```

Extensible changeable image With this setup, the image to be added can be one of any number of possible applications which the user has selection over, this list of selections can also be extended downstream to add additional options for out-of-tree specific applications that are not available in upstream Zephyr. This is more complex to create but is the preferred method for adding images to upstream Zephyr.

`Kconfig.sysbuild`

```
config SUPPORT_OTHER_APP
        bool
        # Conditions can be placed here if this application type is only usable on␣
↪certain platforms
        default y

config SUPPORT_OTHER_APP_MY_IMAGE
        bool
        # Conditions can be placed here if this image is only usable on certain␣
↪platforms
        default y

choice OTHER_APP
        prompt "Other app image"
        # Defaults can be specified here if a default image should be loaded if␣
↪e.g. it is supported
        default OTHER_APP_NONE
        depends on SUPPORT_OTHER_APP

config OTHER_APP_IMAGE_NONE
        bool "None"
        help
          Do not Include an other app image in the build.

config OTHER_APP_IMAGE_MY_IMAGE
        bool "my_image"
        depends on SUPPORT_OTHER_APP_MY_IMAGE
        help
          Include my amazing image as the other app image to use, which does...

endchoice

config OTHER_APP_IMAGE_NAME
        string
```

(continues on next page)

(continued from previous page)

```
        default "my_image" if OTHER_APP_IMAGE_MY_IMAGE
        help
          Name of other app image.

config OTHER_APP_IMAGE_PATH
        string
        default "$(ZEPHYR_MY_IMAGE_MODULE_DIR)/path/to/my_image" if␣
↪OTHER_APP_IMAGE_MY_IMAGE
        help
          Source directory of other app image.
```

Note

Remember to have `source "$(ZEPHYR_BASE)/share/sysbuild/Kconfig"` in the file if this is being applied in an application `Kconfig.sysbuild` file.

`sysbuild.cmake`

```
if(SB_CONFIG_OTHER_APP_IMAGE_PATH)
  ExternalZephyrProject_Add(
    APPLICATION ${SB_CONFIG_OTHER_APP_IMAGE_NAME}
    SOURCE_DIR ${SB_CONFIG_OTHER_APP_IMAGE_PATH}
  )
endif()
```

Additional dependency ordering can be set here if needed, see *Adding dependencies among Zephyr applications* for details, image configuration can also be set here, see *Image configuration* for details.

This secondary image can be enabled when building with west like so:

```
west build -b nrf52840dk/nrf52840 --sysbuild <app> -- -DSB_CONFIG_MY_IMAGE=y
```

This can then be extended by *Modules (External projects)* like so:

`Kconfig.sysbuild`

```
config SUPPORT_OTHER_APP_MY_SECOND_IMAGE
        bool
        default y

choice OTHER_APP

config OTHER_APP_IMAGE_MY_SECOND_IMAGE
        bool "my_second_image"
        depends on SUPPORT_OTHER_APP_MY_SECOND_IMAGE
        help
          Include my other amazing image as the other app image to use, which␣
↪does...

endchoice

config OTHER_APP_IMAGE_NAME
        default "my_second_image" if OTHER_APP_IMAGE_MY_SECOND_IMAGE

config OTHER_APP_IMAGE_PATH
```

(continues on next page)

(continued from previous page)

```
        default "$(ZEPHYR_MY_SECOND_IMAGE_MODULE_DIR)/path/to/my_second_image" if␣
↪OTHER_APP_IMAGE_MY_SECOND_IMAGE
```

As can be seen, no additional CMake changes are needed to add an alternative image as the base CMake code will add the replacement image instead of the original image, if selected.

This alternative secondary image can be enabled when building with west like so:

```
west build -b nrf52840dk/nrf52840 --sysbuild <app> -- -DSB_CONFIG_MY_SECOND_IMAGE=y
```

Image configuration Sysbuild supports being able to set image configuration (Kconfig options) and also supports reading the output of image configuration (Kconfig) which can be used to allow an option to be added to sysbuild itself and then to configure it globally or selectively.

Setting image configuration

Kconfig Sysbuild can be used to set image configuration **before the CMake configuration of images takes place**. An important note about setting Kconfig options in images is that these are persistent and cannot be changed by the images. The following functions can be used to set configuration on an image:

```
set_config_bool(<image> CONFIG_<setting> <value>)
set_config_string(<image> CONFIG_<setting> <value>)
set_config_int(<image> CONFIG_<setting> <value>)
```

For example, to change the default image to output a hex file:

```
set_config_bool(${DEFAULT_IMAGE} CONFIG_BUILD_OUTPUT_HEX y)
```

These can safely be used in an application, board or SoC `sysbuild.cmake` file, as that file is included before the image CMake processes are invoked. When extending *sysbuild using modules* the pre-CMake hook should be used instead, for example:

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_pre_cmake)
  cmake_parse_arguments(PRE_CMAKE "" "" "IMAGES" ${ARGN})

  foreach(image ${PRE_CMAKE_IMAGES})
    set_config_bool(${image} CONFIG_BUILD_OUTPUT_HEX y)
  endforeach()
endfunction()
```

Image configuration script An image configuration script is a CMake file that can be used to configure an image with common configuration values, multiple can be used per image, the configuration should be transferable to different images to correctly configure them based upon options set in sysbuild. MCUboot configuration options are configured in both the application the MCUboot image using this method which allows sysbuild to be the central location for things like the signing key which are then kept in-sync in the main application bootloader images. See *Signing key files* for setting the key to an absolute path or a CMake variable such as `${APP_DIR}`.

Inside image configuration scripts, the `ZCMAKE_APPLICATION` variable is set to the name of the application being configured, the `set_config_*` sysbuild CMake functions can be used to set configuration and the sysbuild Kconfig can be read, for example:

```
if(SB_CONFIG_BOOTLOADER_MCUBOOT AND "${SB_CONFIG_SIGNATURE_TYPE}" STREQUAL "NONE")
  set_config_bool(${ZCMAKE_APPLICATION} CONFIG_MCUBOOT_GENERATE_UNSIGNED_IMAGE y)
endif()
```

Image configuration script (module/application) Module/application image configuration scripts can be set from module or application code, this must be done in a `sysbuild.cmake` file for an application. This can be used to add an image configuration script as follows:

`sysbuild.cmake`

```
# This applies the image configuration script to the default image only
get_property(tmp_conf_scripts TARGET ${DEFAULT_IMAGE} PROPERTY IMAGE_CONF_SCRIPT)
list(APPEND tmp_conf_scripts "$
↪{CMAKE_SOURCE_DIR}/image_configurations/MY_CUSTOM_TYPE_image_default.cmake")
set_target_properties(${DEFAULT_IMAGE} PROPERTIES IMAGE_CONF_SCRIPT "$
↪{tmp_conf_scripts}")
```

Module CMake

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_pre_cmake)
  cmake_parse_arguments(PRE_CMAKE "" "" "IMAGES" ${ARGN})

  # This applies the image configuration script to all images
  foreach(image ${PRE_CMAKE_IMAGES})
    get_property(tmp_conf_scripts TARGET ${image} PROPERTY IMAGE_CONF_SCRIPT)
    list(APPEND tmp_conf_scripts "$
↪{CMAKE_SOURCE_DIR}/image_configurations/MY_CUSTOM_TYPE_image_default.cmake")
    set_target_properties(${image} PROPERTIES IMAGE_CONF_SCRIPT "$
↪{tmp_conf_scripts}")
  endforeach()
endfunction(${SYSBUILD_CURRENT_MODULE_NAME}_pre_cmake)
```

Image configuration script (Zephyr-wide) Global Zephyr provided image configuration scripts, which allow specifying the type when using *ExternalZephyrProject_Add()* require changes to sysbuild code in Zephyr. This should only be added to when adding a new type that any project should be able to select, generally this should only be needed for upstream Zephyr though forked versions of Zephyr might use this to add additional types without restriction.

Image configuration has an allow-list of names which must be set in the Zephyr file share/sysbuild/cmake/modules/sysbuild_extensions.cmake in the *ExternalZephyrProject_Add()* function. After adding a new type, it can be used when adding a sysbuild image, for example:

`sysbuild_extensions.cmake`

Full file path: `share/sysbuild/cmake/modules/sysbuild_extensions.cmake`

```
# ...
# Usage:
#   ExternalZephyrProject_Add(APPLICATION <name>
#                             SOURCE_DIR <dir>
#                             [BOARD <board> [BOARD_REVISION <revision>]]
#                             [APP_TYPE <MAIN|BOOTLOADER|MY_CUSTOM_TYPE>]
#   )
# ...
# APP_TYPE <MAIN|BOOTLOADER|MY_CUSTOM_TYPE>: Application type.
#                                            MAIN indicates this application is␣
↪the main application
#                                            and where user defined settings␣
↪should be passed on as-is
#                                            except for multi image build flags.
#                                            For example, -DCONF_FILES=<files>␣
↪will be passed on to the

  ExternalZephyrProject_Add(
    APPLICATION ${SB_CONFIG_OTHER_APP_IMAGE_NAME}
    SOURCE_DIR ${SB_CONFIG_OTHER_APP_IMAGE_PATH}
    APP_TYPE MY_CUSTOM_TYPE
  )
endif()
```

MY_CUSTOM_TYPE_image_default.cmake

Full file path: share/sysbuild/image_configurations/MY_CUSTOM_TYPE_image_default.cmake

```
# Here, the ZCMAKE_APPLICATION variable will be replaced with the image being␣
↪configured
set_config_bool(${ZCMAKE_APPLICATION} CONFIG_BUILD_OUTPUT_HEX y)
```

Reading image configuration

Kconfig Kconfig values from images can be read by sysbuild **after the CMake configuration of images has taken place**. This can be used to check configuration or to adjust additional sysbuild tasks depending upon configuration. The following function can be used for this purpose:

```
sysbuild_get(<variable> IMAGE <image> [VAR <image-variable>] KCONFIG)
```

This function can only be used when *sysbuild is extended by a module* or inside of a sysbuild/CMakeLists.txt file after find_package(Sysbuild) has been used. An example of outputting values from all images is shown:

Module CMake

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_post_cmake)
  cmake_parse_arguments(POST_CMAKE "" "" "IMAGES" ${ARGN})

  foreach(image ${POST_CMAKE_IMAGES})
    # Note that the variable to read in to must not be set before using the␣
↪sysbuild_get() function
    set(tmp_val)
    sysbuild_get(tmp_val IMAGE ${image} VAR CONFIG_BUILD_OUTPUT_HEX KCONFIG)
    message(STATUS "Image ${image} build hex: ${tmp_val}")
  endforeach()
endfunction()
```

sysbuild/CMakeLists.txt

```
find_package(Sysbuild REQUIRED HINTS $ENV{ZEPHYR_BASE})

project(sysbuild LANGUAGES)

sysbuild_get(tmp_val IMAGE ${DEFAULT_IMAGE} VAR CONFIG_BUILD_OUTPUT_HEX KCONFIG)
message(STATUS "Image ${DEFAULT_IMAGE} build hex: ${tmp_val}")
```

5.7.16 Sysbuild and CMake presets

CMake presets can be used with Sysbuild but not all preset macros will work as expected.

> **Note**
>
> Using CMake presets with sysbuild requires CMake version 3.27 or higher.

As described in *Sysbuild (System build)* then sysbuild is a higher-level build system which means that when CMake presets are used together with sysbuild, then the preset is consumed and processed by sysbuild itself and result is passed to the application.

Running sysbuild with preset.

west build

Here is an example where preset release should be used. For details, see *Sysbuild (multi-domain builds)* in the west build documentation.

```
west build -b reel_board --sysbuild -- --preset=release samples/hello_world
```

cmake

Here is an example using CMake and Ninja.

```
APP_DIR=samples/hello_world cmake -Bbuild -GNinja -DBOARD=reel_board --
↪preset=release share/sysbuild
ninja -Cbuild
```

When using CMake presets with sysbuild then APP_DIR must be set in environment in order for Sysbuild CMake to be able to include the CMakePresets.json from the main Zephyr application's source directory.

> **Note**
>
> As sysbuild changes the top-level cmake project to its own directory, the cmake presets are parsed from there, the application's presets are included from this file verbatim. Therefore relative paths, and macros resolving relative to the source directory will not work as expected, but as relative to share/sysbuild, for example ${sourceDir}.
>
> The ${fileDir} macro can be used to create portable paths relative to the application's directory.

5.8 Application version management

Zephyr supports an application version management system for applications which is built around the system that Zephyr uses for its own version system management. This allows applications to define a version file and have application (or module) code include the auto-generated file and be able to access it, just as they can with the kernel version. This version information is available from multiple scopes, including:

- Code (C/C++)
- Kconfig
- CMake
- Shell

which makes it a very versatile system for lifecycle management of applications. In addition, it can be used when building applications which target supported bootloaders (e.g. MCUboot) allowing images to be signed with correct version of the application automatically - no manual signing steps are required.

5.8.1 VERSION file

Application version information is set on a per-application basis in a file named `VERSION`, which must be placed at the base directory of the application, where the CMakeLists.txt file is located. This is a simple text file which contains the various version information fields, each on a newline. The basic `VERSION` file has the following structure:

```
VERSION_MAJOR =
VERSION_MINOR =
PATCHLEVEL =
VERSION_TWEAK =
EXTRAVERSION =
```

Each field and the values it supports is described below. Zephyr limits the value of each numeric field to a single byte (note that there may be further restrictions depending upon what the version is used for, e.g. bootloaders might only support some of these fields or might place limits on the maximum values of fields):

Field	Data type	Required
VERSION_MAJOR	Numerical (0-255)	X
VERSION_MINOR	Numerical (0-255)	X
PATCHLEVEL	Numerical (0-255)	X
VERSION_TWEAK	Numerical (0-255)	X
EXTRAVERSION	Alphanumerical (Lowercase a-z and 0-9) and “.” or “-”	

When an application is configured using CMake, the version file will be automatically processed, and will be checked automatically each time the version is changed, so CMake does not need to be manually re-ran for changes to this file.

For the sections below, examples are provided for the following `VERSION` file:

```
VERSION_MAJOR = 1
VERSION_MINOR = 2
PATCHLEVEL = 3
VERSION_TWEAK = 4
EXTRAVERSION = unstable.5
```

5.8.2 Application build version

The *application build version* is a separate, more dynamic concept from the one described in the `VERSION` file: it is intended to represent the current state of the application source code at the time of build, and is extracted from source versioning metadata.

By default, if the application is in a Git repository, its contents are generated from the output of the command `git describe --abbrev=12 --always` run in the application folder. This results in a string which contains the most recent tag, the number of commits since that tag, and the abbreviated commit hash.

Setting *APP_BUILD_VERSION* to the desired string value directly overrides this default behavior. This can either be done from the application `CMakeLists.txt` file or on the command line when invoking CMake, e.g. via `cmake -DAPP_BUILD_VERSION="v3.3.0-18-g2c85d92" ...`

5.8.3 Use in code

To use the version information in application code, the version file must be included, then the fields can be freely used. The include file name is `app_version.h` (use `#include <zephyr/app_version.h>`), the following defines are available:

Define	Type	Field(s)	Example
APPVERSION	Numerical	`VERSION_MAJOR` (left shifted by 24 bits), `VERSION_MINOR` (left shifted by 16 bits), `PATCHLEVEL` (left shifted by 8 bits), `VERSION_TWEAK`	0x1020304
APP_VERSION_N	Numerical	`VERSION_MAJOR` (left shifted by 16 bits), `VERSION_MINOR` (left shifted by 8 bits), `PATCHLEVEL`	0x10203
APP_VERSION_M	Numerical	`VERSION_MAJOR`	1
APP_VERSION_M	Numerical	`VERSION_MINOR`	2
APP_PATCHLEVI	Numerical	`PATCHLEVEL`	3
APP_TWEAK	Numerical	`VERSION_TWEAK`	4
APP_EXTRAVERS	String (unquoted)	`EXTRAVERSION`	unstable.5
APP_VERSION_S	String (quoted)	`VERSION_MAJOR`, `VERSION_MINOR`, `PATCHLEVEL`, `EXTRAVERSION`	“1.2.3-unstable.5”
APP_VERSION_E	String (quoted)	`VERSION_MAJOR`, `VERSION_MINOR`, `PATCHLEVEL`, `EXTRAVERSION VERSION_TWEAK`	“1.2.3-unstable.5+4”
APP_VERSION_T	String (quoted)	`VERSION_MAJOR`, `VERSION_MINOR`, `PATCHLEVEL`, `VERSION_TWEAK`	“1.2.3+4”
APP_BUILD_VER	String (unquoted)	None (see *Application build version* above)	v3.3.0-18-g2c85d92

5.8.4 Use in Kconfig

The following variables are available for usage in Kconfig files:

Variable	Type	Field(s)	Example
$(VERSION_MAJOR)	Numerical	VERSION_MAJOR	1
$(VERSION_MINOR)	Numerical	VERSION_MINOR	2
$(PATCHLEVEL)	Numerical	PATCHLEVEL	3
$(VERSION_TWEAK)	Numerical	VERSION_TWEAK	4
$(EXTRAVERSION)	String	EXTRAVERSION	unstable.5
$(APPVERSION)	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION	1.2.3-unstable.5
$(APP_VERSION_EXTEN	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION, VERSION_TWEAK	1.2.3-unstable.5+4
$(APP_VERSION_TWEAI	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, VERSION_TWEAK	1.2.3+4

5.8.5 Use in CMake

The following variable are available for usage in CMake files:

Variable	Type	Field(s)	Example
APPVERSION	Numerical (hex)	VERSION_MAJOR (left shifted by 24 bits), VERSION_MINOR (left shifted by 16 bits), PATCHLEVEL (left shifted by 8 bits), VERSION_TWEAK	0x1020304
APP_VERSION_N	Numerical (hex)	VERSION_MAJOR (left shifted by 16 bits), VERSION_MINOR (left shifted by 8 bits), PATCHLEVEL	0x10203
APP_VERSION_M	Numerical	VERSION_MAJOR	1
APP_VERSION_M	Numerical	VERSION_MINOR	2
APP_PATCHLEVE	Numerical	PATCHLEVEL	3
APP_VERSION_T	Numerical	VERSION_TWEAK	4
APP_VERSION_E	String	EXTRAVERSION	unstable.5
APP_VERSION_S	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION	1.2.3-unstable.5
APP_VERSION_E	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, EXTRAVERSION, VERSION_TWEAK	1.2.3-unstable.5+4
APP_VERSION_T	String	VERSION_MAJOR, VERSION_MINOR, PATCHLEVEL, VERSION_TWEAK	1.2.3+4
APP_BUILD_VER	String	None (see *Application build version* above)	v3.3.0-18-g2c85d92

5.8.6 Use in MCUboot-supported applications

No additional configuration needs to be done to the target application so long as it is configured to support MCUboot and a signed image is generated, the version information will be automatically included in the image data.

5.8.7 Use in Shell

When a shell interface is configured, the following commands are available to retrieve application version information:

Command	Variable	Example
app version	APP_VERSION_STRING	1.2.3-unstable.5
app version-extended	APP_VERSION_EXTENDED_STRING	1.2.3-unstable.5+4
app build-version	APP_BUILD_VERSION	v3.3.0-18-g2c85d92

5.9 Flashing

5.9.1 Flashing configuration

Zephyr supports setting up configuration for flash runners (invoked from *west flash*) which allows for customising how commands are used when programming boards. This configuration is used for *Sysbuild (System build)* projects and allows for configuring when commands are ran for groups of board targets. As an example: a multi-core SoC might want to only allow the `--erase` argument to be used once for all of the cores in the SoC which would prevent multiple erase tasks running in a single `west flash` invocation, which could wrongly clear the memory which is used by the other images being programmed.

Priority

Flashing configuration is singular, it will only be read from a single location, this configuration can reside in the following files starting with the highest priority:

- `soc.yml` (in soc folder)
- `board.yml` (in board folder)

Configuration

Configuration is applied in the yml file by using a `runners` map with a single `run_once` child, this then contains a map of commands as they would be provided to the flash runner e.g. `--reset` followed by a list which specifies the settings for each of these commands (these are grouped by flash runner, and by qualifiers/boards). Commands have associated runners that they apply to using a `runners` list value, this can contain `all` if it applies to all runners, otherwise must contain each runner that it applies to using the runner-specific name. Groups of board targets can be specified using the `groups` key which has a list of board target sets. Board targets are regular expression matches, for `soc.yml` files each set of board targets must be in a `qualifiers` key (only regular expression matches for board qualifiers are allowed, board names must be omitted from these entries). For `board.yml` files each set of board targets must be in a `boards` key, these are lists containing the matches which form a singular group. A final parameter `run` can be set to `first` which means that the command will be ran once with the first image flashing process per set of board targets, or to `last` which will be ran once for the final image flash per set of board targets.

An example flashing configuration for a `soc.yml` is shown below in which the `--recover` command will only be used once for any board targets which used the nRF5340 SoC application or network CPU cores, and will only reset the network or application core after all images for the respective core have been flashed.

```
runners:
  run_once:
    '--recover':
      - run: first
        runners:
          - nrfjprog
        groups:
          - qualifiers:
              - nrf5340/cpunet
              - nrf5340/cpuapp
              - nrf5340/cpuapp/ns
    '--reset':
      - run: last
        runners:
          - nrfjprog
          - jlink
        groups:
          - qualifiers:
```

(continues on next page)

(continued from previous page)

```
            - nrf5340/cpunet
        - qualifiers:
            - nrf5340/cpuapp
            - nrf5340/cpuapp/ns
    # Made up non-real world example to show how to specify different options␣
↪for different
    # flash runners
    - run: first
      runners:
        - some_other_runner
      groups:
        - qualifiers:
            - nrf5340/cpunet
        - qualifiers:
            - nrf5340/cpuapp
            - nrf5340/cpuapp/ns
```

Usage

Commands that are supported by flash runners can be used as normal when flashing non-sysbuild applications, the run once configuration will not be used. When flashing a sysbuild project with multiple images, the flash runner run once configuration will be applied.

For example, building the smp-svr sample for the nrf5340dk which will include MCUboot as a secondary image:

```
cmake -GNinja -Sshare/sysbuild/ -Bbuild -DBOARD=nrf5340dk/nrf5340/cpuapp -
↪DAPP_DIR=samples/subsys/mgmt/mcumgr/smp_svr
cmake --build build
```

Once built with an nrf5340dk connected, the following command can be used to flash the board with both applications and will only perform a single device recovery operation when programming the first image:

```
west flash --recover
```

If the above was ran without the flashing configuration, the recovery process would be ran twice and the device would be unbootable.

5.10 Signing Binaries

Binaries can be optionally signed as part of a build automatically using CMake code, there is also the ability to use `west sign` to sign binaries too, this page describes the former, the latter is documented on *Signing Binaries*.

5.10.1 MCUboot / imgtool

The Zephyr build system has special support for signing binaries for use with the MCUboot bootloader using the imgtool program provided by its developers. You can both build and sign this type of application binary in one step by setting some Kconfig options. If you do, `west flash` will use the signed binaries.

Here is an example workflow, which builds and flashes MCUboot, as well as the hello_world application for chain-loading by MCUboot. Run these commands from the `zephyrproject` workspace you created in the *Getting Started Guide*.

```
west build -b YOUR_BOARD zephyr/samples/hello_world --sysbuild -d␣
↪build-hello-signed -- \
     -DSB_CONFIG_BOOTLOADER_MCUBOOT=y

west flash -d build-hello-signed
```

Notes on the above commands:

- `YOUR_BOARD` should be changed to match your board
- The signing key value is the insecure default provided and used by MCUboot for development and testing
- You can change the `hello_world` application directory to any other application that can be loaded by MCUboot, such as the smp-svr sample.

For more information on these and other related configuration options, see:

- `SB_CONFIG_BOOTLOADER_MCUBOOT`: build the application for loading by MCUboot
- `SB_CONFIG_BOOT_SIGNATURE_KEY_FILE`: the key file, or a comma-separated list of key files, to use when signing images. If you have your own key, change this appropriately; see *Signing key files* for using an absolute path or a CMake variable such as `${APP_DIR}`. When a list is given, MCUboot embeds the public half of every key and accepts an image signed with any of them; the first entry also signs the application, and every entry past the first must be a public-only PEM of the same signature type for `imgtool`.
- `CONFIG_MCUBOOT_EXTRA_IMGTOOL_ARGS`: optional additional command line arguments for `imgtool`
- `CONFIG_MCUBOOT_GENERATE_CONFIRMED_IMAGE`: also generate a confirmed image, which may be more useful for flashing in production environments than the OTA-able default image
- On Windows, if you get "Access denied" issues, the recommended fix is to run `pip3 install imgtool`, then retry with a pristine build directory.

For a worked example of a multi-key bootloader exercised end-to-end under QEMU, see the tests/boot/mcuboot_multiple_keys test.

If your `west flash` *runner* uses an image format supported by imgtool, you should see something like this on your device's serial console when you run `west flash -d build-hello-signed`:

```
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
[00:00:00.004,669] <inf> mcuboot: Starting bootloader
[00:00:00.011,169] <inf> mcuboot: Primary image: magic=unset, swap_type=0x1,␣
↪copy_done=0x3, image_ok=0x3
[00:00:00.021,636] <inf> mcuboot: Boot source: none
[00:00:00.027,374] <inf> mcuboot: Swap type: none
[00:00:00.115,142] <inf> mcuboot: Bootloader chainload address offset: 0xc000
[00:00:00.123,168] <inf> mcuboot: Jumping to the first image slot
*** Booting Zephyr OS build zephyr-v2.3.0-2310-gcebac69c8ae1  ***
Hello World! nrf52840dk_nrf52840
```

Whether `west flash` supports this feature depends on your runner. The `nrfjprog` and `pyocd` runners work with the above flow. If your runner does not support this flow and you would like it to, please send a patch or file an issue for adding support.

5.10.2 Signing key files

When building with sysbuild, `SB_CONFIG_BOOT_SIGNATURE_KEY_FILE` selects the key used to sign images. Its value is propagated to two images:

- the application image, as `CONFIG_MCUBOOT_SIGNATURE_KEY_FILE`, which `imgtool` uses to sign the application; and

- the MCUboot image, as CONFIG_BOOT_SIGNATURE_KEY_FILE, whose public part is built into the bootloader so it can verify that signature.

Warning

The default value points at one of the insecure development keys bundled with MCUboot (for example root-ec-p256.pem). These keys are public — they ship with every Zephyr and MCUboot checkout — so they are only suitable for development and testing. For anything else, generate your own key and keep the private key out of any repository or build directory that you do not control.

How sysbuild resolves the key file path

The value of SB_CONFIG_BOOT_SIGNATURE_KEY_FILE is processed with CMake's string(CONFIGURE) command, so any ${VARIABLE} reference it contains is expanded as a CMake variable before the path is used. After expansion, an absolute path is used as-is; a relative path is resolved by each image independently:

Image	Search order for a relative path
Application (CONFIG_MCUBOOT_SIGNATURE_KE	APPLICATION_CONFIG_DIR, then the west workspace topdir (WEST_TOPDIR)
MCUboot (CONFIG_BOOT_SIGNATURE_KEY_F	APPLICATION_CONFIG_DIR, then the MCUboot module directory

Warning

Each image resolves a relative path against a different base, so a bare relative path points at a different file for each image and usually fails to build. Do not use one: give an absolute path, or anchor the path with a CMake variable.

${APP_DIR} (the main application's source directory) is the recommended anchor: it keeps the key inside your own application, and both images resolve it to the same file. Any CMake variable available when the value is expanded may be used:

```
# sysbuild.conf
SB_CONFIG_BOOT_SIGNATURE_KEY_FILE="${APP_DIR}/keys/my-signing-key.pem"
```

The same resolution rules apply to the optional encryption key file (CONFIG_MCUBOOT_ENCRYPTION_KEY_FILE).

5.10.3 Extending signing externally

The signing script used when running west flash can be extended or replaced to change features or introduce different signing mechanisms. By default with MCUboot enabled, signing is setup by the cmake/mcuboot.cmake file in Zephyr which adds extra post build commands for generating the signed images. The file used for signing can be replaced from a sysbuild scope (if being used) or from a zephyr/zephyr module scope, the priority of which is:

- Sysbuild
- Zephyr property
- Default MCUboot script (if enabled)

From sysbuild, -D<target>_SIGNING_SCRIPT can be used to set a signing script for a specific image or -DSIGNING_SCRIPT can be used to set a signing script for all images, for example:

```
west build -b <board> <application> -DSIGNING_SCRIPT=<file>
```

The zephyr property method is achieved by adjusting the `SIGNING_SCRIPT` property on the `zephyr_property_target`, ideally from by a module by using:

```
if(CONFIG_BOOTLOADER_MCUBOOT)
  set_target_properties(zephyr_property_target PROPERTIES SIGNING_SCRIPT $
↪{CMAKE_CURRENT_LIST_DIR}/custom_signing.cmake)
endif()
```

This will include the custom signing CMake file instead of the default Zephyr one when projects are built with MCUboot signing support enabled. The base Zephyr MCUboot signing file can be used as a reference for creating a new signing system or extending the default behaviour.

Chapter 6

Hardware Support

6.1 Architecture-related Guides

6.1.1 Zephyr support status on ARC processors

Overview

This page describes current state of Zephyr for ARC processors and some future plans. Please note that

- plans are given without exact deadlines
- software features require corresponding hardware to be present and configured the proper way
- not all the features can be enabled at the same time

Support status

Legend: **Y** - yes, supported; **N** - no, not supported; **WIP** - Work In Progress; **TBD** - to be decided

	Processor families				
	EM	**HS3x/4x**	**VPX**	**HS5x**	**HS6x**
Port status	up-streamed	up-streamed	up-streamed	up-streamed	up-streamed
Features					
Closely coupled memories (ICCM, DCCM)[1]	Y	Y	Y	TBD	TBD

Notes

VPX Vector Registers Zephyr supports a limited form sharing of the VPX vector registers known as cooperative sharing. Threads that use these registers must bookend the relevant sections with calls to `arc_vpx_lock()` and `arc_vpx_unlock()` to control access to this resource.

Note

If the system has multiple CPUs, then it is the responsibility of the application developer to both pin the thread to a single CPU before it attempts to get the cooperative lock, and not modify the CPU affinity while it is waiting for or holding that cooperative lock.

[6] currently only ARC VPX scalar port is supported. The support of VPX vector pipeline, VCCM, STU is not included in this port, and require additional development and / or other runtime integration.

[1] usage of CCMs is limited on SMP systems

[2] except the systems with secure features (SecureShield) due to HW limitation

[3] We only support save/restore ACCL/ACCH registers in task's context. Rest of DSP/AGU registers save/restore isn't implemented but kernel itself does not use these registers. This allows single task per core to use DSP/AGU safely.

[5] Single-thread kernel is support only for single core targets

[4] QEMU doesn't support all the ARC processor's HW features. For the detailed info please check the ARC QEMU documentation

Configuration Options The cooperative sharing of the VPX vector registers is selected when configuration option `CONFIG_ARC_VPX_COOPERATIVE_SHARING` is enabled.

6.1.2 Arm Cortex-M Developer Guide

Overview

This page contains detailed information about the status of the Arm Cortex-M architecture porting in the Zephyr RTOS and describes key aspects when developing Zephyr applications for Arm Cortex-M-based platforms.

Key supported features

The table below summarizes the status of key OS features in the different Arm Cortex-M implementation variants.

Architecture variant		Arm v6-M		Arm v7-M
		M0/M1	**M0+**	**M3**
OS Features				
Programmable fault IRQ priorities		N	N	Y
Single-thread kernel support		Y	Y	Y
Thread local storage support		Y	Y	Y
Interrupt handling				
	Regular interrupts	Y	Y	Y
	Dynamic interrupts	Y	Y	Y

	Direct interrupts	Y	Y	Y
	Zero Latency interrupts	N	N	Y
CPU idling		Y	Y	Y
Native system timer (SysTick)		N[1]	Y	Y
Memory protection				
	User mode	N	Y	Y
	HW stack protection (MPU)	N	N	Y
	HW-assisted stack limit checking	N	N	N
	Privileged Execute Never[3]	N	N	N
HW-assisted Control Flow integrity	PACBTI	N	N	N

HW-assisted null-pointer dereference detection		N	N	Y
HW-assisted atomic operations		N	N	Y
Support for non-cacheable regions		N	N	Y
Execute SRAM functions		N	N	Y
Floating Point Services		N	N	N
DSP ISA		N	N	N
Trusted Execution				
	Native TrustZone M support	N	N	N
	TF-M integration	N	N	N
Code relocation		Y	Y	Y
SW-based vector table relaying		Y	Y	Y

HW-assisted timing functions	N		N	Y

Notes

OS features

Threads

Thread stack alignment Each Zephyr thread is defined with its own stack memory. By default, Cortex-M enforces a double word thread stack alignment, see `CONFIG_STACK_ALIGN_DOUBLE_WORD`. If MPU-based HW-assisted stack overflow detection (`CONFIG_MPU_STACK_GUARD`) is enabled, thread stacks need to be aligned with a larger value, reflected by `CONFIG_ARM_MPU_REGION_MIN_ALIGN_AND_SIZE`. In Arm v6-M and Arm v7-M architecture variants, thread stacks are additionally required to align with a value equal to their size, in applications that need to support user mode (`CONFIG_USERSPACE`). The thread stack sizes in that case need to be a power of two. This is all reflected by `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT`, that is enforced in Arm v6-M and Arm v7-M builds with user mode support.

Stack pointers While executing in thread mode the processor is using the Process Stack Pointer (PSP). The processor uses the Main Stack Pointer (MSP) while executing in handler mode, that is, while servicing exceptions and HW interrupts. Using PSP in thread mode *facilitates thread stack pointer manipulation* during thread context switching, without affecting the current execution context flow in handler mode.

In Arm Cortex-M builds a single interrupt stack memory is shared among exceptions and interrupts. The size of the interrupt stack needs to be selected taking into consideration nested interrupts, each pushing an additional stack frame. Developers can modify the interrupt stack size using `CONFIG_ISR_STACK_SIZE`.

The interrupt stack is also used during early boot so the kernel can initialize the main thread's stack before switching to the main thread.

Thread context switching In Arm Cortex-M builds, the PendSV exception is used in order to trigger a context switch to a different thread. PendSV exception is always present in Cortex-M implementations. PendSV is configured with the lowest possible interrupt priority level, in all Cortex-M variants. The main reasons for that design are

- to utilize the tail chaining feature of Cortex-M processors, and thus limit the number of context switch operations that occur.
- to not impact the interrupt latency observed by HW interrupts.

As a result, context switch in Cortex-M is non-atomic, i.e. it may be *preempted* by HW interrupts, however, a context-switch operation must be completed before a new thread context-switch may start.

Typically a thread context-switch will perform the following operations

[1] SysTick is optional in Cortex-M1
[2] Stack limit checking only in Secure builds in Cortex-M23
[3] https://developer.arm.com/documentation/107655/100/RTOS-and-Secure-software-design-considerations/Secure-software-development-design-considerations/Security-and-privilege-combination/Using-PXN-bit?lang=en

- When switching-out the current thread, the processor stores
  - the callee-saved registers (R4 - R11) in the thread's container for callee-saved registers, which is located in kernel memory
  - the thread's current operation *mode*
    - user or privileged execution mode
    - presence of an active floating point context
    - the EXC_RETURN value of the current handler context (PendSV)
  - the floating point callee-saved registers (S16 - S31) in the thread's container for FP callee-saved registers, if the current thread has an active FP context
  - the PSP of the current thread which points to the beginning of the current thread's exception stack frame. The latter contains the caller-saved context and the return address of the switched-out thread.
- When switching-in a new thread the processor
  - restores the new thread's callee-saved registers from the thread's container for callee-saved registers
  - restores the new thread's operation *mode*
  - restores the FP callee-saved registers if the switched-in thread had an active FP context before being switched-out
  - re-programs the dynamic MPU regions to allow a user thread access its stack and application memories, and/or programs a stack-overflow MPU guard at the bottom of the thread's privileged stack
  - restores the PSP for the incoming thread and re-programs the stack pointer limit register (if applicable, see `CONFIG_BUILTIN_STACK_GUARD`)
  - optionally does a stack limit checking for the switched-in thread, if sentinel-based stack limit checking is enabled (see `CONFIG_STACK_SENTINEL`).

PendSV exception return sequence restores the new thread's caller-saved registers and the return address, as part of unstacking the exception stack frame.

The implementation of the context-switch mechanism is present in `arch/arm/core/cortex_m/swap_helper.S`.

Stack limit checking (Arm v8-M) Armv8-M and Armv8.1-M variants support stack limit checking using the MSPLIM and PSPLIM core registers. The feature is enabled when `CONFIG_BUILTIN_STACK_GUARD` is set. When stack limit checking is enabled, both the thread's privileged or user stack, as well as the interrupt stack are guarded by PSPLIM and MSPLIM registers, respectively. MSPLIM is configured *once* during kernel boot, while PSLIM is re-programmed during every thread context-switch or during system calls, when the thread switches from using its default stack to using its privileged stack, and vice versa. PSPLIM re-programming

- has a relatively low runtime overhead (programming is done with MSR instructions)
- does not impact interrupt latency
- does not require any memory areas to be reserved for stack guards
- does not make use of MPU regions

It is, therefore, considered as a lightweight but very efficient stack overflow detection mechanism in Cortex-M applications.

Stack overflows trigger the dedicated UsageFault exception provided by Arm v8-M.

Interrupt handling features This section describes certain aspects around exception and interrupt handling in Arm Cortex-M.

Interrupt priority levels The number of available (configurable) interrupt priority levels is determined by the number of implemented interrupt priority bits in NVIC; this needs to be described for each Cortex-M platform using DeviceTree:

```
&nvic {
        arm,num-irq-priority-bits = <#priority-bits>;
};
```

Reserved priority levels A number of interrupt priority levels are reserved for the OS.

By design, system fault exceptions have the highest priority level. In *Baseline* Cortex-M, this is actually enforced by hardware, as HardFault is the only available processor fault exception, and its priority is higher than any configurable exception priority.

In *Mainline* Cortex-M, the available fault exceptions (e.g. MemManageFault, UsageFault, etc.) are assigned the highest *configurable* priority level. (`CONFIG_CPU_CORTEX_M_HAS_PROGRAMMABLE_FAULT_PRIOS` signifies explicitly that the Cortex-M implementation supports configurable fault priorities.)

This priority level is never shared with HW interrupts (an exception to this rule is described below). As a result, processor faults occurring in regular ISRs will be handled by the corresponding fault handler and will not escalate to a HardFault, *similar to processor faults occurring in thread mode*.

SVC exception is normally configured with the highest configurable priority level (an exception to this rule will be described below). SVCs are used by the Zephyr kernel to dispatch system calls, trigger runtime system errors (e.g. Kernel oops or panic), or implement IRQ offloading.

In Baseline Cortex-M the priority level of SVC may be shared with other exceptions or HW interrupts that are also given the highest configurable priority level (As a result of this, kernel runtime errors during interrupt handling will escalate to HardFault. Additional logic in the fault handling routines ensures that such runtime errors are detected successfully).

In Mainline Cortex-M, however, the SVC priority level is *reserved*, thus normally it is only shared with the fault exceptions of configurable priority. This simplifies the fault handling routines in Mainline Cortex-M architecture, since runtime kernel errors are serviced by the SVC handler (i.e no HardFault escalation, even if the kernel errors occur in ISR context).

HW interrupts in Mainline Cortex-M builds are allocated a priority level lower than the SVC.

One exception to the above rules is when Zephyr applications support Zero Latency Interrupts (ZLIs). Such interrupts are designed to have a priority level higher than any HW or system interrupt. If the ZLI feature is enabled in Mainline Cortex-M builds (see `CONFIG_ZERO_LATENCY_IRQS`), then

- ZLIs are assigned the highest configurable priority level
- SVCs are assigned the second highest configurable priority level
- Regular HW interrupts are assigned priority levels lower than SVC.

The priority level configuration in Cortex-M is implemented in `include/zephyr/arch/arm/cortex_m/exception.h`.

Locking and unlocking IRQs In Baseline Cortex-M locking interrupts is implemented using the PRIMASK register.

```
arch_irq_lock()
```

will set the PRIMASK register to 1, eventually, masking all IRQs with configurable priority. While this fulfils the OS requirement of locking interrupts, the consequence is that kernel runtime errors (triggering SVCs) will escalate to HardFault.

In Mainline Cortex-M locking interrupts is implemented using the BASEPRI register (Mainline Cortex-M builds select `CONFIG_CPU_CORTEX_M_HAS_BASEPRI` to signify that BASEPRI register is implemented.). By modifying BASEPRI (or BASEPRI_MAX) arch_irq_lock() masks all system and HW interrupts with the exception of

- SVCs
- processor faults
- ZLIs

This allows zero latency interrupts to be triggered inside OS critical sections. Additionally, this allows system (processor and kernel) faults to be handled by Zephyr in *exactly the same way*, regardless of whether IRQs have been locked or not when the error occurs. It also allows for system calls to be dispatched while IRQs are locked.

Note

Mainline Cortex-M fault handling is designed and configured in a way that all processor and kernel faults are handled by the corresponding exception handlers and never result in HardFault escalation. In other words, a HardFault may only occur in Zephyr applications that have modified the default fault handling configurations. The main reason for this design was to reserve the HardFault exception for handling exceptional error conditions in safety critical applications.

Dynamic direct interrupts Cortex-M builds support the installation of direct interrupt service routines during runtime. Direct interrupts are designed for performance-critical interrupt handling and do not go through all of the common Zephyr interrupt handling code.

Direct dynamic interrupts are enabled via switching on `CONFIG_DYNAMIC_DIRECT_INTERRUPTS`.

Note that enabling direct dynamic interrupts requires enabling support for dynamic interrupts in the kernel, as well (see `CONFIG_DYNAMIC_INTERRUPTS`).

Zero Latency interrupts As described above, in Mainline Cortex-M applications, the Zephyr kernel reserves the highest configurable interrupt priority level for its own use (SVC). SVCs will not be masked by interrupt locking. Zero-latency interrupt can be used to set up an interrupt at the highest interrupt priority which will not be blocked by interrupt locking. To use the ZLI feature `CONFIG_ZERO_LATENCY_IRQS` needs to be enabled.

Zero latency IRQs have minimal interrupt latency, as they will always preempt regular HW or system interrupts.

Note, however, that since ZLI ISRs will run at a priority level higher than the kernel exceptions they **cannot use** any kernel functionality. Additionally, since the ZLI interrupt priority level is equal to processor fault priority level, faults occurring in ZLI ISRs will escalate to HardFault and will not be handled in the same way as regular processor faults. Developers need to be aware of this limitation.

CPU Idling The Cortex-M architecture port implements both k_cpu_idle() and k_cpu_atomic_idle(). The implementation is present in `arch/arm/core/cortex_m/cpu_idle.c`.

In both implementations, the processor will attempt to put the core to low power mode. In k_cpu_idle() the processor ends up executing WFI (Wait For Interrupt) instruction, while in k_cpu_atomic_idle() the processor will execute a WFE (Wait For Event) instruction.

When using the CPU idling API in Cortex-M it is important to note the following:

- Both k_cpu_idle() and k_cpu_atomic_idle() are *assumed* to be invoked with interrupts locked. This is taken care of by the kernel if the APIs are called by the idle thread.
- After waking up from low power mode, both functions will *restore* interrupts unconditionally, that is, regardless of the interrupt lock status before the CPU idle API was called.

The Zephyr CPU Idling mechanism is detailed in *CPU Idling*.

Memory protection features This section describes certain aspects around memory protection features in Arm Cortex-M applications.

User mode system calls User mode is supported in Cortex-M platforms that implement the standard (Arm) MPU or a similar core peripheral logic for memory access policy configuration and control, such as the NXP MPU for Kinetis platforms. (Currently, CONFIG_ARCH_HAS_USERSPACE is selected if CONFIG_ARM_MPU is enabled by the user in the board default Kconfig settings).

A thread performs a system call by triggering a (synchronous) SVC exception, where

- up to 5 arguments are placed on registers R1 - R5
- system call ID is placed on register R6.

The SVC Handler will branch to the system call preparation logic, which will perform the following operations

- switch the thread's PSP to point to the beginning of the thread's privileged stack area, optionally reprogramming the PSPLIM if stack limit checking is enabled
- modify CONTROL register to switch to privileged mode
- modify the return address in the SVC exception stack frame, so that after exception return the system call dispatcher is executed (in thread privileged mode)

Once the system call execution is completed the system call dispatcher will restore the user's original PSP and PSPLIM and switch the CONTROL register back to unprivileged mode before returning back to the caller of the system call.

System calls execute in thread mode and can be preempted by interrupts at any time. A thread may also be context-switched-out while doing a system call; the system call will resume as soon as the thread is switched-in again.

The system call dispatcher executes at SVC priority, therefore it cannot be preempted by HW interrupts (with the exception of ZLIs), which may observe some additional interrupt latency if they occur during a system call preparation.

MPU-assisted stack overflow detection Cortex-M platforms with MPU may enable CONFIG_MPU_STACK_GUARD to enable the MPU-based stack overflow detection mechanism. The following points need to be considered when enabling the MPU stack guards

- stack overflows are triggering processor faults as soon as they occur
- the mechanism is essential for detecting stack overflows in supervisor threads, or user threads in privileged mode; stack overflows in threads in user mode will always be detected regardless of CONFIG_MPU_STACK_GUARD being set.
- stack overflows are always detected, however, the mechanism does not guarantee that no memory corruption occurs when supervisor threads overflow their stack memory
- CONFIG_MPU_STACK_GUARD will normally reserve one MPU region for programming the stack guard (in certain Arm v8-M configurations with CONFIG_MPU_GAP_FILLING enabled 2 MPU regions are required to implement the guard feature)
- MPU guards are re-programmed at every context-switch, adding a small overhead to the thread swap routine. Compared, however, to the CONFIG_BUILTIN_STACK_GUARD feature, no re-programming occurs during system calls.

- When CONFIG_HW_STACK_PROTECTION is enabled on Arm v8-M platforms the native stack limit checking mechanism is used by default instead of the MPU-based stack overflow detection mechanism; users may override this setting by manually enabling CONFIG_MPU_STACK_GUARD in these scenarios.

Pointer Authentication and Branch Target Identification (PACBTI) The Armv8.1-M Pointer Authentication and Branch Target Identification (PACBTI) extension is an optional extension for the Armv8.1-M architecture profile and consists of the implementation of the following control-flow integrity approaches:

- Return address signing and authentication (PAC-RET) as a mitigation for Return Oriented Programming (ROP) style attack.
- BTI instruction placement (BTI) as a mitigation for Jump Oriented Programming (JOP) style attacks.

When hardware support is present (e.g., Cortex-M85) and compiler support is available, PACBTI can be enabled at build time in Zephyr by selecting one of the below configs:

- CONFIG_ARM_PACBTI_STANDARD
- CONFIG_ARM_PACBTI_PACRET
- CONFIG_ARM_PACBTI_PACRET_LEAF
- CONFIG_ARM_PACBTI_BTI
- CONFIG_ARM_PACBTI_PACRET_BTI
- CONFIG_ARM_PACBTI_PACRET_LEAF_BTI
- CONFIG_ARM_PACBTI_NONE

The config options ensures that compiler flags enabling PACBTI instructions are added to the build, specifically:

- `-mbranch-protection=` for GCC toolchains.

Further, CONFIG_ARM_PAC and CONFIG_ARM_BTI are automatically selected based on the branch protection option chosen for CONFIG_ARM_PACBTI. These configuration options enforce PACBTI by enabling corresponding PACBTI bits in CONTROL register and in the FVP.

To further enhance pointer authentication, Zephyr supports using cryptographically secure, per-thread PAC keys by enabling CONFIG_ARM_PAC_PER_THREAD. For more details on key generation sources and configuration, refer to the Kconfig help for CONFIG_ARM_PAC_PER_THREAD.

Limitations:

- Only builds targeting Armv8.1-M Mainline processors with PACBTI hardware support (e.g., Cortex-M85) are able to fully use this feature.
- Zephyr's integrated SDK currently includes GCC 12.2 which does not support PACBTI so external GCC toolchains (14.3 or later recommended) must be used for PACBTI support. Refer to this document on how to set up toolchains.

For more information about PACBTI, refer to the official Arm documentation and also Arm community blog

Memory map and MPU considerations

Fixed MPU regions By default, when CONFIG_ARM_MPU is enabled a set of *fixed* MPU regions are programmed during system boot.

- One MPU region programs the entire flash area as read-execute. User can override this setting by enabling CONFIG_MPU_ALLOW_FLASH_WRITE, which programs the flash with RWX

permissions. If CONFIG_USERSPACE is enabled unprivileged access on the entire flash area is allowed.

- One MPU region programs the entire SRAM area with privileged-only RW permissions. That is, an MPU region is utilized to disallow execute permissions on SRAM. (An exception to this setting is when CONFIG_MPU_GAP_FILLING is disabled (Arm v8-M only); in that case no SRAM MPU programming is done so the access is determined by the default Arm memory map policies, allowing for privileged-only RWX permissions on SRAM).
- All the memory regions defined in the devicetree with the property zephyr,memory-attr defining the MPU permissions for the memory region. See the next section for more details.

The above MPU regions are defined in arch/arm/core/mpu/arm_mpu_regions.c. Alternative MPU configurations are allowed by enabling CONFIG_CPU_HAS_CUSTOM_FIXED_SOC_MPU_REGIONS. When enabled, this option signifies that the Cortex-M SoC will define and configure its own fixed MPU regions in the SoC definition.

Fixed MPU regions defined in devicetree When the property zephyr,memory-attr is present in a memory node, a new MPU region will be allocated and programmed during system boot. When used with the zephyr,memory-region devicetree compatible, it will result in a linker section being generated associated to that MPU region.

For example, to define a new non-cacheable memory region in devicetree:

```
sram_no_cache: memory@20300000 {
     compatible = "zephyr,memory-region", "mmio-sram";
     reg = <0x20300000 0x100000>;
     zephyr,memory-region = "SRAM_NO_CACHE";
     zephyr,memory-attr = <DT_MEM_ARM_MPU_RAM_NOCACHE>;
};
```

This will automatically create a new MPU entry in with the correct name, base, size and attributes gathered directly from the devicetree. See *Caching Basics* and *Memory Attributes* for more details.

Static MPU regions Additional *static* MPU regions may be programmed once during system boot. These regions are required to enable certain features. See *Caching Basics* for more details.

- a RX region to allow execution from SRAM, when CONFIG_ARCH_HAS_RAMFUNC_SUPPORT is enabled and users have defined functions to execute from SRAM.
- a RX region for relocating text sections to SRAM, when CONFIG_CODE_DATA_RELOCATION_SRAM is enabled
- a nocache region to allow for a non-cacheable SRAM area, when CONFIG_NOCACHE_MEMORY is enabled
- a possibly unprivileged RW region for GCOV code coverage accounting area, when CONFIG_COVERAGE_GCOV is enabled
- a no-access region to implement null pointer dereference detection, when CONFIG_NULL_POINTER_EXCEPTION_DETECTION_MPU is enabled

The boundaries of these static MPU regions are derived from symbols exposed by the linker, in include/linker/linker-defs.h.

Dynamic MPU regions Certain thread-specific MPU regions may be re-programmed dynamically, at each thread context switch:

- an unprivileged RW region for the current thread's stack area (for user threads)
- a read-only region for the MPU stack guard

- unprivileged RW regions for the partitions of the current thread's application memory domain.

Considerations The number of available MPU regions for a Cortex-M platform is a limited resource. Most platforms have 8 MPU regions, while some Cortex-M33 or Cortex-M7 platforms may have up to 16 MPU regions. Therefore there is a relatively strict limitation on how many fixed, static and dynamic MPU regions may be programmed simultaneously. For platforms with 8 available MPU regions it might not be possible to enable all the aforementioned features that require MPU region programming. In most practical applications, however, only a certain set of features is required and 8 MPU regions are, in many cases, sufficient.

In Arm v8-M processors the MPU architecture does not allow programmed MPU regions to overlap. `CONFIG_MPU_GAP_FILLING` controls whether the fixed MPU region covering the entire SRAM is programmed. When it does, a full SRAM area partitioning is required, in order to program the static and the dynamic MPU regions. This increases the total number of required MPU regions. When `CONFIG_MPU_GAP_FILLING` is not enabled the fixed MPU region covering the entire SRAM is not programmed, thus, the static and dynamic regions are simply programmed on top of the always-existing background region (full-SRAM partitioning is not required). Note, however, that the background SRAM region allows execution from SRAM, so when `CONFIG_MPU_GAP_FILLING` is not set Zephyr is not protected against attacks that attempt to execute malicious code from SRAM.

Floating point Services Both unshared and shared FP registers mode are supported in Cortex-M (see *Floating Point Services* for more details).

When FPU support is enabled in the build (`CONFIG_FPU` is enabled), the sharing FP registers mode (`CONFIG_FPU_SHARING`) is enabled by default. This is done as some compiler configurations may activate a floating point context by generating FP instructions for any thread, regardless of whether floating point calculations are performed, and that context must be preserved when switching such threads in and out.

The developers can still disable the FP sharing mode in their application projects, and switch to Unshared FP registers mode, if it is guaranteed that the image code does not generate FP instructions outside the single thread context that is allowed (and supposed) to do so.

Under FPU sharing mode, the callee-saved FPU registers are saved and restored in context-switch, if the corresponding threads have an active FP context. This adds some runtime overhead on the swap routine. In addition to the runtime overhead, the sharing FPU mode

- requires additional memory for each thread to save the callee-saved FP registers
- requires additional stack memory for each thread, to stack the caller-saved FP registers, upon exception entry, if an FP context is active. Note, however, that since lazy stacking is enabled, there is no runtime overhead of FP context stacking in regular interrupts (FP state preservation is only activated in the swap routine in PendSV interrupt).

Misc

Chain-loadable images Cortex-M applications may either be standalone images or chain-loadable, for instance, by a bootloader. Application images chain-loadable by bootloaders (or other applications) normally occupy a specific area in the flash denoted as their *code partition*. `CONFIG_USE_DT_CODE_PARTITION` will ensure that a Zephyr chain-loadable image will be linked into its code partition, specified in DeviceTree.

HW initialization at boot In order to boot properly, chain-loaded applications may require that the core Arm hardware registers and peripherals are initialized in their reset values. Enabling `CONFIG_INIT_ARCH_HW_AT_BOOT` Zephyr to force the initialization of the internal Cortex-M architectural state during boot to the reset values as specified by the corresponding Arm architecture manual.

Software vector relaying In Cortex-M platforms that implement the VTOR register (see CONFIG_CPU_CORTEX_M_HAS_VTOR), chain-loadable images relocate the Cortex-M vector table by updating the VTOR register with the offset of the image vector table.

Baseline Cortex-M platforms without VTOR register might not be able to relocate their vector table which remains at a fixed location. Therefore, a chain-loadable image will require an alternative way to route HW interrupts and system exceptions to its own vector table; this is achieved with software vector relaying.

When a bootloader image enables CONFIG_SW_VECTOR_RELAY it is able to relay exceptions and interrupts based on a vector table pointer that is set by the chain-loadable application. The latter sets the CONFIG_SW_VECTOR_RELAY_CLIENT option to instruct the boot sequence to set the vector table pointer in SRAM so that the bootloader can forward the exceptions and interrupts to the chain-loadable image's software vector table.

While this feature is intended for processors without VTOR register, it may also be used in Mainline Cortex-M platforms.

Code relocation Cortex-M support the code relocation feature. When CONFIG_CODE_DATA_RELOCATION_SRAM is selected, Zephyr will relocate .text, data and .bss sections from the specified files and place it in SRAM. It is possible to relocate only parts of the code sections into SRAM, without relocating the whole image text and data sections. More details on the code relocation feature can be found in *Code And Data Relocation*.

Linking Cortex-M applications

Most Cortex-M platforms make use of the default Cortex-M GCC linker script in include/zephyr/arch/arm/cortex_m/scripts/linker.ld, although it is possible for platforms to use a custom linker script as well.

CMSIS

Cortex-M CMSIS headers are provided through standalone module repositories:

- **CMSIS 5**: zephyrproject-rtos/cmsis
- **CMSIS 6**: zephyrproject-rtos/CMSIS_6

Zephyr has begun transitioning to **CMSIS 6** as the default source for Cortex-M core headers. However, at present, Zephyr includes headers from **both** the CMSIS 6 and legacy CMSIS 5 modules.

The legacy CMSIS 5 headers remain available primarily for compatibility with vendor HALs, while all new architecture-level development should use **CMSIS 6** headers whenever possible.

CONFIG_CPU_CORTEX_M selects CONFIG_HAS_CMSIS_CORE to signify that CMSIS headers are available for all supported Cortex-M variants.

Testing

A list of unit tests for the Cortex-M porting and miscellaneous features is present in tests/arch/arm/. The tests suites are continuously extended and new test suites are added, in an effort to increase the coverage of the Cortex-M architecture support in Zephyr.

QEMU

We use QEMU to verify the implemented features of the Cortex-M architecture port in Zephyr. Adequate coverage is achieved by defining and utilizing a list of QEMU targets, each with a specific architecture variant and Arm peripheral support list.

The table below lists the QEMU platform targets defined in Zephyr along with the corresponding Cortex-M implementation variant and the peripherals these targets emulate.

	QEMU target				
Architecture variant	Arm v6-M	Arm v7-M		Arm v8-M	Arm v8.1-M
	qemu_cortex	qemu_cortex	mps2/an3	mps2/an521/c	mps3/corstone300/an547
Emulated features					
NVIC	Y	Y	Y	Y	Y
BASEPRI	N	Y	Y	Y	Y
SysTick	N	Y	Y	Y	Y
MPU	N	N	Y	Y	Y
FPU	N	N	N	Y	N
SPLIM	N	N	N	Y	Y
TrustZone-M	N	N	N	Y	N

Maintainers & Collaborators

The status of the Arm Cortex-M architecture port in Zephyr is: *maintained*. The updated list of maintainers and collaborators for Cortex-M can be found in `MAINTAINERS.yml`.

6.1.3 ARM64 Developer Guide

Wait with timeout (WFxT)

The Arm WFxT extension provides the WFET and WFIT instructions, which take an absolute virtual counter value as a timeout. Zephyr detects the extension at runtime from the `WFxT` field in `ID_AA64ISAR2_EL1`. Arm64 architecture code can query this support with `is_wfxt_implemented()`, declared in include/zephyr/arch/arm64/lib_helpers.h.

When the Arm architectural timer implements `arch_busy_wait()`, the Arm64 path uses WFET for `k_busy_wait()` if WFxT is implemented. It computes a deadline from `CNTVCT_EL0` and repeats WFET until the counter reaches that deadline. The loop is required because WFET is permitted to return before its timeout. CPUs without WFxT use counter polling instead. See drivers/timer/arm_arch_timer.c for the implementation.

The default Arm64 `arch_cpu_idle()` implementation continues to use WFI. With the Arm architectural timer, the kernel's next timeout is programmed in the system timer and its interrupt wakes the CPU. Replacing WFI with WFIT while retaining that interrupt does not remove the timer programming or interrupt handling. Avoiding the interrupt would require complex changes to kernel timeout accounting, rescheduling, and SMP deadline coordination, adding significant risk and maintenance cost without a demonstrated benefit.

Devicetree-based MMU Region Mapping

On ARM64 platforms the MMU page tables can be populated automatically from devicetree at compile time. Any node with `compatible = "zephyr,memory-region"` that also carries a `zephyr,memory-attr` property will be turned into a static `arm_mmu_region` entry by the architecture startup code — no per-SoC `mmu_regions.c` changes are required.

Supported memory attributes Only **Normal** memory types are accepted. Device memory (peripheral MMIO) must be mapped through the `DEVICE_MMIO` API (see *Device Driver Model*).

The attribute macros are defined in include/zephyr/dt-bindings/memory-attr/memory-attr-arm64.h as composable combinations of the generic `DT_MEM_CACHEABLE` flag and architecture-specific sub-attributes:

DT macro	Description
DT_MEM_ARM64_MMU_NORMAL	Normal write-back cacheable (DT_MEM_CACHEABLE | ATTR_ARM64_CACHE_WB)
DT_MEM_ARM64_MMU_NORMAL_NC	Normal non-cacheable (0)
DT_MEM_ARM64_MMU_NORMAL_WT	Normal write-through cacheable (DT_MEM_CACHEABLE)

Example devicetree overlay

```
#include <zephyr/dt-bindings/memory-attr/memory-attr.h>
#include <zephyr/dt-bindings/memory-attr/memory-attr-arm64.h>

/ {
    soc {
        /* Cacheable shared memory pool */
        shm0: memory@42000000 {
            compatible = "zephyr,memory-region";
            reg = <0x0 0x42000000 0x0 0x1000>;
            zephyr,memory-region = "SHM0";
            zephyr,memory-attr = <DT_MEM_ARM64_MMU_NORMAL>;
        };

        /* Non-cacheable DMA buffer */
        dma_buf: memory@43000000 {
            compatible = "zephyr,memory-region";
            reg = <0x0 0x43000000 0x0 0x1000>;
            zephyr,memory-region = "DMA_BUF";
            zephyr,memory-attr = <DT_MEM_ARM64_MMU_NORMAL_NC>;
        };
    };
};
```

Each region is mapped with `MT_P_RW_U_NA | MT_DEFAULT_SECURE_STATE` combined with the memory type derived from `zephyr,memory-attr`.

Translation table sizing Every mapped region that falls on a different 2 MB boundary requires an additional Level 3 page table. If the boot hangs silently after adding new regions, increase `CONFIG_MAX_XLAT_TABLES` in the board or test configuration:

```
CONFIG_MAX_XLAT_TABLES=16
```

Supported attribute combinations All non-device attribute combinations are valid: the `DT_MEM_CACHEABLE` generic bit selects cacheable vs non-cacheable, and the arch-specific `ATTR_ARM64_CACHE_WB` sub-bit selects write-back vs write-through when cacheable.

6.1.4 Zephyr support status on RISC-V processors

Overview

This page describes current state of Zephyr for RISC-V processors. Currently, there's support for some boards, as well as Qemu support and support for some FPGA implementations such as neorv32 and litex_vexriscv.

Zephyr support includes PMP, *user mode*, several ISA extensions as well as *semihosting*.

User mode and PMP support

When the platform has Physical Memory Protection (PMP) support, enabling it on Zephyr allows user space support and stack protection to be selected.

ISA extensions

It's possible to set in Zephyr which ISA extensions (RV32/64I(E)MAFD(G)QC) are available on a given platform, by setting the appropriate `CONFIG_RISCV_ISA_*` kconfig. Look at `arch/riscv/Kconfig.isa` for more information.

Note that Zephyr SDK toolchain support may not be defined for all combinations.

Supervisor mode (S-mode)

When `CONFIG_RISCV_S_MODE` is enabled, the Zephyr kernel runs in RISC-V Supervisor mode (S-mode) rather than Machine mode (M-mode). This follows the standard RISC-V privilege architecture used by application-class operating systems and is required for MMU support.

A minimal in-tree M-mode runtime (`arch/riscv/core/sbi.S`) acts as firmware. It performs the initial M-mode to S-mode transition at boot and handles S-mode requests via the RISC-V Supervisor Binary Interface (SBI):

- **Boot sequence**: M-mode configures PMP, `medeleg`, `mideleg`, `mcounteren` and `mtvec`, grants S-mode access to the `seed` CSR through `mseccfg` when the Zkr extension is present, then drops to S-mode via `mret`.
- **Timer**: Machine timer interrupts (MTIP) are forwarded to S-mode as supervisor timer interrupts (STIP). S-mode programs the next timer deadline through the SBI `TIME` extension (`sbi_set_timer`).
- **Ecalls**: S-mode ecalls (exception cause 9) are routed to the M-mode runtime via `medeleg`; all other exceptions and interrupts are delegated to S-mode. See *S-mode ecall constraint* below.

No external firmware is required; the in-tree runtime is self-contained.

Known limitations **PLIC external interrupts**: The PLIC driver always configures the M-mode context for hart 0. In S-mode the correct context is the supervisor context, so PLIC-delivered external interrupts (UART, GPIO, SPI, I2C, etc.) do not reach the CPU. The timer interrupt is unaffected as it is forwarded directly by the M-mode runtime via `sip.STIP`, bypassing the PLIC.

S-mode ecall constraint In M-mode, Zephyr uses the `ecall` instruction as a kernel-internal self-trap: because the kernel owns M-mode unconditionally, `ecall` raises exception cause 11 (M-mode ecall), which `_isr_wrapper` dispatches to whatever kernel service was requested (fatal error, `irq_offload`, context switch).

In S-mode this mechanism is unavailable. `ecall` from S-mode always raises cause 9, and cause 9 is **not** delegated to S-mode (`medeleg` bit 9 = 0) because it must reach the M-mode SBI handler — that is the only path by which S-mode can request M-mode services such as programming the timer via `sbi_set_timer`. The `medeleg` bit offers no per-register-value discrimination: delegating cause 9 to S-mode would break SBI; keeping it in M-mode makes cause 9 unavailable for kernel-internal use.

The practical rule for S-mode ports is:

> `ecall` is reserved for the SBI interface. Any kernel mechanism that uses `ecall` in M-mode must be reimplemented with a direct S-mode path.

Two concrete examples in this port:

- `ARCH_EXCEPT` (`include/zephyr/arch/riscv/error.h`) — instead of issuing `ecall` to trigger a fatal-error entry through `_isr_wrapper`, it calls `z_riscv_fatal_error()` directly.

- `arch_irq_offload` (`arch/riscv/core/irq_offload.c`) — instead of issuing `ecall` to enter `_isr_wrapper`'s `do_irq_offload` path, it simulates ISR context directly: disables interrupts, increments `nested`, calls the routine, decrements `nested`, re-enables interrupts, then calls `z_reschedule_unlocked()` to handle any thread that became ready inside the routine.

Support for using an external SBI implementation such as OpenSBI as a West module is left as future work.

SMP support

SMP is supported on RISC-V for both QEMU-virtualized and hardware-based platforms. In order to test the SMP support, one can use qemu_riscv32 or qemu_riscv64 for QEMU-based platforms, or beaglev_fire or mpfs_icicle for hardware-based platforms.

6.1.5 Semihosting Guide

Overview

Semihosting is a mechanism that enables code running on ARM, RISC-V and Xtensa targets to communicate and use the Input/Output facilities on a host computer that is running a debugger or emulator.

More complete documentation on the available functionality is available at the ARM Github documentation.

The RISC-V functionality borrows from the ARM definitions, as described at the RISC-V Github documentation.

Semihosting implementation on Xtensa supports GDB File-I/O extension, which is explained in GDB File-I/O Remote Protocol.

File Operations

Semihosting enables files on the host computer to be opened, read, and modified by an application. This can be useful when attempting to validate the behaviour of code across datasets that are larger than what can fit into ROM of an emulated platform. File paths can be either absolute, or relative to the directory of the running process.

```
const char *path = "./data.bin";
long file_len, bytes_read, fd;
uint8_t buffer[16];

/* Open the data file for reading */
fd = semihost_open(path, SEMIHOST_OPEN_RB);
if (fd < 0) {
   return -ENOENT;
}
/* Read all data from the file */
file_len = semihost_flen(fd);
while(file_len > 0) {
   bytes_read = semihost_read(fd, buffer, MIN(file_len, sizeof(buffer)));
   if (bytes_read < 0) {
      break;
   }
   /* Process read data */
   do_data_processing(buffer, bytes_read);
   /* Update remaining length */
   file_len -= bytes_read;
}
```

(continues on next page)

(continued from previous page)

```
/* Close the file */
semihost_close(fd);
```

Additional Functionality

Additional functionality is available by running semihosting instructions directly with `semihost_exec()` with one of the instructions defined in `semihost_instr`. For complete documentation on the required arguments and return codes, see the ARM Github documentation.

API Reference

Semihosting APIs

6.1.6 x86 Developer Guide

Overview

This page contains information on certain aspects when developing for x86-based platforms.

Virtual Memory

During very early boot, page tables are loaded so technically the kernel is executing in virtual address space. By default, physical and virtual memory are identity mapped and thus giving the appearance of execution taking place in physical address space. The physical address space is marked by dts `DT_CHOSEN_SRAM_ADDR` and `DT_CHOSEN_SRAM_SIZE` while the virtual address space is marked by `CONFIG_KERNEL_VM_BASE` and `CONFIG_KERNEL_VM_SIZE`. Note that `CONFIG_SRAM_OFFSET` controls where the Zephyr kernel is being placed in the memory, and its counterpart `CONFIG_KERNEL_VM_OFFSET`.

Separate Virtual Address Space from Physical Address Space On 32-bit x86, it is possible to have separate physical and virtual address space. Code and data are linked in virtual address space, but are still loaded in physical memory. However, during boot, code and data must be available and also addressable in physical address space before `vm_enter` inside `arch/x86/core/ia32/crt0.S`. After `vm_enter`, code execution is done via virtual addresses and data can be referred via their virtual addresses. This is possible as the page table generation script (`arch/x86/gen_mmu.py`) identity maps the physical addresses at the page directory level, in addition to mapping virtual addresses to the physical memory. Later in the boot process, the entries for identity mapping at the page directory level are cleared in `z_x86_mmu_init()`, effectively removing the identity mapping of physical memory. This unmapping must be done for userspace isolation or else they would be able to access restricted memory via physical addresses. Since the identity mapping is done at the page directory level, there is no need to allocate additional space for the page table. However, additional space may still be required for additional page directory table.

There are restrictions on where virtual address space can be:

- Physical and virtual address spaces must be disjoint. This is required as the entries in page directory table will be cleared. If they are not disjoint, it would clear the entries needed for virtual addresses.
  - If `CONFIG_X86_PAE` is enabled (`=y`), each address space must reside in their own 1GB region, due to each entry of PDP (Page Directory Pointer) covers 1GB of memory. For example:
    - Assuming `CONFIG_SRAM_OFFSET` and `CONFIG_KERNEL_VM_OFFSET` are both `0x0`.
    - `DT_CHOSEN_SRAM_ADDR == 0x00000000` and `CONFIG_KERNEL_VM_BASE = 0x40000000` is valid, while

    - DT_CHOSEN_SRAM_ADDR == 0x00000000 and CONFIG_KERNEL_VM_BASE = 0x20000000 is not.
  - If CONFIG_X86_PAE is disabled (=n), each address space must reside in their own 4MB region, due to each entry of PD (Page Directory) covers 4MB of memory.
  - Both DT_CHOSEN_SRAM_ADDR and CONFIG_KERNEL_VM_BASE must also align with the starting addresses of targeted regions.

Specifying Additional Memory Mappings at Build Time

The page table generation script (arch/x86/gen_mmu.py) generates the necessary multi-level page tables for code execution and data access using the kernel image produced by the first linker pass. Additional command line arguments can be passed to the script to generate additional memory mappings. This is useful for static mappings and/or device MMIO access during very early boot. To pass extra command line arguments to the script, populate a CMake list named X86_EXTRA_GEN_MMU_ARGUMENTS in the board configuration file. Here is an example:

```
set(X86_EXTRA_GEN_MMU_ARGUMENTS
    --map 0xA0000000,0x2000
    --map 0x80000000,0x400000,LWUX,0xB0000000)
```

The argument --map takes the following value: <physical address>,<size>[,<flags:LUWX>[,<virtual address>]], where:

- <physical address> is the physical address of the mapping. (Required)
- <size> is the size of the region to be mapped. (Required)
- <flags> is the flag associated with the mapping: (Optional)
  - L: Large page at the page directory level.
  - U: Allow userspace access.
  - W: Read/write.
  - X: Allow execution.
  - D: Cache disabled.
    - Default is small page (4KB), supervisor only, read only, and execution disabled.
- <virtual address> is the virtual address of the mapping. (Optional)

Note that specifying additional memory mappings requires larger storage space for the pre-allocated page tables (both kernel and per-domain tables). CONFIG_X86_EXTRA_PAGE_TABLE_PAGES is needed to specify how many more memory pages to be reserved for the page tables. If the needed space is not exactly the same as required space, the gen_mmu.py script will print out a message indicating what needs to be the value for the kconfig.

6.1.7 Xtensa Developer Guide

Overview

This page contains information on certain aspects when developing for Xtensa-based platforms.

HiFi Audio Engine DSP

The kernel allows threads to use the HiFi Audio Engine DSP registers on boards that support these registers. The kernel only supports the use of the HiFi registers by threads and not ISRs.

Note

Presently, only the Intel ADSP ACE hardware platforms are configured for HiFi support by default.

Concepts The kernel can be configured for an application to leverage the services provided by the Xtensa HiFi Audio Engine DSP. Three modes of operation are supported, which are described below.

No HiFi registers mode This mode is used when the application has no threads that use the HiFi registers. It is the kernel's default HiFi services mode.

Unshared HiFi registers mode This mode is used when the application has only a single thread that uses the HiFi registers. The HiFi registers are left unchanged whenever a context switch occurs.

Note

The behavior is undefined, if two or more threads attempt to use the HiFi registers, as the kernel does not attempt to detect (nor prevent) multiple threads from using these registers.

Shared HiFi registers mode This mode is used when the application has two or more threads that use HiFi registers. When enabled, the kernel automatically allows all threads to use the HiFi registers. Conceptually, it can be sub-divided into two sub-modes–eager mode and lazy mode. They will both save and restore the HiFi registers, but they differ in when the registers are saved and restored, as well as to where they are saved and from where they are restored.

In the eager sharing model, the HiFi registers are saved and restored during every thread context switch, regardless of whether the thread used them or not. Additional stack space may be required for each thread to account for the extra registers that must be saved. This is default of the two models.

In the lazy sharing model, the kernel tracks the thread that 'owns' the coprocessor. If the 'owning' thread is switched out, the HiFi registers will not be saved until a new thread attempts to use the HiFi, after which that new thread becomes the new owner and its HiFi registers are loaded.

Note

If an SMP system detects that the owner-to-be is still an owner on another CPU, an IPI will be sent to that CPU to initiate the saving of its HiFi registers to memory. The current processor will then spin until the HiFi registers are saved. This spinning may result in sporadically longer delays. For the best performance, it is recommended that a thread using HiFi be pinned to a single CPU.

Configuration Options The unshared HiFi registers mode is selected when configuration option `CONFIG_XTENSA_HIFI_SHARING` is disabled but configuration options `CONFIG_XTENSA_HIFI3` and/or `CONFIG_XTENSA_HIFI4` are enabled.

The shared HiFi registers mode is selected when the configuration option `CONFIG_XTENSA_HIFI_SHARING` is enabled in addition to configuration options `CONFIG_XTENSA_HIFI3` and/or `CONFIG_XTENSA_HIFI4`. Threads must have sufficient stack space for saving the HiFi register values during context switches as described above.

Both eager and lazy HiFi sharing modes require the configuration option CONFIG_XTENSA_HIFI_SHARING to be enabled. Although eager HiFi sharing is the default, it can be explicitly selected by enabling the configuration option CONFIG_XTENSA_EAGER_HIFI_SHARING. To select lazy HiFi sharing instead, enable the configuration option CONFIG_XTENSA_LAZY_HIFI_SHARING.

6.2 Barriers API

Barrier Services APIs

6.3 Caching

6.3.1 Cache Control Configuration

This is a high-level guide to Zephyr's cache interface and Kconfig options related to cache controllers. See *Cache API* for API reference material.

Zephyr has different Kconfig options to control how the cache controller is implemented and controlled.

- CONFIG_CPU_HAS_DCACHE / CONFIG_CPU_HAS_ICACHE: these hidden options should be selected at SoC / platform level when the CPU actually supports a data or instruction cache. The cache controller can be in the core or can be an external cache controller for which a driver is provided.

  These options have the goal to document an available hardware feature and should be set whether we plan to support and use the cache control in Zephyr or not.

- CONFIG_DCACHE / CONFIG_ICACHE: these options must be selected when support for data or instruction cache is present and working in zephyr. Note that if these options are disabled, caching may still be enabled depending on the hardware defaults.

  All the code paths related to cache control must be conditionally enabled depending on these symbols. When the symbol is set the cache is considered enabled and used.

  These symbols say nothing about the actual API interface exposed to the user. For example a platform using the data cache can enable the CONFIG_DCACHE symbol and use some HAL exported function in some platform-specific code to enable and manage the d-cache.

- CONFIG_CACHE_MANAGEMENT: this option must be selected when the cache operations are exposed to the user through a standard API (see *Cache API*).

  When this option is enabled we assume that all the cache functions are implemented in the architectural code or in an external cache controller driver.

- CONFIG_MEM_ATTR: this option allows the user to specify (using *memory region attributes*) a fixed region in memory that will have caching disabled once the kernel has initialized.

- CONFIG_NOCACHE_MEMORY: this option allows the user to specify individual global variables as uncached using __nocache. This will instruct the linker to place any marked variables into a special nocache region in memory and the MPU driver will configure that region as uncached.

- CONFIG_ARCH_CACHE/CONFIG_EXTERNAL_CACHE: mutually exclusive options for CACHE_TYPE used to define whether the cache operations are implemented at arch level or using an external cache controller with a provided driver.

  - CONFIG_ARCH_CACHE: the cache API is implemented by the arch code
  - CONFIG_EXTERNAL_CACHE: the cache API is implemented by a driver that supports the external cache controller. In this case the driver must be located as usual in the drivers/cache/ directory

Cache API

Cache Interface

6.3.2 Caching Basics

This section discusses the basics of cache coherency and under what situations a user needs to explicitly deal with caching. For more detailed info on Zephyr's caching tools, see *Cache Control Configuration* for Zephyr Kconfig options or *Cache API* for the API reference. This section primarily focuses on the data cache though there is typically also an instruction cache for systems with cache support.

Note

The information here assumes that the architecture-specific MPU support is enabled. See the architecture-specific documentation for details.

Note

While cache coherence can be a concern for data shared between SMP cores, Zephyr in general ensures that memory will be seen in a coherent state from multiple cores. Most applications will only need to use the cache APIs for interaction with external hardware like DMA controllers or foreign CPUs running a different OS image. For more information on cache coherence between SMP cores, see `CONFIG_KERNEL_COHERENCE`.

When dealing with memory shared between a processor core and other bus masters, cache coherency needs to be considered. Typically processor caches exist as close to each processor core as possible to maximize performance gain. Because of this, data moved into and out of memory by DMA engines will be stale in the processor's cache, resulting in what appears to be corrupt data. If you are moving data using DMA and the processor doesn't see the data you expect, cache coherency may be the issue.

There are multiple approaches to ensuring that the data seen by the processor core and peripherals is coherent. The simplest is just to disable caching, but this defeats the purpose of having a hardware cache in the first place and results in a significant performance hit. Many architectures provide methods for disabling caching for only a portion of memory. This can be useful when cache coherence is more important than performance, such as when using DMA with SPI. Finally, there is the option to flush or invalidate the cache for regions of memory at runtime.

Globally Disabling the Data Cache

As mentioned above, globally disabling data caching can have a significant performance impact but can be useful for debugging.

Requirements:

- `CONFIG_DCACHE`: DCACHE control enabled in Zephyr.
- `CONFIG_CACHE_MANAGEMENT`: cache API enabled.
- Call `sys_cache_data_disable()` to globally disable the data cache.

Disabling Caching for a Memory Region

Disabling caching for only a portion of memory can be a good performance compromise if performance on the uncached memory is not critical to the application. This is a good option if the application requires many small unrelated buffers that are smaller than a cache line.

Requirements:

- CONFIG_DCACHE: DCACHE control enabled in Zephyr.
- CONFIG_MEM_ATTR: enable the mem-attr library for handling memory attributes in the device tree.
- Annotate your device tree according to *Memory Attributes*.

Assuming the MPU driver is enabled, it will configure the specified regions according to the memory attributes specified during kernel initialization. When using a dedicated uncached region of memory, the linker needs to be instructed to place buffers into that region. This can be accomplished by specifying the memory region explicitly using Z_GENERIC_SECTION:

```
/* SRAM4 marked as uncached in device tree */
uint8_t buffer[BUF_SIZE] Z_GENERIC_SECTION("SRAM4");
```

Note

Configuring a distinct memory region with separate caching rules requires the use of an MPU region which may be a limited resource on some architectures. MPU regions may be needed by other memory protection features such as *userspace*, *stack protection*, or *memory domains*.

Automatically Disabling Caching by Variable

Zephyr has the ability to automatically define an uncached region in memory and allocate variables to it using __nocache. Any variables marked with this attribute will be placed in a special nocache linker region in memory. This region will be configured as uncached by the MPU driver during initialization. This is a simpler option than explicitly declaring a region of memory uncached but provides less control over the placement of these variables, as the linker may allocate this region anywhere in RAM.

Requirements:

- CONFIG_DCACHE: DCACHE control enabled in Zephyr.
- CONFIG_NOCACHE_MEMORY: enable allocation of the nocache linker region and configure it as uncached.
- Add the __nocache attribute at the end of any uncached buffer definition:

```
uint8_t buffer[BUF_SIZE] __nocache;
```

Note

See note above regarding possible limitations on MPU regions. The nocache region is still a distinct MPU region even though it is automatically created by Zephyr instead of being explicitly defined by the user.

Runtime Cache Control

The most performant but most complex option is to control data caching at runtime. The two most relevant cache operations in this case are **flushing** and **invalidating**. Both of these operations operate on the smallest unit of cacheable memory, the cache line. Data cache lines are typically 16 to 128 bytes. See CONFIG_DCACHE_LINE_SIZE. Cache line sizes are typically fixed in hardware and not configurable, but Zephyr does need to know the size of cache lines in order to correctly and efficiently manage the cache. If the buffers in question are smaller than the data cache line size, it may be more efficient to place them in an uncached region, as unrelated data packed into the same cache line may be destroyed when invalidating.

Flushing the cache involves writing all modified cache lines in a specified region back to shared memory. Flush the cache associated with a buffer after the processor has written to it and before a remote bus master reads from that region.

> **Note**
>
> Some architectures support a cache configuration called **write-through** caching in which data writes from the processor core propagate through to shared memory. While this solves the cache coherence problem for CPU writes, it also results in more traffic to main memory which may result in performance degradation.

Invalidating the cache works similarly but in the other direction. It marks cache lines in the specified region as stale, ensuring that the cache line will be refreshed from main memory when the processor next reads from the specified region. Invalidate the data cache of a buffer that a peripheral has written to before reading from that region.

In some cases, the same buffer may be reused for e.g. DMA reads and DMA writes. In that case it is possible to first flush the cache associated with a buffer and then invalidate it, ensuring that the cache will be refreshed the next time the processor reads from the buffer.

Requirements:

- `CONFIG_DCACHE`: DCACHE control enabled in Zephyr.
- `CONFIG_CACHE_MANAGEMENT`: cache API enabled.
- Call `sys_cache_data_flush_range()` to flush a memory region.
- Call `sys_cache_data_invd_range()` to invalidate a memory region.
- Call `sys_cache_data_flush_and_invd_range()` to flush and invalidate.

Alignment

As mentioned in `sys_cache_data_invd_range()` and associated functions, buffers should be aligned to the cache line size. This can be accomplished by using `__aligned`:

```
uint8_t buffer[BUF_SIZE] __aligned(CONFIG_DCACHE_LINE_SIZE);
```

6.4 Zephyr's device emulators/simulators

6.4.1 Overview

Zephyr includes in its codebase a set of device emulators/simulators. With this we refer to SW components which are built together with the embedded SW and present themselves as devices of a given class to the rest of the system.

These device emulators/simulators can be built for any target which has sufficient RAM and flash, even if some may have extra functionality which is only available in some targets.

> **Note**
>
> Zephyr also includes and uses many other types of simulators/emulators, including CPU and platform simulators, radio simulators, and several build targets which allow running the embedded code in the development host.
> Some of Zephyr communication controllers/drivers include also either loopback modes or loopback devices.

This page does not cover any of these.

Note

Drivers which are specific to some platform, like for example the native_sim specific drivers which emulate a peripheral class by connecting to host APIs are not covered by this page.

6.4.2 Available Emulators

ADC emulator

- A fake driver which pretends to be actual ADC, and can be used for testing higher-level API for ADC devices.
- Main Kconfig option: `CONFIG_ADC_EMUL`
- DT binding: `zephyr,adc-emul`

DMA emulator

- Emulated DMA controller
- Main Kconfig option: `CONFIG_DMA_EMUL`
- DT binding: `zephyr,dma-emul`

EEPROM emulator

- Emulate an EEPROM on a flash partition
- Main Kconfig option: `CONFIG_EEPROM_EMULATOR`
- DT binding: `zephyr,emu-eeprom`

EEPROM simulator

- Emulate an EEPROM on RAM
- Main Kconfig option: `CONFIG_EEPROM_SIMULATOR`
- DT binding: `zephyr,sim-eeprom`
- Note: For native targets it is also possible to keep the content as a file on the host filesystem.

External bus and bus connected peripheral emulators

- *Documentation*
- Allow emulating external buses like I2C or SPI and peripherals connected to them.

Flash simulator

- Emulate a flash on RAM
- Main Kconfig option: `CONFIG_FLASH_SIMULATOR`
- DT binding: `zephyr,sim-flash`
- Note: For native targets it is also possible to keep the content as a file on the host filesystem. Check the native_sim flash simulator section.

GPIO emulator

- Emulated GPIO controllers which can be driven from SW
- Main Kconfig option: `CONFIG_GPIO_EMUL`
- DT binding: `zephyr,gpio-emul`

I2C emulator

- Emulated I2C bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_I2C_EMUL`
- DT binding: `zephyr,i2c-emul-controller`

RTC emulator

- Emulated RTC peripheral. See *RTC emulated device section*
- Main Kconfig option: `CONFIG_RTC_EMUL`
- DT binding: `zephyr,rtc-emul`

SPI emulator

- Emulated SPI bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_SPI_EMUL`
- DT binding: `zephyr,spi-emul-controller`

MSPI emulator

- Emulated MSPI bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_MSPI_EMUL`
- DT binding: `zephyr,mspi-emul-controller`

UART emulator

- Emulated UART bus. See *bus emulators*.
- Main Kconfig option: `CONFIG_UART_EMUL`
- DT binding: `zephyr,uart-emul`

6.5 External Bus and Bus Connected Peripherals Emulators

6.5.1 Overview

Zephyr supports a simple emulator framework to support testing of external peripheral drivers without requiring real hardware.

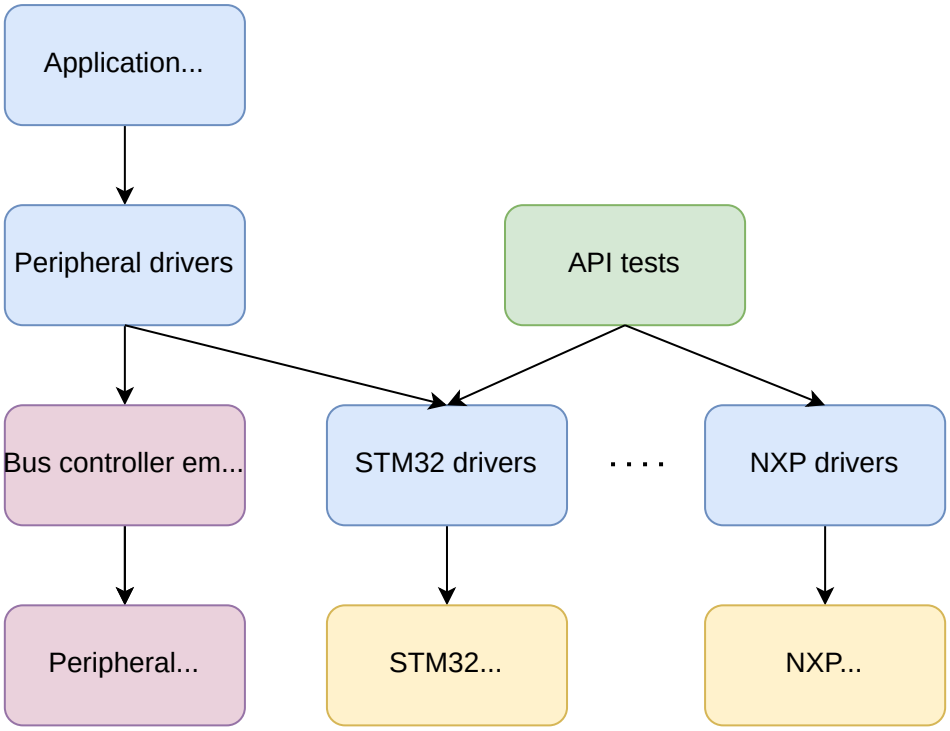
Emulators are used to emulate external hardware devices, to support testing of various subsystems. For example, it is possible to write an emulator for an I2C compass such that it appears on the I2C bus and can be used just like a real hardware device.

Emulators often implement special features for testing. For example a compass may support returning bogus data if the I2C bus speed is too high, or may return invalid measurements if calibration has not yet been completed. This allows for testing that high-level code can handle these situations correctly. Test coverage can therefore approach 100% if all failure conditions are emulated.

6.5.2 Concept

The diagram below shows application code / high-level tests at the top. This is the ultimate application we want to run.

Below that are peripheral drivers, such as the AT24 EEPROM driver. We can test peripheral drivers using a peripheral emulator connected via a bus controller emulator which passes e.g. I2C traffic from the AT24 driver (peripheral driver) to the AT24 simulator (the peripheral emulator).



Separately we can test the STM32 and NXP I2C drivers on real hardware using API tests. These require some sort of peripheral device attached to the bus, but with this, we can validate much of the driver functionality.

Putting the two together, we can test the application and peripheral code entirely on native_sim. Since we know that the I2C driver on the real hardware works, we should expect the application and peripheral drivers to work on the real hardware also.

Using the above framework we can test an entire application (e.g. Embedded Controller) on native_sim using emulators for all non-chip drivers.

With this approach we can:

- Write individual tests for each driver (green), covering all failure modes, error conditions, etc.
- Ensure 100% test coverage for drivers (green)
- Write tests for combinations of drivers, such as GPIOs provided by an I2C GPIO expander driver talking over an I2C bus, with the GPIOs controlling a charger. All of this can work in the emulated environment or on real hardware.
- Write a complex application that ties together all of these pieces and runs on native_sim. We can develop on a host, use source-level debugging, etc.
- Transfer the application to any board which provides the required features (e.g. I2C, enough GPIOs), by adding Kconfig and devicetree fragments.

6.5.3 Creating a Device Driver Emulator

The emulator subsystem is modeled on the *Device Driver Model*. You create an emulator instance using one of the `EMUL_DT_DEFINE()` or `EMUL_DT_INST_DEFINE()` APIs.

Emulators for peripheral devices reuse the same devicetree node as the real device driver. This means that your emulator defines `DT_DRV_COMPAT` using the same `compat` value from the real driver.

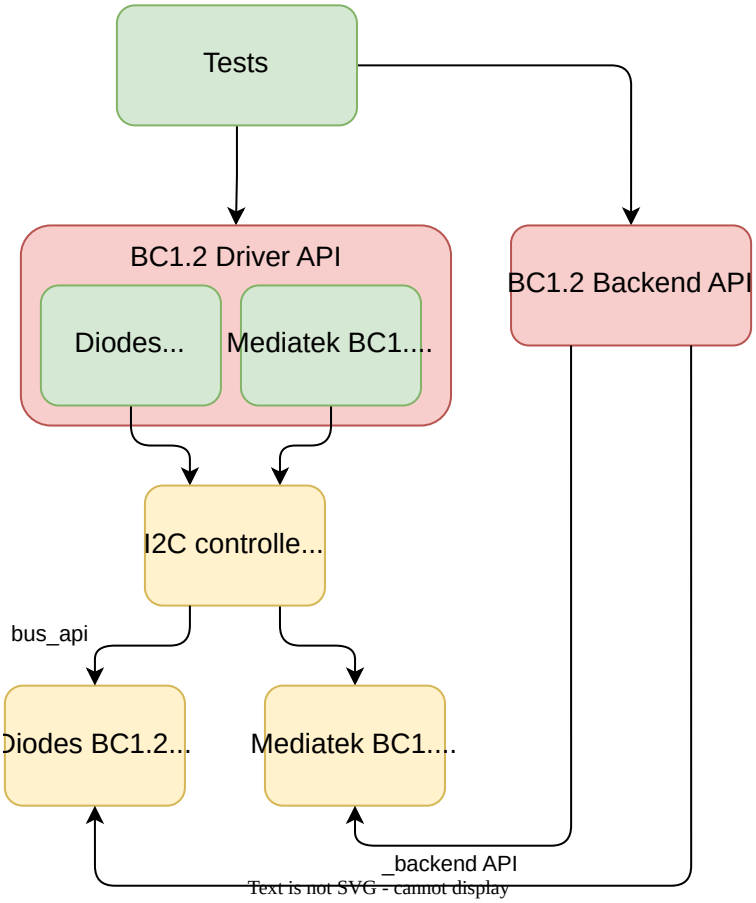
```
/* From drivers/sensor/bm160/bm160.c */
#define DT_DRV_COMPAT bosch_bmi160

/* From drivers/sensor/bmi160/emul_bmi160.c */
#define DT_DRV_COMPAT bosch_bmi160
```

The `EMUL_DT_DEFINE()` function accepts two API types:

1. `bus_api` - This points to the API for the upstream bus that the emulator connects to. The `bus_api` parameter is required. The supported emulated bus types include I2C, SPI, eSPI, and MSPI.
2. `_backend_api` - This points to the device-class specific backend API for the emulator. The `_backend_api` parameter is optional.

The diagram below demonstrates the logical organization of the `bus_api` and `_backend_api` using the BC1.2 charging detector driver as the model device-class.



The real code is shown in green, while the emulator code is shown in yellow.

The `bus_api` connects the BC1.2 emulators to the `native_sim` I2C controller. The real BC1.2 drivers are unchanged and operate exactly as if there was a physical I2C controller present in the system. The `native_sim` I2C controller uses the `bus_api` to initiate register reads and writes to the emulator.

The `_backend_api` provides a mechanism for tests to manipulate the emulator out of band. Each device class defines it's own API functions. The backend API functions focus on high-level behavior and do not provide hooks for specific emulators.

In the case of the BC1.2 charging detector the backend API provides functions to simulate connecting and disconnecting a charger to the emulated BC1.2 device. Each emulator is responsible for updating the correct vendor specific registers and potentially signalling an interrupt.

Example test flow:

1. Test registers BC1.2 detection callback using the Zephyr BC1.2 driver API.
2. Test connects a charger using the BC1.2 emulator backend.
3. Test verifies B1.2 detection callback invoked with correct charger type.
4. Test disconnects a charger using the BC1.2 emulator backend.

With this architecture, the same test can be used will all supported drivers in the same driver class.

6.5.4 Available Emulators

Zephyr includes the following emulators:

- I2C emulator driver, allowing drivers to be connected to an emulator so that tests can be performed without access to the real hardware
- SPI emulator driver, which does the same for SPI
- eSPI emulator driver, which does the same for eSPI. The emulator is being developed to support more functionalities.
- MSPI emulator driver, allowing drivers to be connected to an emulator so that tests can be performed without access to the real hardware.

I2C Emulation features

In the binding of the I2C emulated bus, there's a custom property for address based forwarding. Given the following devicetree node:

```
i2c0: i2c@100 {
  status = "okay";
  compatible = "zephyr,i2c-emul-controller";
  clock-frequency = <I2C_BITRATE_STANDARD>;
  #address-cells = <1>;
  #size-cells = <0>;
  #forward-cells = <1>;
  reg = <0x100 4>;
  forwards = <&i2c1 0x20>;
};
```

The final property, `forwards` indicates that any read/write requests sent to address `0x20` should be sent to `i2c1` with the same address. This allows us to test both the controller and the target end of the communication on the same image.

Note

The `#forward-cells` attribute should always be 1. Each entry in the `forwards` attribute consists of the phandle followed by the address. In the example above, `<&i2c1 0x20>` will forward all read/write operations made to `i2c0` at port `0x20` to `i2c1` on the same port. Since no additional cells are used by the emulated controller, the number of cells should remain 1.

6.5.5 Samples

Here are some examples present in Zephyr:

1. Bosch BMI160 sensor driver connected via both I2C and SPI to an emulator:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/sensor/bmi160
```

2. The same test can be built with a second EEPROM which is an Atmel AT24 EEPROM driver connected via I2C an emulator:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/eeprom/api -- -
↪DDTC_OVERLAY_FILE=at2x_emul.overlay -DEXTRA_CONF_FILE=at2x_emul.conf
```

6.5.6 API Reference

Emulator interfaces

6.6 Firmware

6.6.1 Overview

This class of drivers provides support for interacting with various service-providing (e.g. clock management, power management, pinctrl, etc.) firmware. The list of firmware currently supported by Zephyr is summarized below:

Name	Vendor	Description	Documentation
SCMI	ARM	System Control and Management Interface	Link
TISCI	TI	TI System Controller Interface	Link
QEMU FWCFG	QEMU	QEMU Firmware Configuration	Link
RPI FIRMWARE	Raspberry Pi	Raspberry Pi VideoCore Firmware Interface	Link

6.6.2 API Reference

Usually, the firmware drivers are meant to provide functionality to other classes of drivers. Furthermore, the purpose and functionality may differ from one firmware to another. Consequently, this class of drivers doesn't implement a standard API meant to be used by the end user.

6.6.3 Samples

See firmware.

6.6.4 Resources

ARM System Control and Management Interface

Overview System Control and Management Interface (SCMI) is a specification developed by ARM, which describes a set of OS-agnostic software interfaces used to perform system management (e.g: clock control, pinctrl, etc...). In this context, Zephyr acts as an SCMI agent.

> **Note**
>
> The Zephyr implementation may only include a subset of the features or functionalities mentioned throughout this document.

Standard protocols The set of supported **standard**[1] protocols is summarized below:

ID	Name	Supported version
0x10	Base protocol	2.1
0x11	Power domain management protocol	3.1
0x12	System power management protocol	2.1
0x14	Clock management protocol	3.0
0x19	Pin Control protocol	1.0

Transports The set of supported transports is summarized below:

Name	Description	Compatible
MBOX	Shared memory with mailbox-based doorbell	`arm,scmi`
SMC	Shared memory with SMC-based doorbell	`arm,scmi-smc`

Vendor extensions The SCMI specification allows vendors to introduce additional protocols and provides a degree of freedom with respect to how the platform firmware can behave in certain situations. In the context of this documentation, these are collectively known as **vendor extensions**.

NXP NXP provides an SCMI-compliant platform firmware known as **System Manager (SM)**. You may find its documentation here.

The set of supported NXP-specific protocols is summarized below:

ID	Name	Supported version
0x82	CPU	1.0

The set of supported NXP-specific quirks is summarized below:

1. Depending on how the platform firmware is configured, the shared memory may contain a message CRC field that's checked by the firmware on each received message. See `CONFIG_ARM_SCMI_NXP_VENDOR_EXTENSIONS`.

6.7 Peripherals

Zephyr supports a wide range of hardware peripherals through a set of device driver APIs. They are grouped into the categories below; each card lists the peripherals in that category, or follow the category title for more detail.

Analog

6.7.1 Analog

Analog-to-digital and digital-to-analog converters, comparators, and amplifiers.

Analog-to-Digital Converter (ADC)

Overview

[1] Meaning protocols covered by the SCMI specification.

API Reference

Configuration Options Related configuration options:

- `CONFIG_DAC`

API Reference

DAC

Related code samples

- Digital-to-Analog Converter (DAC)Generate an analog sawtooth signal using the DAC driver API.

Comparator

Overview An analog comparator compares the voltages of two analog signals connected to its negative and positive inputs. If the voltage at the positive input is higher than the negative input, the comparator's output will be high, otherwise, it will be low.

Comparators can typically set a trigger which triggers on output changes. This trigger can either invoke a callback, or its status can be polled.

Related configuration options:

- `CONFIG_COMPARATOR`

Configuration Embedded comparators can typically be configured at runtime. When enabled, an initial configuration must be provided using the devicetree. At runtime, comparators can have their configuration updated using device driver specific APIs. The configuration will be applied when the comparator is resumed.

Power management Comparators are enabled using power management. When resumed, the comparator will actively compare its inputs, producing an output and detecting edges. When suspended, the comparator will be inactive.

Comparator shell The comparator shell provides the `comp` command with a set of subcommands for the *shell* module.

The `comp` shell command provides the following subcommands:

- `get_output` See `comparator_get_output()`
- `set_trigger` See `comparator_set_trigger()`
- `await_trigger` Awaits trigger using the following flow:
  - Set trigger callback using `comparator_set_trigger_callback()`
  - Await callback or time out after default or optionally provided timeout
  - Clear trigger callback using `comparator_set_trigger_callback()`
- `trigger_is_pending` See `comparator_trigger_is_pending()`

Operational Amplifier (OPAMP)

Overview The operational amplifier is an analog device that amplifies differential input signals (difference between inverting and non-inverting input) to give a resulting output voltage.

Configuration When OPAMP is enabled, an initial configuration shall be provided using the devicetree. The OPAMP gain can be adjusted at runtime.

Related configuration options:

- `CONFIG_OPAMP`

Audio

6.7.2 Audio

Audio Codec

Overview The Audio Codec API provides access to digital audio codecs.

Configuration Options Related configuration options:

- `CONFIG_AUDIO_CODEC`

API Reference
Audio Codec Interface

Digital Microphone (DMIC)

Overview The audio DMIC interface provides access to digital microphones.

Digital microphones typically output a PDM (Pulse Density Modulation) bit stream instead of analog audio. PDM uses a 1-bit, high-rate signal in which audio amplitude is represented by the density of 1s and 0s over time.

Because applications usually consume PCM (Pulse Code Modulation) samples rather than raw PDM data, a DMIC controller converts the microphone stream into PCM audio. This conversion includes filtering and decimation: filtering removes the high-frequency noise shaped into the PDM stream, and decimation reduces the bit-stream rate to the desired PCM sample rate.

From a Zephyr point of view, a DMIC device is an audio capture peripheral. The application configures the microphone and controller, starts capture, and reads PCM buffers from the driver.

Key concepts The DMIC API separates configuration into three pieces that mirror the capture path:

1. How the microphone is driven on the PDM side,
2. How incoming PDM channels are arranged, and
3. How converted PCM samples are delivered to the application.

These pieces are combined in `dmic_cfg` and passed to `dmic_configure()`.

PDM I/O configuration (`dmic_cfg.io`)
: This describes the electrical and timing requirements of the microphone interface, such as the supported PDM clock frequency range, duty cycle, and any controller-specific signal polarity settings.

Channel configuration (`dmic_cfg.channel`)
: This tells the driver which physical PDM controller and left or right microphone lane should appear as each logical audio channel in the PCM output. It also declares how many channels and streams the application wants to use.

PCM stream configuration (`dmic_cfg.streams`)
: This defines the PCM data delivered by the driver, including sample rate, sample width, block size, and the `k_mem_slab` used to allocate receive buffers for each enabled stream.

Typical application flow Typical use of the DMIC API is:

1. Get the DMIC device, usually from devicetree.
2. Fill a `dmic_cfg` structure with I/O, channel, and stream settings. See the *Buffering* section below for more details on how to define the memory buffer the DMIC uses to store received PCM data.
3. Call `dmic_configure()`, passing the configuration structure.
4. Start capture with `dmic_trigger()` using `DMIC_TRIGGER_START`.
5. Fetch PCM data with `dmic_read()`.
6. Stop, pause, or reset capture with additional trigger commands as needed.

Buffering Received PCM data is returned through buffers owned by the driver. Applications provide the backing memory through a `k_mem_slab` referenced by each configured PCM stream.

A common pattern is to declare this slab statically:

Listing 1: Declaring a memory slab statically for PCM receive buffers

```
K_MEM_SLAB_DEFINE_STATIC(mem_slab,
                         SAMPLES_PER_BUFFER * sizeof(int16_t),
                         BUFFER_COUNT,
                         sizeof(void *));
```

In this example, each slab block stores one PCM buffer and `BUFFER_COUNT` sets how many buffers can be queued internally before the application reads them using `dmic_read()`.

Shell commands When `CONFIG_AUDIO_DMIC_SHELL` is enabled, a set of `dmic` commands is available. They allow capturing audio from a DMIC device interactively without having to write a dedicated application.

Each subcommand takes the DMIC device name as its first argument, optionally followed by the audio capture parameters (sample rate, number of channels, and PCM sample width).

The following subcommands are available:

`dmic read <device> [<count> [<rate_hz> [<channels> [<pcm_width>]]]]`
: Capture `count` audio blocks and print the peak level per channel. The default `count` is 5; each block is 50 ms of audio.

`dmic vu <device> [<rate_hz> [<channels> [<pcm_width>]]]`
: Display a live, color-coded level meter with peak-hold and clip indication, one bar per channel. Runs until any key is pressed.

`dmic dump <device> [<seconds> [<rate_hz> [<channels> [<pcm_width>]]]]`
: Capture `seconds` of audio and print it as base64-encoded raw PCM, together with the host commands needed to decode and play it back. The default duration is 2 seconds.

The built-in help (e.g. `dmic read --help`) lists the arguments and their defaults.

Inter-IC Sound (I2S) Bus

Overview The I2S (Inter-IC Sound) API provides support for the standard I2S interface as well as common non-standard extensions such as PCM Short/Long Frame Sync and Left/Right Justified Data Formats.

Shell When `CONFIG_I2S_SHELL` is enabled, an `i2s` shell command is available to stream a generated sine test tone over any I2S controller without writing application code. It is transport only; pair it with the `codec` shell to route the audio through a codec.

The tone commands are grouped under `i2s tone`:

- `i2s tone start <device> [frequency_hz] [sample_rate] [bits]` starts a stereo test tone on the given I2S device. `frequency_hz` defaults to 440 Hz, `sample_rate` defaults to 48000 Hz, and `bits` defaults to 16 (valid values are 16, 24 and 32).
- `i2s tone stop` stops the running tone.
- `i2s tone info` shows the current tone stream status.

For example, to stream a 1 kHz, 48 kHz, 16-bit tone:

```
uart:~$ i2s tone start i2s@0 1000 48000 16
Streaming 1000 Hz tone on i2s@0 @ 48000 Hz, 16-bit stereo
uart:~$ i2s tone info
state    : streaming
i2s dev  : i2s@0
tone     : 1000 Hz
rate     : 48000 Hz
format   : 16-bit stereo, 64-frame blocks x 8
uart:~$ i2s tone stop
Stopped
```

The TX buffering used by the shell is controlled by `CONFIG_I2S_SHELL_BLOCK_FRAMES` and `CONFIG_I2S_SHELL_BLOCK_COUNT`.

6.7.3 Communication

Serial buses (I2C, SPI, UART, CAN) and other communication interfaces.

Controller Area Network (CAN)

CAN Controller

- *Overview*
- *Sending*
- *Receiving*
- *Setting the bitrate*
- *SocketCAN*
- *Samples*
- *CAN Controller API Reference*

Overview Controller Area Network is a two-wire serial bus specified by the Bosch CAN Specification, Bosch CAN with Flexible Data-Rate specification and the ISO 11898-1:2003 standard. CAN is mostly known for its application in the automotive domain. However, it is also used in home and industrial automation and other products.

Warning

CAN controllers can only initialize when the bus is in the idle (recessive) state for at least 11 recessive bits. Therefore you have to make sure that CAN RX is high, at least for a short time. This is also necessary for loopback mode.

The bit-timing as defined in ISO 11898-1:2003 looks as following:

Figure 2: CAN Timing. ©Alexander Wachter

A single bit is split into four segments.

- Sync_Seg: The nodes synchronize at the edge of the Sync_Seg. It is always one time quantum in length.
- Prop_Seg: The signal propagation delay of the bus and other delays of the transceiver and node.
- Phase_Seg1 and Phase_Seg2 :Define the sampling point. The bit is sampled at the end of Phase_Seg1.

The bit-rate is calculated from the time of a time quantum and the values defined above. A bit has the length of Sync_Seg plus Prop_Seg plus Phase_Seg1 plus Phase_Seg2 multiplied by the time of single time quantum. The bit-rate is the inverse of the length of a single bit.

A bit is sampled at the sampling point. The sample point is between Phase_Seg1 and PhaseSeg2 and therefore is a parameter that the user needs to choose. The CiA recommends setting the sample point to 87.5% of the bit.

The resynchronization jump width (SJW) defines the amount of time quantum the sample point can be moved. The sample point is moved when resynchronization is needed.

The timing parameters (SJW, bitrate and sampling point, or bitrate, Prop_Seg, Phase_Seg1and Phase_Seg2) are initially set from the device-tree and can be changed at run-time from the timing-API.

CAN uses so-called identifiers to identify the frame instead of addresses to identify a node. This identifier can either have 11-bit width (Standard or Basic Frame) or 29-bit in case of an Extended Frame. The Zephyr CAN API supports both Standard and Extended identifiers concurrently. A CAN frame starts with a dominant Start Of Frame bit. After that, the identifiers follow. This phase is called the arbitration phase. During the arbitration phase, write collisions are allowed. They resolve by the fact that dominant bits override recessive bits. Nodes monitor the bus and notice when their transmission is being overridden and in case, abort their transmission. This effectively gives lower number identifiers priority over higher number identifiers.

Filters are used to allowlist identifiers that are of interest for the specific node. An identifier that doesn't match any filter is ignored. Filters can either match exactly or a specified part of the identifier. This method is called masking. As an example, a mask with 11 bits set for standard or 29 bits set for extended identifiers must match perfectly. Bits that are set to zero in the mask are ignored when matching an identifier. Most CAN controllers implement a limited number of filters in hardware. The number of filters is also limited in Kconfig to save memory.

Errors may occur during transmission. In case a node detects an erroneous frame, it partially overrides the current frame with an error-frame. Error-frames can either be error passive or error active, depending on the state of the controller. In case the controller is in error active state, it sends six consecutive dominant bits, which is a violation of the stuffing rule that all nodes can detect. The sender may resend the frame right after.

An initialized node can be in one of the following states:

- Error-active
- Error-passive
- Bus-off

After initialization, the node is in the error-active state. In this state, the node is allowed to send active error frames, ACK, and overload frames. Every node has a receive- and transmit-error counter. If either the receive- or the transmit-error counter exceeds 127, the node changes to error-passive state. In this state, the node is not allowed to send error-active frames anymore. If the transmit-error counter increases further to 255, the node changes to the bus-off state. In

this state, the node is not allowed to send any dominant bits to the bus. Nodes in the bus-off state may recover after receiving 128 occurrences of 11 concurrent recessive bits.

You can read more about CAN bus in this CAN Wikipedia article.

Zephyr supports following CAN features:

- Standard and Extended Identifiers
- Filters with Masking
- Loopback and Silent mode
- Remote Request

Sending The following code snippets show how to send data.

This basic sample sends a CAN frame with standard identifier 0x123 and eight bytes of data. When passing NULL as the callback, as shown in this example, the send function blocks until the frame is sent and acknowledged by at least one other node or an error occurred. The timeout only takes effect on acquiring a mailbox. When a transmitting mailbox is assigned, sending cannot be canceled.

```
struct can_frame frame = {
        .flags = 0,
        .id = 0x123,
        .dlc = 8,
        .data = {1,2,3,4,5,6,7,8}
};
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));
int ret;

ret = can_send(can_dev, &frame, K_MSEC(100), NULL, NULL);
if (ret != 0) {
        LOG_ERR("Sending failed [%d]", ret);
}
```

This example shows how to send a frame with extended identifier 0x1234567 and two bytes of data. The provided callback is called when the message is sent, or an error occurred. Passing K_FOREVER to the timeout causes the function to block until a transfer mailbox is assigned to the frame or an error occurred. It does not block until the message is sent like the example above.

```
void tx_callback(const struct device *dev, int error, void *user_data)
{
        char *sender = (char *)user_data;

        if (error != 0) {
                LOG_ERR("Sending failed [%d]\nSender: %s\n", error, sender);
        }
}

int send_function(const struct device *can_dev)
{
        struct can_frame frame = {
                .flags = CAN_FRAME_IDE,
                .id = 0x1234567,
                .dlc = 2
        };

        frame.data[0] = 1;
        frame.data[1] = 2;
```

(continues on next page)

(continued from previous page)

```
        return can_send(can_dev, &frame, K_FOREVER, tx_callback, "Sender 1");
}
```

Receiving Frames are only received when they match a filter. The following code snippets show how to receive frames by adding filters.

Here we have an example for a receiving callback as used for `can_add_rx_filter()`. The user data argument is passed when the filter is added.

```
void rx_callback_function(const struct device *dev, struct can_frame *frame, void␣
↪*user_data)
{
        ... do something with the frame ...
}
```

The following snippet shows how to add a filter with a callback function. It is the most efficient but also the most critical way to receive messages. The callback function is called from an interrupt context, which means that the callback function should be as short as possible and must not block. Adding callback functions is not allowed from userspace context.

The filter for this example is configured to match the identifier 0x123 exactly.

```
const struct can_filter my_filter = {
        .flags = 0U,
        .id = 0x123,
        .mask = CAN_STD_ID_MASK
};
int filter_id;
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));

filter_id = can_add_rx_filter(can_dev, rx_callback_function, callback_arg, &
↪my_filter);
if (filter_id < 0) {
  LOG_ERR("Unable to add rx filter [%d]", filter_id);
}
```

Here an example for `can_add_rx_filter_msgq()` is shown. With this function, it is possible to receive frames synchronously. This function can be called from userspace context. The size of the message queue should be as big as the expected backlog.

The filter for this example is configured to match the extended identifier 0x1234567 exactly.

```
const struct can_filter my_filter = {
        .flags = CAN_FILTER_IDE,
        .id = 0x1234567,
        .mask = CAN_EXT_ID_MASK
};
CAN_MSGQ_DEFINE(my_can_msgq, 2);
struct can_frame rx_frame;
int filter_id;
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));

filter_id = can_add_rx_filter_msgq(can_dev, &my_can_msgq, &my_filter);
if (filter_id < 0) {
  LOG_ERR("Unable to add rx msgq [%d]", filter_id);
  return;
```

(continues on next page)

(continued from previous page)

```
}

while (true) {
  k_msgq_get(&my_can_msgq, &rx_frame, K_FOREVER);
  ... do something with the frame ...
}
```

`can_remove_rx_filter()` removes the given filter.

```
can_remove_rx_filter(can_dev, filter_id);
```

Setting the bitrate The bitrate and sampling point is initially set at runtime. To change it from the application, one can use the `can_set_timing()` API. The `can_calc_timing()` function can calculate timing from a bitrate and sampling point in permille. The following example sets the bitrate to 250k baud with the sampling point at 87.5%.

```
struct can_timing timing;
const struct device *const can_dev = DEVICE_DT_GET(DT_CHOSEN(zephyr_canbus));
int ret;

ret = can_calc_timing(can_dev, &timing, 250000, 875);
if (ret > 0) {
  LOG_INF("Sample-Point error: %d", ret);
}

if (ret < 0) {
  LOG_ERR("Failed to calc a valid timing");
  return;
}

ret = can_stop(can_dev);
if (ret != 0) {
  LOG_ERR("Failed to stop CAN controller");
}

ret = can_set_timing(can_dev, &timing);
if (ret != 0) {
  LOG_ERR("Failed to set timing");
}

ret = can_start(can_dev);
if (ret != 0) {
  LOG_ERR("Failed to start CAN controller");
}
```

A similar API exists for calculating and setting the timing for the data phase for CAN FD capable controllers. See `can_set_timing_data()` and `can_calc_timing_data()`.

SocketCAN Zephyr additionally supports SocketCAN, a BSD socket implementation of the Zephyr CAN API. SocketCAN brings the convenience of the well-known BSD Socket API to Controller Area Networks. It is compatible with the Linux SocketCAN implementation, where many other high-level CAN projects build on top. Note that frames are routed to the network stack instead of passed directly, which adds some computation and memory overhead.

Samples We have two ready-to-build samples demonstrating use of the Zephyr CAN API: Zephyr CAN counter sample and SocketCAN sample.

Fake CAN controller

CAN Transceiver

- *Overview*
- *CAN Transceiver API Reference*

Overview A CAN transceiver is an external device that converts the logic level signals from the CAN controller to the bus-levels. The bus lines are called CAN High (CAN H) and CAN Low (CAN L). The transmit wire from the controller to the transceiver is called CAN TX, and the receive wire is called CAN RX. These wires use the logic levels whereas the bus-level is interpreted differentially between CAN H and CAN L. The bus can be either in the recessive (logical one) or dominant (logical zero) state. The recessive state is when both lines, CAN H and CAN L, are roughly at the same voltage level. This state is also the idle state. To write a dominant bit to the bus, open-drain transistors tie CAN H to Vdd and CAN L to ground. The first and last node use a 120-ohm resistor between CAN H and CAN L to terminate the bus. The dominant state always overrides the recessive state. This structure is called a wired-AND.

CAN Shell

- *Overview*

- *Inspection*
- *Configuration*
- *Receiving*
- *Sending*
- *Bus Recovery*

Overview The CAN shell provides a `can` command with a set of subcommands for the *shell* module. It allows for testing and exploring the *CAN Controller* driver API through an interactive interface without having to write a dedicated application. The CAN shell can also be enabled in existing applications to aid in interactive debugging of CAN issues.

The CAN shell provides access to most CAN controller features, including inspection, configuration, sending and receiving of CAN frames, and bus recovery.

In order to enable the CAN shell, the following *Kconfig* options must be enabled:

- `CONFIG_SHELL`
- `CONFIG_CAN`
- `CONFIG_CAN_SHELL`

The following *Kconfig* options enable additional subcommands and features of the `can` command:

- `CONFIG_CAN_FD_MODE` enables CAN FD specific subcommands (e.g. for setting the timing for the CAN FD data phase).
- `CONFIG_CAN_RX_TIMESTAMP` enables printing of timestamps for received CAN frames.
- `CONFIG_CAN_STATS` enables printing of various statistics for the CAN controller in the `can show` subcommand. This depends on `CONFIG_STATS` being enabled as well.
- `CONFIG_CAN_MANUAL_RECOVERY_MODE` enables the `can recover` subcommand.

For example, building the hello_world sample for the frdm_k64f with the CAN shell and CAN statistics enabled:

```
# From the root of the zephyr repository
west build -b frdm_k64f samples/hello_world -- -DCONFIG_SHELL=y -DCONFIG_CAN=y -
↪DCONFIG_CAN_SHELL=y -DCONFIG_STATS=y -DCONFIG_CAN_STATS=y
```

See the *shell* documentation for general instructions on how to connect and interact with the shell. The CAN shell comes with built-in help (unless `CONFIG_SHELL_HELP` is disabled). The built-in help messages can be printed by passing `-h` or `--help` to the `can` command or any of its subcommands. All subcommands also support tab-completion of their arguments.

Tip

All of the CAN shell subcommands take the name of a CAN controller as their first argument, which also supports tab-completion. A list of all devices available can be obtained using the `device list` shell command when `CONFIG_DEVICE_SHELL` is enabled. The examples below all use the device name `can@0`.

Inspection The properties of a given CAN controller can be inspected using the `can show` subcommand as shown below. The properties include the core CAN clock rate, the maximum supported bitrate, the number of RX filters supported, capabilities, current mode, current state, error counters, timing limits, and more:

```
uart:~$ can show can@0
core clock:      144000000 Hz
max bitrate:     5000000 bps
max std filters: 15
max ext filters: 15
capabilities:    normal loopback listen-only fd
mode:            normal
state:           stopped
rx errors:       0
tx errors:       0
timing:          sjw 1..128, prop_seg 0..0, phase_seg1 2..256, phase_seg2 2..128,␣
↪prescaler 1..512
timing data:     sjw 1..16, prop_seg 0..0, phase_seg1 1..32, phase_seg2 1..16,␣
↪prescaler 1..32
transceiver:     passive/none
statistics:
  bit errors:    0
    bit0 errors: 0
    bit1 errors: 0
  stuff errors:  0
  crc errors:    0
  form errors:   0
  ack errors:    0
  rx overruns:   0
```

Note

The statistics are only printed if `CONFIG_CAN_STATS` is enabled.

Configuration The CAN shell allows for configuring the CAN controller mode and timing, along with starting and stopping the processing of CAN frames.

Note

The CAN controller mode and timing can only be changed while the CAN controller is stopped, which is the initial setting upon boot-up. The initial CAN controller mode is set to `normal` and the initial timing is set according to the `bitrate`, `sample-point`, `bitrate-data`, and `sample-point-data` *Devicetree* properties.

Timing The classic CAN bitrate/CAN FD arbitration phase bitrate can be configured using the `can bitrate` subcommand as shown below. The bitrate is specified in bits per second.

```
uart:~$ can bitrate can@0 125000
setting bitrate to 125000 bps
```

If `CONFIG_CAN_FD_MODE` is enabled, the data phase bitrate can be configured using the `can dbitrate` subcommand as shown below. The bitrate is specified in bits per second.

```
uart:~$ can dbitrate can@0 1000000
setting data bitrate to 1000000 bps
```

Both of these subcommands allow specifying an optional sample point in per mille and a (Re)Synchronization Jump Width (SJW) in Time Quanta as positional arguments. Refer to the interactive help of the subcommands for more details.

It is also possible to configure the raw bit timing using the `can timing` and `can dtiming` subcommands. Refer to the interactive help output for these subcommands for details on the required arguments.

Mode The CAN shell allows for setting the mode of the CAN controller using the `can mode` subcommand. An example for enabling loopback mode is shown below.

```
uart:~$ can mode can@0 loopback
setting mode 0x00000001
```

The subcommand accepts multiple modes given on the same command line (e.g. `can mode can@0 fd loopback` for setting CAN FD and loopback mode). Vendor-specific modes can be specified in hexadecimal.

Starting and Stopping After the timing and mode has been configured as needed, the CAN controller can be started using the `can start` subcommand as shown below. This will enable reception and transmission of CAN frames.

```
uart:~$ can start can@0
starting can@0
```

Prior to reconfiguring the timing or mode, the CAN controller needs to be stopped using the `can stop` subcommand as shown below:

```
uart:~$ can stop can@0
stopping can@0
```

Receiving In order to receive CAN frames, one or more CAN RX filters need to be configured. CAN RX filters are added using the `can filter add` subcommand as shown below. The subcommand accepts a CAN ID in hexadecimal format along with an optional CAN ID mask, also in hexadecimal format, for setting which bits in the CAN ID are to be matched. Refer to the interactive help output for this subcommand for further details on the supported arguments.

```
uart:~$ can filter add can@0 010
adding filter with standard (11-bit) CAN ID 0x010, CAN ID mask 0x7ff, data frames␣
↪1, RTR frames 0, CAN FD frames 0
filter ID: 0
```

The filter ID (0 in the example above) returned is to be used when removing the CAN RX filter.

Received CAN frames matching the added filter(s) are printed to the shell. A few examples are shown below:

```
# Dev Flags    ID   Size  Data bytes
can0  --       010   [8]  01 02 03 04 05 06 07 08
can0  B-       010  [08]  01 02 03 04 05 06 07 08
can0  BP       010  [03]  01 aa bb
can0  --  00000010   [0]
can0  --       010   [1]  20
can0  --       010   [8]  remote transmission request
```

The columns have the following meaning:

- Dev
  - Name of the device receiving the frame.
- Flags
  - `B`: The frame has the CAN FD Baud Rate Switch (BRS) flag set.

  - P: The frame has the CAN FD Error State Indicator (ESI) flag set. The transmitting node is in error-passive state.
  - -: Unset flag.
- ID
  - 010: The standard (11-bit) CAN ID of the frame in hexadecimal format, here 10h.
  - 00000010: The extended (29-bit) CAN ID of the frame in hexadecimal format, here 10h.
- Size
  - [8]: The number of frame data bytes in decimal format, here a classic CAN frame with 8 data bytes.
  - [08]: The number of frame data bytes in decimal format, here a CAN FD frame with 8 data bytes.
- Data bytes
  - 01 02 03 04 05 06 07 08: The frame data bytes in hexadecimal format, here the numbers from 1 through 8.
  - remote transmission request: The frame is a Remote Transmission Request (RTR) frame and thus carries no data bytes.

Tip

If CONFIG_CAN_RX_TIMESTAMP is enabled, each line will be prepended with a timestamp from the free-running timestamp counter in the CAN controller.

Configured CAN RX filters can be removed again using the can filter remove subcommand as shown below. The filter ID is the ID returned by the can filter add subcommand (0 in the example below).

```
uart:~$ can filter remove can@0 0
removing filter with ID 0
```

Another option is to use the can dump subcommand, which adds standard (11-bit) and extended (29-bit) CAN filters matching any RX frame, starts the CAN controller, and prints all received CAN frames to the shell:

```
uart:~$ can dump can@0
dumping CAN RX frames on device can@0, press Ctrl+C to exit
```

After exiting the can dump subcommand by pressing Ctrl+C, the added filters are automatically removed and the CAN controller stopped again.

Sending CAN frames can be queued for transmission using the can send subcommand as shown below. The subcommand accepts a CAN ID in hexadecimal format and optionally a number of data bytes, also specified in hexadecimal. Refer to the interactive help output for this subcommand for further details on the supported arguments.

```
uart:~$ can send can@0 010 1 2 3 4 5 6 7 8
enqueuing CAN frame #2 with standard (11-bit) CAN ID 0x010, RTR 0, CAN FD 0, BRS␣
↪0, DLC 8
CAN frame #2 successfully sent
```

Bus Recovery The can recover subcommand can be used for initiating manual recovery from a CAN bus-off event as shown below:

```
uart:~$ can recover can@0
recovering, no timeout
```

The subcommand accepts an optional bus recovery timeout in milliseconds. If no timeout is specified, the command will wait indefinitely for the bus recovery to succeed.

> **Note**
>
> The `recover` subcommand is only available if `CONFIG_CAN_MANUAL_RECOVERY_MODE` is enabled.

Inter-Integrated Circuit (I2C) Bus

> **Note**
>
> The terminology used in Zephyr I2C APIs follows that of the NXP I2C Bus Specification Rev 7.0. These changed from previous revisions as of its release October 1, 2021.

Overview I2C (Inter-Integrated Circuit, pronounced "eye squared see") is a commonly-used two-signal shared peripheral interface bus. Many system-on-chip solutions provide controllers that communicate on an I2C bus. Devices on the bus can operate in two roles: as a "controller" that initiates transactions and controls the clock, or as a "target" that responds to transaction commands. A I2C controller on a given SoC will generally support the controller role, and some will also support the target mode. Zephyr has API for both roles.

I2C Controller API Zephyr's I2C controller API is used when an I2C peripheral controls the bus, particularly the start and stop conditions and the clock. This is the most common mode, used to interact with I2C devices like sensors and serial memory.

This API is supported in all in-tree I2C peripheral drivers and is considered stable.

I2C Target API Zephyr's I2C target API is used when an I2C peripheral responds to transactions initiated by a different controller on the bus. It might be used for a Zephyr application with transducer roles that are controlled by another device such as a host processor.

This API is supported in very few in-tree I2C peripheral drivers. The API is considered experimental, as it is not compatible with the capabilities of all I2C peripherals supported in controller mode.

Configuration Options Related configuration options:

- `CONFIG_I2C`
- `CONFIG_I2C_TRANSFER_TIMEOUT_MS`

Transfer Timeout The I2C subsystem provides two complementary mechanisms to control how long a driver waits for a transfer to complete before returning `-ETIMEDOUT`.

Application-wide default (Kconfig) `CONFIG_I2C_TRANSFER_TIMEOUT_MS` sets the default timeout in milliseconds for all I2C controllers whose drivers opt in by selecting `I2C_TRANSFER_TIMEOUT_SUPPORTED`. A value of `0` means wait forever (`K_FOREVER`). Drivers that do not permit an infinite timeout (e.g. those that program the value directly into a hardware register) use `BUILD_ASSERT_INVALID_I2C_TRANSFER_TIMEOUT` to enforce a non-zero value at build time.

Per-controller DT override Individual controllers can override the application-wide default through the `zephyr,transfer-timeout-ms` devicetree property defined in `dts/bindings/i2c/i2c-controller.yaml`. When the property is absent the driver falls back to `CONFIG_I2C_TRANSFER_TIMEOUT_MS`.

Example board overlay:

```
&i2c1 {
    /* Fast sensor bus - fail quickly on a hung device */
    zephyr,transfer-timeout-ms = <50>;
};

&i2c2 {
    /* EEPROM bus - allow for long internal write cycles */
    zephyr,transfer-timeout-ms = <2000>;
};
```

Drivers that support per-instance timeouts use `I2C_DT_INST_TRANSFER_TIMEOUT` (or `I2C_DT_INST_TRANSFER_TIMEOUT_MS` for raw integer use) which resolve the timeout with the following priority:

1. `zephyr,transfer-timeout-ms` DT property on the controller node
2. `CONFIG_I2C_TRANSFER_TIMEOUT_MS`
3. `K_FOREVER` when the resolved value is `0`

Improved Inter-Integrated Circuit (I3C) Bus

I3C (Improved Inter-Integrated Circuit) is a two-signal shared peripheral interface bus. Devices on the bus can operate in two roles: as a “controller” that initiates transactions and controls the clock, or as a “target” that responds to transaction commands.

Currently, the API is based on I3C Specification version 1.1.1.

- *I3C Controller API*
  - *In-Band Interrupt (IBI)*
  - *Device Tree*
  - *Device Drivers for I3C Devices*
  - *I^2C Devices under I3C Bus*
- *Configuration Options*

- *API Reference*

I3C Controller API Zephyr's I3C controller API is used when an I3C controller controls the bus, particularly the start and stop conditions and the clock. This is the most common mode, used to interact with I3C target devices such as sensors.

Due to the nature of the I3C, there are devices on the bus where they may not have addresses when powered on. Therefore, an additional dynamic address assignment needs to be carried out by the I3C controller. Because of this, the controller needs to maintain separate structures to keep track of device status. This can be done at build time, for example, by creating arrays of device descriptors for both I3C and I^2C devices:

```
static struct i3c_device_desc i3c_device_array[] = I3C_DEVICE_ARRAY_DT_INST(inst);
static struct i3c_i2c_device_desc i2c_device_array[] =␣
↪I3C_I2C_DEVICE_ARRAY_DT_INST(inst);
```

The macros `I3C_DEVICE_ARRAY_DT_INST` and `I3C_I2C_DEVICE_ARRAY_DT_INST` are helper macros to aid in create arrays of device descriptors corresponding to the devicetree nodes under the I3C controller.

Here is a list of generic steps for initializing the I3C controller and the I3C bus inside the device driver initialization function:

1. Initialize the data structure of the I3C controller device driver instance. The usual device defining macros such as `DEVICE_DT_INST_DEFINE` can be used, and the initialization function provided as a parameter to the macro.
   - The `i3c_addr_slots` and `i3c_dev_list` are structures to aid in address assignments and device list management. If this is being used, this struct needs to be initialized by calling `i3c_addr_slots_init()`. These two structures can also be used with various helper functions.
   - Initialize the device descriptors if needed by the controller driver.
2. Initialize the hardware, including but not limited to:
   - Setup pin mux and directions.
   - Setup the clock for the controller.
   - Power on the hardware.
   - Configure the hardware (e.g. SCL clock frequency).
3. Perform bus initialization. There is a generic helper function, `i3c_bus_init()`, which performs the following steps. This function can be used if the controller does not require any special handling during bus initialization.
   1. Do `RSTDAA` to reset dynamic addresses of connected devices. If any connected devices have already been assigned an address, the bookkeeping data structures do not have records of these, for example, at power-on. So it is a good idea to reset and assign them new addresses.
   2. Do `DISEC` to disable any events from devices.
   3. Do `SETDASA` to assign a dynamic address using the static address of the device if so desired.
      - `SETAASA` may not be supported for all connected devices to assign static addresses as dynamic addresses.
      - BCR and DCR need to be obtained separately to populate the relevant fields in the I3C target device descriptor struct.

4. Do ENTDAA to start dynamic address assignment, if there are still devices without addresses.
   - If there is a device waiting for address, it will send its Provisioned ID, BCR, and DCR back. Match the received Provisioned ID to the list of registered I3C devices.
     - If there is a match, assign an address (either from the stated static address if SETDASA has not been done, or use a free address).
       * Also, set the BCR and DCR fields in the device descriptor struct.
     - If there is no match, depending on policy, it can be assigned a free address, or the device driver can stop the assignment process and errors out.
       * Note that the I3C API requires device descriptor to function. A device without a device descriptor cannot be accessed through the API.
   - This step can be skipped if there is no connected devices requiring DAA.
5. These are optional but highly recommended:
   - Do GETMRL and GETMWL to get maximum read/write length.
   - Do GETMXDS to get maximum read/write speed and maximum read turnaround time.
   - The helper function, i3c_bus_init(), would retrieve basic device information such as BCR, DCR, MRL and MWL.
6. Do ENEC to re-enable events from devices.
   - The helper function, i3c_bus_init(), only re-enables hot-join events. IBI event should only be enabled when enabling IBI of a device.

In-Band Interrupt (IBI) If a target device can generate In-Band Interrupt (IBI), the controller needs to be made aware of it.

- i3c_ibi_enable() to enable IBI of a target device.
  - Some controller hardware have IBI slots which need to be programmed so that the controller can recognize incoming IBIs from a particular target device.
    * If the hardware has IBI slots, i3c_ibi_enable() needs to program those IBI slots.
    * Note that there are usually limited IBI slots on the controller so this operation may fail.
  - The implementation in driver should also send the ENEC command to enable interrupt of this target device.
- i3c_ibi_disable() to disable IBI of a target device.
  - If controller hardware makes use of IBI slots, this will remove description of the target device from the slots.
  - The implementation in driver should also send the DISEC command to disable interrupt of this target device.

Device Tree Here is an example for defining a I3C controller in device tree:

```
i3c0: i3c@10000 {
        compatible = "vendor,i3c";

        #address-cells = <0x3>;
        #size-cells = <0x0>;

        reg = <0x10000 0x1000>;
```

(continues on next page)

(continued from previous page)

```
        interrupts = <0x1F 0x0>;

        pinctrl-0 = <&pinmux-i3c>;
        pinctrl-names = "default";

        i2c-scl-hz = <400000>;

        i3c-scl-hz = <12000000>;

        status = "okay";

        i3c-dev0: i3c-dev0@420000ABCD12345678 {
                compatible = "vendor,i3c-dev";

                reg = <0x42 0xABCD 0x12345678>;

                status = "okay";
        };

        i2c-dev0: i2c-dev0@380000000000000050 {
                compatible = "vendor-i2c-dev";

                reg = <0x38 0x0 0x50>;

                status = "okay";
        };
};
```

I3C Devices For I3C devices, the `reg` property has 3 elements:

- The first one is the static address of the device.
  - Can be zero if static address is not used. Address will be assigned during DAA (Dynamic Address Assignment).
  - If non-zero and property `assigned-address` is not set, this will be the address of the device after SETDASA (Set Dynamic Address from Static Address) is issued.
- Second element is the upper 16-bit of the Provisioned ID (PID) which contains the manufacturer ID left-shifted by 1. This is the bits 33-47 (zero-based) of the 48-bit Provisioned ID.
  - Must be non-zero. A zero second element marks the node as an I^2C device, as described below, so the helper macros create a legacy I^2C descriptor for it instead of an I3C one. Specify the PID even when the device is addressed by SETDASA and the PID is otherwise unused.
- Third element contains the lower 32-bit of the Provisioned ID which is a combination of the part ID (left-shifted by 16, bits 16-31 of the PID) and the instance ID (left-shifted by 12, bits 12-15 of the PID).

Note that the unit-address (the part after `@`) must match the `reg` property fully where each element is treated as 32-bit integer, combining to form a 96-bit integer. This is required for properly generating device tree macros.

I^2C Devices For I^2C devices where the device driver has support for working under I3C bus, the device node can be described as a child of the I3C controller. If the device driver is written to only work with I^2C controllers, define the node under the I^2C virtual controller as described below. Otherwise, the `reg` property, similar to I3C devices, has 3 elements:

- The first one is the static address of the device. This must be a valid address as I²C devices do not support dynamic address assignment.
- Second element is always zero.
  - This is used by various helper macros to determine whether the device tree entry corresponds to a I²C device.
- Third element is the LVR (Legacy Virtual Register):
  - bit[31:8] are unused.
  - bit[7:5] are the I²C device index:
    - Index `0`
      - I3C device has a 50 ns spike filter where it is not affected by high frequency on SCL.
    - Index 1
      - I²C device does not have a 50 ns spike filter but can work with high frequency on SCL.
    - Index 2
      - I3C device does not have a 50 ns spike filter and cannot work with high frequency on SCL.
  - bit[4] is the I²C mode indicator:
    - `0` is FM+ mode.
    - 1 is FM mode.

Similar to I3C devices, the unit-address must match the `reg` property fully where each element is treated as 32-bit integer, combining to form a 96-bit integer.

Device Drivers for I3C Devices All of the transfer functions of I3C controller API require the use of device descriptors, `i3c_device_desc`. This struct contains runtime information about a I3C device, such as, its dynamic address, BCR, DCR, MRL and MWL. Therefore, the device driver of a I3C device should grab a pointer to this device descriptor from the controller using `i3c_device_find()`. This function takes an ID parameter of type `i3c_device_id` for matching. The returned pointer can then be used in subsequent API calls to the controller.

I²C Devices under I3C Bus Since I3C is backward compatible with I²C, the I3C controller API can accommodate I2C API calls without modifications if the controller device driver implements the I2C API. This has the advantage of using existing I2C devices without any modifications to their device drivers. However, since the I3C controller API works on device descriptors, any calls to I2C API will need to look up the corresponding device descriptor from the I2C device address. This adds a bit of processing cost to any I2C API calls.

On the other hand, a device driver can be extended to utilize native I2C device support via the I3C controller API. During device initialization, `i3c_i2c_device_find()` needs to be called to retrieve the pointer to the device descriptor. This pointer can be used in subsequent API calls.

Note that, with either methods mentioned above, the devicetree node of the I2C device must be declared according to I3C standard:

The I²C virtual controller device driver provides a way to interface I²C devices on the I3C bus where the associated device drivers can be used as-is without modifications. This requires adding an intermediate node in the device tree:

```
i3c0: i3c@10000 {
        <... I3C controller related properties ...>
        <... Nodes of I3C devices, if any ...>
```

(continues on next page)

(continued from previous page)

```
        i2c-dev0: i2c-dev0@420000000000000050 {
                compatible = "vendor-i2c-dev";

                reg = <0x42 0x0 0x50>;

                status = "okay";
        };
};
```

I3C Target Device API

Serial Peripheral Interface (SPI) Bus

Overview

Terminology The Zephyr SPI API uses the inclusive terminology selected by *Rule A.2: Inclusive Language*, following the OSHWA resolution to redefine SPI signal names:

- The device driving the clock is the *controller*, devices it addresses are *peripherals* (see SPI_OP_MODE_CONTROLLER and SPI_OP_MODE_PERIPHERAL).
- Data signals are named from each device's own perspective: *SDO* (Serial Data Out) and *SDI* (Serial Data In), with *CS* (Chip Select) for the select line.

The former master/slave and MOSI/MISO names remain available as compatibility aliases. They are deprecated since Zephyr v4.5 and will be removed in Zephyr v5.0.

Peripheral Component Interconnect express Bus (PCIe)

Overview

API Reference

PCIe Host

Universal Asynchronous Receiver-Transmitter (UART)

Overview Zephyr provides three different ways to access the UART peripheral. Depending on the method, different API functions are used according to below sections:

1. *Polling API*
2. *Interrupt-driven API*
3. *Asynchronous API* using *Direct Memory Access (DMA)*

Polling is the most basic method to access the UART peripheral. The reading function, `uart_poll_in()`, is a non-blocking function and returns a character or `-1` when no valid data is available. The writing function, `uart_poll_out()`, is a blocking function and the thread waits until the given character is sent.

With the Interrupt-driven API, possibly slow communication can happen in the background while the thread continues with other tasks. The Kernel's *Data Passing* features can be used to communicate between the thread and the UART driver.

The Asynchronous API allows to read and write data in the background using DMA without interrupting the MCU at all. However, the setup is more complex than the other methods.

Warning

Interrupt-driven API and the Asynchronous API should NOT be used at the same time for the same hardware peripheral, since both APIs require hardware interrupts to function properly. Using the callbacks for both APIs would result in interference between each other. `CONFIG_UART_EXCLUSIVE_API_CALLBACKS` is enabled by default so that only the callbacks associated with one API is active at a time.

Configuration Options Most importantly, the Kconfig options define whether the polling API (default), the interrupt-driven API or the asynchronous API can be used. Only enable the features you need in order to minimize memory footprint.

Enhanced Serial Peripheral Interface (eSPI) Bus

Overview The eSPI (enhanced serial peripheral interface) is a serial bus that is based on SPI. It also features a four-wire interface (receive, transmit, clock and target select) and three configurations: single IO, dual IO and quad IO.

The technical advancements include lower voltage signal levels (1.8V vs. 3.3V), lower pin count, and the frequency is twice as fast (66MHz vs. 33MHz) Because of its enhancements, the eSPI is used to replace the LPC (lower pin count) interface, SPI, SMBus and sideband signals.

See eSPI interface specification for additional details.

Multi-bit SPI Bus

The MSPI (multi-bit SPI) is provided as a generic API to accommodate advanced SPI peripherals and devices that typically require command, address and data phases, and multiple signal lines during these phases. While the API supports advanced features such as *XIP* and scrambling, it is also compatible with generic SPI.

- *MSPI Controller API*
  - *Transceive*
  - *Device Tree*
  - *Multi Peripheral*
- *Configuration Options*
- *API Reference*

MSPI Controller API Zephyr's MSPI controller API may be used when a multi-bit SPI controller is present. E.g. Ambiq MSPI, QSPI, OSPI, Flexspi, etc. The API supports single to hex SDR/DDR IO with variable latency and advanced features such as *XIP* and scrambling. Applicable devices include but not limited to high-speed, high density flash/psram memory devices, displays and sensors.

The MSPI interface contains controller drivers that are SoC platform specific and implement the MSPI APIs, and device drivers that reference these APIs. The relationship between the controller and device drivers is many-to-many to allow for easy switching between platforms.

Here is a list of generic steps for initializing the MSPI controller and the MSPI bus inside the device driver initialization function:

1. Initialize the data structure of the MSPI controller driver instance. The usual device defining macros such as `DEVICE_DT_INST_DEFINE` can be used, and the initialization function, config and data provided as a parameter to the macro.
2. Initialize the hardware, including but not limited to:
   - Check `mspi_cfg` against hardware's own capabilities to prevent incorrect usages.

- Setup default pinmux.
- Setup the clock for the controller.
- Power on the hardware.
- Configure the hardware using `mspi_cfg` and possibly more platform specific settings.
- Usually, the `mspi_cfg` is filled from device tree and contains static, boot time parameters. However, if needed, one can use `mspi_config()` to re-initialize the hardware with new parameters during runtime.
- Release any lock if applicable.

3. Perform device driver initialization. As usually, `DEVICE_DT_INST_DEFINE` can be used. Inside device driver initialization function, perform the following required steps.
   1. Call `mspi_dev_config()` with device specific hardware settings obtained from device datasheets.
      - The `mspi_dev_cfg` should be filled by device tree and helper macro `MSPI_DEVICE_CONFIG_DT` can be used.
      - The controller driver should then validate the members of `mspi_dev_cfg` to prevent incorrect usage.
      - The controller driver should implement a mutex to protect from accidental access.
      - The controller driver may also switch between different devices based on `mspi_dev_id`.
   2. Call API for additional setups if supported by hardware
      - `mspi_memmap_config()` for memory mapped access (e.g. *XIP*)
      - `mspi_scramble_config()` for scrambling feature
      - `mspi_timing_config()` for platform specific timing setup.
   3. Register any callback with `mspi_register_callback()` if needed.
   4. Release the controller mutex lock.

Transceive The transceive request is of type `mspi_xfer` which allows dynamic change to the transfer related settings once the mode of operation is determined and configured by `mspi_dev_config()`.

The API also supports bulk transfers with different starting addresses and sizes with `mspi_xfer_packet`. However, it is up to the controller implementation whether to support scatter IO and callback management. The controller can determine which user callback to trigger based on `mspi_bus_event_cb_mask` upon completion of each async/sync transfer if the callback had been registered using `mspi_register_callback()`. Or not to trigger any callback at all with `MSPI_BUS_NO_CB` even if the callbacks are already registered. If the implemented driver support it, the API supports `MSPI_BUS_XFER_COMPLETE_CB` to signal when a transfer finishes and `MSPI_BUS_TIMEOUT_CB` to signal when a transfer or request has timed-out. In which case that a controller supports hardware command queue, user could take full advantage of the hardware performance if scatter IO and callback management are supported by the driver implementation.

Device Tree Here is an example for defining an MSPI controller in device tree: The mspi controller's bindings should reference mspi-controller.yaml as one of the base.

```
mspi0: mspi@400 {
        status = "okay";
        compatible = "zephyr,mspi-emul-controller";
```

(continues on next page)

(continued from previous page)

```
        reg = <0x400 0x4>;
        #address-cells = <0x1>;
        #size-cells = <0x0>;

        clock-frequency = <0x17d7840>;
        op-mode = "MSPI_CONTROLLER";
        duplex = "MSPI_HALF_DUPLEX";
        ce-gpios = <&gpio0 0x5 0x1>, <&gpio0 0x12 0x1>;
        dqs-support;

        pinctrl-0 = <&pinmux-mspi0>;
        pinctrl-names = "default";
};
```

Here is an example for defining an MSPI device in device tree: The mspi device's bindings should reference mspi-device.yaml as one of the base.

```
&mspi0 {

        mspi_dev0: mspi_dev0@0 {
                status = "okay";
                compatible = "zephyr,mspi-emul-device";

                reg = <0x0>;
                size = <0x10000>;

                mspi-max-frequency = <0x2dc6c00>;
                mspi-io-mode = "MSPI_IO_MODE_QUAD";
                mspi-data-rate = "MSPI_DATA_RATE_SINGLE";
                mspi-hardware-ce-num = <0x0>;
                read-instruction = <0xb>;
                write-instruction = <0x2>;
                instruction-length = "INSTR_1_BYTE";
                address-length = "ADDR_4_BYTE";
                rx-dummy = <0x8>;
                tx-dummy = <0x0>;
                memmap-config = <0x0 0x0 0x0 0x0>;
                ce-break-config = <0x0 0x0>;
        };

};
```

User should specify target operating parameters in the DTS such as `mspi-max-frequency`, `mspi-io-mode` and `mspi-data-rate` even though they may subject to change during runtime. It should represent the typical configuration of the device during normal operations.

Multi Peripheral With `mspi_dev_id` defined as collection of the device index and CE GPIO from device tree, the API supports multiple devices on the same controller instance. The controller driver implementation may or may not support device switching, which can be performed either by software or by hardware. If the switching is handled by software, it should be performed in `mspi_dev_config()` call.

The device driver should record the current operating conditions of the device to support software controlled device switching by saving and updating `mspi_dev_cfg` and other relevant mspi struct or private data structures. In particular, `mspi_dev_id` which contains the identity of the device needs to be used for every API call.

System Management Bus (SMBus)

- *Overview*
- *SMBus Controller API*
- *Configuration Options*
- *API Reference*

Overview System Management Bus (SMBus) is derived from I2C for communication with devices on the motherboard. A system may use SMBus to communicate with the peripherals on the motherboard without using dedicated control lines. SMBus peripherals can provide various manufacturer information, report errors, accept control parameters, etc.

Devices on the bus can operate in three roles: as a Controller that initiates transactions and controls the clock, a Peripheral that responds to transaction commands, or a Host, which is a specialized Controller, that provides the main interface to the system's CPU. Zephyr has API for the Controller role.

SMBus peripheral devices can initiate communication with Controller with two methods:

- **Host Notify protocol**: Peripheral device that supports the Host Notify protocol behaves as a Controller to perform the notification. It writes a three-bytes message to a special address "SMBus Host (0x08)" with own address and two bytes of relevant data.
- **SMBALERT# signal**: Peripheral device uses special signal SMBALERT# to request attention from the Controller. The Controller needs to read one byte from the special "SMBus Alert Response Address (ARA) (0x0c)". The peripheral device responds with a data byte containing its own address.

Currently, the API is based on SMBus Specification version 2.0

Note

See *Rule A.2: Inclusive Language* for information about the terminology used in this API.

SMBus Controller API Zephyr's SMBus controller API is used when an SMBus device controls the bus, particularly the start and stop conditions and the clock. This is the most common mode used to interact with SMBus peripherals.

Local Interconnect Network (LIN)

Overview LIN (Local Interconnect Network) is a serial bus system. Since 2016, it is standardized internationally by ISO. In 2025, several parts of the ISO 17987 series have been updated. The ISO 17987 document series covers the requirements of the seven OSI (Open Systems Interconnection) layers and the corresponding conformance test plans.

LIN lower layers The LIN data link layer, often called the LIN protocol, specifies a commander-responder protocol. The LIN Commander uses one or more pre-programmed scheduling tables to start the sending and receiving to the LIN frames. These scheduling tables contain at least the relative timing, when the LIN frame sending is initiated. The LIN frame consists of two parts: header and response. The LIN Commander sends the header, while either one dedicated LIN Responder or the LIN Commander itself transmits the response.

The header comprises the 1-byte Break, the Inter-Byte Space, the 1-byte SYNC (0x55), the Identifier, and the Response Space. The responses consist of the payload-bytes and the CRC byte.

Transmitted data within the LIN frame is transmitted serially as 8-bit data-bytes with one additional start bit, one additional stop-bit, but no parity bit. Note that the break field in the header has no start bit and no stop bit.

Bit rates may vary within the range of 1 kbit/s to 20 kbit/s. Bit values on the bus are recessive (logical high) or dominant (logical low). The time normal is considered by the LIN Commanders stable clock source, the smallest entity is one bit time (52 µs at a bitrate of 19,2 kbit/s). Two bus states are defined: sleep mode and active mode. While data is on the bus, all LIN-nodes are requested to be in active mode. After a specified timeout, the nodes enter the sleep mode and are released back to active mode by a wake-up frame. This frame may be sent by any node requesting activity on the bus, either the LIN Commander following its internal schedule, or one of the attached LIN Responders being activated by its internal software application. After all nodes are awakened, the LIN Commander continues to schedule the next LIN frame.

For more technical information on LIN you may visit LIN on Wikipedia.

Zephyr LIN controller support following LIN features:

- Send and receive LIN frames in commander and responder mode.
- Filters with header masking (Responder mode) that allow a header ID to trigger a responder callback.
- Wake up pulse sending.

Samples We have samples demonstrating the use of Zephyr LIN controller API:

- lin-ncv7430: Demonstrates how to use the LIN API in commander mode.
- lin-ncv7430-responder: Demonstrates how to use the LIN API in responder mode by mocking the NCV7430 LED Controller.

LIN Transceivers A LIN transceiver is an external device that converts the logic level signals from the LIN controller to the LIN bus levels. Some boards integrate LIN transceiver control (enable/wake pins) directly via the `lin-transceiver-gpio` compatible; the LIN controller driver enables and disables the transceiver automatically as part of `lin_start()` and `lin_stop()`, so applications should not normally need to call the transceiver API directly.

1-Wire Bus

Overview 1-Wire is a low speed half-duplex serial bus using only a single wire plus ground for both data transmission and device power supply. Similarly to I2C, 1-Wire uses a bidirectional open-collector data line, and is a single master multidrop bus. This means one master initiates all data exchanges with the slave devices. The 1-Wire bus supports longer bus lines than I2C, while it reaches speeds of up to 15.4 kbps in standard mode and up to 125 kbps in overdrive mode. Reliable communication in standard speed configuration is possible with 10 nodes over a bus length of 100 meters. Using overdrive speed, 3 nodes on a bus of 10 meters length are expected to work solid. Optimized timing parameters and fewer nodes on the bus may allow to reach larger bus extents.

The implementation details are specified in the BOOK OF IBUTTON STANDARDS.

W1 Master API Zephyr's 1-Wire Master API is used to interact with 1-Wire slave devices like temperature sensors and serial memories.

In Zephyr this API is split into the following layers.

- The link layer handles basic communication functions such as bus reset, presence detect and bit transfer operations. It is the only hardware-dependent layer in Zephyr. This layer is supported by a driver using the Zephyr *Universal Asynchronous Receiver-Transmitter (UART)* interface, which should work on most Zephyr platforms. In the future, a GPIO/Timer based driver and hardware specific drivers might be added.

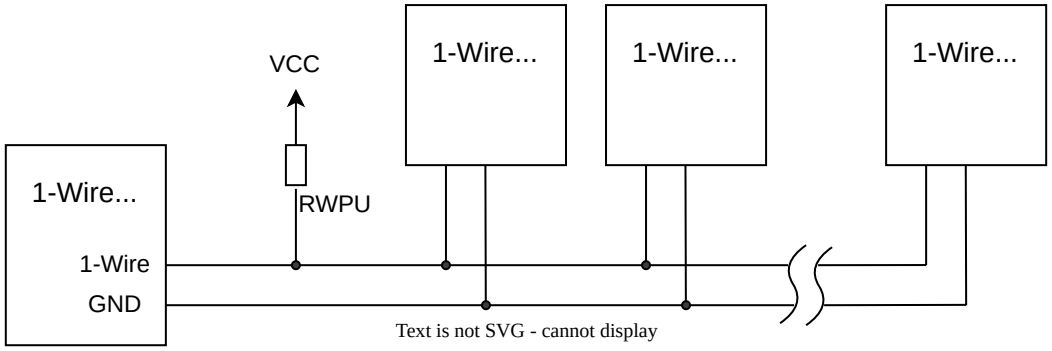

Fig. 1: A typical 1-Wire bus topology

- The 1-Wire network layer handles all means for slave identification and bus arbitration. This includes ROM commands like Match ROM, or Search ROM.
  - All slave devices have a unique 64-bit identification number, which includes a 8-bit 1-Wire Family Code and a 8-bit CRC.
  - In order to find slaves on the bus, the standard specifies an search algorithm which successively detects all slaves on the bus. This algorithm is described in the 1-Wire Search Algorithm Application Note.
- Transport layer and Presentation layer functions are not implemented in the generic 1-Wire driver and therefore must be handled in individual slave drivers.

The 1-Wire API is considered experimental.

- `CONFIG_W1_NET`

W1 Serial Driver The `zephyr,w1-serial` driver implements the 1-Wire interface using a UART peripheral. Individual 1-Wire bits are encoded as bytes sent over the UART. For standard speed, it uses 115200 Baud for data and 9600 Baud for reset/presence detection. For overdrive speed, it uses configurable baud rates with a default of 1000000 Baud for data and 115200 Baud for reset/presence.

Pulse IO

Overview The Pulse IO subsystem provides a vendor-neutral API for hardware that generates and captures timed digital edges on a single GPIO line. Several MCU families ship a dedicated peripheral for this purpose under different names. Pulse IO abstracts that hardware class so client drivers such as addressable LED strips, infrared transmit and receive, stepper pulse generation, frequency and duty measurement, and one-wire style protocols can bind once and run on any SoC that provides a backend.

Related configuration options:

- `CONFIG_PULSE_IO`

Submission modes A channel is locked to one submission mode at configure time, selected from those the backend advertises through its capabilities.

`PULSE_IO_MODE_SYMBOL`
: The application submits an array of `pulse_symbol`, each carrying an explicit level and a duration in ticks of the configured resolution. Consecutive symbols may have arbitrary, unrelated durations. Use it for protocols whose edge lengths vary within one stream, such as infrared remotes, one-wire and stepper acceleration ramps.

`PULSE_IO_MODE_CELL`
: The application submits an array of `pulse_cell`. Every cell has the same period, set once in the channel configuration, and each cell carries either a level or a duty value within that period. Use it for naturally periodic streams where only the per-period level or duty changes, such as addressable LED bit shaping or varying-duty PWM. Cells are more memory efficient than symbols for these cases.

Backends advertise the supported modes in `pulse_io_caps`. Requesting an unsupported mode causes `pulse_io_channel_configure()` to return `-ENOTSUP`.

Configuration Clients query `pulse_io_get_capabilities()` at probe time to decide which mode and feature set to use, reserve a channel with `pulse_io_channel_get()`, and configure it with `pulse_io_channel_configure()` before any transfer. Blocking transfers use `pulse_io_transmit_sync()` and `pulse_io_receive_sync()`; asynchronous and streaming transfers use the RTIO path.

The byte-to-symbol helper `pulse_io_encode_bytes()` and its inverse `pulse_io_decode_bytes()` convert between a protocol byte stream and pulse symbols using a per-bit template.

RTIO A backend may optionally integrate with *Real Time I/O (RTIO)*, exposing an iodev submit path along with encoder and decoder vtables fetched through `pulse_io_get_encoder()` and `pulse_io_get_decoder()`. With RTIO the client encodes a payload into a symbol buffer, submits it through an RTIO queue, and decodes any captured reply, gaining queued and chained transfers, streaming receive, and the userspace path provided by the RTIO framework. The RTIO ops are optional; a backend that does not implement them leaves the corresponding driver API members `NULL` and the accessors return `-ENOSYS`.

Display

6.7.4 Display

Visual output, video interfaces, and LED and lighting control.

Display

The Display subsystem in Zephyr provides a unified way to interact with a wide range of display devices. The Display API is transport-agnostic: it describes what you want the display to do, without exposing how the data moves over the wire.

MIPI Display Bus Interface (DBI) The **MIPI DBI** specification defines several parallel and serial buses for connecting a host to a display controller. In Zephyr, DBI support provides bus-level primitives for command writes, reads, pixel transfers, reset, and related operations that a driver uses internally to implement the generic API.

Applications do not use DBI functions directly. Instead, they call the generic Display API (e.g., to write pixels), and the display driver handles the DBI protocol under the hood.

MIPI-DBI defines 3 interface types:

- Type A: Motorola 6800 parallel bus
- Type B: Intel 8080 parallel bus
- Type C: SPI Type serial bit bus with 3 options:
  1. 9 write clocks per byte, final bit is command/data selection bit
  2. Same as above, but 16 write clocks per byte
  3. 8 write clocks per byte. Command/data selected via GPIO pin

Currently, the API does not support Type C controllers with 16 write clocks (option 2).

MIPI Display Serial Interface (DSI) The **MIPI DSI** standard is a high-speed differential serial bus designed for modern color TFT panels. Zephyr's DSI support provides the primitives needed by drivers to implement the generic Display API on top of a DSI link.

As with DBI, applications never call DSI functions directly. They remain portable by using the generic Display API, while the driver handles the DSI transactions internally.

Auxiliary Display (auxdisplay)

Overview Auxiliary Displays are text-based displays that have simple interfaces for displaying textual, numeric or alphanumeric data, as opposed to the *Display*, auxiliary displays do not support custom graphical output to displays (and most often monochrome), the most advanced custom feature supported is generation of custom characters. These inexpensive displays are commonly found with various configurations and sizes, a common display size is 16 characters by 2 lines.

This API is unstable and subject to change.

Video

The video driver API offers a generic interface to video devices.

Basic Operation

Video Device A video device is the abstraction of a hardware or software video function, which can produce, process, consume or transform video data. The video API is designed to offer flexible way to create, handle and combine various video devices.

Endpoint Each video device can have one or more endpoints. Output endpoints configure video output function and generate data. Input endpoints configure video input function and consume data.

Video Buffer A video buffer provides the transport mechanism for the data. There is no particular requirement on the content. The requirement for the content is defined by the endpoint format. A video buffer can be queued to a device endpoint for filling (input ep) or consuming (output ep) operation, once the operation is achieved, buffer can be dequeued for post-processing, release or reuse.

Controls A video control is accessed and identified by a CID (control identifier). It represents a video control property. Different devices will have different controls available which can be generic, related to a device class or vendor specific. The set/get control functions provide a generic scalable interface to handle and create controls.

Video Control IDs

Light-Emitting Diode (LED)

Overview The LED API provides access to Light Emitting Diodes, both in individual and strip form. It abstracts the differences between simple GPIO-driven LEDs, PWM-dimmable LEDs, dedicated LED controller ICs, and addressable LED strips behind a small set of common operations.

Two related subsystems are exposed:

- **LED** — general-purpose API for controlling discrete or controller-backed LEDs (on/off, brightness, color, blink)
- **LED Strip** — API tailored to addressable LED strings such as WS2812 and APA102 where each pixel carries its own color value

LED Operations A driver implements a subset of the operations below. Calls to optional operations return `-ENOSYS` if the underlying driver does not provide them.

Mandatory operations (at least one of):

- `led_on()` / `led_off()` — turn an LED fully on or off
- `led_set_brightness()` — set brightness in the range 0 to `LED_BRIGHTNESS_MAX` (100); when implemented, this is also used automatically by `led_on()` and `led_off()`

Optional operations:

- `led_blink()` — start the LED blinking with given on/off durations
- `led_set_color()` — set the per-channel color values of a multi-color LED
- `led_get_info()` — retrieve the `led_info` describing a particular LED (label, index, color mapping)
- `led_write_channels()` — write a range of raw channel values, used by drivers that expose LEDs as an array of channels

LED Indexing Each LED controlled by a driver is addressed by a zero-based `led` index. Multi-color LEDs occupy a single index; their color channels are submitted together to `led_set_color()`.

The color channel order for a multi-color LED is described by the `color_mapping` field of `led_info`. Each entry is one of the `LED_COLOR_ID_*` values defined in `include/zephyr/dt-bindings/led/led.h`:

- `LED_COLOR_ID_WHITE`
- `LED_COLOR_ID_RED`
- `LED_COLOR_ID_GREEN`
- `LED_COLOR_ID_BLUE`
- `LED_COLOR_ID_AMBER`
- `LED_COLOR_ID_VIOLET`
- `LED_COLOR_ID_YELLOW`
- `LED_COLOR_ID_IR`

Device Tree Configuration Simple LEDs are typically described as child nodes of an LED controller and referenced via a devicetree alias:

```
/ {
    aliases {
        led0 = &status_led;
    };

    leds {
        compatible = "gpio-leds";
        status_led: led_0 {
            gpios = <&gpio0 13 GPIO_ACTIVE_HIGH>;
            label = "Status LED";
```

(continues on next page)

(continued from previous page)

```
        };
    };
};
```

For multi-color LEDs, color information is encoded with the `color-mapping` property using `LED_COLOR_ID_*` values from `include/zephyr/dt-bindings/led/led.h`.

Usage Examples Basic on/off control using a devicetree alias:

```
#include <zephyr/drivers/led.h>
#include <zephyr/devicetree.h>

#define LED_NODE DT_ALIAS(led0)
static const struct device *led_dev = DEVICE_DT_GET(DT_PARENT(LED_NODE));
static const uint32_t led_idx = DT_NODE_CHILD_IDX(LED_NODE);

int turn_on_status_led(void)
{
    if (!device_is_ready(led_dev)) {
        return -ENODEV;
    }
    return led_on(led_dev, led_idx);
}
```

Setting brightness (0 to 100):

```
/* Dim the LED to 25% brightness */
led_set_brightness(led_dev, led_idx, 25);
```

Blinking with a 500 ms on / 500 ms off pattern:

```
int err = led_blink(led_dev, led_idx, 500, 500);

if (err == -ENOSYS) {
    /* Driver does not implement blink natively */
}
```

Setting the color of a multi-color (RGB) LED:

```
/* Order of the values must match the color_mapping reported by
 * led_get_info(); for a standard RGB mapping the order is R, G, B.
 */
const uint8_t purple[] = { 0x80, 0x00, 0x80 };

led_set_color(led_dev, led_idx, ARRAY_SIZE(purple), purple);
```

DALI

DALI is the digital addressable lighting interface, a communication standard for professional lighting solutions. This API is unstable and subject to change.

Basic Operation The DALI standard uses a communication model that is based on the exchange of frames via a bus system. A frame is manchester encoded data, terminated by a stop condition. The DALI standard requires specific behaviour of transmitter and receiver.

GPIO & Input

6.7.5 GPIO & Input

General-purpose I/O and input devices.

General-Purpose Input/Output (GPIO)

Overview A General-Purpose Input/Output (GPIO) is a digital signal pin that does not have a specific function but can be controlled by software to function as an input or an output.

The GPIO API provides a generic method to interact with General Purpose Input/Output (GPIO) pins. It allows applications to configure pins as inputs or outputs, read and write their state, and manage interrupts. Key features include:

Pin Configuration
: Configure pins as input, output, or disconnected. Support for internal pull-up/pull-down resistors and drive strength configuration.

Data Access
: Read input values and write output values.

Interrupts
: Configure interrupts on pin state changes (rising edge, falling edge, level low, level high) and register callbacks to handle these interrupts.

Devicetree Integration
: GPIOs are typically defined in the Devicetree, allowing drivers and applications to reference them in a hardware-agnostic way using `gpio_dt_spec`.

Devicetree Configuration GPIO controllers are defined in the Devicetree as nodes with the `gpio-controller` property. The `#gpio-cells` property typically specifies that 2 cells are used to describe a GPIO: the pin number and the flags.

Example of a GPIO controller definition:

```
gpio0: gpio@40022000 {
    compatible = "ti,cc13xx-cc26xx-gpio";
    reg = <0x40022000 0x400>;
    interrupts = <0 0>;
    gpio-controller;
    #gpio-cells = <2>;
};
```

Example of referencing a GPIO:

```
leds {
    compatible = "gpio-leds";
    led0: led_0 {
        gpios = <&gpio0 25 GPIO_ACTIVE_HIGH>;
        label = "Green LED";
    };
};
```

Basic Operation GPIO operations are usually performed on a `gpio_dt_spec` structure, which is a container for the GPIO pin information specified in the Devicetree.

This structure is typically populated using `GPIO_DT_SPEC_GET` macro (or any of its variants).

Listing 2: Populating a gpio_dt_spec structure for a GPIO pin defined as alias `led0`

```
#define LED0_NODE DT_ALIAS(led0)
static const struct gpio_dt_spec led = GPIO_DT_SPEC_GET(LED0_NODE, gpios);
```

The `gpio_dt_spec` structure can then be used to perform GPIO operations.

Listing 3: Configure a GPIO pin (`led` from the previous snippet) as output, initially inactive, and then set it to its active level.

```
int ret;

ret = gpio_pin_configure_dt(&led, GPIO_OUTPUT_INACTIVE);
if (ret < 0) {
    return ret;
}

ret = gpio_pin_set_dt(&led, 1);
if (ret < 0) {
    return ret;
}
```

Refer to blinky for a complete example of basic operations on GPIOs using the `gpio_dt_spec` structure.

GPIO operations can also be performed directly on a GPIO controller device, in which case you will use the GPIO API functions that take a device pointer as an argument. For example `gpio_pin_configure()` instead of `gpio_pin_configure_dt()`.

GPIO Hogs GPIO hogs provide a mechanism to automatically configure GPIO pins during system initialization. This is useful for pins that need to be set to a specific state (e.g., reset lines, power enables) and don't require runtime control by an application.

Hogs are defined in the Devicetree as children of a GPIO controller node.

- The `gpio-hog` property marks the node as a hog.
- The `gpios` property specifies the pin and its active state.
- One of `input`, `output-low`, or `output-high` properties specifies the configuration.

Example Devicetree overlay:

```
&gpio0 {
    hog1 {
        gpio-hog;
        gpios = <1 GPIO_ACTIVE_LOW>;
        output-high;
    };

    hog2 {
        gpio-hog;
        gpios = <2 GPIO_ACTIVE_HIGH>;
        output-low;
    };
};
```

If you need runtime control of a pin configured as a hog beyond the initial state being automatically set during system initialization, you may consider using the *Regulators* instead, with a

`regulator-fixed` Devicetree node.

Memory & Storage

6.7.6 Memory & Storage

Non-volatile memory, flash storage, EEPROM, and memory controllers.

Flash

Overview **Flash offset concept**

Offsets used by the user API are expressed in relation to the flash memory beginning address. This rule shall be applied to all flash controller regular memory that layout is accessible via API for retrieving the layout of pages (see `CONFIG_FLASH_PAGE_LAYOUT`).

An exception from the rule may be applied to a vendor-specific flash dedicated-purpose region (such a region obviously can't be covered under API for retrieving the layout of pages).

EEPROM Shell

- *Overview*
- *EEPROM Size*
- *Writing Data*
- *Reading Data*

Overview The EEPROM shell provides an `eeprom` command with a set of subcommands for the *shell* module. It allows testing and exploring the *EEPROM* driver API through an interactive interface without having to write a dedicated application. The EEPROM shell can also be enabled in existing applications to aid in interactive debugging of EEPROM issues.

In order to enable the EEPROM shell, the following *Kconfig* options must be enabled:

- `CONFIG_SHELL`
- `CONFIG_EEPROM`
- `CONFIG_EEPROM_SHELL`

For example, building the hello_world sample for the native_sim with the EEPROM shell:

```
# From the root of the zephyr repository
west build -b native_sim samples/hello_world -- -DCONFIG_SHELL=y -DCONFIG_EEPROM=y␣
↪-DCONFIG_EEPROM_SHELL=y
```

See the *shell* documentation for general instructions on how to connect and interact with the shell. The EEPROM shell comes with built-in help (unless `CONFIG_SHELL_HELP` is disabled). The built-in help messages can be printed by passing `-h` or `--help` to the `eeprom` command or any of its subcommands. All subcommands also support tab-completion of their arguments.

Tip

All of the EEPROM shell subcommands take the name of an EEPROM peripheral as their first argument, which also supports tab-completion. A list of all devices available can be obtained using the `device list` shell command when `CONFIG_DEVICE_SHELL` is enabled. The examples below all use the device name `eeprom@0`.

EEPROM Size The size of an EEPROM can be inspected using the `eeprom size` subcommand as shown below:

```
uart:~$ eeprom size eeprom@0
32768 bytes
```

Writing Data Data can be written to an EEPROM using the `eeprom write` subcommand. This subcommand takes at least three arguments; the EEPROM device name, the offset to start writing to, and at least one data byte. In the following example, the hexadecimal sequence of bytes `0x0d 0x0e 0x0a 0x0d 0x0b 0x0e 0x0e 0x0f` is written to offset `0x0`:

```
uart:~$ eeprom write eeprom@0 0x0 0x0d 0x0e 0x0a 0x0d 0x0b 0x0e 0x0e 0x0f
Writing 8 bytes to EEPROM...
Verifying...
Verify OK
```

It is also possible to fill a portion of the EEPROM with the same pattern using the `eeprom fill` subcommand. In the following example, the pattern `0xaa` is written to 16 bytes starting at offset `0x8`:

```
uart:~$ eeprom fill eeprom@0 0x8 16 0xaa
Writing 16 bytes of 0xaa to EEPROM...
Verifying...
Verify OK
```

Reading Data Data can be read from an EEPROM using the `eeprom read` subcommand. This subcommand takes three arguments; the EEPROM device name, the offset to start reading from, and the number of bytes to read:

```
uart:~$ eeprom read eeprom@0 0x0 8
Reading 8 bytes from EEPROM, offset 0...
00000000: 0d 0e 0a 0d 0b 0e 0e 0f                         |........        |
```

Secure Digital (SD card) interface

Zephyr can communicate with an attached SD card either using a system's native SD card interface or over SPI (Serial Peripheral Interface). Some devices can also communicate with MMC (MultiMediaCard) devices.

Applications can use Zephyr's *the disk access API* to use SD cards as storage devices, or Zephyr's SD card subsystem to directly read from and write to a card.

SD Host Controller (SDHC) An SD host controller (SDHC) is a device capable of sending commands to an SD card. These commands can be sent using a system's native SD card interface, or over SPI.

Applications should generally not use the SD host controller API directly, instead they should use Zephyr's SD card subsystem.

Requests The core of the SD host controller (SDHC) API is the `sdhc_request()` API. Requests contain a `sdhc_command` command structure, and an optional `sdhc_data` data structure. The caller may check the return code, or the `response` field of the SD command structure to determine if the SDHC request succeeded. The data structure allows the caller to specify a number of blocks to transfer, and a buffer location to read or write them from. Whether the provided buffer is used for sending or reading data depends on the command opcode provided.

Host Controller I/O The `sdhc_set_io()` API allows the user to change I/O settings of the SD host controller, such as clock frequency, I/O voltage, and card power. Not all controllers will support applying all I/O settings. For example, SPI mode controllers typically cannot toggle power to the SD card.

Related configuration options:

- `CONFIG_SDHC`

API Reference

SDHC

Battery Backed RAM (BBRAM)

The BBRAM APIs allow interfacing with the unique properties of this memory region. The following common types of BBRAM properties are easily accessed via this API:

- IBBR (invalid) state - check that the BBRAM is not corrupt.
- VSBY (voltage standby) state - check if the BBRAM is using standby voltage.
- VCC (active power) state - check if the BBRAM is on normal power.
- Size - get the size (in bytes) of the BBRAM region.

Along with these, the API provides a means for reading and writing to the memory region via `bbram_read()` and `bbram_write()` respectively. Both functions are expected to only succeed if the BBRAM is in a valid state and the operation is bounded to the memory region.

API Reference

BBRAM

Retained Memory

Overview The retained memory driver API provides a way of reading from/writing to memory areas whereby the contents of the memory is retained whilst the device is powered (data may be lost in low power modes).

Configuration Options Related configuration options:

- CONFIG_RETAINED_MEM
- CONFIG_RETAINED_MEM_INIT_PRIORITY
- CONFIG_RETAINED_MEM_MUTEX_FORCE_DISABLE

Mutex protection Mutex protection of retained memory drivers is enabled by default when applications are compiled with multithreading support. This means that different threads can safely call the retained memory functions without clashing with other concurrent thread function usage, but means that retained memory functions cannot be used from ISRs. It is possible to disable mutex protection globally on all retained memory drivers by enabling CONFIG_RETAINED_MEM_MUTEX_FORCE_DISABLE - users are then responsible for ensuring that the function calls do not conflict with each other.

API Reference

Retained memory

I2C EEPROM Target

Overview

API Reference

I2C EEPROM Target

Memory Controller (MEMC)

Overview The MEMC API provides a generic interface for accessing external memory devices such as PSRAM and NOR flash. It supports two access modes:

- **Memory-mapped:** The controller exposes the device through a direct CPU-accessible address window. The driver may implement memc_driver_api.get_mem_base to advertise the mapped base address, allowing memc_read() and memc_write() to use memcpy automatically. Alternatively, the driver may provide no runtime API at all if the hardware maps memory transparently - in this case upper layers access the device directly using a platform-specific base address.
- **Bus transaction:** The controller issues explicit bus commands (e.g., MSPI) for each transfer. The driver implements memc_driver_api.read and memc_driver_api.write. Used when no memory-mapped aperture exists on the controller.

memc_read() and memc_write() automatically select the memory-mapped path when available, falling back to bus transactions otherwise.

Additional optional APIs are provided for device introspection: memc_get_size() returns the device capacity and memc_read_id() returns device identification bytes.

Legacy (Init-Only) Drivers Existing memc drivers that pass NULL as the API pointer to DEVICE_DT_INST_DEFINE are not affected by this API. Callers should use DEVICE_API_IS to test whether a device implements the memc interface before calling any memc function:

```
if (DEVICE_API_IS(memc, dev)) {
   memc_read(dev, offset, buf, sizeof(buf));
} else {
   /* Legacy init-only driver - device is memory-mapped.
    * Access via platform-specific base address.
    */
```

(continues on next page)

(continued from previous page)

```
    memcpy(buf, (const uint8_t *)MEMC_BASE + offset, sizeof(buf));
}
```

Calling `memc_read()` or `memc_write()` on a device that does not implement the memc API returns `-ENOTSUP`.

Power

6.7.7 Power

Power management, charging, regulators, reset, and wake-up controllers.

BC1.2 Devices (Experimental)

The Battery Charging specification, currently at revision 1.2, is commonly referred to as just BC1.2. BC1.2 defines limits and detection mechanisms for USB devices to draw current exceeding the USB 2.0 specification limit of 0.5A, 2.5W.

The BC1.2 specification uses the term Charging Port for the device that supplies VBUS on the USB connection and the term Portable Device for the device that sinks current from the USB connection.

Note that the BC1.2 Specification uses the acronym PD for Portable Device. This should not be confused with the USB-C Power Delivery, which also uses the acronym PD.

On many devices, BC1.2 is the fallback mechanism to determine the connected charger capability on USB type C ports when the attached type-C partner does not support Power Delivery.

Key parameters from the BC1.2 Specification include:

Parameter	Symbol	Range
Allowed PD (portable device) Current Draw from Charging Port	IDEV_CHG	1.5 A
Charging Downstream Port Rated Current	ICDP	1.5 - 5.0 A
Maximum Configured Current when connected to a SDP	ICFG_MAX	500 mA
Dedicated Charging Port Rated Current	IDCP	1.5 - 5.0 A
Suspend current	ISUSP	2.5 mA
Unit load current	IUNIT	100 mA

While the ICDP and IDCP rated currents go up to 5.0 A, the BC1.2 current is limited by the IDEV_CHG parameter. So the BC1.2 support is capped at 1.5 A in the Zephyr implementation when using portable-device mode.

Basic Operation The BC1.2 device driver provides only two APIs, `bc12_set_role()` and `bc12_set_result_cb()`.

The application calls `bc12_set_role()` to transition the BC1.2 device to either a disconnected, portable-device, or charging port mode.

For the disconnected state, the BC1.2 driver powers down the detection chip. The power down operation is vendor specific.

The application calls `bc12_set_role()` with the type set to BC12_PORTABLE_DEVICE when both the following conditions are true:

- The application configured the port as an upstream facing port, i.e. a USB device port.
- The application detects VBUS on the USB connection.

For portable-device mode, the BC1.2 driver powers up the detection chip and starts charger detection. At completion of the charger detection, the BC1.2 driver notifies the callback registered with `bc12_set_result_cb()`. By default, the BC1.2 driver clamps the current to 1.5A to comply with the BC1.2 specification.

To comply with the USB 2.0 specification, when the driver detects a SDP (Standard Downstream Port) charging partner or if BC1.2 detection fails, the driver reports the available current as ISUSP (2.5 mA). The application may increase the current draw to IUNIT (100 mA) when the connected USB host resumes the USB bus and may increase the current draw to ICFG_MAX (500 mA) when the USB host configures the USB device.

Charging port mode is used by the application when the USB port is configured as a downstream facing port, i.e. a USB host port. For charging port mode, the BC1.2 driver powers up the detection chip and configures the charger type specified by a devicetree property. If the driver supports detection of plug and unplug events, the BC1.2 driver notifies the callback registered with `bc12_set_result_cb()` to indicate the current connection state of the portable device partner.

Configuration Options Related configuration options:

- `CONFIG_USB_BC12`

API Reference

Battery Charging (BC1.2)

BC1.2 backed emulator APIs

Chargers

The charger subsystem exposes an API to uniformly access battery charger devices.

A charger device, or charger peripheral, is a device used to take external power provided to the system as an input and provide power as an output downstream to the battery pack(s) and system. The charger device can exist as a module, an integrated circuit, or as a functional block in a power management integrated circuit (PMIC).

The action of charging a battery pack is referred to as a charge cycle. When the charge cycle is executed the battery pack is charged according to the charge profile configured on the charger device. The charge profile is defined in the battery pack's specification that is provided by the manufacturer. On charger devices with a control port, the charge profile can be configured by the host controller by setting the relevant properties, and can be adjusted at runtime to respond to environmental changes.

Basic Operation

Initiating a Charge Cycle A charge cycle is initiated or terminated using `charger_charge_enable()`.

Properties Fundamentally, a property is a configurable setting, state, or quantity that a charger device can measure.

Chargers typically support multiple properties, such as temperature readings of the battery-pack or present-time current/voltage.

Properties are fetched by the client one at a time using `charger_get_prop()`. Properties are set by the client one at a time using `charger_set_prop()`.

API Reference

Battery Charger

Related code samples

- ChargerCharge a battery using the charger driver API.
- Multi-Function Device (MFD) with Charger, Fuel Gauge, and RegulatorsDemonstrate a multi-function device using charger, fuel gauge, and regulator subsystems.

Fuel Gauge

The fuel gauge subsystem exposes an API to uniformly access battery fuel gauge devices.

Basic Operation

Properties Fundamentally, a property is a quantity that a fuel gauge device can measure.

Fuel gauges typically support multiple properties, such as temperature readings of the battery-pack or present-time current/voltage.

Properties are fetched by the client one at a time using `fuel_gauge_get_prop()`, or fetched in a batch using `fuel_gauge_get_props()`. Buffer properties, e.g. device name, are fetched by using `fuel_gauge_get_buffer_prop()`.

Properties are set by the client one at a time using `fuel_gauge_set_prop()`, or set in a batch using `fuel_gauge_set_props()`. Buffer properties, e.g. a battery configuration image, are set by using `fuel_gauge_set_buffer_prop()`.

Battery Cutoff Many fuel gauges embedded within battery packs expose a register address that when written to with a specific payload will do a battery cutoff. This battery cutoff is often referred to as ship, shelf, or sleep mode due to its utility in reducing battery drain while devices are stored or shipped.

The fuel gauge API exposes battery cutoff with the `fuel_gauge_battery_cutoff()` function.

Caching The Fuel Gauge API explicitly provides no caching for its clients.

API Reference

Fuel Gauge

Related code samples

- Multi-Function Device (MFD) with Charger, Fuel Gauge, and RegulatorsDemonstrate a multi-function device using charger, fuel gauge, and regulator subsystems.

Fuel gauge backend emulator APIs

Regulators

This subsystem provides control of voltage and current regulators. A common example is a GPIO that controls a transistor that supplies current to a device that is not always needed. Another example is a PMIC, typically a much more complex device.

The `*-supply` devicetree properties are used to identify the regulator(s) that a devicetree node directly depends on. Within the driver for the node the regulator API is used to issue requests for power when the device is to be active, and release the power request when the device shuts down.

The simplest case where a regulator is needed is one where there is only one client. For those situations the cost of using the regulator device infrastructure is not justified, and `*-gpios` devicetree properties should be used. There is no device interface to these regulators as they are entirely controlled within the driver for the corresponding node, e.g. a sensor.

Reset Controller

Overview Reset controllers are units that control the reset signals to multiple peripherals. The reset controller API allows peripheral drivers to request control over their reset input signals, including the ability to assert, deassert and toggle those signals. Also, the reset status of the reset input signal can be checked.

Mainly, the line_assert and line_deassert API functions are optional because in most cases we want to toggle the reset signals.

USB Type-C Port Controller (TCPC)

Overview TCPC (USB Type-C Port Controller) The TCPC is a device used to simplify the implementation of a USB-C system by providing the following three function:

- VBUS and VCONN control USB Type-C: The TCPC may provide a Source device, the mechanism to control VBUS sourcing, and a Sink device, the mechanism to control VBUS sinking. A similar mechanism is provided for the control of VCONN.
- CC control and sensing: The TCPC implements logic for controlling the CC pin pull-up and pull-down resistors. It also provides a way to sense and report what resistors are present on the CC pin.
- Power Delivery message reception and transmission USB Power Delivery: The TCPC sends and receives messages constructed in the TCPM and places them on the CC lines.

TCPC API The TCPC device driver functions as the liaison between the TCPC device and the application software; this is accomplished by the Zephyr's API provided by the device driver that's used to communicate with and control the TCPC device.

Wakeup Controller (WUC)

Overview The Wakeup Controller (WUC) API provides a common interface for enabling and managing wakeup sources that can bring the system out of low-power states. WUC devices are typically described in Devicetree and referenced by clients using `wuc_dt_spec`.

Devicetree Configuration Wakeup controllers are referenced from client nodes with the `wakeup-ctrls` property. The property encodes a phandle to the WUC device and an identifier for the wakeup source.

Example Devicetree fragment:

```
wuc0: wakeup-controller@40000000 {
    compatible = "nxp,mcx-wuc";
    reg = <0x40000000 0x1000>;
    #wakeup-ctrl-cells = <1>;
};

button0: button@0 {
    wakeup-ctrls = <&wuc0 10>;
};
```

Basic Operation Applications typically obtain a `wuc_dt_spec` using `WUC_DT_SPEC_GET` and then enable or disable the wakeup source as needed.

Listing 4: Enable a wakeup source from Devicetree

```
#define BUTTON0_NODE DT_NODELABEL(button0)

static const struct wuc_dt_spec button_wuc =
    WUC_DT_SPEC_GET(BUTTON0_NODE);

if (!device_is_ready(button_wuc.dev)) {
    return -ENODEV;
}

return wuc_enable_wakeup_source_dt(&button_wuc);
```

If a driver supports it, applications can check and clear a wakeup source's triggered state. When not implemented, the APIs return `-ENOSYS`.

Listing 5: Check and clear a wakeup source

```
int ret;

ret = wuc_check_wakeup_source_triggered_dt(&button_wuc);
if (ret > 0) {
    (void)wuc_clear_wakeup_source_triggered_dt(&button_wuc);
}
```

Sensors

6.7.8 Sensors

Environmental and motion sensors, GNSS, biometrics, and sensor interfaces.

Sensors

The sensor driver API provides functionality to uniformly read, configure, and setup event handling for devices that take real world measurements in meaningful units.

Sensors range from very simple temperature-reading devices that must be polled with a fixed scale to complex devices taking in readings from multitudes of sensors and themselves producing new inferred sensor data such as step counts, presence detection, orientation, and more.

Supporting this wide breadth of devices is a demanding task and the sensor API attempts to provide a uniform interface to them.

Using Sensors Using sensors from an application there are some APIs and terms that are helpful to understand. Sensors in Zephyr are composed of *Sensor Channels*, *Sensor Attributes*, and *Sensor Triggers*. Attributes and triggers may be device or channel specific.

> **Note**
>
> Getting samples from sensors using the sensor API today can be done in one of two ways. A stable and long-lived API *Fetch and Get*, or a newer but rapidly stabilizing API *Read and Decode*. It's expected that in the near future *Fetch and Get* will be deprecated in favor of *Read and Decode*. Triggers are handled entirely differently for *Fetch and Get* or *Read and Decode* and the differences are noted in each of those sections.

Sensor Attributes *Attributes*, enumerated in `sensor_attribute`, are immutable and mutable properties of a sensor and its channels.

Attributes allow for obtaining metadata and changing configuration of a sensor. Common configuration parameters like channel scale, sampling frequency, adjusting channel offsets, signal filtering, power modes, on chip buffers, and event handling options are very common. Attributes provide a flexible API for inspecting and manipulating such device properties.

Attributes are specified using `sensor_attribute` which can be used with `sensor_attr_get()` and `sensor_attr_set()` to get and set a sensors attributes.

A quick example...

```
const struct device *accel_dev = DEVICE_DT_GET(DT_ALIAS(accel0));
struct sensor_value accel_sample_rate;
int rc;

rc = sensor_attr_get(accel_dev, SENSOR_CHAN_ACCEL_XYZ,␣
↪SENSOR_ATTR_SAMPLING_FREQUENCY, &accel_sample_rate);
if (rc != 0) {
            printk("Failed to get sampling frequency\n");
}

printk("Sample rate for accel %p is %d.06%d\n", accel_dev, accel_sample_rate.val1,␣
↪accel_sample_rate.val2*1000000);

accel_sample_rate.val1 = 2000;

rc = sensor_attr_set(accel_dev, SENSOR_CHAN_ACCEL_XYZ,␣
↪SENSOR_ATTR_SAMPLING_FREQUENCY, accel_sample_rate);
```

(continues on next page)

(continued from previous page)

```
if (rc != 0) {
            printk("Failed to set sampling frequency\n");
}
```

Sensor Channels *Channels*, enumerated in `sensor_channel`, are quantities that a sensor device can measure.

Sensors may have multiple channels, either to represent different axes of the same physical property (e.g. acceleration); or because they can measure different properties altogether (ambient temperature, pressure and humidity). Sensors may have multiple channels of the same measurement type to enable measuring many readings of perhaps temperature, light intensity, amperage, voltage, or capacitance for example.

A channel is specified in Zephyr using a `sensor_chan_spec` which is a pair containing both the channel type (`sensor_channel`) and channel index. At times only `sensor_channel` is used but this should be considered historical since the introduction of `sensor_chan_spec` for Zephyr 3.7.

Sensor Triggers *Triggers*, enumerated in `sensor_trigger_type`, are sensor generated events. Typically sensors allow setting up these events to cause digital line signaling for easy capture by a microcontroller. The events can then commonly be inspected by reading registers to determine which event caused the digital line signaling to occur.

There are many kinds of triggers sensors provide, from informative ones such as data ready to physical events such as taps or steps.

Power Management Power management of sensors is often a non-trivial task as sensors may have multiple power states for various channels. Some sensors may allow for low noise, low power, or suspending channels potentially saving quite a bit of power at the cost of noise or sampling speed performance. In very low power states sensors may lose their state, turning off even the digital logic portion of the device.

All this is to say that power management of sensors is typically application specific! Often the channel states are mutable using *Sensor Attributes*. While total device suspending and resume can be done using the power management ref counting APIs if the device implements the necessary functionality.

Most likely the API sensors should use for their fully suspended/resume power states is *Device Runtime Power Management* using explicit calls at an application level to `pm_device_runtime_get()` and `pm_device_runtime_put()`.

In the future, with *Read and Decode* its possible that automatic management of device power management would be possible in the streaming case as the application informs the driver of usage at all times through requests to read on given events.

Device Tree In the context of sensors device tree provides the initial hardware configuration for sensors on a per device level. Each device must specify a device tree binding in Zephyr, and ideally, a set of hardware configuration options for things such as channel power modes, data rates, filters, decimation, and scales. These can then be used in a boards devicetree to configure a sensor to its initial state.

```
#include <zephyr/dt-bindings/icm42688.h>

&spi0 {
    /* SPI bus options here, not shown */

    accel_gyro0: icm42688p@0 {
        compatible = "invensense,icm42688", "invensense,icm4268x";
```

(continues on next page)

(continued from previous page)

```
        reg = <0>;
        int-gpios = <&pioc 6 GPIO_ACTIVE_HIGH>; /* SoC specific pin to select for␣
↪interrupt line */
        spi-max-frequency = <DT_FREQ_M(24)>; /* Maximum SPI bus frequency */
        accel-pwr-mode = <ICM42688_ACCEL_LN>; /* Low noise mode */
        accel-odr = <ICM42688_ACCEL_ODR_2000>; /* 2000 Hz sampling */
        accel-fs = <ICM42688_ACCEL_FS_16>; /* 16G scale */
        gyro-pwr-mode = <ICM42688_GYRO_LN>; /* Low noise mode */
        gyro-odr = <ICM42688_GYRO_ODR_2000>; /* 2000 Hz sampling */
        gyro-fs = <ICM42688_GYRO_FS_16>; /* 16G scale */
    };
};
```

Fetch and Get The stable and long existing APIs for reading sensor data and handling triggers are:

- `sensor_sample_fetch()`
- `sensor_sample_fetch_chan()`
- `sensor_channel_get()`
- `sensor_trigger_set()`

These functions work together. The fetch APIs block the calling context which must be a thread until the requested `sensor_channel` (or all channels) has been obtained and stored into the driver instance's private data.

The channel data most recently fetched can then be obtained as a `sensor_value` by calling `sensor_channel_get()` for each channel type.

Warning

It should be noted that calling fetch and get from multiple contexts without a locking mechanism is undefined and most sensor drivers do not attempt to internally provide exclusive access to the device during or between these calls.

Polling Using fetch and get sensor can be read in a polling manner from software threads.

#include <zephyr/sys/printk.h>
#include <stdio.h>

int main(void)
{
        const struct device *const dev = DEVICE_DT_GET(DT_ALIAS(magn0));
        struct sensor_value value_x, value_y, value_z;
        int ret;
```

(continues on next page)

(continued from previous page)

```
        if (!device_is_ready(dev)) {
                printk("sensor: device not ready.\n");
                return 0;
        }

        printk("Polling magnetometer data from %s.\n", dev->name);

        while (1) {
                ret = sensor_sample_fetch(dev);
                if (ret) {
                        printk("sensor_sample_fetch failed ret %d\n", ret);
                        return 0;
                }

                ret = sensor_channel_get(dev, SENSOR_CHAN_MAGN_X, &value_x);
                ret = sensor_channel_get(dev, SENSOR_CHAN_MAGN_Y, &value_y);
                ret = sensor_channel_get(dev, SENSOR_CHAN_MAGN_Z, &value_z);
                printf("( x y z ) = ( %f  %f  %f )\n",
                       sensor_value_to_double(&value_x),
                       sensor_value_to_double(&value_y),
                       sensor_value_to_double(&value_z));

                k_sleep(K_MSEC(500));
        }
        return 0;
}
```

Triggers Triggers in the stable API require enabling triggers with a device specific Kconfig. The device specific Kconfig typically allows selecting the context the trigger runs. The application then needs to register a callback with a function signature matching `sensor_trigger_handler_t` using `sensor_trigger_set()` for the specific triggers (events) to listen for.

> **Note**
>
> Triggers may not be set from user mode threads, and the callback is not run in a user mode context.

There are typically two options provided for each driver where to run trigger handlers. Either the trigger handler is run using the system work queue thread (*Workqueue Threads*) or a dedicated thread. A great example can be found in the BMI160 driver which has Kconfig options for selecting a trigger mode. See `CONFIG_BMI160_TRIGGER_NONE`, `CONFIG_BMI160_TRIGGER_GLOBAL_THREAD` (work queue), `CONFIG_BMI160_TRIGGER_OWN_THREAD` (dedicated thread).

Some notable attributes of using a driver dedicated thread vs the system work queue.

- Driver dedicated threads have dedicated stack (RAM) which only gets used for that single trigger handler function.
- Driver dedicated threads *do* get their own priority typically which lets you prioritize trigger handling among other threads.
- Driver dedicated threads will not have head of line blocking if the driver needs time to handle the trigger.

Note

In all cases it's very likely there will be variable delays from the actual interrupt to your callback function being run. In the work queue (GLOBAL_THREAD) case the work queue itself can be the source of variable latency!

        if (rc != 0) {
                printk("Failed to set trigger handler for taps, error %d\n", rc);
                return rc;
        }

        return rc;
}
```

Read and Decode The quickly stabilizing APIs for reading sensor data are:

- `sensor_read()`
- `sensor_read_async_mempool()`
- `sensor_get_decoder()`
- `sensor_decode()`

Benefits over *Fetch and Get* These APIs allow for a wider usage of sensors, sensor types, and data flows with sensors. These are the future looking APIs in Zephyr and solve many issues that have been run into with *Fetch and Get*.

`sensor_read()` and similar functions acquire sensor encoded data into a buffer provided by the caller. Decode (`sensor_decode()`) then decodes the sensor specific encoded data into fixed point `q31_t` values as vectors per channel. This allows further processing using fixed point DSP functions that work on vectors of data to be done (e.g. low-pass filters, FFT, fusion, etc).

Reading is by default asynchronous in its implementation and takes advantage of *Real Time I/O (RTIO)* to enable chaining asynchronous requests, or starting requests against many sensors simultaneously from a single call context.

This enables incredibly useful code flows when working with sensors such as:

- Obtaining the raw sensor data, decoding never, later, or on a separate processor (e.g. a phone).
- Starting a read for sensors directly from an interrupt handler. No dedicated thread needed saving precious stack space. No work queue needed introducing variable latency. Starting a read for multiple sensors simultaneously from a single call context (interrupt/thread/work queue).
- Requesting multiple reads to the same device for Ping-Pong (double buffering) setups.
- Creating entire pipelines of data flow from sensors allowing for software defined virtual sensors (*Sensing Subsystem*) all from a single thread with DAG process ordering.
- Potentially pre-programming DMAs to trigger on GPIO events, leaving the CPU entirely out of the loop in handling sensor events like FIFO watermarks.

Additionally, other shortcomings of *Fetch and Get* related to memory and trigger handling are solved.

- Triggers result in enqueued events, not callbacks.
- Triggers can be setup to automatically fetch data. Potentially enabling pre-programmed DMA transfers on GPIO interrupts.
- Far less likely triggers are missed due to long held interrupt masks from callbacks and context swapping.
- Sensor FIFOs supported by wiring up FIFO triggers to read data into mempool allocated buffers.
- All sensor processing can be done in user mode (memory protected) threads.
- Multiple sensor channels of the same type are better supported.

Note

For *Read and Decode* benefits to be fully realized requires *Real Time I/O (RTIO)* compliant communication access to the sensor. Typically this means an *Real Time I/O (RTIO)* enabled bus driver for SPI or I2C.

Polling Read Polling reads with *Read and Decode* can be accomplished by instantiating a polling I/O device (akin to a file descriptor) for the sensor with the desired channels to poll. Requesting either blocking or non-blocking reads, then optionally decoding the data into fixed point values.

Polling a temperature sensor and printing its readout is likely the simplest sample to show how this all works.

```
/*
 * Copyright (c) 2024 Intel Corporation
 *
 * SPDX-License-Identifier: Apache-2.0
 */

#include <zephyr/drivers/sensor.h>

#define TEMP_CHANNEL {SENSOR_CHAN_AMBIENT_TEMP, 0}

const struct device *const temp0 = DEVICE_DT_GET(DT_ALIAS(temp0));

SENSOR_DT_READ_IODEV(temp_iodev, DT_ALIAS(temp0), TEMP_CHANNEL);
RTIO_DEFINE(temp_ctx, 1, 1);

int main(void)
{
        int rc;
        uint8_t buf[8];
        struct sensor_q31_data temp_data = {0};
        struct sensor_decode_context temp_decoder = SENSOR_DECODE_CONTEXT_INIT(
                SENSOR_DECODER_DT_GET(DT_ALIAS(temp0)), buf,␣
↪SENSOR_CHAN_AMBIENT_TEMP, 0);

        while (1) {
                /* Blocking read */
                rc = sensor_read(temp_iodev, &temp_ctx, buf, sizeof(buf));

                if (rc != 0) {
                        printk("sensor_read() failed %d\n", rc);
                }

                /* Decode the data into a single q31 */
                sensor_decode(&temp_decoder, &temp_data, 1);

                printk("Temperature " PRIsensor_q31_data "\n",
                       PRIsensor_q31_data_arg(temp_data, 0));

                k_msleep(1);
        }
}
```

Polling Read with Multiple Sensors One of the benefits of Read and Decode is the ability to concurrently read many sensors with many channels in one thread. Effectively read requests are started asynchronously for all sensors and their channels. When each read completes we then decode the sensor data. Examples speak loudly and so a sample showing how this might work with multiple temperature sensors with multiple temperature channels:

```
/*

                        uint32_t temp_fits[2] = { 0, 0 };

                        decoder->decode(buf, {SENSOR_CHAN_AMBIENT_TEMP, 0},
                                        &temp_fits[0], 1, &temp_data[0]);
                        decoder->decode(buf, {SENSOR_CHAN_AMBIENT_TEMP, 1},
                                        &temp_fits[1], 1, &temp_data[1]);

                        /* Done with the buffer, release it */
                        rtio_release_buffer(&temp_ctx, buf, buf_len);

                        printk("Temperature for %s channel 0 " PRIsensor_q31_data
↪", channel 1 "
                            PRIsensor_q31_data "\n",
                            dev->name,
                            PRIsensor_q31_data_arg(temp_data[0], 0),
                            PRIsensor_q31_data_arg(temp_data[1], 0));
                }
        }

        k_msleep(1);
}
```

Streaming Handling triggers with *Read and Decode* works by setting up a stream I/O device configuration. A stream specifies the set of triggers to capture and if data should be captured with the event.

Note

Implementing the driver side of the sensor API requires an understanding how the sensor APIs are used. Please read through *Using Sensors* first!

Implementing Sensor Drivers

Implementing Attributes

- SHOULD implement attribute setting in a blocking manner.
- SHOULD provide the ability to get and set channel scale if supported by the device.
- SHOULD provide the ability to get and set channel sampling rate if supported by the device.

Implementing Fetch and Get

- SHOULD implement `sensor_sample_fetch_t` as a blocking call that stashes the specified channels (or all sensor channels) as driver instance data.
- SHOULD implement `sensor_channel_get_t` without side effects manipulating driver state returning stashed sensor readings.
- SHOULD implement `sensor_trigger_set_t` storing the address of the `sensor_trigger` rather than copying the contents. This is so `CONTAINER_OF` may be used for trigger callback context.

Implementing Read and Decode

- MUST implement `sensor_submit_t` as a non-blocking call.
- SHOULD implement `sensor_submit_t` using *Real Time I/O (RTIO)* to do non-blocking bus transfers if possible.
- MAY implement `sensor_submit_t` using a work queue if *Real Time I/O (RTIO)* is unsupported by the bus.
- SHOULD implement `sensor_submit_t` checking the `rtio_sqe` is of type `RTIO_SQE_RX` (read request).
- SHOULD implement `sensor_submit_t` checking all requested channels supported or respond with an error if not.
- SHOULD implement `sensor_submit_t` checking the provided buffer is large enough for the requested channels.
- SHOULD implement `sensor_submit_t` in a way that directly reads into the provided buffer avoiding copying of any kind, with few exceptions.
- MUST implement `sensor_decoder_api` with pure stateless functions. All state needed to convert the raw sensor readings into fixed point SI united values must be in the provided buffer.
- MUST implement `sensor_get_decoder_t` returning the `sensor_decoder_api` for that device type.

- X-NUCLEO-IKS4A1 shield - Standard (Mode 1)Interact with all the sensors of an X-NUCLEO-IKS4A1 shield using Standard mode.

Sensor emulator backend API

GNSS (Global Navigation Satellite System)

Overview GNSS is a general term which covers satellite systems used for navigation, like GPS (Global Positioning System). GNSS services are usually accessed through GNSS modems which receive and process GNSS signals to determine their position, or more specifically, their antennas position. They usually additionally provide a precise time synchronization mechanism, commonly named PPS (Pulse-Per-Second).

Subsystem support The GNSS subsystem is based on the *Modem modules*. The GNSS subsystem covers everything from sending and receiving commands to and from the modem, to parsing, creating and processing NMEA0183 messages.

Adding support for additional NMEA0183 based GNSS modems requires little more than implementing power management and configuration for the specific GNSS modem.

Adding support for GNSS modems which use other protocols and/or buses than the usual NMEA0183 over UART is possible, but will require a bit more work from the driver developer.

Power management GNSS receivers typically begin acquiring and tracking GNSS signals as soon as they are powered on, unless configured otherwise. In order to preserve power, an application can either remove power from the GNSS receiver or stop the internal GNSS engine from actively acquiring and tracking signals. The latter option halts position computation while keeping the receiver powered with reduced power consumption and the communication link to the host application available for other operations or for resuming the GNSS engine.

In the GNSS subsystem, this can be done using the `gnss_stop()` API call. This is distinct from Zephyr's device power management (suspend/resume): the receiver remains powered and able to communicate with the host application, but GNSS tracking is stopped.

GNSS tracking can be resumed using `gnss_start()`. The application can specify a `gnss_start_mode`, which affects time-to-first-fix. A hot start preserves navigation data and allows the receiver to reacquire signals quickly, while warm and cold starts discard some or all navigation data, respectively, resulting in longer acquisition times.

GNSS device drivers must ensure the GNSS modem starts tracking when resumed from a suspended or powered-off state, without requiring the application to call `gnss_start()` explicitly. Most receivers will end up performing a cold start in this situation, simply because they lost their tracking data while unpowered, but a driver may instead attempt a warm or hot start if the modem retained enough state to do so faster. The requirement is that tracking resumes automatically on power up; clearing navigation data is only a side effect of the modem having been unpowered, not an intended part of resuming from suspend.

Biometrics

Overview The biometrics API provides a unified interface for biometric sensors such as fingerprint scanners, iris scanners, and face recognition modules. These sensors are commonly used for secure authentication in embedded systems, access control devices, and IoT applications.

The API supports the full lifecycle of biometric operations including enrollment, template management, and matching. Sensors can store templates on-device or on the host system depending on hardware capabilities.

A typical fingerprint enrollment process requires capturing multiple samples of the same finger to create a reliable template. The matching process compares a captured sample against stored templates to verify identity.

Motion & Actuation

6.7.9 Motion & Actuation

PWM, stepper motors, haptics, buzzers, and other actuators.

Haptics

Overview The haptics API allows for the control of haptic driver devices for the purposes of performing haptic feedback events.

During a haptic feedback event the haptic device drives a signal to an actuator. The source of the haptic event signal varies depending on the capabilities of the haptic device.

Some examples of haptic signal sources are analog signals, preprogrammed (ROM) wavetables, synthesized (RAM) wavetables, and digital audio streams.

Additionally, haptic driver devices often offer controls for adjusting and tuning the drive signal to meet the electrical requirements of their respective actuators.

Pulse Width Modulation (PWM)

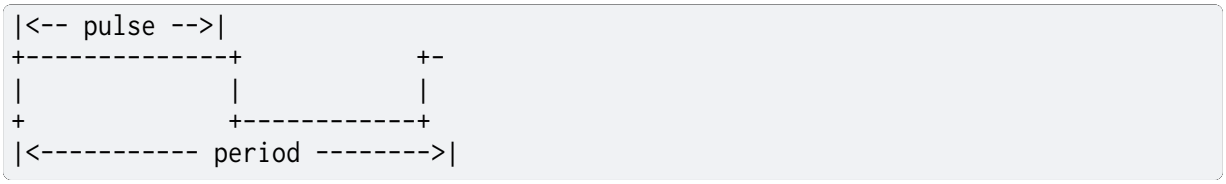
Overview Pulse Width Modulation (PWM) is a technique for encoding information or controlling power delivery by varying the duty cycle of a digital signal. A PWM signal switches between high and low states at a fixed frequency; the fraction of each period spent in the high state is the *duty cycle*.

Common uses of PWM in embedded systems:

- **LED brightness control** — duty cycle maps directly to perceived brightness
- **DC motor speed control** — average voltage is proportional to duty cycle
- **Servo motor positioning** — pulse width encodes the desired angle
- **Audio tone generation** — varying frequency produces audible tones
- **Power conversion** — buck/boost converters and class-D amplifiers

PWM Signal Parameters A PWM signal is described by three values:

- **Period** — the total duration of one on/off cycle, in nanoseconds
- **Pulse width** — the duration of the high (active) portion, in nanoseconds
- **Duty cycle** — the ratio of pulse width to period (expressed as a percentage); a 50% duty cycle means the signal is high for half the period



Zephyr PWM Driver Model Each PWM controller exposes one or more independent *channels*. A channel is identified by a zero-based index and drives a single output pin.

All PWM drivers implement the same API defined in `include/zephyr/drivers/pwm.h`. The central function is `pwm_set()`, which programs the period and pulse width for a channel. Helper macros convert common time units to nanoseconds:

- `PWM_HZ` — frequency in Hz (e.g. `PWM_HZ(1000)` 1 ms period)
- `PWM_KHZ` — frequency in kHz
- `PWM_USEC` — period or pulse width in microseconds
- `PWM_MSEC` — period or pulse width in milliseconds

Device Tree Configuration PWM pins are described in devicetree under the `pwms` property. Each entry specifies the controller phandle, channel number, period in nanoseconds, and optional polarity flags:

```
/ {
    my_node {
        pwms = <&pwm0 0 PWM_MSEC(20) PWM_POLARITY_NORMAL>;
        pwm-names = "servo";
    };
};
```

In C, retrieve the spec with the `PWM_DT_SPEC_GET` family of macros:

```
static const struct pwm_dt_spec servo =
    PWM_DT_SPEC_GET(DT_NODELABEL(my_node));
```

Usage Examples Setting duty cycle using a `pwm_dt_spec`:

```
#include <zephyr/drivers/pwm.h>

static const struct pwm_dt_spec led_pwm =
    PWM_DT_SPEC_GET(DT_ALIAS(pwm_led0));

int set_led_brightness(uint8_t percent)
{
    if (!device_is_ready(led_pwm.dev)) {
        return -ENODEV;
    }

    /* pulse = period * duty_cycle / 100 */
    uint32_t pulse = led_pwm.period / 100 * percent;

    return pwm_set_dt(&led_pwm, led_pwm.period, pulse);
}
```

Setting a servo position (1–2 ms pulse within a 20 ms period):

```
#include <zephyr/drivers/pwm.h>

#define SERVO_PERIOD_NS   PWM_MSEC(20)
#define SERVO_MIN_PULSE   PWM_USEC(1000)
#define SERVO_MAX_PULSE   PWM_USEC(2000)

int set_servo_angle(const struct device *pwm_dev, uint32_t channel,
```

(continues on next page)

(continued from previous page)

```
                    uint8_t angle_deg)
{
    uint32_t pulse = SERVO_MIN_PULSE +
        (SERVO_MAX_PULSE - SERVO_MIN_PULSE) * angle_deg / 180;

    return pwm_set(pwm_dev, channel, SERVO_PERIOD_NS, pulse,
                   PWM_POLARITY_NORMAL);
}
```

PWM Capture Some PWM controllers support *input capture*, which measures the period and/or pulse width of an incoming signal. This is useful for decoding PWM signals from external sources such as RC receivers or sensor outputs.

Enable capture with `pwm_configure_capture()` and `pwm_enable_capture()`:

```
void pwm_capture_cb(const struct device *dev, uint32_t channel,
                    uint32_t period_cycles, uint32_t pulse_cycles,
                    int status, void *user_data)
{
    if (status != 0) {
        return;
    }
    /* convert cycles to nanoseconds using pwm_get_cycles_per_sec() */
}

/* configure for single-shot capture of both period and pulse */
pwm_configure_capture(dev, channel,
                      PWM_CAPTURE_TYPE_BOTH | PWM_CAPTURE_MODE_SINGLE,
                      pwm_capture_cb, NULL);
pwm_enable_capture(dev, channel);
```

Steppers

The stepper driver subsystem consists of two device driver APIs:

Stepper API The stepper driver API provides a common interface for stepper drivers.

- Configure **micro-stepping resolution** using `stepper_set_micro_step_res()` and `stepper_get_micro_step_res()`.
- **Enable** the stepper driver using `stepper_enable()`.
- **Disable** the stepper driver using `stepper_disable()`.
- Register an **event callback** using `stepper_set_event_cb()`.

Stepper Motion Controller API The stepper motion controller API provides a common interface for stepper motion controllers.

- Configure **reference position** in microsteps using `stepper_ctrl_set_reference_position()` and `stepper_ctrl_get_actual_position()`.
- Set **step interval** in nanoseconds between steps using `stepper_ctrl_set_microstep_interval()`
- **Move by** +/- micro-steps also known as **relative movement** using `stepper_ctrl_move_by()`.
- **Move to** a specific position also known as **absolute movement** using `stepper_ctrl_move_to()`.
- Run continuously with a **constant step interval** in a specific direction until a stop is detected using `stepper_ctrl_run()`.
- **Stop** the stepper using `stepper_ctrl_stop()`.
- Check if the stepper is **moving** using `stepper_ctrl_is_moving()`.
- Register an **event callback** using `stepper_ctrl_set_event_cb()`.

Device Tree In the context of stepper motion controllers, devicetree provides the initial hardware configuration for stepper drivers on a per device level. Each device must specify a device tree binding in Zephyr, and ideally, a set of hardware configuration options for things such as current settings, ramp parameters and furthermore. These can then be used in a boards devicetree to configure a stepper driver to its initial state.

Driver Composition Scenarios Below are two typical scenarios:

Integrated Stepper Motion Control and Driver A device composed of both motion controller and stepper driver blocks in a single IC is modeled as a multi-functional device in devicetree, and has two software drivers implementing Stepper Motion Controller and Stepper Hardware Driver APIs respectively. An example of such device is `adi,tmc50xx`.

```
/ {
    aliases {
        x_axis_stepper_ctrl = &tmc50xx_0_motion_controller;
        y_axis_stepper_ctrl =  &tmc50xx_1_motion_controller;
```

(continues on next page)

(continued from previous page)

```
        x_axis_stepper_driver = &tmc50xx_0_stepper_driver;
        y_axis_stepper_driver = &tmc50xx_1_stepper_driver;
    };
};

&spi0 {
    /* SPI bus options here, not shown */

    /* Dual controller/driver for up to two 2-phase bipolar stepper motors */
    tmc50xx: tmc50xx@0 {
        compatible = "adi,tmc50xx";
        reg = <0>;
        spi-max-frequency = <DT_FREQ_M(8)>; /* Maximum SPI bus frequency */

        poscmp-enable; test-mode; lock-gconf; /* ADI TMC Global configuration␣
↪flags */
        clock-frequency = <DT_FREQ_M(16)>; /* Internal/External Clock frequency */

        tmc50xx_0_stepper_driver: stepper-driver-0 {
            idx = <0>;
             compatible = "adi,tmc50xx-stepper-driver";
             micro-step-res = <256>;
             /* ADI TMC stallguard settings specific to TMC50XX */
             stallguard2-threshold=<30>;
         };

        tmc50xx_0_motion_controller: motion-controller-0 {
            idx = <0>;
            compatible = "adi,tmc50xx-stepper-ctrl";
            ...
            vmax = <900000>;
            amax = <50000>;
            ...
            activate-stallguard2;
            ...
         };

        tmc50xx_1_stepper_driver: stepper-driver-1 {
            idx = <1>;
             compatible = "adi,tmc50xx-stepper-driver";
             micro-step-res = <256>;
             /* ADI TMC stallguard settings specific to TMC50XX */
             stallguard2-threshold=<30>;
         };

        tmc50xx_1_motion_controller: motion-controller-1 {
            idx = <1>;
            compatible = "adi,tmc50xx-stepper-ctrl";
            ...
            vstart = <1000>;
            ...
            stallguard-threshold-velocity=<200000>;
         };
     };
};
```

Following the aforementioned configurations, the stepper driver subsystem can be used in the

application code as follows:

```
static const struct device *x_stepper_ctrl =␣
↪DEVICE_DT_GET(DT_ALIAS(x_axis_stepper_ctrl));
static const struct device *x_stepper_driver =␣
↪DEVICE_DT_GET(DT_ALIAS(x_axis_stepper_driver));
static const struct device *y_stepper_ctrl =␣
↪DEVICE_DT_GET(DT_ALIAS(y_axis_stepper_ctrl));
static const struct device *y_stepper_driver =␣
↪DEVICE_DT_GET(DT_ALIAS(y_axis_stepper_driver));
...
stepper_ctrl_move_to(x_stepper_ctrl, 200);
stepper_ctrl_stop(x_stepper_ctrl);
stepper_disable(x_stepper_driver);
stepper_disable(y_stepper_driver);
```

Individual Stepper Motion Controller and Driver Following is an example of a device tree configuration for a stepper driver with a dedicated stepper motion controller:

```
/ {
    aliases {
        stepper_driver = &tmc2209
        stepper_ctrl = &step_dir_motion_control;
    };

    tmc2209: tmc2209 {
        compatible = "adi,tmc2209";
        enable-gpios = <&gpioa 6 GPIO_ACTIVE_HIGH>;
        m0-gpios = <&gpiob 0 GPIO_ACTIVE_HIGH>;
        m1-gpios = <&gpioa 7 GPIO_ACTIVE_HIGH>;
    };

    step_dir_motion_control: step-dir-motion-control {
        compatible = "zephyr,gpio-step-dir-stepper-ctrl";
        step-gpios = <&gpioa 9 GPIO_ACTIVE_HIGH>;
        dir-gpios = <&gpioc 7 GPIO_ACTIVE_HIGH>;
        invert-direction;
        stepper-driver = <&tmc2209>;
    };
};
```

Following the aforementioned configurations, the stepper driver subsystem can be used in the application code as follows:

```
static const struct device *stepper_driver =␣
↪DEVICE_DT_GET(DT_ALIAS(stepper_driver));
static const struct device *stepper_ctrl = DEVICE_DT_GET(DT_ALIAS(stepper_ctrl));
...
stepper_ctrl_move_to(stepper_ctrl, 200);
stepper_ctrl_stop(stepper_ctrl);
stepper_disable(stepper_driver);
```

Stepper Motion Controller API Test Suite The stepper motion controller API test suite provides a set of tests that can be used to verify the functionality of stepper motion controllers.

```

Trinamic

Trinamic Stepper Controller

Buzzer

The buzzer subsystem exposes an API to drive buzzer hardware uniformly, regardless of whether the underlying part is a passive piezo driven by a PWM channel or an active buzzer controlled by a single GPIO line.

Basic Operation Applications obtain a buzzer device through devicetree and drive it through the functions in include/zephyr/drivers/buzzer.h:

Buzzer API calls do not wait for the requested tone duration. Durations describe how long the hardware should keep emitting a tone, not how long the calling thread should sleep; use `BUZZER_DURATION_FOREVER` to play until an explicit stop.

- `buzzer_tone()` plays a tone at a specific frequency for a specific duration. The hardware keeps emitting the tone for the requested duration and the driver silences it automatically.
- `buzzer_beep()` plays the buzzer's natural operating frequency, encoded by the board file in the period cell of the `pwms` DT property (typically the piezo's mechanical resonance, which is the loudest tone the part can produce). On active buzzers the call is equivalent to driving the GPIO line on, since the hardware oscillator determines the actual pitch.
- `buzzer_set_volume()` adjusts the perceived loudness. Zero silences immediately; non-zero values are stored and applied on the next tone. Active buzzers, lacking analog volume control, map zero to silent and any non-zero value to their single audible level.
- `buzzer_stop()` cancels any in-progress tone immediately.

Backends Two devicetree-discoverable backends are provided:

- `pwm-buzzer` for passive piezo buzzers driven from a PWM channel. The PWM channel period sets the audio frequency and the duty cycle sets the perceived volume; the driver derives both from the application's tone and volume requests.
- `gpio-buzzer` for active buzzers driven through a single GPIO. The driver toggles the line on for any non-zero frequency and off for `BUZZER_FREQ_REST`.

System & Diagnostics

6.7.10 System & Diagnostics

System information, synchronization, DMA, and diagnostics.

Hardware Information

Overview The HW Info API provides access to hardware information such as device identifiers and reset cause flags.

Reset cause flags can be used to determine why the device was reset; for example due to a watchdog timeout or due to power cycling. Different devices support different subset of flags. Use `hwinfo_get_supported_reset_cause()` to retrieve the flags that are supported by that device.

Most implementations are SoC specific, reading the identifiers from vendor registers or memory. The generic `zephyr,hwinfo-nvmem` backend sources the device ID, and optionally the EUI-64, from NVMEM cells (see *Non-Volatile Memory (NVMEM)*).

Hardware Spinlocks (HWSPINLOCK)

Overview An HWSPINLOCK device is a peripheral used to protect shared resources across clusters in the system. Each HWSPINLOCK instance is providing one or more spinlocks. The api is similar to regular zephyr spinlocks.

Spinlock APIs

Because we also want to protect the spinlock resource to be used by multiple cores in the same cluster, each HWSPINLOCK device include a regular zephyr spinlock, and use it to lock the access to HWSPINLOCK hardware.

API Reference

Entropy

Overview The entropy API provides functions to retrieve entropy values from entropy hardware present on the platform. The entropy APIs are provided for use by the random subsystem and cryptographic services. They are not suitable to be used as random number generation functions.

API Reference

Entropy

Error Detection And Correction (EDAC)

Error Detection And Correction is a mechanism used to detect and correct errors while storing or reading data.

In Band Error Correction Code (IBECC)

Overview The mechanism initially found in Intel Elkhart Lake SOCs and later boards is an integrated memory controller with IBECC.

The In-Band Error Correction Code (IBECC) improves reliability by providing error detection and correction. IBECC can work for all or for specific regions of physical memory space. The IBECC is useful for memory technologies that do not support the out-of-band ECC.

IBECC adds memory overhead of 1/32 of the memory. This memory is not accessible and used to store ECC syndrome data. IBECC converts read / write transactions to two separate transactions: one for actual data and another for cache line containing ECC value.

There is a debug feature IBECC Error Injection which helps to debug and verify IBECC functionality. ECC errors are injected on the write path and cause ECC errors on the read path.

IBECC Configuration There are three IBECC operation modes which can be selected by Bootloader. They are listed below:

- OPERATION_MODE = 0x0 sets functional mode to protect requests based on address range
- OPERATION_MODE = 0x1 sets functional mode to all requests not be protected and to ignore range checks

- OPERATION_MODE = 0x2 sets functional mode to protect all requests and ignore range checks

IBECC operational mode is configured through BIOS or Bootloader. For operation mode 0 there are more BIOS configuration options such as memory regions.

Due to high security risk Error Injection capability should not be enabled for production. Error Injection is only enabled for tests.

IBECC Logging IBECC logs the following fields:

- Error Address
- Error Syndrome
- Error Type
  - Correctable Error (CE) - error is detected and corrected by IBECC module.
  - Uncorrectable Error (UE) - error is detected by IBECC module and not automatically corrected.

The IBECC driver provides error type for the higher-level application to implement desired policy with respect for handling those memory errors. Error syndrome is not used in the IBECC driver but provided to higher-level application.

Usage notes Exceptional care needs to be taken with Non Maskable Interrupt (NMI). NMI will arrive at any time, even if the local CPU has disabled interrupts. That means that no locking mechanism can protect code against an NMI happening. Zephyr's IPC mechanisms universally use local IRQ locking as the base layer for all higher-level synchronization primitives. So, you cannot share anything that is "protected" by a lock with an NMI, because the protection does not work. The only tool you have available for synchronization in the Zephyr API that works against an NMI is the atomic layer. This also applies to callback function which is called by NMI handler.

Coredump Device

Overview The coredump device is a pseudo-device driver with two types.A COREDUMP_TYPE_MEMCPY type exposes device tree bindings for memory address/size values to be included in any dump. And the driver exposes an API to add/remove dump memory regions at runtime. A COREDUMP_TYPE_CALLBACK device requires exactly one entry in the memory-regions array with a size of 0 and a desired size. The driver will statically allocate memory of the desired size and provide an API to register a callback function to fill that memory when a dump occurs.

Platform Environment Control Interface (PECI)

Overview The Platform Environment Control Interface, abbreviated as PECI, is a thermal management standard introduced in 2006 with the Intel Core 2 Duo Microprocessors. The PECI interface allows external devices to read processor temperature, perform processor manageability functions, and manage processor interface tuning and diagnostics. The PECI bus driver APIs enable the interaction between Embedded Microcontrollers and CPUs.

Direct Memory Access (DMA)

Overview Direct Memory Access (Controller) is a commonly provided type of co-processor that can typically offload transferring data to and from peripherals and memory.

The DMA API is not a portable API and really cannot be as each DMA has unique memory requirements, peripheral interactions, and features. The API in effect provides a union of all useful DMA functionality drivers have needed in the tree. It can still be a good abstraction, with care, for peripheral devices for vendors where the DMA IP might be very similar but have slight variances.

The DMA drivers in general do not handle cache coherency; this is left up to the developer as requirements vary dramatically depending on the application. See *Caching Basics* for an overview of cache management in Zephyr.

Driver Implementation Expectations

Synchronization and Ownership From an API point of view, a DMA channel is a single-owner object, meaning the drivers should not attempt to wrap a channel with kernel synchronization primitives such as mutexes or semaphores. If DMA channels require mutating shared registers, those register updates should be wrapped in a spin lock.

This enables the entire API to be low-cost and callable from any call context, including ISRs where it may be very useful to start/stop/suspend/resume/reload a channel transfer.

Transfer Descriptor Memory Management Drivers should not attempt to use heap allocations of any kind. If object pools are needed for transfer descriptors then those should be setup in a way that does not break the promise of ISR-allowable calls. Many drivers choose to create a simple static descriptor array per channel with the size of the descriptor array adjustable using Kconfig.

Channel State Machine Expectations DMA channels should be viewed as state machines that the DMA API provides transition events for in the form of API calls. Every driver is expected to maintain its own channel state tracking. The busy state of the channel should be inspectable at any time with `dma_get_status()`.

A diagram, showing those expected possible state transitions and their API calls is provided here for reference.

Multiplexer (MUX)

Overview The MUX subsystem provides a unified API for hardware signal multiplexers, it lets consumer drivers route an input signal to an output by referencing a MUX controller through standard devicetree `mux-controls` or `mux-states` phandle-array properties, without depending on any vendor-specific HAL.

The subsystem distinguishes two consumer-side patterns:

- `mux-controls` — the consumer references a controller and supplies the *state* (which input to route, or which output pattern to write) at runtime via `mux_control_set()`. Use this when the routing changes during normal operation.
- `mux-states` — the consumer references a controller *and* a fixed state in devicetree (the trailing cell of the specifier is the state value). The runtime call `mux_state_apply()` programs that fixed state in one line. Use this when the routing is decided at integration time and never changes after init.

Devicetree bindings

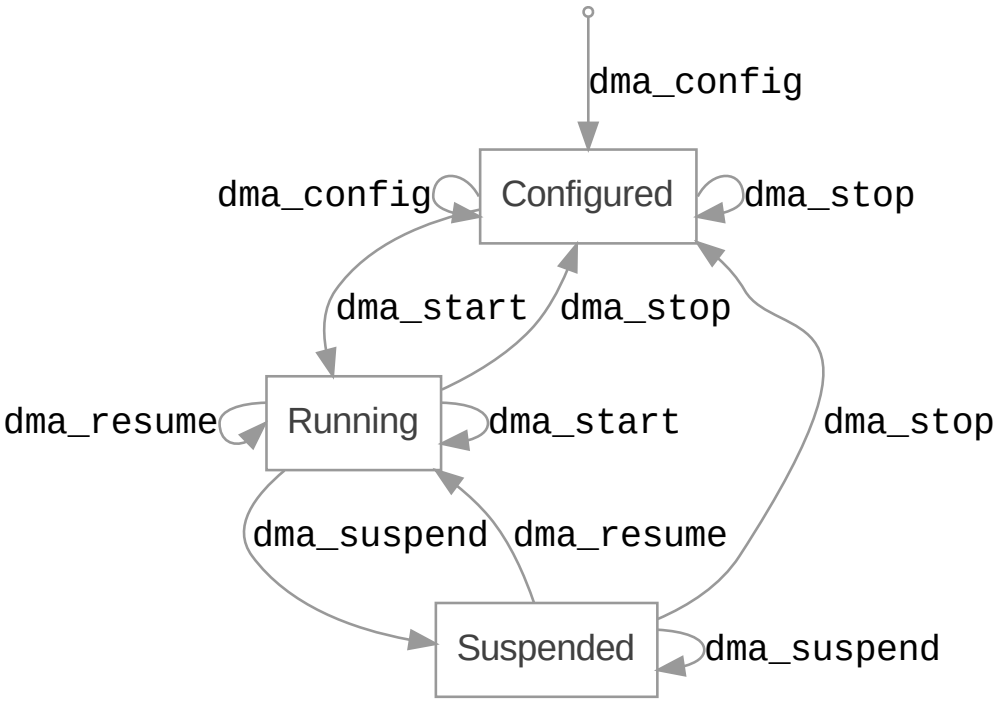

Fig. 2: DMA state finite state machine

Controller side Every MUX controller binding includes `mux-controller.yaml` (in `dts/bindings/mux/`) and declares two cell-count properties:

- `#mux-control-cells` — number of cells in a `mux-controls` specifier, used purely to address the desired control line within the controller.
- `#mux-state-cells` — number of cells in a `mux-states` specifier; equals `#mux-control-cells + 1`. The trailing cell carries the state value and is extracted by the framework into `mux_state::state` at compile time.

Backends are free to name the addressing cells after their hardware (`channel`, `output`, `index`, `device/input`, ...) and to name the trailing state cell after its hardware semantics (`state`, `input`, `connection`, `source`, ...).

Consumer side Consumers include `mux-consumer.yaml` and may set:

- `mux-controls` — list of phandle + addressing-cells tuples.
- `mux-control-names` — optional names matching `mux-controls` entries.
- `mux-states` — list of phandle + addressing-cells + trailing state cell tuples.
- `mux-state-names` — optional names matching `mux-states` entries.

- LiteX clock control driverUse LiteX clock control driver to generate multiple clock signals.

Clock Monitor

Overview The clock monitor API provides access to hardware peripherals that observe a clock signal at runtime and report when its frequency drifts outside expected bounds or stops entirely. It is intended for functional-safety and diagnostic use cases — detecting failed oscillators, lost reference clocks, or out-of-spec frequency drift on critical clock trees.

Operating Modes Both modes share one lifecycle: configure with `clock_monitor_configure()`, begin operation with `clock_monitor_start()`, end it with `clock_monitor_stop()`.

The API exposes two operating modes:

`CLOCK_MONITOR_MODE_WINDOW`
: Continuous threshold check. The hardware compares the monitored clock's frequency against programmable high and low bounds derived from `clock_monitor_window_cfg.expected_hz` and `clock_monitor_window_cfg.tolerance_ppm`. Threshold crossings are delivered asynchronously through the user callback installed at configure time.

`CLOCK_MONITOR_MODE_MEASURE`
: One frequency measurement per `clock_monitor_start()`, delivered through the configure-time callback (`CLOCK_MONITOR_EVT_MEASURE_DONE` plus the measured value in Hz). The device automatically returns to the configured (stopped) state before the callback runs, so no `clock_monitor_stop()` is needed on the happy path. To repeat the measurement, call `clock_monitor_start()` again from the callback — both `clock_monitor_start()` and `clock_monitor_stop()` are ISR-safe (the same idiom as re-arming a counter alarm from its callback).

For MEASURE mode, the API provides no blocking wait: the application owns the timeout. The usual pattern is to wait on a semaphore given from the callback with an application-chosen timeout and call `clock_monitor_stop()` on the timeout path to abort the in-flight measurement. Alternatively, the most recent result can be polled with `clock_monitor_get_rate()` — also the retrieval path for user-mode threads, where callbacks may not be installed.

Events Events are delivered as a bitmask in `clock_monitor_event_data.events`:

- `CLOCK_MONITOR_EVT_FREQ_HIGH` — monitored frequency exceeded the upper threshold (WINDOW mode).
- `CLOCK_MONITOR_EVT_FREQ_LOW` — monitored frequency fell below the lower threshold (WINDOW mode).
- `CLOCK_MONITOR_EVT_CLOCK_LOST` — monitored clock stopped producing edges within the measurement window (MEASURE mode hardware failure).
- `CLOCK_MONITOR_EVT_MEASURE_DONE` — measurement completed successfully (MEASURE mode); `clock_monitor_event_data.measured_hz` holds the result.

The configure-time callback is the only event delivery path. For MEASURE mode the most recent completed result additionally remains retrievable by polling `clock_monitor_get_rate()`. WINDOW-mode user-mode observers, where callbacks may not be installed, receive events via a supervisor-side relay (e.g. `k_msgq` fed from the callback).

Configuration A clock monitor must be configured via `clock_monitor_configure()` before it is started. The configuration carries the operating mode, the mode-specific parameters (expected frequency, tolerance, measurement window) and an optional asynchronous callback. Configuring is only possible while the monitor is stopped; reconfiguration is done by calling `clock_monitor_configure()` again with a new mode/parameter set — there is no separate teardown operation. See `clock_monitor_configure()` in the *API Reference* for the full list of return codes.

Real-Time Clock (RTC)

Overview

Table 2: **Glossary**

Word	Definition
Real-time clock	Low power device tracking time using broken-down time
Real-time counter	Low power counter which can be used to track time
RTC	Acronym for real-time clock

An RTC is a low power device which tracks time using broken-down time. It should not be confused with low-power counters which sometimes share the same name, acronym, or both.

RTCs are usually optimized for low energy consumption and are usually kept running even when the system is in a low power state.

RTCs usually contain one or more alarms which can be configured to trigger at a given time. These alarms are commonly used to wake up the system from a low power state.

Devicetree bindings RTC bindings must include the `rtc-device.yaml` binding, which includes the `base.yaml` binding and the required `alarms-count` property.

```
include: rtc-device.yaml
```

Device driver design

Driver init RTCs are never powered off by the system. On init, drivers should expect the RTC is either:

- Powered, configured, and running.
- Powered, unconfigured, and stopped.

On init, drivers shall ensure the RTC is configured correctly, while preserving the time, alarms, and running status.

Time is set by calling `rtc_set_time()`, at which point the RTC will start running. Alarms pending status is cleared by `rtc_alarm_is_pending()` or by an alarm callback resulting from `rtc_alarm_set_callback()`.

GPIO routed interrupts RTCs with connected interrupt output pins shall configure and enable them on init. The host may enable and disable interrupts for its GPIOs, but RTC interrupt output pins must remain enabled.

This ensures consistent behavior between internally and externally connected RTCs, and allows for system wakeup through GPIO on any enabled RTC event like alarms or update.

Note

RTCs with unconnected interrupt output pins are not allowed to periodically poll the RTC to emulate it being connected. `rtc_alarm_set_callback()` and `rtc_update_set_callback()` shall return `-ENOTSUP` in this case.

Clock output If supported, the clock output configuration is defined in the devicetree. The output is configured by the driver on init.

Configuration Options Related configuration options:

- `CONFIG_RTC`
- `CONFIG_RTC_ALARM`
- `CONFIG_RTC_UPDATE`
- `CONFIG_RTC_CALIBRATION`

RTC

Related code samples

- Real-Time Clock (RTC)Set and read the date/time from a Real-Time Clock.

Fake RTC

RTC device driver test suite The test suite validates the behavior of the RTC device driver. It is designed to be portable between boards. It uses the device tree alias `rtc` to designate the RTC device to test.

This test suite tests the following:

- Setting and getting the time.
- RTC Time incrementing correctly.
- Alarms if supported by hardware, with and without callback enabled

- Calibration if supported by hardware.

The calibration test tests a range of values which are printed to the console to be manually compared. The user must review the set and gotten values to ensure they are valid.

By default, only the mandatory setting and getting of time is enabled for testing. To test the optional alarms, update event callback and clock calibration, these must be enabled by selecting `CONFIG_RTC_ALARM`, `CONFIG_RTC_UPDATE` and `CONFIG_RTC_CALIBRATION`.

The following examples build the test suite for the `native_sim` board. To build the test suite for a different board, replace the `native_sim` board with your board.

To build the test application with the default configuration, testing only the mandatory features, the following command can be used for reference:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/rtc/rtc_api
```

To build the test with additional RTC features enabled, use menuconfig to enable the additional features by updating the configuration. The following command can be used for reference:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/rtc/rtc_api
west build -t menuconfig
```

Then build the test application using the following command:

```
# From the root of the zephyr repository
west build -b native_sim tests/drivers/rtc/rtc_api
```

To run the test suite, flash and run the application on your board, the output will be printed to the console.

> **Note**
>
> The tests take up to 30 seconds each if they are testing real hardware.

RTC emulated device The emulated RTC device fully implements the RTC API, and will behave like a real RTC device, with the following limitations:

- RTC time is not persistent across application initialization.
- RTC alarms are not persistent across application initialization.
- RTC time will drift over time.

Every time an application is initialized, the RTC's time and alarms are reset. Reading the time using `rtc_get_time()` will return `-ENODATA`, until the time is set using `rtc_set_time()`. The RTC will then behave as a real RTC, until the application is reset.

The emulated RTC device driver is built for the compatible `zephyr,rtc-emul` and will be included if `CONFIG_RTC` is selected.

History of RTCs in Zephyr RTCs have been supported before this API was created, using the *Counter* API. The unix timestamp was used to convert between broken-down time and the unix timestamp within the RTC drivers, which internally used the broken-down time representation.

The disadvantages of this approach were that hardware counters could not be set to a specific count, requiring all RTCs to use device specific APIs to set the time, converting from unix time to broken-down time, unnecessarily in some cases, and some common features missing, like input clock calibration and the update callback.

6.8 Pin Control

This is a high-level guide to pin control. See *Pin Control API* for API reference material.

6.8.1 Introduction

The hardware blocks that control pin multiplexing and pin configuration parameters such as pin direction, pull-up/down resistors, etc. are named **pin controllers**. The pin controller's main users are SoC hardware peripherals, since the controller enables exposing peripheral signals, like for example, map `I2C0 SDA` signal to pin `PX0`. Not only that, but it usually allows configuring certain pin settings that are necessary for the correct functioning of a peripheral, for example, the slew-rate depending on the operating frequency. The available configuration options are vendor/SoC dependent and can range from simple pull-up/down options to more advanced settings such as debouncing, low-power modes, etc.

The way pin control is implemented in hardware is vendor/SoC specific. It is common to find a *centralized* approach, that is, all pin configuration parameters are controlled by a single hardware block (typically named pinmux), including signal mapping. The figure below illustrates this approach. `PX0` can be mapped to `UART0_TX`, `I2C0_SCK` or `SPI0_MOSI` depending on the `AF` control bits. Other configuration parameters such as pull-up/down are controlled in the same block via `CONFIG` bits. This model is used by several SoC families, such as many from NXP and STM32.

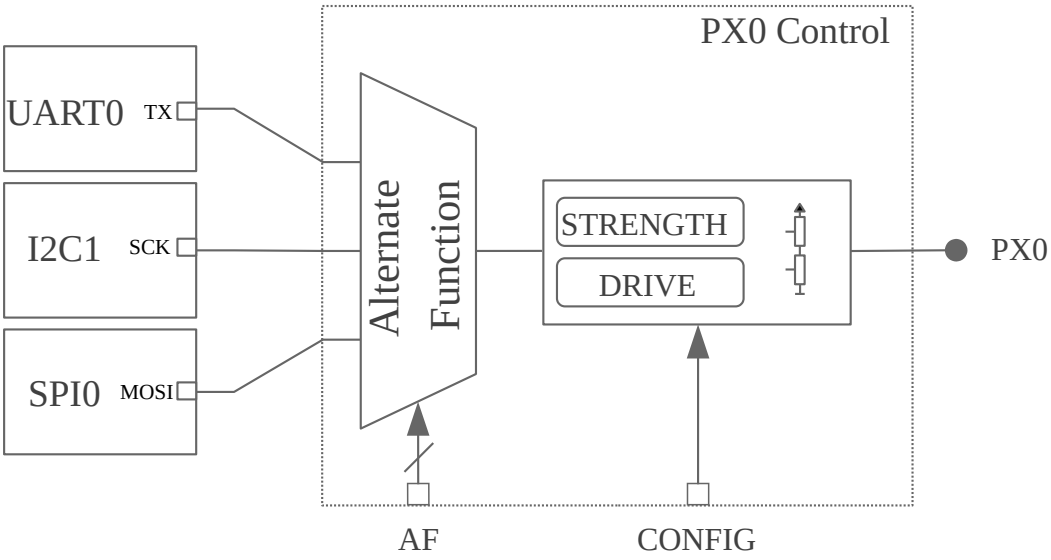

Fig. 3: Example of pin control centralized into a single per-pin block

Other vendors/SoCs use a *distributed* approach. In such case, the pin mapping and configuration are controlled by multiple hardware blocks. The figure below illustrates a distributed approach where pin mapping is controlled by peripherals, such as in Nordic nRF SoCs.

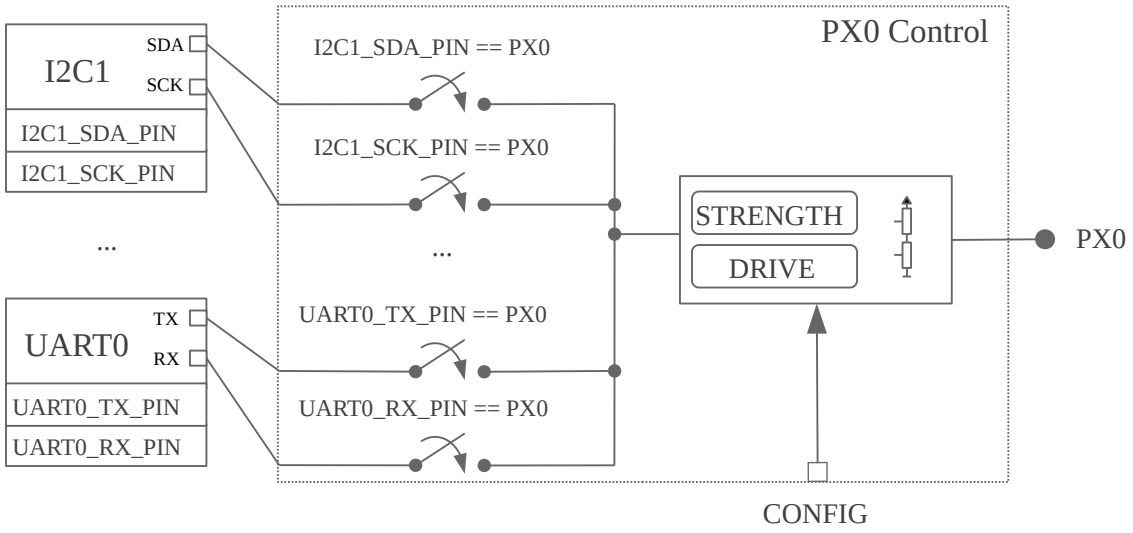

Fig. 4: Example pin control distributed between peripheral registers and per-pin block

From a user perspective, there is no difference in pin controller usage regardless of the hardware implementation: a user will always apply a state. The only difference lies in the driver implementation. In general, implementing a pin controller driver for a hardware that uses a distributed approach requires more effort, since the driver needs to gather knowledge of peripheral dependent registers.

Pin control vs. GPIO

Some functionality covered by a pin controller driver overlaps with GPIO drivers. For example, pull-up/down resistors can usually be enabled by both the pin control driver and the GPIO driver. In Zephyr context, the pin control driver purpose is to perform peripheral signal multiplexing and configuration of other pin parameters required for the correct operation of that peripheral. Therefore, the main users of the pin control driver are SoC peripherals. In contrast, GPIO drivers are for general purpose control of a pin, that is, when its logic level is read or controlled manually.

6.8.2 State model

For a device driver to operate correctly, a certain pin configuration needs to be applied. Some device drivers require a static configuration, usually set up at initialization time. Others need to change the configuration at runtime depending on the operating conditions, for example, to enable a low-power mode when suspending the device. Such requirements are modeled using **states**, a concept that has been adapted from the one in the Linux kernel. Each device driver owns a set of states. Each state has a unique name and contains a full pin configuration set (see the figure below). This effectively means that states are independent of each other, so they do not need to be applied in any specific order. Another advantage of the state model is that it isolates device drivers from pin configuration.

Table 3: Example pin configuration encoded using the states model

UART0 peripheral			
default state		sleep state	
TX	• Pin: PA0 • Pull: NONE • Low Power: NO	TX	• Pin: PA0 • Pull: NONE • Low Power: YES
RX	• Pin: PA1 • Pull: UP • Low Power: NO	RX	• Pin: PA1 • Pull: NONE • Low Power: YES

Standard states

The name assigned to pin control states or the number of them is up to the device driver requirements. In many cases a single state applied at initialization time will be sufficient, but in some other cases more will be required. In order to make things consistent, a naming convention has been established for the most common use cases. The figure below details the standardized states and its purpose.

Table 4: Standardized state names

State	Identifier	Purpose
default	PINCTRL_STATE_DEFAULT	State of the pins when the device is in operational state
sleep	PINCTRL_STATE_SLEEP	State of the pins when the device is in low power or sleep modes

Note that other standard states could be introduced in the future.

Custom states

Some device drivers may require using custom states beyond the standard ones. To achieve that, the device driver needs to have in its scope definitions for the custom state identifiers named as PINCTRL_STATE_{STATE_NAME}, where {STATE_NAME} is the capitalized state name. For example, if mystate has to be supported, a definition named PINCTRL_STATE_MYSTATE needs to be in the driver's scope.

Note

It is important that custom state identifiers start from PINCTRL_STATE_PRIV_START

If custom states need to be accessed from outside the driver, for example to perform dynamic pin control, custom identifiers should be placed in a header that is publicly accessible.

Skipping states

In most situations, the states defined in Devicetree will be the ones used in the compiled firmware. However, there are some cases where certain states will be conditionally used depending on a compilation flag. A typical case is the sleep state. This state is only used in practice if CONFIG_PM or CONFIG_PM_DEVICE is enabled. If a firmware variant without these power management configurations is needed, one should in theory remove the sleep state from Devicetree to not waste ROM space storing such unused state.

States can be skipped by the pinctrl Devicetree macros if a definition named PINCTRL_SKIP_{STATE_NAME} expanding to 1 is present when pin control configuration is defined.

In case of the sleep state, the pinctrl API already provides such definition conditional to the availability of device power management:

```
#if !defined(CONFIG_PM) && !defined(CONFIG_PM_DEVICE)
/** Out of power management configurations, ignore "sleep" state. */
#define PINCTRL_SKIP_SLEEP 1
#endif
```

6.8.3 Dynamic pin control

Dynamic pin control refers to the capability of changing pin configuration at runtime. This feature can be useful in situations where the same firmware needs to run onto slightly different boards, each having a peripheral routed at a different set of pins. This feature can be enabled by setting CONFIG_PINCTRL_DYNAMIC.

Note

Dynamic pin control should only be used on devices that have not been initialized. Changing pin configurations while a device is operating may lead to unexpected behavior. Since Zephyr does not support device de-initialization yet, this functionality should only be used during early boot stages.

One of the effects of enabling dynamic pin control is that pinctrl_dev_config will be stored in RAM instead of ROM (not states or pin configurations, though). The user can then use pinctrl_update_states() to update the states stored in pinctrl_dev_config with a new set. This effectively means that the device driver will apply the pin configurations stored in the updated states when it applies a state.

6.8.4 Devicetree representation

Because Devicetree is meant to describe hardware, it is the natural choice when it comes to storing pin control configuration. In the following sections you will find an overview on how states and pin configurations are represented in Devicetree.

States

Given a device, each of its pin control state is represented in Devicetree by pinctrl-N properties, being N the state index starting from zero. The pinctrl-names property is then used to assign a unique identifier for each state property by index, for example, pinctrl-names list entry 0 is the name for pinctrl-0.

```
periph0: periph@0 {
    ...
    /* state 0 ("default") */
    pinctrl-0 = <...>;
    ...
    /* state N ("mystate") */
    pinctrl-N = <...>;
    /* names for state 0 up to state N */
    pinctrl-names = "default", ..., "mystate";
    ...
};
```

Pin configuration

There are multiple ways to represent the pin configurations in Devicetree. However, all end up encoding the same information: the pin multiplexing and the pin configuration parameters. For example, `UART_RX` is mapped to `PX0` and pull-up is enabled. The representation choice largely depends on each vendor/SoC, so the Devicetree binding files for the pin control drivers are the best place to look for details.

A popular and versatile option is shown in the example below. One of the advantages of this choice is the grouping capability based on shared pin configuration. This allows to reduce the verbosity of the pin control definitions. Another advantage is that the pin configuration parameters for a particular state are enclosed in a single Devicetree node.

```
/* board.dts */
#include "board-pinctrl.dtsi"

&periph0 {
    pinctrl-0 = <&periph0_default>;
    pinctrl-names = "default";
};
```

```
/* vnd-soc-pkgxx.h
 * File with valid mappings for a specific package (may be autogenerated).
 * This file is optional, but recommended.
 */
...
#define PERIPH0_SIGA_PX0 VNDSOC_PIN(X, 0, MUX0)
#define PERIPH0_SIGB_PY7 VNDSOC_PIN(Y, 7, MUX4)
#define PERIPH0_SIGC_PZ1 VNDSOC_PIN(Z, 1, MUX2)
...
```

```
/* board-pinctrl.dtsi */
#include <vnd-soc-pkgxx.h>

&pinctrl {
    /* Node with pin configuration for default state */
    periph0_default: periph0_default {
        group1 {
            /* Mappings: PERIPH0_SIGA -> PX0, PERIPH0_SIGC -> PZ1 */
            pinmux = <PERIPH0_SIGA_PX0>, <PERIPH0_SIGC_PZ1>;
            /* Pins PX0 and PZ1 have pull-up enabled */
            bias-pull-up;
        };
        ...
        groupN {
            /* Mappings: PERIPH0_SIGB -> PY7 */
            pinmux = <PERIPH0_SIGB_PY7>;
        };
    };
};
```

Another popular model is based on having a node for each pin configuration and state. While this model may lead to shorter board pin control files, it also requires to have one node for each pin mapping and state, since in general, nodes can not be reused for multiple states. This method is discouraged if autogeneration is not an option.

Note

Because all Devicetree information is parsed into a C header, it is important to make sure its size is kept to a minimum. For this reason it is important to prefix pre-generated nodes with `/omit-if-no-ref/`. This prefix makes sure that the node is discarded when not used.

```
/* board.dts */
#include "board-pinctrl.dtsi"

&periph0 {
    pinctrl-0 = <&periph0_siga_px0_default &periph0_sigb_py7_default
                 &periph0_sigc_pz1_default>;
    pinctrl-names = "default";
};
```

```
/* vnd-soc-pkgxx.dtsi
 * File with valid nodes for a specific package (may be autogenerated).
 * This file is optional, but recommended.
 */

&pinctrl {
    /* Mapping for PERIPH0_SIGA -> PX0, to be used for default state */
    /omit-if-no-ref/ periph0_siga_px0_default: periph0_siga_px0_default {
        pinmux = <VNDSOC_PIN(X, 0, MUX0)>;
    };

    /* Mapping for PERIPH0_SIGB -> PY7, to be used for default state */
    /omit-if-no-ref/ periph0_sigb_py7_default: periph0_sigb_py7_default {
        pinmux = <VNDSOC_PIN(Y, 7, MUX4)>;
    };

    /* Mapping for PERIPH0_SIGC -> PZ1, to be used for default state */
    /omit-if-no-ref/ periph0_sigc_pz1_default: periph0_sigc_pz1_default {
        pinmux = <VNDSOC_PIN(Z, 1, MUX2)>;
    };
};
```

```
/* board-pinctrl.dts */
#include <vnd-soc-pkgxx.dtsi>

/* Enable pull-up for PX0 (default state) */
&periph0_siga_px0_default {
    bias-pull-up;
};

/* Enable pull-up for PZ1 (default state) */
&periph0_sigc_pz1_default {
    bias-pull-up;
};
```

Note

It is discouraged to add pin configuration defaults in pre-defined nodes. In general, pin configurations depend on the board design or on the peripheral working conditions, so the decision should be made by the board. For example, enabling a pull-up by default may not always be

desired because the board already has one or because its value depends on the operating bus speed. Another downside of defaults is that user may not be aware of them, for example:

```
/* not evident that "periph0_siga_px0_default" also implies "bias-pull-up" */
/omit-if-no-ref/ periph0_siga_px0_default: periph0_siga_px0_default {
    pinmux = <VNDSOC_PIN(X, 0, MUX0)>;
    bias-pull-up;
};
```

6.8.5 Implementation guidelines

Pin control drivers

Pin control drivers need to implement a single function: `pinctrl_configure_pins()`. This function receives an array of pin configurations that need to be applied. Furthermore, if `CONFIG_PINCTRL_STORE_REG` is set, it also receives the associated device register address for the given pins. This information may be required by some drivers to perform device specific actions.

The pin configuration is stored in an opaque type that is vendor/SoC dependent: `pinctrl_soc_pin_t`. This type needs to be defined in a header named `pinctrl_soc.h` file that is in the Zephyr's include path. It can range from a simple integer value to a struct with multiple fields. `pinctrl_soc.h` also needs to define a macro named `Z_PINCTRL_STATE_PINS_INIT` that accepts two arguments: a node identifier and a property name (`pinctrl-N`). With this information the macro needs to define an initializer for all pin configurations contained within the `pinctrl-N` property of the given node.

Regarding Devicetree pin configuration representation, vendors can decide which option is better for their devices. However, the following guidelines should be followed:

- Use `pinctrl-N` (N=0, 1, ...) and `pinctrl-names` properties to define pin control states. These properties are defined in `dts/bindings/pinctrl/pinctrl-device.yaml`.
- Use standard pin configuration properties as defined in `dts/bindings/pinctrl/pincfg-node.yaml`.

Representations not following these guidelines may be accepted if they are already used by the same vendor in other operating systems, e.g. Linux.

Device drivers

In this section you will find some tips on how a device driver should use the `pinctrl` API to successfully configure the pins it needs.

The device compatible needs to be modified in the corresponding binding so that the `pinctrl-device.yaml` is included. For example:

```
include: [base.yaml, pinctrl-device.yaml]
```

This file is needed to add `pinctrl-N` and `pinctrl-names` properties to the device.

From a device driver perspective there are two steps that need to be performed to be able to use the `pinctrl` API. First, the pin control configuration needs to be defined. This includes all states and pins. `PINCTRL_DT_DEFINE` or `PINCTRL_DT_INST_DEFINE` macros should be used for this purpose. Second, a reference to the device instance `pinctrl_dev_config` needs to be stored, since it is required to later use the API. This can be achieved using the `PINCTRL_DT_DEV_CONFIG_GET` and `PINCTRL_DT_INST_DEV_CONFIG_GET` macros.

It is worth to note that the only relationship between a device and its associated pin control configuration is based on variable naming conventions. The way an instance of `pinctrl_dev_config` is named for a corresponding device instance allows to later obtain a reference to it given the device's Devicetree node identifier. This allows to minimize ROM usage, since only devices requiring pin control will own a reference to a pin control configuration.

Once the driver has defined the pin control configuration and kept a reference to it, it is ready to use the API. The most common way to apply a state is by using `pinctrl_apply_state()`. It is also possible to use the lower level function `pinctrl_apply_state_direct()` to skip state lookup if it is cached in advance (e.g. at init time). Since state lookup time is expected to be fast, it is recommended to use `pinctrl_apply_state()`.

The example below contains a complete example of a device driver that uses the `pinctrl` API.

```
/* A driver for the "mydev" compatible device */
#define DT_DRV_COMPAT mydev

...
#include <zephyr/drivers/pinctrl.h>
...

struct mydev_config {
    ...
    /* Reference to mydev pinctrl configuration */
    const struct pinctrl_dev_config *pcfg;
    ...
};

...

static int mydev_init(const struct device *dev)
{
    const struct mydev_config *config = dev->config;
    int ret;
    ...
    /* Select "default" state at initialization time */
    ret = pinctrl_apply_state(config->pcfg, PINCTRL_STATE_DEFAULT);
    if (ret < 0) {
        return ret;
    }
    ...
}

#define MYDEV_DEFINE(i)                                                    \
    /* Define all pinctrl configuration for instance "i" */               \
    PINCTRL_DT_INST_DEFINE(i);                                             \
    ...                                                                    \
    static const struct mydev_config mydev_config_##i = {                 \
        ...                                                                \
        /* Keep a ref. to the pinctrl configuration for instance "i" */    \
        .pcfg = PINCTRL_DT_INST_DEV_CONFIG_GET(i),                         \
        ...                                                                \
    };                                                                     \
    ...                                                                    \
                                                                           \
    DEVICE_DT_INST_DEFINE(i, mydev_init, NULL, &mydev_data##i,             \
                          &mydev_config##i, ...);

DT_INST_FOREACH_STATUS_OKAY(MYDEV_DEFINE)
```

6.9 Porting

These pages document how to port Zephyr to new hardware.

6.9.1 Architecture Porting Guide

An architecture port is needed to enable Zephyr to run on an ISA (instruction set architecture) or an ABI (Application Binary Interface) that is not currently supported.

The following are examples of ISAs and ABIs that Zephyr supports:

- x86_32 ISA with System V ABI
- ARMv7-M ISA with Thumb2 instruction set and ARM Embedded ABI (aeabi)
- ARCv2 ISA

For information on Kconfig configuration, see *Setting Kconfig configuration values*. Architectures use a Kconfig configuration scheme similar to boards.

An architecture port can be divided in several parts; most are required and some are optional:

- **The early boot sequence**: each architecture has different steps it must take when the CPU comes out of reset (required).
- **Interrupt and exception handling**: each architecture handles asynchronous and unrequested events in a specific manner (required).
- **Thread context switching**: the Zephyr context switch is dependent on the ABI and each ISA has a different set of registers to save (required).
- **Thread creation and termination**: A thread's initial stack frame is ABI and architecture-dependent, and thread abortion possibly as well (required).
- **Device drivers**: most often, the system clock timer and the interrupt controller are tied to the architecture (some required, some optional).
- **Utility libraries**: some common kernel APIs rely on a architecture-specific implementation for performance reasons (required).
- **CPU idling/power management**: most architectures implement instructions for putting the CPU to sleep (partly optional, most likely very desired).
- **Fault management**: for implementing architecture-specific debug help and handling of fatal error in threads (partly optional).
- **Linker scripts and toolchains**: architecture-specific details will most likely be needed in the build system and when linking the image (required).
- **Memory Management and Memory Mapping**: for architecture-specific details on supporting memory management and memory mapping.

- **Stack Objects**: for architecture-specific details on memory protection hardware regarding stack objects.
- **User Mode Threads**: for supporting threads in user mode.
- **GDB Stub**: for supporting GDB stub to enable remote debugging.

Early Boot Sequence

The goal of the early boot sequence is to take the system from the state it is after reset to a state where is can run C code and thus the common kernel initialization sequence. Most of the time, very few steps are needed, while some architectures require a bit more work to be performed.

Common steps for all architectures:

- Setup an initial stack.
- If running an XIP (eXecute-In-Place) kernel, copy initialized data from ROM to RAM.
- If not using an ELF loader, zero the BSS section.
- Jump to `z_cstart()`, the early kernel initialization
  - `z_cstart()` is responsible for context switching out of the fake context running at startup into the main thread.

Some examples of architecture-specific steps that have to be taken:

- If given control in real mode on x86_32, switch to 32-bit protected mode.
- Setup the segment registers on x86_32 to handle boot loaders that leave them in an unknown or broken state.
- Initialize a board-specific watchdog on Cortex-M3/4.
- Switch stacks from MSP to PSP on Cortex-M.
- Use a different approach than calling into z_swap() on Cortex-M to prevent race conditions.
- Setup FIRQ and regular IRQ handling on ARCv2.

Early Boot Sequence Hooks Zephyr exposes several hooks (described in include/zephyr/platform/hooks.h) that allow execution of SoC- or board-specific code at precise moments of the boot process.

The kernel takes care of calling most of the hooks from architecture-agnostic code. However, some hooks must be called during the early boot sequence; since the sequence is implemented in architecture-specific code, the call to the hooks must also be done there. The following gives a rough overview of the early boot sequence and when hooks should be called by architecture-specific code:

1. Execution begins in an architecture-specific entry point whose name matches `CONFIG_KERNEL_ENTRY`.
2. Architecture-specific state is re-initialized immediately (if `CONFIG_INIT_ARCH_HW_AT_BOOT` is enabled).
3. `soc_early_reset_hook()` is called.

> **Note**
>
> It is not necessary to set up a valid stack before calling this hook. However, the hook is allowed to overwrite the stack pointer before returning. The architecture-specific code must not expect the stack pointer register value to be preserved across the call to `soc_early_reset_hook()`.

On architectures with multiple stack pointers, there is usually a *"primary"* stack pointer accessible directly and *"secondary"* stack pointer register(s). `soc_early_reset_hook()` implementations may overwrite the *"primary"* stack pointer must **not** read or modify the value of any *"secondary"* stack pointer. (This allows the architecture-specific code to set up any *"secondary"* stack pointer it desires before calling `soc_early_reset_hook()`)

For example, the ARM Cortex-A architecture defines several execution modes, each of which has its own stack pointer register `sp_mode`. When the processor is executing in mode `X`, operations involving the `sp` general-purpose register operate on `sp_X`. On this architecture, assuming that the processor is executing in mode `M` when `soc_early_reset_hook()` is called, the hook is allowed to overwrite `sp_M` (accessible through `sp`) but **must not** read or overwrite any other `sp_mode` (where `mode != M`).

`soc_early_reset_hook()` implementations are allowed to not return execution to the architecture-specific code, in which case they "take over" the system. Such hooks are not subject to the aforementioned rules and may read or overwrite any stack pointer. However, when such an implementation is provided, the rest of the early boot sequence obviously does not execute.

4. An initial stack is set up for next steps of the early boot sequence.
5. Architecture-specific "*resume from suspend-to-RAM*" logic is executed

Note

Refer to `CONFIG_PM_S2RAM` and the architecture-specific implementation for more details, but note that the rest of the early boot sequence is not executed if this logic determines that an exit from suspend-to-RAM is ongoing.

6. `soc_reset_hook()` is called.
7. *Architecture-specific operations (in assembly) are performed here...*
8. `z_prep_c()` is called. This architecture-specific function is implemented in C.
9. `z_prep_c()` immediately calls `soc_prep_hook()`.
10. *Architecture-specific operations (in C) are performed here...*
11. `z_cstart()` is called. Architecture-agnostic code begins executing.

Interrupt and Exception Handling

Each architecture defines interrupt and exception handling differently.

When a device wants to signal the processor that there is some work to be done on its behalf, it raises an interrupt. When a thread does an operation that is not handled by the serial flow of the software itself, it raises an exception. Both, interrupts and exceptions, pass control to a handler. The handler is known as an ISR (Interrupt Service Routine) in the case of interrupts. The handler performs the work required by the exception or the interrupt. For interrupts, that work is device-specific. For exceptions, it depends on the exception, but most often the core kernel itself is responsible for providing the handler.

The kernel has to perform some work in addition to the work the handler itself performs. For example:

- Prior to handing control to the handler:
  - Save the currently executing context.
  - Possibly getting out of power saving mode, which includes waking up devices.
  - Updating the kernel uptime if getting out of tickless idle mode.

- After getting control back from the handler:
  - Decide whether to perform a context switch.
  - When performing a context switch, restore the context being context switched in.

This work is conceptually the same across architectures, but the details are completely different:

- The registers to save and restore.
- The processor instructions to perform the work.
- The numbering of the exceptions.
- etc.

It thus needs an architecture-specific implementation, called the interrupt/exception stub.

Another issue is that the kernel defines the signature of ISRs as:

```
void (*isr)(void *parameter)
```

Architectures do not have a consistent or native way of handling parameters to an ISR. As such there are two commonly used methods for handling the parameter.

- Using some architecture defined mechanism, the parameter value is forced in the stub. This is commonly found in X86-based architectures.
- The parameters to the ISR are inserted and tracked via a separate table requiring the architecture to discover at runtime which interrupt is executing. A common interrupt handler demuxer is installed for all entries of the real interrupt vector table, which then fetches the device's ISR and parameter from the separate table. This approach is commonly used in the ARC and ARM architectures via the `CONFIG_GEN_ISR_TABLES` implementation. You can find examples of the stubs by looking at `_interrupt_enter()` in x86, `_isr_wrapper()` in ARM, or the full implementation description for ARC in arch/arc/core/isr_wrapper.S.

Each architecture also has to implement primitives for interrupt control:

- locking interrupts: `irq_lock()`, `irq_unlock()`.
- registering interrupts: `IRQ_CONNECT()`.
- programming the priority if possible `irq_priority_set()`.
- enabling/disabling interrupts: `irq_enable()`, `irq_disable()`.

Note

`IRQ_CONNECT` is a macro that uses assembler and/or linker script tricks to connect interrupts at build time, saving boot time and text size.

The vector table should contain a handler for each interrupt and exception that can possibly occur. The handler can be as simple as a spinning loop. However, we strongly suggest that handlers at least print some debug information. The information helps figuring out what went wrong when hitting an exception that is a fault, like divide-by-zero or invalid memory access, or an interrupt that is not expected (*spurious interrupt*). See the ARM implementation in arch/arm/core/cortex_m/fault.c for an example.

Thread Context Switching

Multi-threading is the basic purpose to have a kernel at all. Zephyr supports two types of threads: preemptible and cooperative. The rules for determining the next thread to schedule are handled by the kernel. However, it is up to the architecture port to implement the method of the context switch itself.

Zephyr provides two mutually exclusive interfaces for context switching. The preferred interface to use is `arch_switch` which is selected when `CONFIG_USE_SWITCH` is enabled. The alternative interface is `arch_swap`–selected when `CONFIG_USE_SWITCH` is disabled. When porting to a new architecture, only one of these needs to implemented; however, for SMP platforms it must be `arch_switch`.

A context switch can happen in several circumstances:

- When a thread executes a blocking operation, such as taking a semaphore that is currently unavailable.
- When a preemptible thread unblocks a thread of higher priority by releasing the object on which it was blocked.
- When an interrupt unblocks a thread of higher priority than the one currently executing, if the currently executing thread is preemptible.
- When a thread runs to completion.
- When a thread causes a fatal exception and is removed from the running threads. For example, referencing invalid memory,

Therefore, the context switching must thus be able to handle all these cases.

There are two types of context switches: *cooperative* and *preemptive*.

- A *cooperative* context switch happens when a thread willfully gives the control to another thread. There are two cases where this happens
  - When a thread explicitly yields.
  - When a thread tries to take an object that is currently unavailable and is willing to wait until the object becomes available.
- A *preemptive* context switch happens either because an ISR or a thread causes an operation that schedules a thread of higher priority than the one currently running, if the currently running thread is preemptible. An example of such an operation is releasing an object on which the thread of higher priority was waiting.

Note

Control is never taken from cooperative thread when one of them is the running thread.

A cooperative context switch is always done by having a thread call the internal kernel routine `z_swap` (or one of its variants). This in turn will call either `arch_switch` or `arch_swap` as appropriate. When these are called, no checks are done to determine if the context switch is to happen–the context switch must happen.

Note

On 32-bit x86, `arch_swap` is generic enough and the architecture flexible enough that it can be called when exiting an interrupt to provoke the context switch. This should not be taken as a rule, since neither the ARM Cortex-M nor ARCv2 port do this.

Since `z_swap` is cooperative, the caller-saved registers from the ABI are already on the stack. There is no need to save them in the k_thread structure.

A context switch can also be performed preemptively. This happens upon exiting an ISR, in the kernel interrupt exit stub:

- `_interrupt_enter` on x86 after the handler is called.
- `z_arm_exc_exit` and `z_arm_int_exit` on ARM.

- `_firq_exit` and `_rirq_exit` on ARCv2.

The decision logic to invoke the context switch is simple and is only performed when exiting a non-nested interrupt:

When `CONFIG_USE_SWITCH` is enabled ...

- The interrupt exit code shall call `z_get_next_switch_handle()`, and return to the thread context identified by the returned switch handle

When `CONFIG_USE_SWITCH` is not enabled ...

- The interrupt exit code shall fetch the cached thread from the ready queue, and:
  - If the cached thread is not the current thread, invoke the context switch.
  - Otherwise do not invoke it.

This is simple, but crucial: if this is not implemented correctly, the kernel will not function as intended and will experience bizarre crashes, mostly due to stack corruption.

Thread Creation and Termination

To start a new thread, a stack frame must be constructed so that the context switch can pop it the same way it would pop one from a thread that had been context switched out. This is to be implemented in an architecture-specific `_new_thread` internal routine.

The thread entry point is also not to be called directly, i.e. it should not be set as the PC (program counter) for the new thread. Rather it must be wrapped in `_thread_entry`. This means that the PC in the stack frame shall be set to `_thread_entry`, and the thread entry point shall be passed as the first parameter to `_thread_entry`. The specifics of this depend on the ABI.

The need for an architecture-specific thread termination implementation depends on the architecture. There is a generic implementation, but it might not work for a given architecture.

One reason that has been encountered for having an architecture-specific implementation of thread termination is that aborting a thread might be different if aborting because of a graceful exit or because of an exception. This is the case for ARM Cortex-M, where the CPU has to be taken out of handler mode if the thread triggered a fatal exception, but not if the thread gracefully exits its entry point function.

This means implementing an architecture-specific version of `k_thread_abort()`, and setting the Kconfig option `CONFIG_ARCH_HAS_THREAD_ABORT` as needed for the architecture (e.g. see arch/arm/core/cortex_m/Kconfig).

Thread Local Storage

To enable thread local storage on a new architecture:

1. Implement `arch_tls_stack_setup()` to setup the TLS storage area in stack. Refer to the toolchain documentation on how the storage area needs to be structured. Some helper functions can be used:
   - Function `z_tls_data_size()` returns the size needed for thread local variables (excluding any extra data required by toolchain and architecture).
   - Function `z_tls_copy()` prepares the TLS storage area for thread local variables. This only copies the variable themselves and does not do architecture and/or toolchain specific data.
2. In the context switching, grab the `tls` field inside the new thread's `struct k_thread` and put it into an appropriate register (or some other variable) for access to the TLS storage area. Refer to toolchain and architecture documentation on which registers to use.
3. In kconfig, add `select ARCH_HAS_THREAD_LOCAL_STORAGE` to kconfig related to the new architecture.

4. Run the `tests/kernel/threads/tls` to make sure the new code works.

Device Drivers

The kernel requires very few hardware devices to function. In theory, the only required device is the interrupt controller, since the kernel can run without a system clock. In practice, to get access to most, if not all, of the sanity check test suite, a system clock is needed as well. Since these two are usually tied to the architecture, they are part of the architecture port.

Interrupt Controllers There can be significant differences between the interrupt controllers and the interrupt concepts across architectures.

For example, x86 has the concept of an IDT and different interrupt controllers. The position of an interrupt in the IDT determines its priority.

On the other hand, the ARM Cortex-M has the NVIC (Nested Vectored Interrupt Controller) as part of the architecture definition. There is no need for an IDT-like table that is separate from the NVIC vector table. The position in the table has nothing to do with priority of an IRQ: priorities are programmable per-entry.

The ARCv2 has its interrupt unit as part of the architecture definition, which is somewhat similar to the NVIC. However, where ARC defines interrupts as having a one-to-one mapping between exception and interrupt numbers (i.e. exception 1 is IRQ1, and device IRQs start at 16), ARM has IRQ0 being equivalent to exception 16 (and weirdly enough, exception 1 can be seen as IRQ-15).

All these differences mean that very little, if anything, can be shared between architectures with regards to interrupt controllers.

System Clock x86 has APIC timers and the HPET as part of its architecture definition. ARM Cortex-M has the SYSTICK exception. Finally, ARCv2 has the timer0/1 device.

Kernel timeouts are handled in the context of the system clock timer driver's interrupt handler.

Console Over Serial Line There is one other device that is almost a requirement for an architecture port, since it is so useful for debugging. It is a simple polling, output-only, serial port driver on which to send the console (`printk`, `printf`) output.

It is not required, and a RAM console (`CONFIG_RAM_CONSOLE`) can be used to send all output to a circular buffer that can be read by a debugger instead.

Utility Libraries

The kernel depends on a few functions that can be implemented with very few instructions or in a lock-less manner in modern processors. Those are thus expected to be implemented as part of an architecture port.

- Atomic operators.
  - If instructions do exist for a given architecture, the implementation is configured using the `CONFIG_ATOMIC_OPERATIONS_ARCH` Kconfig option.
  - If instructions do not exist for a given architecture, a generic version that wraps `irq_lock()` or `irq_unlock()` around non-atomic operations exists. It is configured using the `CONFIG_ATOMIC_OPERATIONS_C` Kconfig option.
- Find-least-significant-bit-set and find-most-significant-bit-set.
  - If instructions do not exist for a given architecture, it is always possible to implement these functions as generic C functions.

It is possible to use compiler built-ins to implement these, but be careful they use the required compiler barriers.

CPU Idling/Power Management

The kernel provides support for CPU power management with two functions: `arch_cpu_idle()` and `arch_cpu_atomic_idle()`.

`arch_cpu_idle()` can be as simple as calling the power saving instruction for the architecture with interrupts unlocked, for example `hlt` on x86, `wfi` or `wfe` on ARM, `sleep` on ARC. This function can be called in a loop within a context that does not care if it get interrupted or not by an interrupt before going to sleep. There are basically two scenarios when it is correct to use this function:

- In a single-threaded system, in the only thread when the thread is not used for doing real work after initialization, i.e. it is sitting in a loop doing nothing for the duration of the application.
- In the idle thread.

`arch_cpu_atomic_idle()`, on the other hand, must be able to atomically re-enable interrupts and invoke the power saving instruction. It can thus be used in real application code, again in single-threaded systems.

Normally, idling the CPU should be left to the idle thread, but in some very special scenarios, these APIs can be used by applications.

Both functions must exist for a given architecture. However, the implementation can be simply the following steps, if desired:

1. unlock interrupts
2. NOP

However, a real implementation is strongly recommended.

Fault Management

In the event of an unhandled CPU exception, the architecture code must call into `z_fatal_error()`. This function dumps out architecture-agnostic information and makes a policy decision on what to do next by invoking `k_sys_fatal_error()`. This function can be overridden to implement application-specific policies that could include locking interrupts and spinning forever (the default implementation) or even powering off the system (if supported).

Toolchain and Linking

Toolchain support has to be added to the build system.

Some architecture-specific definitions are needed in include/zephyr/toolchain/gcc.h. See what exists in that file for currently supported architectures.

Each architecture also needs its own linker script, even if most sections can be derived from the linker scripts of other architectures. Some sections might be specific to the new architecture, for example the SCB section on ARM and the IDT section on x86.

Memory Management and Memory Mapping

If the target platform enables paging and requires drivers to memory-map their I/O regions, `CONFIG_MMU` needs to be enabled and the following API implemented:

- `arch_mem_map()`
- `arch_mem_unmap()`
- `arch_page_phys_get()`

Stack Objects

The presence of memory protection hardware affects how stack objects are created. All architecture ports must specify the required alignment of the stack pointer, which is some combination of CPU and ABI requirements. This is defined in architecture headers with ARCH_STACK_PTR_ALIGN and is typically something small like 4, 8, or 16 bytes.

Two types of thread stacks exist:

- "kernel" stacks defined with K_KERNEL_STACK_DEFINE() and related APIs, which can host kernel threads running in supervisor mode or used as the stack for interrupt/exception handling. These have significantly relaxed alignment requirements and use less reserved data. No memory is reserved for privilege elevation stacks.
- "thread" stacks which typically use more memory, but are capable of hosting thread running in user mode, as well as any use-cases for kernel stacks.

If CONFIG_USERSPACE is not enabled, "thread" and "kernel" stacks are equivalent.

Additional macros may be defined in the architecture layer to specify the alignment of the base of stack objects, any reserved data inside the stack object not used for the thread's stack buffer, and how to round up stack sizes to support user mode threads. In the absence of definitions some defaults are assumed:

- ARCH_KERNEL_STACK_RESERVED: default no reserved space
- ARCH_THREAD_STACK_RESERVED: default no reserved space
- ARCH_KERNEL_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_OBJ_ALIGN: default align to ARCH_STACK_PTR_ALIGN
- ARCH_THREAD_STACK_SIZE_ALIGN: default round up to ARCH_STACK_PTR_ALIGN

All stack creation macros are defined in terms of these.

Stack objects all have the following layout, with some regions potentially zero-sized depending on configuration. There are always two main parts: reserved memory at the beginning, and then the stack buffer itself. The bounds of some areas can only be determined at runtime in the context of its associated thread object. Other areas are entirely computable at build time.

Some architectures may need to carve-out reserved memory at runtime from the stack buffer, instead of unconditionally reserving it at build time, or to supplement an existing reserved area (as is the case with the ARM FPU). Such carve-outs will always be tracked in `thread.stack_info.start`. The region specified by `thread.stack_info.start` and `thread.stack_info.size` is always fully accessible by a user mode thread. `thread.stack_info.delta` denotes an offset which can be used to compute the initial stack pointer from the very end of the stack object, taking into account storage for TLS and ASLR random offsets.

```
+---------------------+ <- thread.stack_obj
| Reserved Memory     | } K_(THREAD|KERNEL)_STACK_RESERVED
+---------------------+
| Carved-out memory   |
|.....................| <- thread.stack_info.start
| Unused stack buffer |
|                     |
|.....................| <- thread's current stack pointer
| Used stack buffer   |
|                     |
|.....................| <- Initial stack pointer. Computable
| ASLR Random offset  |      with thread.stack_info.delta
+---------------------| <- thread.userspace_local_data
| Thread-local data   |
+---------------------+ <- thread.stack_info.start + thread.stack_info.size
```

At present, Zephyr does not support stacks that grow upward.

No Memory Protection If no memory protection is in use, then the defaults are sufficient.

HW-based stack overflow detection This option uses hardware features to generate a fatal error if a thread in supervisor mode overflows its stack. This is useful for debugging, although for a couple reasons, you can't reliably make any assertions about the state of the system after this happens:

- The kernel could have been inside a critical section when the overflow occurs, leaving important global data structures in a corrupted state.
- For systems that implement stack protection using a guard memory region, it's possible to overshoot the guard and corrupt adjacent data structures before the hardware detects this situation.

To enable the `CONFIG_HW_STACK_PROTECTION` feature, the system must provide some kind of hardware-based stack overflow protection, and enable the `CONFIG_ARCH_HAS_STACK_PROTECTION` option.

Two forms of HW-based stack overflow detection are supported: dedicated CPU features for this purpose, or special read-only guard regions immediately preceding stack buffers.

`CONFIG_HW_STACK_PROTECTION` only catches stack overflows for supervisor threads. This is not required to catch stack overflow from user threads; `CONFIG_USERSPACE` is orthogonal.

This feature only detects supervisor mode stack overflows, including stack overflows when handling system calls. It doesn't guarantee that the kernel has not been corrupted. Any stack overflow in supervisor mode should be treated as a fatal error, with no assertions about the integrity of the overall system possible.

Stack overflows in user mode are recoverable (from the kernel's perspective) and require no special configuration; `CONFIG_HW_STACK_PROTECTION` only applies to catching overflows when the CPU is in supervisor mode.

CPU-based stack overflow detection If we are detecting stack overflows in supervisor mode via special CPU registers (like ARM's SPLIM), then the defaults are sufficient.

Guard-based stack overflow detection We are detecting supervisor mode stack overflows via special memory protection region located immediately before the stack buffer that generates an exception on write. Reserved memory will be used for the guard region.

`ARCH_KERNEL_STACK_RESERVED` should be defined to the minimum size of a memory protection region. On most ARM CPUs this is 32 bytes. `ARCH_KERNEL_STACK_OBJ_ALIGN` should also be set to the required alignment for this region.

MMU-based systems should not reserve RAM for the guard region and instead simply leave an non-present virtual page below every stack when it is mapped into the address space. The stack object will still need to be properly aligned and sized to page granularity.

```
+---------------------------+ <- thread.stack_obj
| Guard reserved memory     | } K_KERNEL_STACK_RESERVED
+---------------------------+
| Guard carve-out           |
|...........................| <- thread.stack_info.start
| Stack buffer              |
.                           .
```

Guard carve-outs for kernel stacks are uncommon and should be avoided if possible. They tend to be needed for two situations:

- The same stack may be re-purposed to host a user thread, in which case the guard is unnecessary and shouldn't be unconditionally reserved. This is the case when privilege elevation stacks are not inside the stack object.
- The required guard size is variable and depends on context. For example, some ARM CPUs have lazy floating point stacking during exceptions and may decrement the stack pointer by a large value without writing anything, completely overshooting a minimally-sized guard and corrupting adjacent memory. Rather than unconditionally reserving a larger guard, the extra memory is carved out if the thread uses floating point.

User mode enabled Enabling user mode activates two new requirements:

- A separate fixed-sized privilege mode stack, specified by `CONFIG_PRIVILEGED_STACK_SIZE`, must be allocated that the user thread cannot access. It is used as the stack by the kernel when handling system calls. If stack guards are implemented, a stack guard region must be able to be placed before it, with support for carve-outs if necessary.
- The memory protection hardware must be able to program a region that exactly covers the thread's stack buffer, tracked in `thread.stack_info`. This implies that `ARCH_THREAD_STACK_SIZE_ADJUST()` will need to round up the requested stack size so that a region may cover it, and that `ARCH_THREAD_STACK_OBJ_ALIGN()` is also specified per the granularity of the memory protection hardware.

This becomes more complicated if the memory protection hardware requires that all memory regions be sized to a power of two, and aligned to their own size. This is common on older MPUs and is known with `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT`.

`thread.stack_info` always tracks the user-accessible part of the stack object, it must always be correct to program a memory protection region with user access using the range stored within.

Non power-of-two memory region requirements On systems without power-of-two region requirements, the reserved memory area for threads stacks defined by `K_THREAD_STACK_RESERVED` may be used to contain the privilege mode stack. The layout could be something like:

```
+-----------------------------+ <- thread.stack_obj
| Other platform data         |
+-----------------------------+
| Guard region (if enabled)   |
+-----------------------------+
| Guard carve-out (if needed) |
|.............................|
| Privilege elevation stack   |
+-----------------------------| <- thread.stack_obj +
| Stack buffer                |      K_THREAD_STACK_RESERVED =
.                             .      thread.stack_info.start
```

The guard region, and any carve-out (if needed) would be configured as a read-only region when the thread is created.

- If the thread is a supervisor thread, the privilege elevation region is just extra stack memory. An overflow will eventually crash into the guard region.
- If the thread is running in user mode, a memory protection region will be configured to allow user threads access to the stack buffer, but nothing before or after it. An overflow in user mode will crash into the privilege elevation stack, which the user thread has no access to. An overflow when handling a system call will crash into the guard region.

On an MMU system there should be no physical guards; the privilege mode stack will be mapped into kernel memory, and the stack buffer in the user part of memory, each with non-present virtual guard pages below them to catch runtime stack overflows.

Other platform data may be stored before the guard region, but this is highly discouraged if such data could be stored in `thread.arch` somewhere.

`ARCH_THREAD_STACK_RESERVED` will need to be defined to capture the size of the reserved region containing platform data, privilege elevation stacks, and guards. It must be appropriately sized such that an MPU region to grant user mode access to the stack buffer can be placed immediately after it.

Power-of-two memory region requirements Thread stack objects must be sized and aligned to the same power of two, without any reserved memory to allow efficient packing in memory. Thus, any guards in the thread stack must be completely carved out, and the privilege elevation stack must be allocated elsewhere.

`ARCH_THREAD_STACK_SIZE_ADJUST()` and `ARCH_THREAD_STACK_OBJ_ALIGN()` should both be defined to `Z_POW2_CEIL()`. `K_THREAD_STACK_RESERVED` must be 0.

For the privilege stacks, the `CONFIG_GEN_PRIV_STACKS` must be, enabled. For every thread stack found in the system, a corresponding fixed-size kernel stack used for handling system calls is generated. The address of the privilege stacks can be looked up quickly at runtime based on the thread stack address using `z_priv_stack_find()`. These stacks are laid out the same way as other kernel-only stacks.

```
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj)
| Reserved memory             | } K_KERNEL_STACK_RESERVED
+-----------------------------+
| Guard carve-out (if needed) |
|.............................|
| Privilege elevation stack   |
|                             |
+-----------------------------+ <- z_priv_stack_find(thread.stack_obj) +
                                     K_KERNEL_STACK_RESERVED +
                                     CONFIG_PRIVILEGED_STACK_SIZE

+-----------------------------+ <- thread.stack_obj
| MPU guard carve-out         |
| (supervisor mode only)      |
|.............................| <- thread.stack_info.start
| Stack buffer                |
.                             .
```

The guard carve-out in the thread stack object is only used if the thread is running in supervisor mode. If the thread drops to user mode, there is no guard and the entire object is used as the stack buffer, with full access to the associated user mode thread and `thread.stack_info` updated appropriately.

User Mode Threads

To support user mode threads, several kernel-to-arch APIs need to be implemented, and the system must enable the `CONFIG_ARCH_HAS_USERSPACE` option. Please see the documentation for each of these functions for more details:

- `arch_buffer_validate()` to test whether the current thread has access permissions to a particular memory region
- `arch_user_mode_enter()` which will irreversibly drop a supervisor thread to user mode privileges. The stack must be wiped.
- `arch_syscall_oops()` which generates a kernel oops when system call parameters can't be validated, in such a way that the oops appears to be generated from where the system call was invoked in the user thread

- arch_syscall_invoke0() through arch_syscall_invoke6() invoke a system call with the appropriate number of arguments which must all be passed in during the privilege elevation via registers.
- arch_is_user_context() return nonzero if the CPU is currently running in user mode
- arch_mem_domain_max_partitions_get() which indicates the max number of regions for a memory domain. MMU systems have an unlimited amount, MPU systems have constraints on this.

Some architectures may need to update software memory management structures or modify hardware registers on another CPU when memory domain APIs are invoked. If so, CONFIG_ARCH_MEM_DOMAIN_SYNCHRONOUS_API must be selected by the architecture and some additional APIs must be implemented. This is common on MMU systems and uncommon on MPU systems:

- arch_mem_domain_thread_add()
- arch_mem_domain_thread_remove()
- arch_mem_domain_partition_add()
- arch_mem_domain_partition_remove()

Please see the doxygen documentation of these APIs for details.

In addition to implementing these APIs, there are some other tasks as well:

- _new_thread() needs to spawn threads with K_USER in user mode
- On context switch, the outgoing thread's stack memory should be marked inaccessible to user mode by making the appropriate configuration changes in the memory management hardware.. The incoming thread's stack memory should likewise be marked as accessible. This ensures that threads can't mess with other thread stacks.
- On context switch, the system needs to switch between memory domains for the incoming and outgoing threads.
- Thread stack areas must include a kernel stack region. This should be inaccessible to user threads at all times. This stack will be used when system calls are made. This should be fixed size for all threads, and must be large enough to handle any system call.
- A software interrupt or some kind of privilege elevation mechanism needs to be established. This is closely tied to how the _arch_syscall_invoke macros are implemented. On system call, the appropriate handler function needs to be looked up in _k_syscall_table. Bad system call IDs should jump to the K_SYSCALL_BAD handler. Upon completion of the system call, care must be taken not to leak any register state back to user mode.

GDB Stub

To enable GDB stub for remote debugging on a new architecture:

1. Create a new gdbstub.h header file under appropriate architecture include directory (include/zephyr/arch/<arch>/gdbstub.h).
   - Create a new struct struct gdb_ctx as the GDB context.
     - Must define a member named exception of type unsigned int to store the GDB exception reason. This value needs to be set before entering z_gdb_main_loop().
     - Architecture can define as many members as needed for GDB stub to function.
     - Pointer to this struct needs to be passed to z_gdb_main_loop(), where this pointer will be passed to other GDB stub functions.
2. Functions for entering and exiting GDB stub main loop.

- If the architecture relies on interrupts to service breakpoints, interrupt service routines (ISR) need to be implemented, which will serve as the entry point to GDB stub main loop.
- These functions need to save and restore context so code execution can continue as if no breakpoints have been encountered.
- These functions need to call `z_gdb_main_loop()` after saving execution context to go into the GDB stub main loop to receive commands from GDB.
- Before calling `z_gdb_main_loop()`, `gdb_ctx.exception` must be set to specify the exception reason.

3. Implement necessary functions to support GDB stub functionality:
   - `arch_gdb_init()`
     - This needs to initialize necessary bits to support GDB stub functionality, for example, setting up the GDB context and connecting debug interrupts.
     - This must stop code execution via architecture specific method (e.g. raising debug interrupts). This allows GDB to connect during boot.
   - `arch_gdb_continue()`
     - This function is called when GDB sends a `c` or `continue` command to continue code execution.
   - `arch_gdb_step()`
     - This function is called when GDB sends a `si` or `stepi` command to execute one machine instruction, before returning to GDB prompt.
   - Hardware register read/write functions:
     - Since the GDB stub is running on the target, manipulation of hardware registers need to cached to avoid affecting the execution of GDB stub. Think of it as context switching, where the execution context is changed to the GDB stub. So that the register values of the running thread before context switch need to be stored. Manipulation of register values must only be done to this cached copy. The updated values will then be written to hardware registers before switching back to the previous running thread.
     - `arch_gdb_reg_readall()`
       - This collects all hardware register values that would appear in a `g`/`G` packets which will be sent back to GDB. The format of the G-packet is architecture specific. Consult GDB on what is expected.
       - Note that, for most architectures, a valid G-packet must be returned and sent to GDB. If a packet without incorrect length is sent to GDB, GDB will abort the debugging session.
     - `arch_gdb_reg_writeall()`
       - This takes a G-packet sent by GDB and populates the hardware registers with values from the G-packet.
     - `arch_gdb_reg_readone()`
       - This reads the value of one hardware register and sends the result to GDB.
     - `arch_gdb_reg_writeone()`
       - This writes the value of one hardware register received from GDB.
   - Breakpoints:
     - `arch_gdb_add_breakpoint()` and `arch_gdb_remove_breakpoint()`

  - GDB may decide to use software breakpoints which modifies the memory at the breakpoint locations to replace the instruction with software breakpoint or trap instructions. GDB will then restore the memory content once execution reaches the breakpoints. GDB supports this by default and there is usually no need to handle software breakpoints in the architecture code (where breakpoint type is `0`).
  - Hardware breakpoints (type `1`) are required if the code is in ROM or flash that cannot be modified at runtime. Consult the architecture datasheet on how to enable hardware breakpoints.
  - If hardware breakpoints are not supported by the architecture, there is no need to implement these in architecture code. GDB will then rely on software breakpoints.

4. For architecture where certain memory regions are not accessible, an array named `gdb_mem_region_array` of type `gdb_mem_region` needs to be defined to specify regions that are accessible. For each array item:
   - `gdb_mem_region.start` specifies the start of a memory region.
   - `gdb_mem_region.end` specifies the end of a memory region.
   - `gdb_mem_region.attributes` specifies the permission of a memory region.
     - `GDB_MEM_REGION_RO`: region is read-only.
     - `GDB_MEM_REGION_RW`: region is read-write.
   - `gdb_mem_region.alignment` specifies read/write alignment of a memory region. Use `0` if there is no alignment requirement and read/write can be done byte-by-byte.

6.9.2 SoC Porting Guide

This page describes how to add support for a new *SoC* in Zephyr, be it in the upstream Zephyr project or locally in your own repository.

SoC Definitions

It is expected that you are familiar with the board concept in Zephyr. A high level overview of the hardware support hierarchy and terms used in the Zephyr documentation can be seen in *Hardware support hierarchy*.

For SoC porting, the most important terms are:

- SoC: the exact system on a chip the board's CPU is part of.
- SoC series: a group of tightly related SoCs.
- SoC family: a wider group of SoCs with similar characteristics.
- CPU cluster: a cluster of one or more CPU cores.
- CPU core: a particular CPU instance of a given architecture.
- Architecture: an instruction set architecture.

Architecture See *Architecture Porting Guide*.

Create your SoC directory

Each SoC must have a unique name. Use the official name given by the SoC vendor and check that it's not already in use. In some cases someone else may have contributed a SoC with identical name. If the SoC name is already in use, then you should probably improve the existing SoC instead of creating a new one. The script `list_hardware` can be used to retrieve a list of all SoCs known in Zephyr, for example `./scripts/list_hardware.py --soc-root=. --socs` from the Zephyr base directory for a list of names that are already in use.

Start by creating the directory `zephyr/soc/<VENDOR>/soc1`, where `<VENDOR>` is your vendor sub-directory.

Note

A `<VENDOR>` subdirectory is mandatory if contributing your SoC to Zephyr, but if your SoC is placed in a local repo, then any folder structure under `<your-repo>/soc` is permitted. The `<VENDOR>` subdirectory must match a vendor defined in the list in dts/bindings/vendor-prefixes.txt. If the SoC vendor does not have a prefix in that list, then one must be created.

Note

The SoC directory name does not need to match the name of the SoC. Multiple SoCs can even be defined in one directory. In Zephyr, SoCs are often organized in sub-folders in a common SoC Family or SoC Series tree.

Your SoC directory should look like this:

```
soc/<VENDOR>/<soc-name>
├── soc.yml
├── soc.h
├── CMakeLists.txt
├── Kconfig
├── Kconfig.soc
└── Kconfig.defconfig
```

Replace `<soc-name>` with your SoC's name.

The mandatory files are:

1. `soc.yml`: a YAML file describing the high-level meta data of the SoC such as:
   - SoC name: the name of the SoC
   - CPU clusters: CPU clusters if the SoC contains one or more clusters
   - SoC series: the SoC series to which the SoC belong
   - SoC family: the SoC family to which the series belong
2. `soc.h`: a header file which can be used to describe or provide configuration macros for the SoC. The `soc.h` will often be included in drivers, sub-systems, boards, and other source code found in Zephyr.
3. `Kconfig.soc`: the base SoC configuration which defines a Kconfig SoC symbol in the form of `config SOC_<soc-name>` and provides the SoC name to the Kconfig `SOC` setting. If the `soc.yml` describes a SoC family and series, then those must also be defined in this file. Kconfig settings outside of the SoC tree must not be selected. To select general Zephyr Kconfig settings the `Kconfig` file must be used.
4. `CMakeLists.txt`: CMake file loaded by the Zephyr build system. This CMake file can define additional include paths and/or source files to be used when a build targets the SoC. Also the base line linker script to use must be defined.

The optional files are:

- `Kconfig`, `Kconfig.defconfig` software configuration in *Configuration System (Kconfig)* format. These select the architecture and peripherals available.

Write your SoC YAML

The SoC YAML file describes the SoC family, SoC series, and SoC at a high level.

Detailed configurations, such as hardware description and configuration are done in devicetree and Kconfig.

The skeleton of a simple SoC YAML file containing just one SoC is:

```
socs:
  - name: <soc1>
```

It is possible to have multiple SoC located in the SoC folder. For example if they belong to a common family or series it is recommended to locate such SoC in a common tree. Multiple SoCs and SoC series in a common folder can be described in the `soc.yml` file as:

```
family:
  - name: <family-name>
    series:
      - name: <series-1-name>
        socs:
          - name: <soc1>
            cpuclusters:
```

(continues on next page)

(continued from previous page)

```
            - name: <coreA>
            - name: <coreB>
              ...
        - name: <soc2>
    - name: <series-2-name>
      ...
```

Write your SoC devicetree

SoC devicetree include files are located in the `<zephyr-repo>/dts` folder under a corresponding `<ARCH>/<VENDOR>`.

The SoC `dts/<ARCH>/<VENDOR>/<soc>.dtsi` describes your SoC hardware in the Devicetree Source (DTS) format and must be included by any boards which use the SoC.

If a highlevel `<arch>.dtsi` file exists, then a good starting point is to include this file in your `<soc>.dtsi`.

In general, `<soc>.dtsi` should look like this:

```
#include <arch>/<arch>.dtsi

/ {
        chosen {
                /* common chosen settings for your SoC */
        };

        cpus {
                #address-cells = <m>;
                #size-cells = <n>;

                cpu@0 {
                device_type = "cpu";
                compatible = "<compatibles>";
                /* ... your CPU definitions ... */
        };

        soc {
                /* Your SoC definitions and peripherals */
                /* such as ram, clock, buses, peripherals. */
        };
};
```

Hint

It is possible to structure multiple `<VENDOR>/<soc>.dtsi` files in sub-directories for a cleaner file system structure. For example organized pre SoC series, like this: `<VENDOR>/<SERIES>/<soc>.dtsi`.

Multiple CPU clusters Devicetree reflects the hardware. The memory space and peripherals available to one CPU cluster can be very different from another CPU cluster, therefore each CPU cluster will often have its own `.dtsi` file.

CPU cluster `.dtsi` files should follow the naming scheme `<soc>_<cluster>.dtsi`. A `<soc>_<cluster>.dtsi` file will look similar to a SoC `.dtsi` without CPU clusters.

Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your SoC needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in *Setting Kconfig configuration values*.

There is one mandatory Kconfig file in the SoC directory, and two optional files for a SoC:

```
soc/<vendor>/<your soc>
├── Kconfig.soc
├── Kconfig
└── Kconfig.defconfig
```

`Kconfig.soc`
: A shared Kconfig file which can be sourced both in Zephyr Kconfig and sysbuild Kconfig trees.

  This file selects the SoC family and series in the Kconfig tree and potential other SoC related Kconfig settings. In some cases a SOC_PART_NUMBER. This file must not select anything outside the reusable Kconfig SoC tree.

  A `Kconfig.soc` may look like this:

```
config SOC_FAMILY_<SOC_FAMILY_NAME>
        bool

config SOC_SERIES_<SOC_SERIES_NAME>
        bool
        select SOC_FAMILY_<SOC_FAMILY_NAME>

config SOC_<SOC_NAME>
        bool
        select SOC_SERIES_<SOC_SERIES_NAME>

config SOC_FAMILY
        default "<soc_family_name>" if SOC_FAMILY_<SOC_FAMILY_NAME>

config SOC_SERIES
        default "<soc_series_name>" if SOC_SERIES_<SOC_SERIES_NAME>

config SOC
        default "<soc_name>" if SOC_<SOC_NAME>
```

  Notice that `SOC_NAME` is a pure uppercase version of the SoC name, `SOC_SERIES_NAME` is a pure uppercase version of SoC series name and `SOC_FAMILY_NAME` is a pure uppercase version of the SoC family name. If these fields do not appear in the `soc.yml` file then they should not be present in the `Kconfig.soc` file.

  The Kconfigs `SOC`, `SOC_SERIES` and `SOC_FAMILY` settings are globally defined as strings and therefore the `Kconfig.soc` file shall only define the default string values and not the types. Notice that the string values must match the values used in the `soc.yml` file.

Note

The build system supports any variation of case for `soc_name`, `soc_series_name` and `soc_family_mame`, but when submitting boards for inclusion in Zephyr itself, these must be purely lowercase versions of the Kconfig names

`Kconfig`
: Included by soc/Kconfig.

  This file can add Kconfig settings which are specific to the current SoC.

  The `Kconfig` will often indicate given hardware support using a setting of the form `HAS_<support>`.

```
config SOC_<SOC_NAME>
        select ARM
        select CPU_HAS_FPU
```

  If the setting name is identical to an existing Kconfig setting in Zephyr and only modifies the default value of said setting, then `Kconfig.defconfig` should be used instead.

`Kconfig.defconfig`
: SoC specific default values for Kconfig options.

  Not all SoCs have a `Kconfig.defconfig` file.

  The entire file should be inside a pair of `if SOC_<SOC_NAME>` / `endif` or `if SOC_SERIES_<SERIES_NAME>` / `endif`, like this:

```
if SOC_<SOC_NAME>

config NUM_IRQS
        default 32

endif # SOC_<SOC_NAME>
```

Multiple CPU clusters CPU clusters must provide additional Kconfig settings in the `Kconfig.soc` file. This will usually be in the form of `SOC_<SOC_NAME>_<CLUSTER>` so for a given `soc1` with two clusters `clusterA` and `clusterB`, then this will look like:

SoC's When a SoC defines CPU cluster

```
config SOC_SOC1_CLUSTERA
        bool
        select SOC_SOC1

config SOC_SOC1_CLUSTERB
        bool
        select SOC_SOC1
```

6.9.3 Board Porting Guide

To add Zephyr support for a new *board*, you at least need a *board directory* with various files in it. Files in the board directory inherit support for at least one SoC and all of its features. Therefore, Zephyr must support your *SoC* as well.

Transition to the current hardware model

Shortly after Zephyr 3.6.0 was released, a new hardware model was introduced to Zephyr. This new model overhauls the way both SoCs and boards are named and defined, and adds support for features that had been identified as important over the years. Among them:

- Support for multi-core, multi-arch AMP (Asymmetrical Multi Processing) SoCs
- Support for multi-SoC boards
- Support for reusing the SoC and board Kconfig trees outside of the Zephyr build system

- Support for advanced use cases with *Sysbuild (System build)*
- Removal of all existing arbitrary and inconsistent uses of Kconfig and folder names

All the documentation in this page refers to the current hardware model. Please refer to the documentation in Zephyr v3.6.0 (or earlier) for information on the previous, now obsolete, hardware model.

More information about the rationale, development and concepts behind the new model can be found in the original issue, the original Pull Request and, for a complete set of changes introduced, the hardware model v2 commit.

Some non-critical features, enhancements and improvements of the new hardware model are still in development. Check the hardware model v2 enhancements issue for a complete list.

The transition from the previous hardware model to the current one (commonly referred to as "hardware model v2") requires modifications to all existing board and SoC definitions. A decision was made not to provide direct backwards compatibility for the previous model, which leaves users transitioning from a previous version of Zephyr to one including the new model (v3.7.0 and onwards) with two options if they have an out-of-tree board (or SoC):

1. Convert the out-of-tree board to the current hardware model (recommended)
2. Take the SoC definition from Zephyr v3.6.0 and copy it to your downstream repository (ensuring that the build system can find it via a *zephyr module* or `SOC_ROOT`). This will allow your board, defined in the previous hardware model, to continue to work

When converting your board from the previous to the current hardware model, we recommend first reading through this page to understand the model in detail. You can then use the example-application conversion Pull Request as an example on how to port a simple board. Additionally, a conversion script is available and works reliably in many cases (though multi-core SoCs may not be handled entirely). Finally, the hardware model v2 commit contains the full conversion of all existing boards from the old to the current model, so you can use it as a complete conversion reference.

Hardware support hierarchy

Zephyr's hardware support is based on a series of hierarchical abstractions. Primarily, each *board* has one or more *SoC*. Each SoC can be optionally classed into an *SoC series*, which in turn may optionally belong to an *SoC family*. Each SoC has one or more *CPU cluster*, each containing one or more *CPU core* of a particular *architecture*.

You can visualize the hierarchy in the diagram below:

Below are some examples of the hierarchy described in this section, in the form of a *board* per row with its corresponding hierarchy entries. Notice how the *SoC series* and *SoC family* levels are not always used.

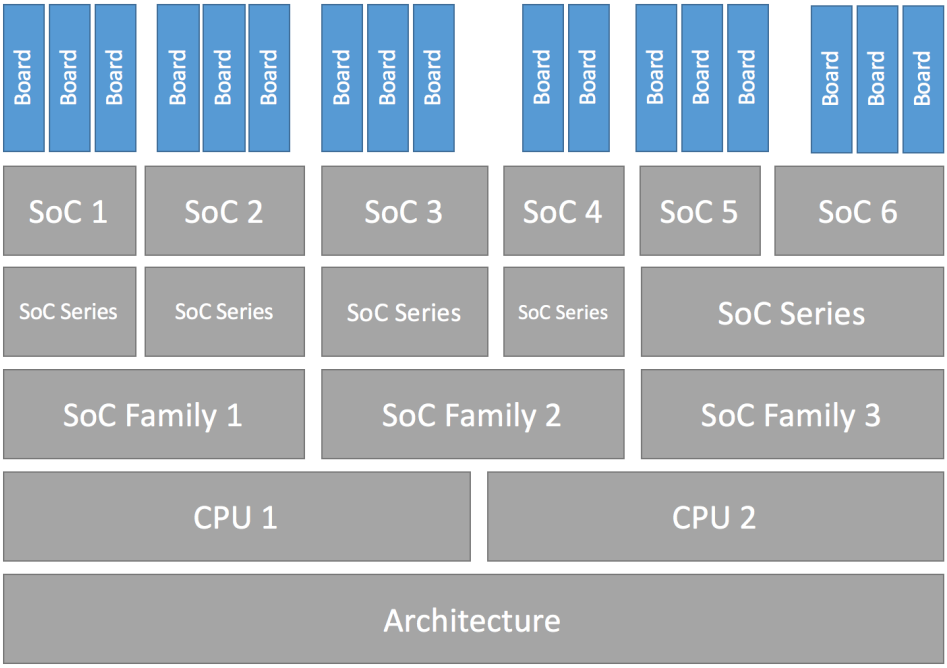

Fig. 5: Hardware support Hierarchy

board name	*board qualifiers*	*SoC*	*SoC Series*	*SoC family*	CPU core	*architecture*
nrf52dk	nrf52832	nRF52832	nRF52	Nordic nRF	Arm Cortex-M4	ARMv7-M
frdm_k64f	mk64f12	MK64F12	Kinetis K6x	NXP Kinetis	Arm Cortex-M4	ARMv7-M
rv32m1_vega	openisa_rv32m1/r	RV32M1	(Not used)	(Not used)	RI5CY	RISC-V RV32
nrf5340dk	nrf5340/cpuapp	nRF5340	nRF53	Nordic nRF	Arm Cortex-M33	ARMv8-M
	nrf5340/cpunet	nRF5340	nRF53	Nordic nRF	Arm Cortex-M33	ARMv8-M
mimx8mp_e	mimx8ml8/a53	i.MX8M Plus	i.MX8M	NXP i.MX	Arm Cortex-A53	ARMv8-A
	mimx8ml8/m7	i.MX8M Plus	i.MX8M	NXP i.MX	Arm Cortex-M7	ARMv7-M
	mimx8ml8/adsp	i.MX8M Plus	i.MX8M	NXP i.MX	Cadence HIFI4	Xtensa LX6

Additional details about terminology can be found in the next section.

Board terminology

The previous section introduced the hierarchical manner in which Zephyr classifies and implements hardware support. This section focuses on the terminology used around hardware support, and in particular when defining and working with boards and SoCs.

The overall set of terms used around the concept of board in Zephyr is depicted in the image below, which uses the bl5340_dvk board as reference.

The diagram shows the different terms that are used to describe boards:

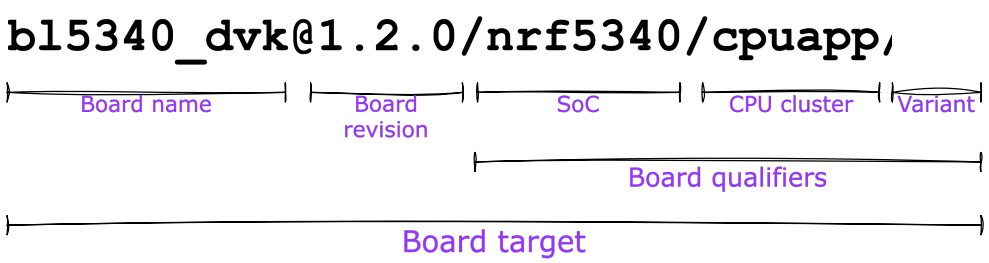

Fig. 6: Board terminology diagram

- The *board name*: `bl5340_dvk`
- The optional *board revision*: `1.2.0`
- The *board qualifiers*, that optionally describe the *SoC*, *CPU cluster* and *variant*: `nrf5340/cpuapp/ns`
- The *board target*, which uniquely identifies a combination of the above and can be used to specify the hardware to build for when using the tooling provided by Zephyr: `bl5340_dvk@1.2.0/nrf5340/cpuapp/ns`

Formally this can also be seen as *board name*`[@`*revision*`][/`*board qualifiers*`]`, which can be extended to *board name*`[@`*revision*`][/`*SoC*`[/`*CPU cluster*`][/`*variant*`]]`.

If a board contains only one single-core SoC, then the SoC can be omitted from the board target. This implies that if the board does not define any board qualifiers, the board name can be used as a board target. Conversely, if board qualifiers are part of the board definition, then the SoC can be omitted by leaving it out but including the corresponding forward-slashes: `//`.

Continuing with the example above, The board bl5340_dvk is a single SoC board where the SoC defines two CPU clusters: `cpuapp` and `cpunet`. One of the CPU clusters, `cpuapp`, additionally defines a non-secure board variant, `ns`.

The board qualifiers `nrf5340/cpuapp/ns` can be read as:

- `nrf5340`: The SoC, which is a Nordic nRF5340 dual-core SoC
- `cpuapp`: The CPU cluster `cpuapp`, which consists of a single Cortex-M33 CPU core. The number of cores in a CPU cluster cannot be determined from the board qualifiers.
- `ns`: a variant, in this case `ns` is a common variant name in Zephyr denoting a non-secure build for boards supporting *Trusted Firmware-M (TF-M)*.

Not all SoCs define CPU clusters or variants. For example a simple board like the thingy52 contains a single SoC with no CPU clusters and no variants. For `thingy52` the board target `thingy52/nrf52832` can be read as:

- `thingy52`: board name.
- `nrf52832`: The board qualifiers, in this case identical to the SoC, which is a Nordic nRF52832.

Make sure your SoC is supported

Start by making sure your SoC is supported by Zephyr. If it is, it's time to *Create your board directory*. If you don't know, try:

- checking boards for names that look relevant, and reading individual board documentation to find out for sure.
- asking your SoC vendor

If you need to add a SoC, CPU cluster, or even architecture support, this is the wrong page, but here is some general advice.

Architecture See *Architecture Porting Guide*.

CPU Core CPU core support files go in `core` subdirectories under arch, e.g. arch/x86/core.

See *Install a Toolchain* for information about toolchains (compiler, linker, etc.) supported by Zephyr. If you need to support a new toolchain, *Build and Configuration Systems* is a good place to start learning about the build system. Please reach out to the community if you are looking for advice or want to collaborate on toolchain support.

SoC Zephyr SoC support files are in architecture-specific subdirectories of soc. They are generally grouped by SoC family.

When adding a new SoC family or series for a vendor that already has SoC support within Zephyr, please try to extract common functionality into shared files to avoid duplication. If there is no support for your vendor yet, you can add it in a new directory `zephyr/soc/<VENDOR>/<YOUR-SOC>`; please use self-explanatory directory names.

Create your board directory

Once you've found an existing board that uses your SoC, you can usually start by copy/pasting its board directory and changing its contents for your hardware.

You need to give your board a unique name. Run `west boards` for a list of names that are already taken, and pick something new. Let's say your board is called `plank` (please don't actually use that name).

Start by creating the board directory `zephyr/boards/<VENDOR>/plank`, where `<VENDOR>` is your vendor subdirectory. (You don't have to put your board directory in the zephyr repository, but it's the easiest way to get started. See *Custom Board, Devicetree and SOC Definitions* for documentation on moving your board directory to a separate repository once it's working.)

> **Note**
>
> A `<VENDOR>` subdirectory is mandatory if contributing your board to Zephyr, but if your board is placed in a local repo, then any folder structure under `<your-repo>/boards` is permitted. If the vendor is defined in the list in dts/bindings/vendor-prefixes.txt then you must use that vendor prefix as `<VENDOR>`. `others` may be used as vendor prefix if the vendor is not defined.

> **Note**
>
> The board directory name does not need to match the name of the board. Multiple boards can even be defined in one directory.

Your board directory should look like this:

```
boards/<VENDOR>/plank
├── board.yml
├── board.cmake
├── CMakeLists.txt
├── doc
│   ├── plank.webp
│   └── index.rst
├── Kconfig.plank
├── Kconfig.defconfig
├── plank_<qualifiers>_defconfig
```

(continues on next page)

(continued from previous page)

```
├── plank_<qualifiers>.dts
└── plank_<qualifiers>.yaml
```

Replace `plank` with your board's name, of course.

The mandatory files are:

1. `board.yml`: a YAML file describing the high-level meta data of the boards such as the boards names, their SoCs, and variants. CPU clusters for multi-core SoCs are not described in this file as they are inherited from the SoC's YAML description.
2. `plank_<qualifiers>.dts`: a hardware description in *devicetree* format. This declares your SoC, connectors, and any other hardware components such as LEDs, buttons, sensors, or communication peripherals (USB, Bluetooth controller, etc).
3. `Kconfig.plank`: the base software configuration for selecting SoC and other board and SoC related settings. Kconfig settings outside of the board and SoC tree must not be selected. To select general Zephyr Kconfig settings the `Kconfig` file must be used.

The optional files are:

- `Kconfig`, `Kconfig.defconfig` software configuration in *Configuration System (Kconfig)* formats. This provides default settings for software features and peripheral drivers.
- `plank_defconfig` and `plank_<qualifiers>_defconfig`: software configuration in Kconfig `.conf` format.
- `board.cmake`: used for *Flash and debug support*
- `CMakeLists.txt`: if you need to add additional source files to your build.
- `doc/index.rst`, `doc/plank.webp`: documentation for and a picture of your board. You only need this if you're *Contributing your board* to Zephyr.
- `plank_<qualifiers>.yaml`: a YAML file with miscellaneous metadata used by the *Test Runner (Twister)*.

Board qualifiers of the form `<soc>/<cpucluster>/<variant>` are normalized so that / is replaced with _ when used for filenames, for example: `soc1/foo` becomes `soc1_foo` when used in filenames.

Write your board YAML

The board YAML file describes the board at a high level. This includes the SoC, board variants, and board revisions.

Detailed configurations, such as hardware description and configuration are done in devicetree and Kconfig.

The skeleton of the board YAML file is:

```
board:
  name: <board-name>
  full_name: <board-full-name>
  vendor: <board-vendor>
  revision:
    format: <major.minor.patch|letter|number|custom>
    default: <default-revision-value>
    exact: <true|false>
    revisions:
    - name: <revA>
    - name: <revB>
      ...
```

(continues on next page)

(continued from previous page)

```
  socs:
  - name: <soc-1>
    variants:
    - name: <variant-1>
    - name: <variant-2>
      variants:
      - name: <sub-variant-2-1>
        ...
  - name: <soc-2>
    ...
```

It is possible to have multiple boards located in the board folder. If multiple boards are placed in the same board folder, then the file `board.yml` must describe those in a list as:

```
boards:
- name: <board-name-1>
  vendor: <board-vendor>
  full_name: <board-full-name>
  ...
- name: <board-name-2>
  vendor: <board-vendor>
  full_name: <board-full-name>
  ...
...
```

Write your devicetree

The devicetree file `boards/<vendor>/plank/plank_<qualifiers>.dts` describes your board hardware in the Devicetree Source (DTS) format (as usual, change `plank` to your board's name). If you're new to devicetree, see *Introduction to devicetree*.

In general, `plank_<qualifiers>.dts` should look like this:

```
/dts-v1/;
#include <your_soc_vendor/your_soc.dtsi>

/ {
        model = "A human readable name";
        compatible = "yourcompany,plank";

        chosen {
                zephyr,console = &your_uart_console;
                zephyr,sram = &your_memory_node;
                /* other chosen settings  for your hardware */
        };

        /*
         * Your board-specific hardware: buttons, LEDs, sensors, etc.
         */

        leds {
                compatible = "gpio-leds";
                led0: led_0 {
                        gpios = </* GPIO your LED is hooked up to */>;
                        label = "LED 0";
                };
```

(continues on next page)

(continued from previous page)

```
                /* ... other LEDs ... */
        };

        buttons {
                compatible = "gpio-keys";
                /* ... your button definitions ... */
        };

        /* These aliases are provided for compatibility with samples */
        aliases {
                led0 = &led0; /* now you support the blinky sample! */
                /* other aliases go here */
        };
};

&some_peripheral_you_want_to_enable { /* like a GPIO or SPI controller */
        status = "okay";
};

&another_peripheral_you_want {
        status = "okay";
};
```

In the case a board has only a single SoC, without any board variants then the dts file can be named `<plank>.dts` instead, however this is not recommended due to the file silently be unused if a variant or other SoC is added to the board.

If you're in a hurry, simple hardware can usually be supported by copy/paste followed by trial and error. If you want to understand details, you will need to read the rest of the devicetree documentation and the devicetree specification.

Example: FRDM-K64F and Hexiwear K64 This section contains concrete examples related to writing your board's devicetree.

The FRDM-K64F and Hexiwear K64 board devicetrees are defined in frdm_k64fs.dts and hexiwear_k64.dts respectively. Both boards have NXP SoCs from the same Kinetis SoC family, the K6X.

Common devicetree definitions for K6X are stored in nxp_k6x.dtsi, which is included by both board `.dts` files. nxp_k6x.dtsi in turn includes armv7-m.dtsi, which has common definitions for Arm v7-M cores.

Since nxp_k6x.dtsi is meant to be generic across K6X-based boards, it leaves many devices disabled by default using `status` properties. For example, there is a CAN controller defined as follows (with unimportant parts skipped):

```
can0: can@40024000 {
     ...
     status = "disabled";
     ...
};
```

It is up to the board `.dts` or application overlay files to enable these devices as desired, by setting `status = "okay"`. The board `.dts` files are also responsible for any board-specific configuration of the device, such as adding nodes for on-board sensors, LEDs, buttons, etc.

For example, FRDM-K64 (but not Hexiwear K64) `.dts` enables the CAN controller and sets the bus speed:

```
&can0 {
     status = "okay";
};
```

The `&can0 { ... };` syntax adds/overrides properties on the node with label `can0`, i.e. the `can@4002400` node defined in the `.dtsi` file.

Other examples of board-specific customization is pointing properties in `aliases` and `chosen` to the right nodes (see *Aliases and chosen nodes*), and making GPIO/pinmux assignments.

Write Kconfig files

Zephyr uses the Kconfig language to configure software features. Your board needs to provide some Kconfig settings before you can compile a Zephyr application for it.

Setting Kconfig configuration values is documented in detail in *Setting Kconfig configuration values*.

There is one mandatory Kconfig file in the board directory, and several optional files for a board named `plank`:

```
boards/<vendor>/plank
├── Kconfig
├── Kconfig.plank
├── Kconfig.defconfig
└── plank_<qualifiers>_defconfig
```

`Kconfig.plank`
: A shared Kconfig file which can be sourced both in Zephyr Kconfig and sysbuild Kconfig trees.

  This file selects the SoC in the Kconfig tree and potential other SoC related Kconfig settings. This file must not select anything outside the reusable Kconfig board and SoC trees.

  A `Kconfig.plank` may look like this:

  ```
  config BOARD_PLANK
          select SOC_SOC1
  ```

  The Kconfig symbols `BOARD_`*board* and `BOARD_`*normalized_board_target* are constructed by the build system, therefore no type shall be defined in above code snippet.

`Kconfig`
: Included by boards/Kconfig.

  This file can add Kconfig settings which are specific to the current board.

  Not all boards have a `Kconfig` file.

  A board specific setting should be defining a custom setting and usually with a prompt, like this:

  ```
  config BOARD_FEATURE
          bool "Board specific feature"
  ```

  If the setting name is identical to an existing Kconfig setting in Zephyr and only modifies the default value of said setting, then `Kconfig.defconfig` should be used instead.

`Kconfig.defconfig`
: Board-specific default values for Kconfig options.

  Not all boards have a `Kconfig.defconfig` file.

  The entire file should be inside an `if BOARD_PLANK` / `endif` pair of lines, like this:

```
if BOARD_PLANK

config FOO
        default y

if NETWORKING

config SOC_ETHERNET_DRIVER
        default y

endif # NETWORKING

endif # BOARD_PLANK
```

plank_<qualifiers>_defconfig (or plank_defconfig in limited circumstances)
A Kconfig fragment that is merged as-is into the final build directory `.config` whenever an application is compiled for your board.

`plank_defconfig` can only be used with boards that have no qualifiers, no variants and a single SoC present, though this style of naming is not recommended due to samples/tests or downstream usage breaking suddenly without warning if a new SoC or board variant/qualifier is added to an board in upstream Zephyr.

Note

Multiple files are not merged and there is no fallback mechanism for files, this means if there is a board with 2 different SoCs and each one has 2 board variants, a `plank_defconfig` file would be wholly unused, for the first qualifier and variant `plank_<soc1>_<variant1>_defconfig` will be used, it will not include other file.

The `_defconfig` should contain mandatory settings for your UART, console, etc. The results are architecture-specific, but typically look something like this:

```
CONFIG_GPIO=y
CONFIG_CONSOLE=y
CONFIG_UART_CONSOLE=y
CONFIG_SERIAL=y
```

plank_x_y_z_defconfig / plank_<qualifiers>_x_y_z_defconfig
A Kconfig fragment that is merged as-is into the final build directory `.config` whenever an application is compiled for your board revision `x.y.z`.

Build, test, and fix

Now it's time to build and test the application(s) you want to run on your board until you're satisfied.

For example:

```
west build -b plank samples/hello_world
west flash
```

For `west flash` to work, see *Flash and debug support* below. You can also just flash `build/zephyr/zephyr.elf`, `zephyr.hex`, or `zephyr.bin` with any other tools you prefer.

Before submitting a board upstream, verify that every board target you add can pass the project's minimum open source test suite using only code from the mainline Zephyr repository and its modules. The suite currently consists of:

- `samples/philosophers`

- `tests/kernel`

For example, build the suite for a board target with:

```
west twister -p plank -T samples/philosophers -T tests/kernel
```

For boards with multiple SoCs, CPU clusters, variants, or revisions, repeat the test suite for each new board target. A hello_world build is also recommended as a quick smoke check, for example:

```
west build -p always -b plank/soc1/foo samples/hello_world
west build -p always -b plank@1.0.0/soc1/foo samples/hello_world
```

Use *Sysbuild (System build)* if the board target requires it. When using board testing metadata, such as `testing: only_tags` in the board target YAML file, make sure the target is still validated against the minimum test suite in local testing or CI.

General recommendations

For consistency and to make it easier for users to build applications which remain board agnostic, please follow these guidelines when porting a board you intend to contribute to Zephyr:

Enable valuable components in Devicetree
: Devicetree nodes for valuable onboard components (LEDs, buttons, sensors, onboard USB/Ethernet/BLE/Wi-Fi, etc.) must be **enabled by default** and have correct pin control and driver configuration so that they work out of the box.

Keep subsystems disabled by default (Kconfig)
: Do not enable subsystems in the board defconfig unless they are strictly required for basic board operation, or are explicitly listed as exceptions in these recommendations.

Configure system clock and tick source
: Set up a functioning system clock and tick source.

Provide a default console
: Use the `zephyr,console` chosen node to point to the UART controller used for console output.

  Boards with built-in debug or a USB-to-UART adapter should set the console to the UART controller connected to that adapter.

  USB-only boards without any debug adapter must include the common USB CDC-ACM Kconfig and DTS fragments to enable CDC-ACM UART as a default backend for logging and shell.

Add *shield interface* definitions
: For boards exposing standard expansion headers, add connector nodes and pin-muxing. Enable only the peripherals needed for the expected/standard connector functionality.

Configure pins and peripheral instances
: Map peripherals to the correct pins (e.g., SPI on Arduino SPI pins) and provide default pinmux entries supporting the board's features.

Enable networking interfaces
: If networking hardware is present, configure default interfaces for each supported technology so that networking samples work out of the box.

Enable GPIO controllers
: All GPIO ports connected to onboard components or expansion headers should be enabled.

Enable MPU and stack protection
: It is recommended to enable the MPU when available (unless memory resources are too limited). When the MPU is enabled, it is recommended to also enable hardware stack protection (`CONFIG_HW_STACK_PROTECTION`) to ease debugging by allowing the kernel to detect stack overflows.

Flash and debug support

Zephyr supports *Building, Flashing and Debugging* via west extension commands.

To add `west flash` and `west debug` support for your board, you need to create a `board.cmake` file in your board directory. This file's job is to configure a "runner" for your board. (There's nothing special you need to do to get `west build` support for your board.)

"Runners" are Zephyr-specific Python classes that wrap *flash and debug host tools* and integrate with west and the zephyr build system to support `west flash` and related commands. Each runner supports flashing, debugging, or both. You need to configure the arguments to these Python scripts in your `board.cmake` to support those commands like this example `board.cmake`:

```
board_runner_args(jlink "--device=nrf52" "--speed=4000")
board_runner_args(pyocd "--target=nrf52" "--frequency=4000000")

include(${ZEPHYR_BASE}/boards/common/nrfutil.board.cmake)
include(${ZEPHYR_BASE}/boards/common/nrfjprog.board.cmake)
include(${ZEPHYR_BASE}/boards/common/jlink.board.cmake)
include(${ZEPHYR_BASE}/boards/common/pyocd.board.cmake)
```

This example configures the `nrfutil`, `nrfjprog`, `jlink`, and `pyocd` runners.

Warning

Runners usually have names which match the tools they wrap, so the `jlink` runner wraps Segger's J-Link tools, and so on. But the runner command line options like `--speed` etc. are specific to the Python scripts.

Note

Runners and board configuration should be created without being targeted to a single operating system if the tool supports multiple operating systems, nor should it rely upon special system setup/configuration. For example; do not assume that a user will have prior knowledge/configuration or (if using Linux) special udev rules installed, do not assume one specific `/dev/X` device for all platforms as this will not be compatible with Windows or macOS, and allow for overriding of the selected device so that multiple boards can be connected to a single system and flashed/debugged at the choice of the user.

For more details:

- Run `west flash --context` to see a list of available runners which support flashing, and `west flash --context -r <RUNNER>` to view the specific options available for an individual runner.
- Run `west debug --context` and `west debug --context <RUNNER>` to get the same output for runners which support debugging.
- Run `west flash --help` and `west debug --help` for top-level options for flashing and debugging.
- See *Configuration Options* for Python APIs.
- Look for `board.cmake` files for other boards similar to your own for more examples.

To see what a `west flash` or `west debug` command is doing exactly, run it in verbose mode:

```
west --verbose flash
west --verbose debug
```

Verbose mode prints any host tool commands the runner uses.

The order of the `include()` calls in your `board.cmake` matters. The first `include` sets the default runner if it's not already set. For example, including `nrfjprog.board.cmake` first means that `nrfjprog` is the default flash runner for this board. Since `nrfjprog` does not support debugging, `jlink` is the default debug runner.

Multiple board revisions

See *Building for a board revision* for basics on this feature from the user perspective.

Board revisions are described in the `revision` entry of the `board.yml`.

```
board:
  revision:
    format: <major.minor.patch|letter|number|custom>
    default: <default-revision-value>
    exact: <true|false>
    revisions:
    - name: <revA>
    - name: <revB>
```

Zephyr natively supports the following revision formats:

- `major.minor.patch`: match a three digit revision, such as `1.2.3`.
- `number`: matches integer revisions
- `letter`: matches single letter revisions from `A` to `Z` only

Fuzzy revision matching Fuzzy revision matching is enabled per default.

If the user selects a revision between those available, the closest revision number that is not larger than the user's choice is used. For example, if the board `plank` defines revisions `0.5.0`, and `1.5.0` and the user builds for `plank@0.7.0`, the build system will target revision `0.5.0`.

The build system will print this at CMake configuration time:

```
-- Board: plank, Revision: 0.7.0 (Active: 0.5.0)
```

This allows you to only create revision configuration files for board revision numbers that introduce incompatible changes.

Similarly for `letter` revision format, if revisions `A`, `D`, and `F` are defined and the user builds for `plank@E`, the build system will target revision `D`.

Exact revision matching Exact revision matching is enabled when `exact: true` is specified in the revision section in `board.yml`.

When exact is defined then building for `plank@0.7.0` in the above example will result in the following error message:

```
Board revision `0.7.0` not found.  Please specify a valid board revision.
```

Board revision configuration adjustment When the user builds for board `plank@<revision>` it is possible to make adjustments to the board's normal configuration.

As described in the *Write your devicetree* and *Write Kconfig files* sections the board default configuration is created from the files `<board>.dts` / `<board>_<qualifiers>.dts` and `<board>_defconfig` / `<board>_<qualifiers>_defconfig`. When building for a specific board revision, the above files are used as a starting point and the following board files will be used in addition:

- <board>_<qualifiers>_<revision>_defconfig: a specific revision defconfig which is only used for the board and SOC / variants identified by <board>_<qualifiers>.
- <board>_<qualifiers>_<revision>.overlay: a specific revision dts overlay which is only used for the board and SOC / variants identified by <board>_<qualifiers>.

This split allows boards with multiple SoCs, multi-core SoCs, or variants to place common revision adjustments which apply to all SoCs and variants in a single file, while still providing the ability to place SoC or variant specific adjustments in a dedicated revision file.

Using the plank board from previous sections, then we could have the following revision adjustments:

```
boards/zephyr/plank
├── plank_soc1_foo_1_5_0.overlay   # DTS overlay for plank board when building for␣
↪soc1 variant foo on revision 1.5.0
└── plank_soc1_foo_1_5_0_defconfig # Kconfig adjustment for plank board when␣
↪building for soc1 variant foo on revision 1.5.0
```

Custom revision.cmake files

Some boards may not use board revisions supported natively by Zephyr. For example string revisions.

One reason why Zephyr doesn't support string revisions is that strings can take many forms and it's not always clear if the given strings are just strings, such as blue, green, red, etc. or if they provide an order which can be matched against higher or lower revisions, such as alpha, beta`, gamma.

Due to the sheer number of possibilities with strings, including the possibility of doing regex matches internally, then string revisions must be done using custom revision type.

To indicate to the build system that custom revisions are used, the format field in the revision section of the board.yml must be written as:

```
board:
  revision:
    format: custom
```

When using custom revisions then a revision.cmake must be created in the board directory.

The revision.cmake will be included by the build system when building for the board and it is the responsibility of the file to validate the revision specified by the user.

The BOARD_REVISION variable holds the revision value specified by the user.

To signal to the build system that it should use a different revision than the one specified by the user, revision.cmake can set the CMake variable *ACTIVE_BOARD_REVISION* to the revision to use instead. The corresponding Kconfig files and devicetree overlays must be named <board>_<ACTIVE_BOARD_REVISION>_defconfig and <board>_<ACTIVE_BOARD_REVISION>.overlay.

Contributing your board

If you want to contribute your board to Zephyr, first – thanks!

There are some extra things you'll need to do:

1. Make sure you've followed all the *General recommendations*. They are requirements for boards included with Zephyr.
2. Add documentation for your board using the template file doc/templates/board.tmpl. See *Documentation Generation* for information on how to build your documentation before submitting your pull request.

3. Prepare a pull request adding your board which follows the *Contribution Guidelines*.

Board extensions

The board hardware model in Zephyr allows you to extend an existing board with new board variants. Such board extensions can be done in your custom repository and thus outside of the Zephyr repository.

Extending an existing board with an extra variant allows you to adjust an existing board and thereby during build to select building for the existing, unmodified board, or the new variant.

To extend an existing board, first create a `board.yml` in your extended board. Make sure to use the directory structure described in *Create your board directory*.

The skeleton of the board YAML file for extending a board is:

```
board:
  extend: <existing-board-name>
  variants:
    - name: <new-variant>
      qualifier: <existing-qualifier>
```

When extending a board, your board directory should look like:

```
boards/<VENDOR>/plank
├── board.yml
├── plank_<new-qualifiers>_defconfig
└── plank_<new-qualifiers>.dts
```

Replace `plank` with the real name of the board you extend.

In some cases you might want to also adjust additional settings, like the `Kconfig.defconfig` or `Kconfig.board`. Therefore it is also possible to provide the following in addition when extending a board.

```
boards/<VENDOR>/plank
├── board.cmake
├── Kconfig
├── Kconfig.plank
├── Kconfig.defconfig
└── plank_<new-qualifiers>.yaml
```

6.9.4 Shields

Shields, also known as “add-on” or “daughter boards”, attach to a board to extend its features and services for easier and modularized prototyping. In Zephyr, the shield feature provides Zephyr-formatted shield descriptions for easier compatibility with applications.

Shield activation

Activate support for one or more shields by adding the matching `--shield` arguments to the west command:

```
west build -b your_board --shield x_nucleo_idb05a1 --shield␣
↪x_nucleo_iks01a1 your_app
```

Alternatively, it could be set by default in a project’s CMakeLists.txt:

```
set(SHIELD x_nucleo_iks01a1)
```

Shield interfaces

A shield is defined by two key characteristics:

1. **Physical connectors** - the mechanical interface
2. **Electrical signals** - what each pin actually does

The connection between a shield and a board happens through Devicetree files:

- Board side: The board's devicetree file uses a *GPIO nexus node* to map connector pins to the microcontroller's actual GPIO pins. It also defines labels for buses exposed through the connector (like `arduino_i2c`, `arduino_spi`, `arduino_uart`).
- Shield side: The shield's .overlay file references these same labels to describe how its components connect to the board.

At build time, the board's devicetree and the shield's overlay are combined to create a complete picture of the hardware setup.

For example, let's say you have a board with an Arduino connector but no built-in accelerometer. You can add one using an Arduino shield:

1. The board's Devicetree defines an `arduino_i2c` label: it is the I2C bus made available on the Arduino connector
2. The accelerometer shield's overlay file also references `arduino_i2c` to indicate it uses that same I2C bus. If it needs to use GPIO pins from the connector, it references the GPIO nexus node defined by the board's Devicetree (e.g. `arduino_header`).

When you then build for this board with this shield, Zephyr automatically "wires them" together.

> **Note**
>
> Some boards and shields may only support a limited set of features of a shield hardware interface. Refer to their documentation for more details.

Arduino MKR This is the form factor of the Arduino MKR boards.

Relevant devicetree node labels:

- `arduino_mkr_header` See `arduino-mkr-header` for details on GPIO pin definitions and includes for use in devicetree files.
- `arduino_mkr_i2c`
- `arduino_mkr_spi`
- `arduino_mkr_serial`

Arduino Nano This is the form factor of the Arduino Nano boards.

Relevant devicetree node labels:

- `arduino_nano_header` See `arduino-nano-header` for details on GPIO pin definitions and includes for use in devicetree files.
- `arduino_nano_i2c`
- `arduino_nano_spi`
- `arduino_nano_serial`

Fig. 7: Arduino MKR Zero, an example of a board with the Arduino MKR shield interface

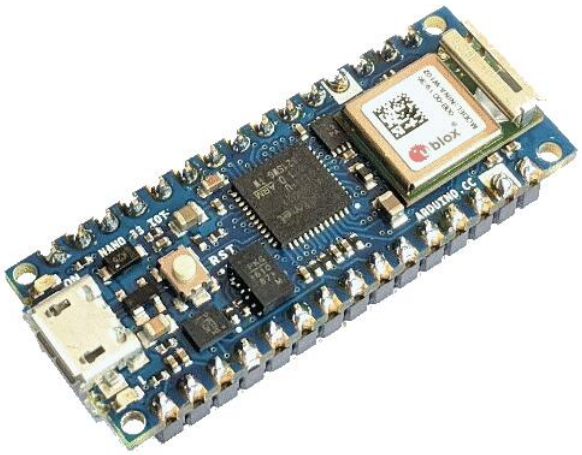

Fig. 8: Arduino Nano 33 IOT, an example of a board with the Arduino Nano shield interface

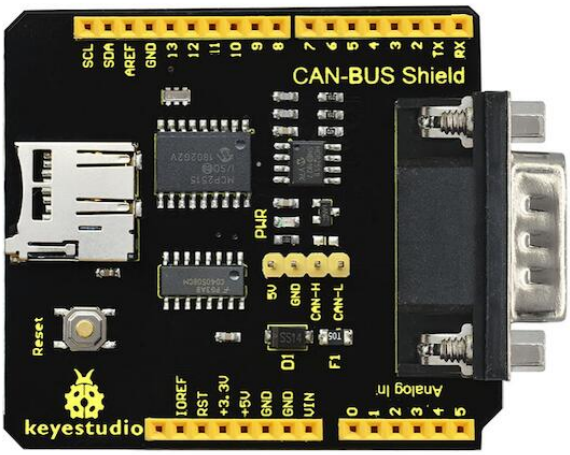

Fig. 9: Keyestudio CAN-BUS, an example of an Arduino shield (Credit: Keyestudio)

Arduino Uno R3 This is the form factor of the Arduino Uno R3 board.

Relevant devicetree node labels:

- `arduino_header` See `arduino-header-r3` for details on GPIO pin definitions and includes for use in devicetree files.
- `arduino_adc` See `arduino,uno-adc`
- `arduino_pwm` See `arduino-header-pwm`
- `arduino_serial`
- `arduino_i2c`
- `arduino_spi`

For technical details, see Arduino Uno R3 pinout.

Camera and display connectors These describe connections to cameras and displays (strictly speaking not shields).

- `arducam,dvp-20pin-connector`
- `nxp,cam-44pins-connector`
- `nxp,parallel-lcd-connector`
- `raspberrypi,csi-connector`
- `st,dsi-lcd-qsh-030-connector`
- `st,dvp-cam-zif-30-connector`
- `weact,dcmi-camera-connector`

ESP-01 This is an 8-pin header for ESP-01 Wi-Fi modules.

Relevant devicetree node labels:

- `esp_01_header` See `esp-01-header` for details on GPIO pin definitions and includes for use in devicetree files.
- `esp_01_serial`

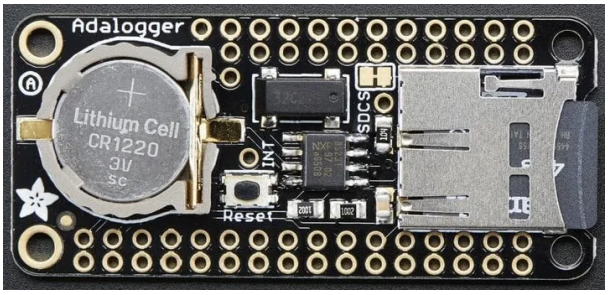

Fig. 10: Adafruit Adalogger, an example of a Featherwing (Credit: Adafruit)

Feather This is the form factor of the Adafruit Feather series of boards. Shields intended for Feather boards are called Featherwings.

Relevant devicetree node labels:

- `feather_header` See `adafruit-feather-header` for GPIO pin definitions.
- `feather_adc`
- `feather_i2c`
- `feather_serial`
- `feather_spi`

Microbit This is for the edge connector of the Microbit boards.

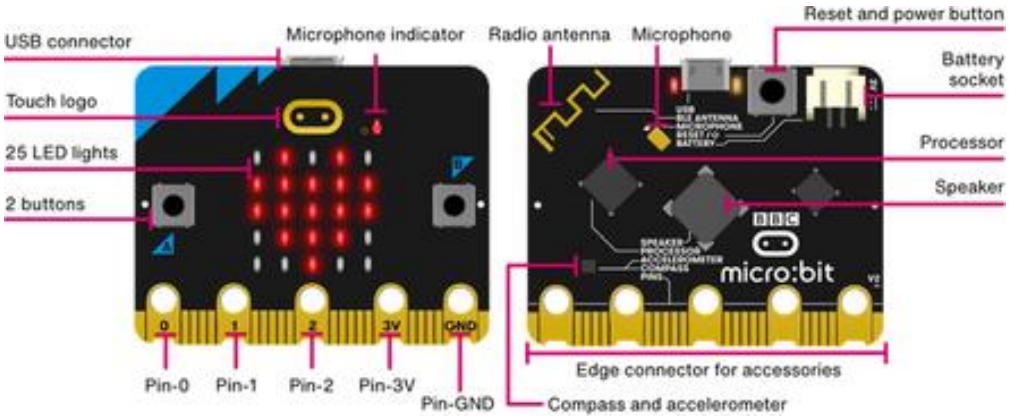

Fig. 11: Microbit V2 board uses the Microbit shield interface

See `microbit,edge-connector` for GPIO pin definitions and links to technical requirements.

mikroBUS™ This is an interface standard for add-on boards, developed by Mikroe.

Relevant devicetree node labels:

- `mikrobus_header` See `mikro-bus` for GPIO pin definitions and links to technical specifications.
- `mikrobus_adc`
- `mikrobus_i2c`
- `mikrobus_pwm`
- `mikrobus_spi`
- `mikrobus_serial`

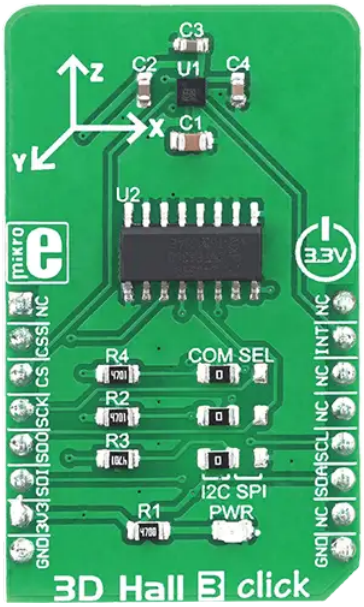

Fig. 12: 3D Hall 3 Click, an example of a mikroBUS™ shield

Note that boards with several mikroBUS™ connectors might define for example `mikrobus_2_spi`.

Pico This is the form factor of the Raspberry Pi Pico boards.

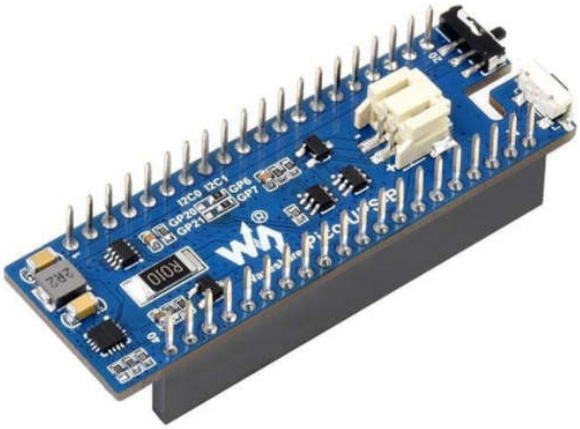

Fig. 13: Waveshare Pico UPS-B, an example of a Pico shield

Relevant devicetree node labels:

- `pico_header` See `raspberrypi,pico-header` for GPIO pin definitions.
- `pico_i2c` A node label that refers to the same node as either the node label `pico_i2c0` or `pico_i2c1`. It references the node that should be used with priority or as default.
- `pico_i2c0`
- `pico_i2c1`
- `pico_serial`
- `pico_spi`

ST Morpho Development boards from ST Microelectronics often uses the ST Morpho shield interface.

Fig. 14: X-NUCLEO-GFX01M2, an example of an ST Morpho shield

Relevant devicetree node labels:

- `st_morpho_header` See `st-morpho-header` for details on GPIO pin definitions and includes for use in devicetree files.
- `st_morpho_lcd_spi`
- `st_morpho_flash_spi`

ST Zio STM32 Nucleo-144 development boards from ST Microelectronics expose the ST Zio connector, an extension of the Arduino Uno V3 connector that gives access to more of the STM32 I/Os through four headers (CN7, CN8, CN9 and CN10).

Relevant devicetree node labels:

- `st_zio_header` See `st-zio-header` for details on GPIO pin definitions and includes for use in devicetree files.

STMod+ This is a 20-pin expansion connector found on some STMicroelectronics Discovery and Evaluation boards.

Relevant devicetree node labels:

- `stmod_plus_connector` See `st,stmod-plus-connector` for details on GPIO pin definitions and includes for use in devicetree files.
- `stmod_adc`
- `stmod_i2c`
- `stmod_pwm`
- `stmod_serial`
- `stmod_spi`

Boards may expose additional interface labels when a peripheral is wired to the STMod+ connector and enabled in the board devicetree.

WisBlock This is a modular interface standard for add-on boards, developed by RAKwireless. It defines Core, Sensor, I/O and Power Slots, each accepting a module of the matching class through a 24-pin or 40-pin WisConnector.

Relevant devicetree node labels:

- `wisblock_io` See `wisblock-io-slot` for GPIO pin definitions.

Fig. 15: RAK19007, an example of a WisBlock Base Board (Credit: RAKwireless)

- `wisblock_sensor_a` See `wisblock-sensor-slot` for GPIO pin definitions.
- `wisblock_adc`
- `wisblock_pwm`
- `wisblock_i2c1`
- `wisblock_i2c2`
- `wisblock_i2s`
- `wisblock_pdm`
- `wisblock_spi`
- `wisblock_uart0`
- `wisblock_uart1`

Note that Sensor Slots are labeled `wisblock_sensor_a` through `wisblock_sensor_f` after the Slot they implement.

Xiao This is the form factor of the Seeeduino XIAO boards.

Relevant devicetree node labels:

- `xiao_d` See `seeed,xiao-gpio` for GPIO pin definitions.
- `xiao_spi`
- `xiao_i2c`
- `xiao_serial`
- `xiao_adc`
- `xiao_dac`

zephyr_i2c / Stemma QT / Quiic These are four-pin I2C connectors. SparkFun calls these connectors “Qwiic”, and Adafruit calls them “Stemma QT”. The I2C connectors have four pins; GND, +3.3 Volt, I2C data and I2C clock. The most common physical connector is the 1.0 mm pitch JST-SH.

Fig. 16: Seeed Studio XIAO Expansion Board, an example of a Xiao shield (Credit: Seeed Studio)

Due to the different brand names, the interface is labeled “zephyr_i2c”.

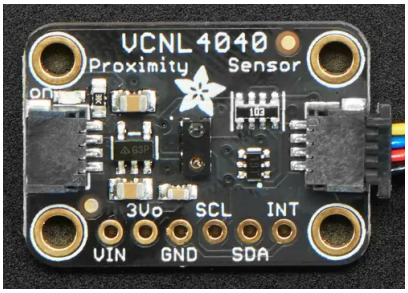

Fig. 17: Adafruit VCNL4040, an example of a zephyr_i2c shield (Credit: Adafruit)

See `stemma-qt-connector` and `grove-header` for descriptions and links to further details.

Relevant devicetree node labels:

- `zephyr_i2c`

ST M.2 serial memory connector Some STMicroelectronics Nucleo-144 development boards expose an ST-specific M.2 serial memory connector used to interface with external serial memories through XSPI, together with auxiliary signals such as I2C and connector GPIOs.

Fig. 18: B-M2MEM-PACK1, an example of an ST M.2 memory shield.

Relevant devicetree node labels:

- `m2mem_connector` See `st,m2-memory-connector` for details on GPIO pin definitions and includes for use in devicetree files.
- `m2mem_i2c`
- `m2mem_xspi`

Shield porting and configuration

Shield configuration files are available in the board directory under boards/shields:

```
boards/shields/<shield>
├── shield.yml
├── <shield>.overlay
├── Kconfig.shield
├── Kconfig.defconfig
└── pre_dt_shield.cmake
```

These files provides shield configuration as follows:

- **shield.yml**: This file provides metadata about the shield in YAML format. It must contain the following fields:
  - `name`: Name of the shield used in Kconfig and build system (required)
  - `full_name`: Full commercial name of the shield (required)
  - `vendor`: Manufacturer/vendor of the shield (required)
  - `supported_features`: List of hardware features the shield supports (optional). In order to help users identify the features a shield supports without having to dig into its overlay file, the `supported_features` field can be used to list the types of features the shield supports. The values should be the same as the ones defined in the dts/bindings/binding-types.txt file.

  Example:

  ```
  name: foo_shield
  full_name: Foo Shield for Arduino
  vendor: acme
  supported_features:
    - display
    - input
  ```

- **<shield>.overlay**: This file provides a shield description in devicetree format that is merged with the board's *devicetree* before compilation.
- **Kconfig.shield**: This file defines shield Kconfig symbols that will be used for default shield configuration. To ease use with applications, the default shield configuration here should be consistent with those in the *Write your devicetree*.
- **Kconfig.defconfig**: This file defines the default shield configuration. It is made to be consistent with the *Write your devicetree*. Hence, shield configuration should be done by keeping in mind that features activation is application responsibility.
- **pre_dt_shield.cmake**: This optional file can be used to pass additional arguments to the devicetree compiler `dtc`.

Besides, in order to avoid name conflicts with devices that may be defined at board level, it is advised, specifically for shields devicetree descriptions, to provide a device nodelabel is the form <device>_<shield>, for instance:

```
sdhc_myshield: sdhc@1 {
        reg = <1>;
        ...
};
```

Adding Source Code

It is possible to add source code to shields, as a way to meet configuration requirements that are specific to the shield (e.g: initialization routines, timing constraints, etc), in order to enable it for proper operation with the different Zephyr components.

> **Note**
>
> Source code in shields shall not be used for purposes other than the one described above. Generic functionalities that could be reused among shields (and/or targets) shall not be captured here.

To effectively incorporate source code: add a `CMakeLists.txt` file, as well as the corresponding source files (referenced in CMake similar to other areas of Zephyr, e.g: boards).

Board compatibility

Hardware shield-to-board compatibility depends on the use of well-known connectors used on popular boards (such as Arduino and 96boards). For software compatibility, boards must also provide a configuration matching their supported connectors.

This should be done at two different level:

- Pinmux: Connector pins should be correctly configured to match shield pins
- Devicetree: A board *devicetree* file, `BOARD.dts` should define an alternate nodelabel for each connector interface. For example, for Arduino I2C:

```
arduino_i2c: &i2c1 {};
```

Board specific shield configuration If modifications are needed to fit a shield to a particular board or board revision, you can override a shield description for a specific board by adding board or board revision overriding files to a shield, as follows:

```
boards/shields/<shield>
└── boards
    ├── <board>_<revision>.overlay
    ├── <board>.overlay
    ├── <board>.defconfig
    ├── <board>_<revision>.conf
    └── <board>.conf
```

Shield variants

Some shields may support several variants or revisions. In that case, it is possible to provide multiple version of the shields description:

```
boards/shields/<shield>
├── <shield_v1>.overlay
├── <shield_v1>.defconfig
├── <shield_v2>.overlay
└── <shield_v2>.defconfig
```

In this case, a shield-particular revision name can be used:

```
west build -b None --shield shield_v2 your_app
```

You can also provide a board-specific configuration to a specific shield revision:

```
boards/shields/<shield>
├── <shield_v1>.overlay
├── <shield_v1>.defconfig
├── <shield_v2>.overlay
├── <shield_v2>.defconfig
└── boards
    └── <shield_v2>
        ├── <board>.overlay
        └── <board>.defconfig
```

GPIO nexus nodes

GPIOs accessed by the shield peripherals must be identified using the shield GPIO abstraction, for example from the `arduino-header-r3` compatible. Boards that provide the header must map the header pins to SOC-specific pins. This is accomplished by including a nexus node that looks like the following into the board devicetree file:

```
arduino_header: connector {
        compatible = "arduino-header-r3";
        #gpio-cells = <2>;
        gpio-map-mask = <0xffffffff 0xffffffc0>;
        gpio-map-pass-thru = <0 0x3f>;
        gpio-map = <0 0 &gpioa 0 0>,    /* A0 */
                   <1 0 &gpioa 1 0>,    /* A1 */
                   <2 0 &gpioa 4 0>,    /* A2 */
                   <3 0 &gpiob 0 0>,    /* A3 */
                   <4 0 &gpioc 1 0>,    /* A4 */
                   <5 0 &gpioc 0 0>,    /* A5 */
                   <6 0 &gpioa 3 0>,    /* D0 */
                   <7 0 &gpioa 2 0>,    /* D1 */
                   <8 0 &gpioa 10 0>,   /* D2 */
                   <9 0 &gpiob 3 0>,    /* D3 */
                   <10 0 &gpiob 5 0>,   /* D4 */
                   <11 0 &gpiob 4 0>,   /* D5 */
                   <12 0 &gpiob 10 0>,  /* D6 */
                   <13 0 &gpioa 8 0>,   /* D7 */
                   <14 0 &gpioa 9 0>,   /* D8 */
                   <15 0 &gpioc 7 0>,   /* D9 */
                   <16 0 &gpiob 6 0>,   /* D10 */
                   <17 0 &gpioa 7 0>,   /* D11 */
                   <18 0 &gpioa 6 0>,   /* D12 */
                   <19 0 &gpioa 5 0>,   /* D13 */
                   <20 0 &gpiob 9 0>,   /* D14 */
                   <21 0 &gpiob 8 0>;   /* D15 */
};
```

This specifies how Arduino pin references like `<&arduino_header 11 0>` are converted to SOC gpio pin references like `<&gpiob 4 0>`.

In Zephyr GPIO specifiers generally have two parameters (indicated by `#gpio-cells = <2>`): the pin number and a set of flags. The low 6 bits of the flags correspond to features that can be configured in devicetree. In some cases it's necessary to use a non-zero flag value to tell the driver how a particular pin behaves, as with:

```
drdy-gpios = <&arduino_header 11 GPIO_ACTIVE_LOW>;
```

After preprocessing this becomes `<&arduino_header 11 1>`. Normally the presence of such a flag would cause the map lookup to fail, because there is no map entry with a non-zero flags value. The `gpio-map-mask` property specifies that, for lookup, all bits of the pin and all but the low 6 bits of the flags are used to identify the specifier. Then the `gpio-map-pass-thru` specifies that the low 6 bits of the flags are copied over, so the SOC GPIO reference becomes `<&gpiob 4 1>` as intended.

See nexus node for more information about this capability.

6.10 Virtualization

These pages document Zephyr virtualization facilities.

6.10.1 Virtual I/O (VIRTIO)

Overview

Virtual I/O (VIRTIO) is a protocol used for communication with various devices, typically used in virtualized environments. Its main goal is to provide an efficient and standardized mechanism for interfacing with virtual devices from within a virtual machine. The communication relies on virtqueues and standard transfer methods like PCI or MMIO.

Concepts

Virtio defines various components used during communication and initialization. It specifies both the host (named “device” in the specification) and guest (named “driver” in the specification) sides. Currently Zephyr can only work as a guest. On top of the facilities exposed by the Virtio driver, a driver for a specific device (e.g. network card) can be implemented.

A high-level overview of a system with a Virtio device is shown below.

Configuration space Each device provides configuration space, used for initialization and configuration. It allows selection of device and driver features, enabling specific virtqueues and setting their addresses. Once the device is configured, most of its configuration cannot be changed without resetting the device. The exact layout of the configuration space depends on the transfer method.

Driver and device features The configuration space provides a way to negotiate feature bits, determining some non-mandatory capabilities of the devices. The exact available feature bits depend on the device and platform.

Device-specific configuration Some of the devices offer device-specific configuration space, providing additional configuration options.

Virtqueues The main mechanism used for transferring data between host and guest is a virtqueue. Specific devices have different numbers of virtqueues, for example devices supporting bidirectional transfer usually have one or more tx/rx virtqueue pairs. Virtio specifies two types of virtqueues: split virtqueues and packed virtqueues. Zephyr currently supports only split virtqueues.

Split virtqueues A split virtqueue consists of three parts: descriptor table, available ring and used ring.

The descriptor table holds descriptors of buffers, that is their physical addresses, lengths and flags. Each descriptor is either device writeable or driver writeable. The descriptors can be

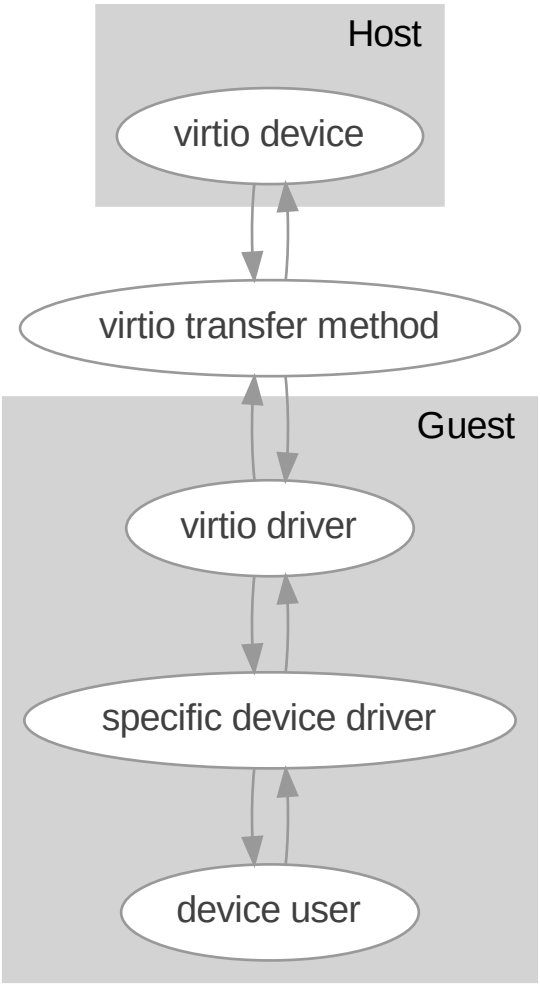

Fig. 19: Virtual I/O overview

chained, creating descriptor chains. Typically a chain begins with descriptors containing the data for the device to read and ends with the device writeable part, where the device places its response.

The main part of the available ring is a circular buffer of references (in the form of indexes) to the descriptors in the descriptor table. Once the guest decides to send the data to the host, it adds the index of the head of the descriptor chain to the top of the available ring.

The used ring is similar to the available ring, but it's used by the host to return descriptors to the guest. In addition to storing descriptor indexes, it also provides information about the amount of data written to them.

Common Virtio libraries

Zephyr provides an API for interfacing with Virtio devices and virtqueues, which allows performing necessary operations over the lifetime of the Virtio device.

Device initialization Once the Virtio driver finishes performing low-level initialization common to the all devices using a given transfer method, like finding device on the bus and mapping Virtio structures, the device specific driver steps in and performs the next stages of initialization with the help of the Virtio API.

The first thing the device-specific driver does is feature bits negotiation. It uses `virtio_read_device_feature_bit()` to determine which features the device offers, and then selects the ones it needs using `virtio_write_driver_feature_bit()`. After all required features have been selected, the device-specific driver calls `virtio_commit_feature_bits()`. Then, virtqueues are initialized with `virtio_init_virtqueues()`. This function enumerates the virtqueues, invoking the provided callback `virtio_enumerate_queues` to determine the required size of each virtqueue. Initialization process is finalized by calling `virtio_finalize_init()`. From this point, if none of the functions returned errors, the virtqueues are operational. If the specific device provides one, the device-specific config can be obtained by calling `virtio_get_device_specific_config()`.

Virtqueue operation Once the virtqueues are operational, they can be used to send and receive data. To do so, the pointer to the nth virtqueue has to be acquired using `virtio_get_virtqueue()`. To send data consisting of a descriptor chain, `virtq_add_buffer_chain()` has to be used. Along the descriptor chain, it takes pointer to the callback that will be invoked once the device returns the given descriptor chain. After that, the virtqueue has to be notified using `virtio_notify_virtqueue()` from the Virtio API.

Guest-side Virtio drivers

Currently Zephyr provides drivers for Virtio over PCI and Virtio over MMIO and drivers for three devices using virtio - virtiofs, used to access the filesystem of the host, virtio-entropy, used as an entropy source, and virtio-blk, used to access a block device.

Virtiofs This driver provides support for virtiofs - a filesystem allowing a virtual machine guest to access a directory on the host. It uses FUSE messages to communicate between the host and the guest in order to perform filesystem operations such as opening and reading files. Every time the guest wants to perform some filesystem operation it places in the virtqueue a descriptor chain starting with the device readable part, containing the FUSE input header and input data, and ending it with the device writeable part, with place for the FUSE output header and output data.

Virtio-entropy This driver allows using virtio-entropy as an entropy source in Zephyr. The operation of this device is simple - the driver places a buffer in the virtqueue and receives it back, filled with random data.

Virtio-blk This driver exposes a virtio-blk block device to Zephyr's disk access layer, so it can be used through the *Disk Access API* and, on top of it, a filesystem. It keeps a single request in flight, submitting a descriptor chain made of a request header, the caller's data buffer as one or more scatter-gather segments, and a status byte. See *VirtIO Block* for details.

Virtio samples

A sample showcasing the use of a driver relying on Virtio is provided in virtiofs. If you wish to check code interfacing directly with the Virtio driver, you can check the virtiofs driver, especially `virtiofs_init()` for initialization and `virtiofs_send_receive()` with the `virtiofs_recv_cb()` for data transfer to/from the Virtio device.

Virtqueue Interface

Chapter 7

Contributing to Zephyr

Contributions from the community are the backbone of the project. Whether it is by submitting code, improving documentation, or proposing new features, your efforts are highly appreciated. This page lists useful resources and guidelines to help you in your contribution journey.

7.1 General Guidelines

7.1.1 Contribution Guidelines

As an open-source project, we welcome and encourage the community to submit patches directly to the project. In our collaborative open source environment, standards and methods for submitting changes help reduce the chaos that can result from an active development community.

This document explains how to participate in project conversations, log bugs and enhancement requests, and submit patches to the project so your patch will be accepted quickly in the codebase.

Prerequisites

As a contributor, you'll want to be familiar with the Zephyr project, how to configure, install, and use it as explained in the Zephyr Project website and how to set up your development environment as introduced in the Zephyr *Getting Started Guide*.

You should be familiar with common developer tools such as Git and CMake, and platforms such as GitHub.

If you haven't already done so, you'll need to create a (free) GitHub account on https://github.com and have Git tools available on your development system.

Note

The Zephyr development workflow supports all 3 major operating systems (Linux, macOS, and Windows) but some of the tools used in the sections below are only available on Linux and macOS. On Windows, instead of running these tools yourself, you will need to rely on the Continuous Integration (CI) service using Github Actions, which runs automatically on GitHub when you submit your Pull Request (PR). You can see any failure results in the workflow details link near the end of the PR conversation list. See *Continuous Integration* for more information

Licensing

Licensing is very important to open source projects. It helps ensure the software continues to be available under the terms that the author desired.

Zephyr uses the Apache 2.0 license (as found in the LICENSE file in the project's GitHub repo) to strike a balance between open contribution and allowing you to use the software however you would like to. The Apache 2.0 license is a permissive open source license that allows you to freely use, modify, distribute and sell your own products that include Apache 2.0 licensed software. (For more information about this, check out articles such as Why choose Apache 2.0 licensing and Top 10 Apache License Questions Answered).

A license tells you what rights you have as a developer, as provided by the copyright holder. It is important that the contributor fully understands the licensing rights and agrees to them. Sometimes the copyright holder isn't the contributor, such as when the contributor is doing work on behalf of a company.

Components using other Licenses There are some imported or reused components of the Zephyr project that use other licensing, as described in *Licensing of Zephyr Project components*.

Importing code into the Zephyr OS from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board.

By carefully reviewing potential contributions and also enforcing a *Developer Certification of Origin (DCO)* for contributed code, we can ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

See *Contributing External Components* for more information about this contributing and review process for imported components.

Licensing of Zephyr Project components Zephyr as a whole is licensed under the Apache 2.0 License. It does, however, import or reuse a small number of packages, scripts and other files that are covered by other licenses. In some cases there is no way to add a license header to those files, so their licensing is declared centrally, in a machine-readable form, in the REUSE.toml file at the root of the repository (following the REUSE specification).

The sections below are **generated automatically** from that metadata, so they always reflect the actual state of the tree. To add, update or remove an entry, edit the corresponding `[[annotations]]` block in REUSE.toml rather than this page (see *Contributing External Components*).

Note

This page lists licensing *exceptions* only. It does **not** define the license of the Zephyr project itself, which is Apache 2.0 as specified in the LICENSE file at the root of the repository.

Bootstrap JavaScript and CSS Files

Origin
getbootstrap.com

License
MIT

Used by the dashboard tool only and never linked into a Zephyr firmware image.

Files (2):

- scripts/dashboard/static/css/bootstrap-chop.css
- scripts/dashboard/static/js/bootstrap-chop.js

Bosch BMI08x Sensor Configuration File

Origin
github.com/BoschSensortec/BMI08x-Sensor-API

License
BSD-3-Clause

Enabled by
`CONFIG_BMI08X`

Sensor configuration data compiled into the firmware only when the BMI08x driver is enabled.

Files (1):

- drivers/sensor/bosch/bmi08x/bmi08x_config_file.h

Coccinelle Scripts

Origin
coccinelle.gitlabpages.inria.fr/website

License
GPL-2.0

Used by Coccinelle, a tool for transforming C code, and never linked into the firmware.

Files (8):

- scripts/coccicheck
- scripts/coccinelle/array_size.cocci
- scripts/coccinelle/deref_null.cocci
- scripts/coccinelle/mini_lock.cocci
- scripts/coccinelle/noderef.cocci
- scripts/coccinelle/returnvar.cocci
- scripts/coccinelle/semicolon.cocci

ENE KB1200_EVB Board OpenOCD Configuration

Origin
openocd.org

License
GPL-2.0-or-later

Used by OpenOCD when programming and debugging the kb1200_evb board. Never linked into the firmware.

Files (1):

- boards/ene/kb1200_evb/support/openocd.cfg

FUSE Interface Definition Header File

License
`GPL-2.0 WITH Linux-syscall-note OR BSD-2-Clause`

Enabled by
`CONFIG_FUSE_CLIENT`

Used under the BSD-2-Clause option of its dual license. Only built when the gating option is enabled.

Files (1):

- subsys/fs/fuse_client/fuse_abi.h

GCOV Coverage Header File

Origin
gcc.gnu.org

License
`GPL-3.0-or-later WITH GCC-exception-3.1`

Enabled by
`CONFIG_COVERAGE_GCOV`

Linked into the firmware only when GCOV coverage is enabled; covered by the GCC Runtime Library Exception.

Files (1):

- subsys/testsuite/coverage/coverage.h

getopt Command-line Parsing Files

Origin
www.netbsd.org

License
BSD-3-Clause

Enabled by
CONFIG_GETOPT

Compiled into the firmware only when getopt() support is enabled.

Files (3):

- lib/utils/getopt/README
- lib/utils/getopt/getopt.c
- lib/utils/getopt/getopt_long.c

Godot Documentation Theme Files

Origin
github.com/godotengine/godot-docs

License
CC-BY-3.0

Customize the Sphinx theme used to render the documentation and are never linked into a firmware.

- doc/_static/css/light.css
- doc/_static/js/custom.js

HTTP Parser Files

Origin
github.com/nodejs/http-parser

License
MIT

Enabled by
CONFIG_HTTP_PARSER

Compiled into the firmware only when the HTTP parser is enabled.

Files (5):

- include/zephyr/net/http/parser.h
- include/zephyr/net/http/parser_state.h
- include/zephyr/net/http/parser_url.h
- subsys/net/lib/http/http_parser.c
- subsys/net/lib/http/http_parser_url.c

Kconfiglib Configuration Library

Origin
github.com/ulfalizer/Kconfiglib

License
ISC

Used to process Kconfig files at build time and never linked into the firmware.

Files (4):

- scripts/kconfig/guiconfig.py
- scripts/kconfig/kconfig.py
- scripts/kconfig/kconfiglib.py
- scripts/kconfig/menuconfig.py

littlefs Configuration Files

Origin
github.com/littlefs-project/littlefs

License
BSD-3-Clause

Enabled by
`CONFIG_FILE_SYSTEM_LITTLEFS`

Compiled into the firmware only when the littlefs file system is enabled.

Files (2):

- modules/littlefs/zephyr_lfs_config.h
- modules/littlefs/zephyr_lfs_crc.c

Minimal libc atoi File

Origin
musl.libc.org

License
MIT

Enabled by
`CONFIG_MINIMAL_LIBC`

Compiled into the firmware only when the minimal C library is selected.

Files (1):

- lib/libc/minimal/source/stdlib/atoi.c

Minimal libc BSD String and Conversion Files

License
BSD-3-Clause

Enabled by
`CONFIG_MINIMAL_LIBC`

Compiled into the firmware only when the minimal C library is selected.

Files (5):

- lib/libc/minimal/source/stdlib/strtol.c
- lib/libc/minimal/source/stdlib/strtoll.c
- lib/libc/minimal/source/stdlib/strtoul.c
- lib/libc/minimal/source/stdlib/strtoull.c
- lib/libc/minimal/source/string/strstr.c

Modern CMake Sphinx Domain

Origin
gitlab.kitware.com/cmake/cmake/-/tree/master/Utilities/Sphinx

License
BSD-3-Clause

Provide the CMake domain used to render the documentation and are never linked into a firmware.

Files (3):

- doc/_extensions/moderncmakedomain/__init__.py
- doc/_extensions/moderncmakedomain/cmake.py
- doc/_extensions/moderncmakedomain/colors.py

noUiSlider Library

Origin
refreshless.com/nouislider

License
MIT

Provides the flash/RAM range sliders in the board catalog and is never linked into a firmware.

Files (2):

- doc/_extensions/zephyr/domain/static/css/nouislider.min.css
- doc/_extensions/zephyr/domain/static/js/nouislider.min.js

OP-TEE Message Interface Headers

Origin
www.op-tee.org

License
BSD-2-Clause

Enabled by
`CONFIG_OPTEE`

Compiled into the firmware only when the OP-TEE driver is enabled.

Files (3):

- drivers/tee/optee/optee_msg.h
- drivers/tee/optee/optee_rpc_cmd.h
- drivers/tee/optee/optee_smc.h

OpenThread Spinel HDLC RCP Host Interface Files

Origin
openthread.io

License
BSD-3-Clause

Enabled by
`CONFIG_HDLC_RCP_IF`

Linked into the firmware only when the Spinel HDLC RCP host interface is enabled.

Files (3):

- modules/openthread/platform/hdlc_interface.cpp
- modules/openthread/platform/hdlc_interface.hpp
- modules/openthread/platform/radio_spinel.cpp

Popper.js Library

Origin
popper.js.org

License
MIT

Used by Tippy.js to position the documentation's Doxygen tooltips and is never linked into a firmware.

Files (1):

- doc/_extensions/zephyr/doxytooltip/static/tippy/popper.min.js

POSIX fnmatch Files

License
BSD-3-Clause

Enabled by
`CONFIG_POSIX_C_LIB_EXT`

Compiled into the firmware only when the POSIX C library extensions are enabled.

Files (2):

- include/zephyr/posix/fnmatch.h
- subsys/portability/posix/c_lib_ext/fnmatch.c

POSIX sys/stat.h Header

License
BSD-3-Clause

Provides the POSIX file-status definitions; compiled into the firmware wherever it is included.

Files (1):

- include/zephyr/posix/sys/stat.h

Python Devicetree Library Files

Origin
github.com/zephyrproject-rtos/python-devicetree

License
BSD-3-Clause

Parse devicetree sources at build time and are never linked into the firmware.

Tippy.js Library

Origin
atomiks.github.io/tippyjs

License
MIT

Renders the tooltips of the documentation's Doxygen tooltip extension and is never linked into a firmware.

Files (1):

- doc/_extensions/zephyr/doxytooltip/static/tippy/tippy-bundle.umd.min.js

UF2 Conversion Script

Origin
github.com/microsoft/uf2

License
MIT

Converts firmware images to UF2 at build time and is never linked into the firmware.

Files (1):

- scripts/build/uf2conv.py

USB Device Stack Headers

License
BSD-3-Clause

Enabled by
`CONFIG_USB_DEVICE_STACK`

Part of the legacy USB device stack, compiled into the firmware only when it is enabled.

Files (2):

- include/zephyr/usb/class/usb_dfu.h
- include/zephyr/usb/usb_device.h

WireGuard VPN Files

Origin
github.com/smartalock/wireguard-lwip

License
BSD-3-Clause

Enabled by
`CONFIG_WIREGUARD`

Compiled into the firmware only when WireGuard is enabled.

Files (7):

- subsys/net/lib/wireguard/crypto/crypto.c
- subsys/net/lib/wireguard/crypto/crypto.h
- subsys/net/lib/wireguard/crypto/refc/blake2s.c
- subsys/net/lib/wireguard/crypto/refc/blake2s.h
- subsys/net/lib/wireguard/crypto/refc/hchacha20.c

- subsys/net/lib/wireguard/wg_crypto.c

Xen Hypervisor Interface Files

Origin
xenproject.org

License
MIT

Enabled by
`CONFIG_XEN`

Compiled into the firmware only when Xen guest support is enabled.

Files (1):

- drivers/xen/gnttab.c

xoshiro128++ PRNG

Origin
prng.di.unimi.it

License
CC0-1.0

Enabled by
`CONFIG_XOSHIRO_RANDOM_GENERATOR`

Compiled into the firmware only when the xoshiro128++ PRNG is selected.

Files (1):

- subsys/random/random_xoshiro128.c

Xtensa Startup Assembly Files

License
MIT

Enabled by
`CONFIG_XTENSA_RESET_VECTOR`

Compiled into the firmware only when the Xtensa reset vector is enabled.

Files (2):

- arch/xtensa/core/startup/memctl_default.S
- arch/xtensa/core/startup/memerror_vector.S

Copyright and License Notices Zephyr follows SPDX/REUSE-style file headers. Add a machine-readable copyright notice and a license identifier at the top of each file so tooling can detect them (for example *west spdx*, which uses the REUSE tool).

The Zephyr Project follows the Community Best Practice for copyright notices from the Linux Foundation, therefore we recommend using the following copyright notice:

```
SPDX-FileCopyrightText: Copyright The Zephyr Project Contributors
```

Include the license identifier alongside it:

```
SPDX-License-Identifier: Apache-2.0
```

Practical guidance:

- Place both lines at the very top of the file using the file's native comment syntax.
- If you authored substantial, original content, you *may* add an additional line for yourself or your organization.

Developer Certification of Origin (DCO)

To make a good faith effort to ensure licensing criteria are met, the Zephyr project requires the Developer Certificate of Origin (DCO) process to be followed.

The DCO is an attestation attached to every contribution made by every developer. In the commit message of the contribution, (described more fully later in this document), the developer simply adds a `Signed-off-by` statement and thereby agrees to the DCO.

When a developer submits a patch, it is a commitment that the contributor has the right to submit the patch per the license. The DCO agreement is shown below and at https://developercertificate.org/.

```
Developer's Certificate of Origin 1.1

By making a contribution to this project, I certify that:

(a) The contribution was created in whole or in part by me and I
    have the right to submit it under the open source license
    indicated in the file; or

(b) The contribution is based upon previous work that, to the
    best of my knowledge, is covered under an appropriate open
    source license and I have the right under that license to
    submit that work with modifications, whether created in whole
    or in part by me, under the same open source license (unless
    I am permitted to submit under a different license), as
    Indicated in the file; or

(c) The contribution was provided directly to me by some other
    person who certified (a), (b) or (c) and I have not modified
    it.

(d) I understand and agree that this project and the contribution
    are public and that a record of the contribution (including
    all personal information I submit with it, including my
    sign-off) is maintained indefinitely and may be redistributed
    consistent with this project or the open source license(s)
    involved.
```

DCO Sign-Off The "sign-off" in the DCO is a "Signed-off-by:" line in each commit's log message. The Signed-off-by: line must be in the following format:

```
Signed-off-by: Your Name <your.email@example.com>
```

For your commits, replace:

- `Your Name` with your legal name (pseudonyms, hacker handles, and the names of groups are not allowed)
- `your.email@example.com` with the real email address you are using to author the commit. Pseudo or anonymized emails such as `you-id+your-username@users.noreply.github.com` are not allowed. The email must match the one you use to author the commit (CI will fail if there is no match).

You can automatically add the Signed-off-by: line to your commit body using `git commit -s`. Use other commits in the zephyr git history as examples. See *Git Setup* for instructions on configuring user and email settings in Git.

Additional requirements:

- If you are altering an existing commit created by someone else, you must add your Signed-off-by: line without removing the existing one.

AI Coding Assistants

This section provides guidance for contributors using AI tools and assistants when contributing to the Zephyr project.

Licensing and Legal Requirements All contributions must comply with the licensing requirements of the project and be compatible with Zephyr's licensing (e.g. Apache-2.0, see *Licensing* for more details).

Signed-off-by and Developer Certificate of Origin AI agents **must not** add `Signed-off-by` tags. Only humans can legally certify the *Developer Certification of Origin (DCO)*. The human submitter is responsible for:

- Reviewing all AI-generated code.
- Ensuring compliance with licensing requirements.
- Adding their own Signed-off-by tag to certify the DCO.
- Taking full responsibility for the contribution.

Usage disclosure and attribution When AI tools are being used to help write a contribution, proper attribution helps track the evolving role of AI in the development process. Contributions should include an `Assisted-by:` tag in the following format:

```
Assisted-by: [Agent Name]:[Model Version] [Tool1] [Tool2]
```

Where:

- `[Agent Name]` is the name of the AI tool or framework.
- `[Model Version]` is the specific model version used.
- `[Tool1] [Tool2]` are optional specialized analysis tools used.

Basic development tools (git, gcc, make, editors) should not be listed.

Example:

```
Assisted-by: Claude:claude-opus-4.6 coccinelle
```

Source Tree Structure

To clone the main Zephyr Project repository use the instructions in *Get Zephyr and install Python dependencies*.

This section describes the main repository's source tree. In addition to the Zephyr kernel itself, you'll also find the sources for technical documentation, sample code, supported board configurations, and a collection of subsystem tests. All of these are available for developers to contribute to and enhance.

Understanding the Zephyr source tree can help locate the code associated with a particular Zephyr feature.

At the top of the tree, several files are of importance:

`CMakeLists.txt`
: The top-level file for the CMake build system, containing a lot of the logic required to build Zephyr.

`Kconfig`
: The top-level Kconfig file, which refers to the file `Kconfig.zephyr` also found in the top-level directory.

  See *the Kconfig section of the manual* for detailed Kconfig documentation.

`west.yml`
: The *West (Zephyr's meta-tool)* manifest, listing the external repositories managed by the west command-line tool.

The Zephyr source tree also contains the following top-level directories, each of which may have one or more additional levels of subdirectories not described here.

`arch`
: Architecture-specific kernel and system-on-chip (SoC) code. Each supported architecture (for example, x86 and ARM) has its own subdirectory, which contains additional subdirectories for the following areas:

  - architecture-specific kernel source files
  - architecture-specific kernel include files for private APIs

`soc`
: SoC related code and configuration files.

`boards`
: Board related code and configuration files.

`doc`
: Zephyr technical documentation source files and tools used to generate the https://docs.zephyrproject.org web content.

`drivers`
: Device driver code.

`dts`
: *devicetree* source files used to describe non-discoverable board-specific hardware details.

`include`
: Include files for all public APIs, except those defined under `lib`.

`kernel`
: Architecture-independent kernel code.

`lib`
: Library code, including the minimal standard C library.

`misc`
: Miscellaneous code that doesn't belong to any of the other top-level directories.

`samples`
: Sample applications that demonstrate the use of Zephyr features.

`scripts`
: Various programs and other files used to build and test Zephyr applications.

`cmake`
: Additional build scripts needed to build Zephyr.

`subsys`
: Subsystems of Zephyr, including:

  - USB device stack code
  - Networking code, including the Bluetooth stack and networking stacks
  - File system code
  - Bluetooth host and controller

`tests`
: Test code and benchmarks for Zephyr features.

`share`
: Additional architecture independent data. It currently contains Zephyr's CMake package.

Pull Requests and Issues

Before starting on a patch, first check in our issues Zephyr Project Issues system to see what's been reported on the issue you'd like to address. Have a conversation on the Zephyr devel mailing list (or the Zephyr Discord Server) to see what others think of your issue (and proposed solution). You may find others that have encountered the issue you're finding, or that have similar ideas for changes or additions. Send a message to the Zephyr devel mailing list to introduce and discuss your idea with the development community.

It's always a good practice to search for existing or related issues before submitting your own. When you submit an issue (bug or feature request), the triage team will review and comment on the submission, typically within a few business days.

You can find all open pull requests on GitHub and open Zephyr Project Issues in Github issues.

Git Setup

We need to know who you are, and how to contact you. To add this information to your Git installation, set the Git configuration variables `user.name` to your full name, and `user.email` to your email address.

For example, if your name is `Zephyr Developer` and your email address is `z.developer@example.com`:

```
git config --global user.name "Zephyr Developer"
git config --global user.email "z.developer@example.com"
```

Note

`user.name` must be your full name (first and last at minimum), not a pseudonym or hacker handle. The email address that you use in your Git configuration must match the email ad-

dress you use to sign your commits. If they don't match, the CI system will fail your pull request.

If you intend to edit commits using the Github.com UI, ensure that your github profile `email address` and profile `name` also match those used in your git configuration (`user.name` & `user.email`).

Pull Request Guidelines

When opening a new Pull Request, adhere to the following guidelines to ensure compliance with Zephyr standards and facilitate the review process.

If in doubt, it's advisable to explore existing Pull Requests within the Zephyr repository. Use the search filters and labels to locate PRs related to changes similar to the ones you are proposing.

Note

GitHub's default code UI uses 4-character tabs. However, Zephyr follows the Linux kernel coding style, which uses 8-character tabs.

To ensure your view of the code is consistent with other developers, please go to your user preferences on GitHub and change the tab width to 8 spaces.

Commit Message Guidelines Changes are submitted as Git commits. Each commit has a *commit message* describing the change. Acceptable commit messages look like this:

```
[area]: [summary of change]

[Commit message body (must be non-empty)]

Signed-off-by: [Your Full Name] <[your.email@address]>
```

You need to change text in square brackets (`[like this]`) above to fit your commit.

Here is an example of a good commit message.

```
drivers: sensor: abcd1234: fix bus I/O error handling

The abcd1234 sensor driver is failing to check the flags field in
the response packet from the device which signals that an error
occurred. This can lead to reading invalid data from the response
buffer. Fix it by checking the flag and adding an error path.

Signed-off-by: Zephyr Developer <z.developer@example.com>
```

[area]: [summary of change] This line is called the commit's *title*. Titles must be:

- one line
- less than 72 characters long
- followed by a completely blank line

[area]
The `[area]` prefix usually identifies the area of code being changed. It can also identify the change's wider context if multiple areas are affected.

Here are some examples:

- `doc:` ... for documentation changes

- `drivers: foo:` for foo driver changes
- `Bluetooth: Shell:` for changes to the Bluetooth shell
- `net: ethernet:` for Ethernet-related networking changes
- `dts:` for treewide devicetree changes
- `style:` for code style changes

If you're not sure what to use, try running `git log FILE`, where `FILE` is a file you are changing, and using previous commits that changed the same file as inspiration.

[summary of change]
The `[summary of change]` part should be a quick description of what you've done. Here are some examples:

- `doc: update wiki references to new site`
- `drivers: sensor: sensor_shell: fix channel name collision`

Warning

An empty commit message body is not permitted. Even for trivial changes, please include a descriptive commit message body. Your pull request will fail CI checks if you do not.

Commit Message Body This part of the commit should explain what your change does, and why it's needed. Be specific. A body that says `"Fixes stuff"` will be rejected. Be sure to include the following as relevant:

- **what** the change does,
- **why** you chose that approach,
- **what** assumptions were made, and
- **how** you know it works – for example, which tests you ran.

Each line in your commit message should usually be 75 characters or less. Use newlines to wrap longer lines. Exceptions include lines with long URLs, email addresses, etc.

For examples of accepted commit messages, you can refer to the Zephyr GitHub changelog.

Tip

You should have set your *Git Setup* already. Create your commit with `git commit -s` to add the Signed-off-by: line automatically using this information.

Signed-off-by: ... For open source licensing reasons, your commit must include a Signed-off-by: line that looks like this:

```
Signed-off-by: [Your Full Name] <[your.email@address]>
```

For example, if your full name is `Zephyr Developer` and your email address is `z.developer@example.com`:

```
Signed-off-by: Zephyr Developer <z.developer@example.com>
```

This means that you have personally made sure your change complies with the *Developer Certification of Origin (DCO)*. For this reason, you must use your legal name. Pseudonyms or "hacker aliases" are not permitted.

Your name and the email address you use must match the name and email in the Git commit's `Author:` field.

See the *Contributor Expectations* for a more complete discussion of contributor and reviewer expectations.

Adding Links If your change addresses a specific GitHub issue, include a reference in the pull request description using the following format:

```
Fixes zephyrproject-rtos/zephyr#[issue number]
```

For pull requests to the Zephyr project only, the short form can also be used, for example:

```
Fixes #[issue number]
```

Replace [issue number] with the relevant GitHub issue number. For example:

```
Fixes zephyrproject-rtos/zephyr#1234
```

This syntax ensures that the issue is automatically closed when the pull request is merged. Always specify the full repository path (zephyrproject-rtos/zephyr) to avoid ambiguity, especially when working across multiple repositories.

The same format can also be used in commit messages.

For linking to additional external resources—such as related issues, datasheets, or technical reference manuals—use the `Link:` tag:

```
Link: https://github.com/zephyrproject-rtos/zephyr/issues/<issue number>
```

Continuous Integration (CI) The Zephyr Project operates a Continuous Integration (CI) system that runs on every Pull Request (PR) in order to verify several aspects of the PR:

- Git commit formatting
- Coding Style
- Twister builds for multiple architectures and boards
- Documentation build to verify any doc changes

CI is run on Github Actions and it uses the same tools described in the *CI Tests* section. The CI results must be green indicating "All checks have passed" before the Pull Request can be merged. CI is run when the PR is created, and again every time the PR is modified with a commit.

The current status of the CI run can always be found at the bottom of the GitHub PR page, below the review status. Depending on the success or failure of the run you will see:

- "All checks have passed"
- "All checks have failed"

In case of failure you can click on the "Details" link presented below the failure message in order to navigate to `Github Actions` and inspect the results. Once you click on the link you will be taken to the `Github actions` summary results page where a table with all the different builds will be shown. To see what build or test failed click on the row that contains the failed (i.e. non-green) build.

Running CI Tests Locally

check_compliance.py The scripts/ci/check_compliance.py script serves as a valuable tool for assessing code compliance with Zephyr's established guidelines and best practices. The script acts as wrapper for a suite of tools that performs various checks, including linters and formatters.

Developers are encouraged to run the script locally to validate their changes before opening a new Pull Request:

```
./scripts/ci/check_compliance.py -c <commit range>
```

The checks run in parallel, using one worker process per CPU. Pass `-p N` to limit the number of worker processes to `N`, or `-p 1` to run the checks sequentially.

```
./scripts/ci/check_compliance.py -p 1 -c <commit range>
```

Note

On Windows if the .pl extension has not yet been associated with an application, then the first time a .pl file is run without specifying an interpreter, Windows will ask what application will open Perl files. Set the default app to Strawberry Perl. By default the executable is installed at `C:\Strawberry\perl\bin\perl.exe`.

KeepSorted Check The KeepSorted check ensures that specified blocks of code, configuration, or documentation remain in sorted order.

To use the KeepSorted check, wrap your sorted content between dedicated lines containing start and stop markers, typically using comments:

```
// zephyr-keep-sorted-start
option_a
option_b
option_c
// zephyr-keep-sorted-stop
```

KeepSorted Marker Options The sorting behavior of each block can be customized in several ways. To do this, one or more of the following parameters can be added on the same line as the start marker itself:

re(regex_pattern)
: Enables regex mode where only lines matching the specified regular expression are checked for sorting. Other lines are ignored.

  Example checking sorted properties in a yaml file:

```
# zephyr-keep-sorted-start re(^\s+\- name:)
projects:
  - name: application
    revision: main
  - name: library1
    revision: feature-branch
  - name: library2
    revision: main
# zephyr-keep-sorted-stop
```

strip(characters)
: Strips the specified characters from lines before performing the sort comparison. This is useful when lines have optional prefixes or suffixes that should be ignored during sorting.

  Example stripping quotes from yaml dictionary keys:

```
# zephyr-keep-sorted-start strip(":)
ACPI:
  status: odd fixes
"West project: acpica":
  status: odd fixes
# zephyr-keep-sorted-stop
```

nofold
: Disables line folding. By default, indented lines following a main line are concatenated (folded) together for sorting comparison. The `nofold` option disables this behavior and ignores indented lines.

ignorecase
: Enables case-insensitive sorting using Python's str.casefold. This allows mixing uppercase and lowercase items in sorted blocks without causing sort order violations. Defaults to Python's string ordering if omitted.

Multiple options can be combined on the same marker line:

```
.. zephyr-keep-sorted-start re(^\* \w) ignorecase
* Shell
  Some important message about the shell.

* STM32
  Updates for this vendor.
.. zephyr-keep-sorted-stop
```

> **Note**
>
> twister is only fully supported on Linux; on Windows and MacOS the execution of tests is not supported on all target devices.

twister If you think your change may break some test, you can submit your PR as a draft and let the project CI automatically run the *Test Runner (Twister)* for you.

If a test fails, you can check from the CI run logs how to rerun it locally, for example:

```
west twister -p native_sim -s␣
↪tests/drivers/build_all/sensor/drivers.sensor.generic_test
```

Static Code Analysis

Coverity Scan is a free service for static code analysis of Open Source projects. It is based on Coverity's commercial product and is able to analyze C, C++ and Java code.

Coverity's static code analysis doesn't run the code. Instead of that it uses abstract interpretation to gain information about the code's control flow and data flow. It's able to follow all possible code paths that a program may take. For example the analyzer understands that malloc() returns a memory that must be freed with free() later. It follows all branches and function calls to see if all possible combinations free the memory. The analyzer is able to detect all sorts of issues like resource leaks (memory, file descriptors), NULL dereferencing, use after free, unchecked return values, dead code, buffer overflows, integer overflows, uninitialized variables, and many more.

The results are available on the Coverity Scan website. In order to access the results you have to create an account yourself. From the Zephyr project page, you may select "Add me to project" to be added to the project. New members must be approved by an admin.

Static analysis of the Zephyr codebase is conducted on a bi-weekly basis. GitHub issues are automatically created for any issues detected by static analysis tools. These issues will have the same (or equivalent) priority initially defined by the tool.

To ensure accountability and efficient issue resolution, they are assigned to the respective maintainer who is responsible for the affected code.

A dedicated team comprising members with expertise in static analysis, code quality, and software security ensures the effectiveness of the static analysis process and verifies that identified issues are properly triaged and resolved in a timely manner.

Workflow If after analyzing the Coverity report it is concluded that it is a false positive please set the classification to either "False positive" or "Intentional", the action to "Ignore", owner to your own account and add a comment why the issue is considered false positive or intentional.

Update the related Github issue in the zephyr project with the details, and only close it after completing the steps above on scan service website. Any issues closed without a fix or without ignoring the entry in the scan service will be automatically reopened if the issue continues to be present in the code.

Contribution Workflow

One general practice we encourage, is to make small, controlled changes. This practice simplifies review, makes merging and rebasing easier, and keeps the change history clear and clean.

When contributing to the Zephyr Project, it is also important you provide as much information as you can about your change, update appropriate documentation, and test your changes thoroughly before submitting.

The general GitHub workflow used by Zephyr developers uses a combination of command line Git commands and browser interaction with GitHub. As it is with Git, there are multiple ways of getting a task done. We'll describe a typical workflow here:

1. Create a Fork of Zephyr to your personal account on GitHub. (Click on the fork button in the top right corner of the Zephyr project repo page in GitHub.)
2. On your development computer, change into the `zephyr` folder that was created when you *obtained the code*:

   ```
   cd zephyrproject/zephyr
   ```

   Rename the default remote pointing to the upstream repository from `origin` to `upstream`:

   ```
   git remote rename origin upstream
   ```

   Let Git know about the fork you just created, naming it `origin`:

   ```
   git remote add origin https://github.com/<your github id>/zephyr
   ```

   and verify the remote repos:

   ```
   git remote -v
   ```

   The output should look similar to:

   ```
   origin   https://github.com/<your github id>/zephyr (fetch)
   origin   https://github.com/<your github id>/zephyr (push)
   upstream https://github.com/zephyrproject-rtos/zephyr (fetch)
   upstream https://github.com/zephyrproject-rtos/zephyr (push)
   ```

3. Create a topic branch (off of `main`) for your work (if you're addressing an issue, we suggest including the issue number in the branch name):

```
git switch main
git switch -c fix_comment_typo
```

Some Zephyr subsystems do development work on a separate branch from `main` so you may need to indicate this in your checkout:

```
git switch -c fix_out_of_date_patch origin/net
```

4. Make changes, test locally, change, test, test again, ... (Check out the prior chapter on *twister* as well).
5. When things look good, start the pull request process by adding your changed files:

   ```
   git add [file(s) that changed, add -p if you want to be more specific]
   ```

   You can see files that are not yet staged using:

   ```
   git status
   ```

6. Verify changes to be committed look as you expected:

   ```
   git diff --cached
   ```

7. Commit your changes to your local repo:

   ```
   git commit -s
   ```

   The `-s` option automatically adds your `Signed-off-by:` to your commit message. Your commit will be rejected without this line that indicates your agreement with the *Developer Certification of Origin (DCO)*. See the *Commit Message Guidelines* section for specific guidelines for writing your commit messages.
8. Push your topic branch with your changes to your fork in your personal GitHub account:

   ```
   git push origin fix_comment_typo
   ```

9. In your web browser, go to your forked repo and click on the `Compare & pull request` button for the branch you just worked on and you want to open a pull request with.
10. Review the pull request changes, and verify that you are opening a pull request for the `main` branch. The title and message from your commit message should appear as well.
11. A bot will assign one or more suggested reviewers (based on the MAINTAINERS file in the repo). If you are a project member, you can select additional reviewers now too.
12. Click on the submit button and your pull request is sent and awaits review. Email will be sent as review comments are made, or you can check on your pull request at https://github.com/zephyrproject-rtos/zephyr/pulls.
13. While you're waiting for your pull request to be accepted and merged, you can create another branch to work on another issue. (Be sure to make your new branch off of `main` and not the previous branch.):

    ```
    git switch main
    git switch -c fix_another_issue
    ```

    and use the same process described above to work on this new topic branch.
14. If reviewers do request changes to your patch, you can interactively rebase commit(s) to fix review issues. In your development repo:

    ```
    git rebase -i <offending-commit-id>^
    ```

In the interactive rebase editor, replace `pick` with `edit` to select a specific commit (if there's more than one in your pull request), or remove the line to delete a commit entirely. Then edit files to fix the issues in the review.

As before, inspect and test your changes. When ready, continue the patch submission:

```
git add [file(s)]
git rebase --continue
```

Update commit comment if needed, and continue:

```
git push --force origin fix_comment_typo
```

By force pushing your update, your original pull request will be updated with your changes so you won't need to resubmit the pull request.

15. After pushing the requested change, check on the PR page if there is a merge conflict. If so, rebase your local branch:

```
git fetch --all
git rebase --ignore-whitespace upstream/main
```

The `--ignore-whitespace` option stops `git apply` (called by rebase) from changing any whitespace. Resolve the conflicts and push again:

```
git push --force origin fix_comment_typo
```

> **Note**
>
> While amending commits and force pushing is a common review model outside GitHub, and the one recommended by Zephyr, it's not the main model supported by GitHub. Forced pushes can cause unexpected behavior, such as not being able to use "View Changes" buttons except for the last one - GitHub complains it can't find older commits. You're also not always able to compare the latest reviewed version with the latest submitted version. When rewriting history GitHub only guarantees access to the latest version.

16. If the CI run fails, you will need to make changes to your code in order to fix the issues and amend your commits by rebasing as described above. Additional information about the CI system can be found in *Continuous Integration*.

Contribution Tips The following is a list of tips to improve and accelerate the review process of Pull Requests. If you follow them, chances are your pull request will get the attention needed and it will be ready for merge sooner than later:

1. When pushing follow-up changes, use the `--keep-base` option of git-rebase
2. On the PR page, check if the change can still be merged with no merge conflicts
3. Make sure title of PR explains what is being fixed or added
4. Make sure your PR has a body with more details about the content of your submission
5. Make sure you reference the issue you are fixing in the body of the PR
6. Watch early CI results immediately after submissions and fix issues as they are discovered
7. Revisit PR after 1-2 hours to see the status of all CI checks, make sure all is green
8. If you get request for changes and submit a change to address them, make sure you click the "Re-request review" button on the GitHub UI to notify those who asked for the changes

Identifying Contribution Origin When adding a new file to the tree, it is important to detail the source of origin on the file, provide attributions, and detail the intended usage. In cases where the file is an original to Zephyr, the commit message should include the following ("Original" is the assumption if no Origin tag is present):

```
Origin: Original
```

In cases where the file is *imported from an external project*, the commit message shall contain details regarding the original project, the location of the project, the SHA-id of the origin commit for the file and the intended purpose.

For example, a copy of a locally maintained import:

```
Origin: Contiki OS
License: BSD 3-Clause
URL: https://www.contiki-os.org/
commit: 853207acfdc6549b10eb3e44504b1a75ae1ad63a
Purpose: Introduction of networking stack.
```

For example, a copy of an externally maintained import in a module repository:

```
Origin: Tiny Crypt
License: BSD 3-Clause
URL: https://github.com/01org/tinycrypt
commit: 08ded7f21529c39e5133688ffb93a9d0c94e5c6e
Purpose: Introduction of TinyCrypt
```

Contributions to External Modules

Follow the guidelines in the *Modules (External projects)* section for contributing *new modules* and submitting changes to *existing modules*.

Treewide Changes

This section describes contributions that are treewide changes and some additional associated requirements that apply to them. These requirements exist to try to give such changes increased review and user visibility due to their large impact.

Definition and Decision Making A *treewide change* is defined as any change to Zephyr APIs, coding practices, or other development requirements that either implies required changes throughout the zephyr source code repository or can reasonably be expected to do so for a wide class of external Zephyr-based source code.

This definition is informal by necessity. This is because the decision on whether any particular change is treewide can be subjective and may depend on additional context.

Project maintainers should use good judgement and prioritize the Zephyr developer experience when deciding when a proposed change is treewide. Protracted disagreements can be resolved by the Zephyr Project's Technical Steering Committee (TSC), but please avoid premature escalation to the TSC.

Requirements for Treewide Changes

- The zephyr repository must apply the 'treewide' GitHub label to any issues or pull requests that are treewide changes
- The person proposing a treewide change must create an RFC issue describing the change, its rationale and impact, etc. before any pull requests related to the change can be merged

- The project's Architecture Working Group (WG) must include the issue on the agenda and discuss whether the project will accept or reject the change before any pull requests related to the change can be merged (with escalation to the TSC if consensus is not reached at the WG)
- The Architecture WG must specify the procedure for merging any PRs associated with each individual treewide change, including any required approvals for pull requests affecting specific subsystems or extra review time requirements
- The person proposing a treewide change must email devel@lists.zephyrproject.org about the RFC if it is accepted by the Architecture WG before any pull requests related to the change can be merged

Examples Some example past treewide changes are:

- the deprecation of version 1 of the *Logging API* in favor of version 2 (see commit 262cc55609)
- the removal of support for a legacy *Devicetree bindings* syntax (6bf761fc0a)

Note that adding a new version of a widely used API while maintaining support for the old one is not a treewide change. Deprecation and removal of such APIs, however, are treewide changes.

Specialized driver requirements

Drivers for standalone devices should use the Zephyr bus APIs (SPI, I2C...) whenever possible so that the device can be used with any SoC from any vendor implementing a compatible bus.

If it is not technically possible to achieve full performance using the Zephyr APIs due to specialized accelerators in a particular SoC family, one could extend the support for an external device by providing a specialized path for that SoC family. However, the driver must still provide a regular path (via Zephyr APIs) for all other SoCs. Every exception must be approved by the Architecture WG in order to be validated and potentially to be learned/improved from.

7.1.2 Contributor Expectations

The Zephyr project encourages *contributors* to submit changes as smaller pull requests. Smaller pull requests (PRs) have the following benefits:

- Reviewed more quickly and reviewed more thoroughly. It's easier for reviewers to set aside a few minutes to review smaller changes several times than it is to allocate large blocks of time to review a large PR.
- Less wasted work if reviewers or maintainers reject the direction of the change.
- Easier to rebase and merge. Smaller PRs are less likely to conflict with other changes in the tree.
- Easier to revert if the PR breaks functionality.

> **Note**
>
> This page does not apply to draft PRs which can have any size, any number of commits and any combination of smaller PRs for testing and preview purposes. Draft PRs have no review expectation and PRs created as drafts from the start do not notify anyone by default.

Defining Smaller PRs

- Smaller PRs should encompass one self-contained logical change.

- When adding a new large feature or API, the PR should address only one part of the feature. In this case create an *RFC proposal* to describe the additional parts of the feature for reviewers.
- PRs should include tests or samples under the following conditions:
  - Adding new features or functionality.
  - Modifying a feature, especially for API behavior contract changes.
  - Fixing a hardware agnostic bug. The test should fail without the bug fixed and pass with the fix applied.
- PRs must update any documentation affected by a functional code change.
- If introducing a new API, the PR must include an example usage of the API. This provides context to the reviewer and prevents submitting PRs with unused APIs.

Multiple Commits on a Single PR

Contributors are further encouraged to break up PRs into multiple commits. Keep in mind each commit in the PR must still build cleanly and pass all the CI tests.

For example, when introducing an extension to an API, contributors can break up the PR into multiple commits targeting these specific changes:

1. Introduce the new APIs, including shared devicetree bindings
2. Update driver implementation X, with driver specific devicetree bindings
3. Update driver implementation Y
4. Add tests for the new API
5. Add a sample using the API
6. Update the documentation

Large Changes

Large changes to the Zephyr project must submit an *RFC proposal* describing the full scope of change and future work. The RFC proposal provides the required context to reviewers, but allows for smaller, incremental, PRs to get reviewed and merged into the project. The RFC should also define the minimum viable implementation.

Changes which require an RFC proposal include:

- Submitting a new feature.
- Submitting a new API.
- *Treewide Changes*.
- Other large changes that can benefit from the RFC proposal process.

Maintainers have the discretion to request that contributors create an RFC for PRs that are too large or complicated.

PR Requirements

Important

Pull requests that do not meet the quality expectations outlined below are less likely to receive reviewer engagement, and reviewers may request changes on such pull requests without detailed feedback.

Contributors are expected to self-review their changes and ensure all requirements are met before requesting a review.

- Each commit in the PR must provide a commit message following the *Commit Message Guidelines*.
- No fixup or merge commits are allowed, see *Contribution Workflow* for more information.
- The PR description must include a summary of the changes and their rationales.
- All files in the PR must comply with *Licensing Requirements*.
- The code must follow the Zephyr *Coding Style Guidelines* and *Coding Guidelines*.
- The PR must pass all CI checks, as described in *Pull Request Merge Criteria*. Contributors may mark a PR as draft and explicitly request reviewers to provide early feedback, even with failing CI checks.
- Commits in a pull request should represent clear, logical units of change that are easy to review and maintain bisectability. The following guidelines expand on this principle:

  1. Distinct, Logical Units of Change

     Each commit should correspond to a self-contained, meaningful change. For example, adding a feature, fixing a bug, or refactoring existing code should be separate commits. Avoid mixing different types of changes (e.g., feature implementation and unrelated refactoring) in the same commit.

  2. Retain Bisectability

     Every commit in the pull request must build successfully and pass all relevant tests. This ensures that git bisect can be used effectively to identify the specific commit that introduced a bug or issue.

  3. Squash Intermediary or Non-Final Development History

     During development, commits may include intermediary changes (e.g., partial implementations, temporary files, or debugging code). These should be squashed or rewritten before submitting the pull request. Remove non-final artifacts, such as:

     – Temporary renaming of files that are later renamed again.

     – Code that was rewritten or significantly changed in later commits.

  4. Ensure Clean History Before Submission

     Use interactive rebasing (git rebase -i) to clean up the commit history before submitting the pull request. This helps in:

     – Squashing small, incomplete commits into a single cohesive commit.

     – Ensuring that each commit remains bisectable.

     – Maintaining proper attribution of authorship while improving clarity.

  5. Renaming and Code Rewrites

     If files or code are renamed or rewritten in later commits during development, squash or rewrite earlier commits to reflect the final structure. This ensures that:

     – The history remains clean and easy to follow.

     – Bisectability is preserved by eliminating redundant renaming or partial rewrites.

  6. Attribution of Authorship

     While cleaning up the commit history, ensure that authorship attribution remains accurate.

7. Readable and Reviewable History

   The final commit history should be easy to understand for future maintainers. Logical units of change should be grouped into commits that tell a clear, coherent story of the work done.

- When major new functionality is added, tests for the new functionality shall be added to the automated test suite. All API functions should have test cases and there should be tests for the behavior contracts of the API. Maintainers and reviewers have the discretion to determine if the provided tests are sufficient. The examples below demonstrate best practices on how to test APIs effectively.
  - Kernel timer tests provide around 85% test coverage for the kernel timer, measured by lines of code.
  - Emulators for off-chip peripherals are an effective way to test driver APIs. The fuel gauge tests use the smart battery emulator, providing test coverage for the fuel gauge API and the smart battery driver.
  - Code coverage reports for the Zephyr project are available on Codecov.
- Incompatible changes to APIs must also update the release notes for the next release detailing the change. APIs marked as experimental are excluded from this requirement.
- Changes to APIs must increment the API version number according to the API version rules.
- Documentation must be added and/or updated to reflect the changes in the code introduced by the PR. The documentation changes must use the proper terminology as present in the existing pages, and must be written in American English. If you include images as part of the documentation, those must follow the rules in *Images*. Please refer to *Documentation Guidelines* for additional information.
- PRs must also satisfy all *Pull Request Merge Criteria* before a member of the release engineering team merges the PR into the zephyr tree.

Maintainers may request that contributors break up a PR into smaller PRs and may request that they create an *RFC proposal*.

Workflow Suggestions That Help Reviewers

- Unless they applied the reviewer's recommendation exactly, authors must not resolve and hide comments, they must let the initial reviewer do it. The Zephyr project does not require all comments to be resolved before merge. Leaving some completed discussions open can sometimes be useful to understand the greater picture.
- Respond to comments using the "Start Review" and "Add Review" green buttons in the "Files changed" view. This allows responding to multiple comments and publishing the responses in bulk. This reduces the number of emails sent to reviewers.
- As GitHub does not implement `git range-diff`, try to minimize rebases in the middle of a review. If a rebase is required, push this as a separate update with no other changes since the last push of the PR. When pushing a rebase only, add a comment to the PR indicating which commit is the rebase.

Getting PRs Reviewed The Zephyr community is a diverse group of individuals, with different levels of commitment and priorities. As such, reviewers and maintainers may not get to a PR right away.

- After 1 week of inactivity, ping the Assignee or reviewers on the PR by adding a comment to the PR.
- After 2 weeks of inactivity, post a message on the #pr-help channel on Discord linking to the PR.

PR Technical Escalation In cases where a contributor objects to change requests from reviewers, Zephyr defines the following escalation process for resolving technical disagreements.

Before escalation of technical disagreements, follow the steps below:

- Resolve in the PR among assignee, maintainers and reviewer.
  - Assignee to act as moderator if applicable.
- If no progress is made, the assignee (maintainer) has the right to dismiss stale, unrelated or irrelevant change requests by reviewers giving the reviewers a minimum of 1 business day to respond and revisit their initial change requests or start the escalation process.

  The assignee has the responsibility to document the reasoning for dismissing any reviews in the PR and should notify the reviewer about their review being dismissed.

  To give the reviewers time to respond and escalate, the assignee is expected to block the PR from being merged either by not approving the PR or by setting the *DNM* label.

Escalation can be triggered by any party participating in the review process (assignee, reviewers or the original author of the change) following the steps below:

- Escalate to the Architecture Working Group by adding the *Architecture Review* label on the PR. Beside the weekly meeting where such escalations are processed, the Architecture Working Group shall facilitate an offline review of the escalation if requested, especially if any of the parties can't attend the meeting.
- If all avenues of resolution and escalation have failed, assignees can escalate to the TSC and get a binding resolution in the TSC by adding the *TSC* label on the PR.
- The Assignee is expected to ensure the resolution of the escalation and the outcome is documented in the related pull request or issues on Github.

7.1.3 Reviewer Expectations

- Be respectful when commenting on PRs. Refer to the Zephyr Code of Conduct for more details.
- The Zephyr Project recognizes that reviewers and maintainers have limited bandwidth. As a reviewer, prioritize review requests in the following order:
  1. PRs related to items in the Zephyr Release Plan or those targeting the next release during the stabilization period (after RC1).
  2. PRs where the reviewer has requested blocking changes.
  3. PRs assigned to the reviewer as the area maintainer.
  4. All other PRs.
- Reviewers shall strive to advance the PR to a mergeable state with their feedback and engagement with the PR author.
- Try to provide feedback on the entire PR in one shot. This provides the contributor an opportunity to address all comments in the next PR update.
- Partial reviews are permitted, but the reviewer must add a comment indicating what portion of the PR they reviewed. Examples of useful partial reviews include:
  - Domain specific reviews (e.g. Devicetree).
  - Code style changes that impact the readability of the PR.
  - Reviewing commits separately when the requested changes cascade into the later commits.
- Avoid increasing scope of the PR by requesting new features, especially when there is a corresponding *RFC* associated with the PR. Instead, reviewers should add suggestions as a

comment to the *RFC*. This also encourages more collaboration as it is easier for multiple contributors to work on a feature once the minimum implementation has merged.

- When using the "Request Changes" option, mark trivial, non-functional, requests as "Non-blocking" in the comment. Reviewers should approve PRs once only non-blocking changes remain. The PR author has discretion as to whether they address all non-blocking comments. PR authors should acknowledge every review comment in some way, even if it's just with an emoticon.
- Style changes that the reviewer disagrees with but that are not documented as part of the project can be pointed out as non-blocking, but cannot constitute a reason for a request for changes. The reviewer can optionally correct any potential inconsistencies in the tree, document the new guidelines or rules, and then enforce them as part of the review.
- Whenever requesting style related changes, reviewers should be able to point out the corresponding guideline, rule or rationale in the project's documentation. This does not apply to certain types of requests for changes, notably those specific to the changes being submitted (e.g. the use of a particular data structure or the choice of locking primitives).
- Reviewers shall be *clear* about what changes they are requesting when the "Request Changes" option is used. Requested changes shall be in the scope of the PR in question and following the contribution and style guidelines of the project. Furthermore, reviewers must be able to point back to the exact issues in the PR that triggered a request for changes.
- Reviewers should not request changes for issues which are automatically caught by CI, as this causes the pull request to remain blocked even after CI failures have been addressed and may unnecessarily delay it from being merged.
- Reviewers shall not close a PR due to technical or structural disagreement. If requested changes cannot be resolved within the review process, the *PR Technical Escalation* path shall be used for any potential resolution path, which may include closing the PR.
- When using AI tools to assist in reviewing code or drafting responses:
  - Reviewers are responsible for following up on comments generated by the AI tools they may be using (e.g. GitHub Copilot).
  - Reviewers must never paste raw, unverified LLM output as a PR comment.
  - In general: all AI-generated feedback must be vetted, verified, and contextualized by a human reviewer who assumes full accountability for the accuracy and tone of the comment or review.

7.1.4 Coding Guidelines

Main rules

The coding guideline rules are based on MISRA-C 2012 and are a **subset** of MISRA-C. The subset is listed in the table below with a summary of the rules, its MISRA-C severity and the equivalent rules from other standards for reference.

The severity and other references in the table below are for informational purposes only. The listed rules are all required for Zephyr and all new code should comply with the rules listed below.

> **Note**
>
> For existing Zephyr maintainers and collaborators, if you are unable to obtain a copy through your employer, a limited number of copies will be made available through the project. If you need a copy of MISRA-C 2012, please send email to safety@lists.zephyrproject.org and provide details on reason why you can't obtain one through other options and expected contributions once you have one. The safety committee will review all requests.

Table 1: Main rules

Zephyr rule	Description	MISRA-C 2012 reference	CERT C reference
1	Any implementation-defined behaviour on which the output of the program depends shall be documented and understood	Dir 1.1	FLP30-C MSC09-C EXP11-C
2	All source files shall compile without any compilation errors	Dir 2.1	N/A
3	All code shall be traceable to documented requirements	Dir 3.1	N/A
4	Run-time failures shall be minimized	Dir 4.1	N/A
5	All usage of assembly language should be documented	Dir 4.2	N/A
6	Sections of code should not be “commented out”	Dir 4.4	MSC04-C
7	Identifiers in the same name space with overlapping visibility should be typographically unambiguous	Dir 4.5	DCL02-C
8	typedefs that indicate size and signedness should be used in place of the basic numerical types	Dir 4.6	N/A
9	If a function returns error information, then that error information shall be tested	Dir 4.7	N/A
10	If a pointer to a structure or union is never dereferenced within a translation unit, then the implementation of the object should be hidden	Dir 4.8 example 1 Dir 4.8 example 2	DCL12-C
11	A function should be used in preference to a function-like macro where they are interchangeable	Dir 4.9	PRE00-C
12	Precautions shall be taken in order to prevent the contents of a header file being included more than once	Dir 4.10	PRE06-C
13	The validity of values passed to library functions shall be checked	Dir 4.11	N/A
14	Dynamic memory allocation shall not be used	Dir 4.12	API03-C API04-C STR01-C
15	Functions which are designed to provide operations on a resource should be called in an appropriate sequence	Dir 4.13	N/A
16	The validity of values received from external sources shall be checked	Dir 4.14	N/A
17	Language extensions should not be used	Rule 1.2	MSC04-C
18	There shall be no occurrence of undefined or critical unspecified behaviour	Rule 1.3	N/A
19	A project shall not contain unreachable code	Rule 2.1 example 1 Rule 2.1 example 2	MSC12-C

continues on next page

Table 1 – continued from previous page

Zephyr rule	Description	MISRA-C 2012 reference	CERT C reference
20	There shall be no dead code	Rule 2.2	DCL22-C MSC12-C
21	A project should not contain unused type declarations	Rule 2.3	N/A
22	A function should not contain unused label declarations	Rule 2.6	N/A
23	There should be no unused parameters in functions	Rule 2.7	N/A
24	The character sequences /* and // shall not be used within a comment	Rule 3.1	MSC04-C
25	Line-splicing shall not be used in // comments	Rule 3.2	N/A
26	Octal and hexadecimal escape sequences shall be terminated	Rule 4.1	MSC09-C
27	Trigraphs should not be used	Rule 4.2	PRE07-C
28	External identifiers shall be distinct	Rule 5.1 example 1 Rule 5.1 example 2	DCL23-C
29	Identifiers declared in the same scope and name space shall be distinct	Rule 5.2	DCL23-C
30	An identifier declared in an inner scope shall not hide an identifier declared in an outer scope	Rule 5.3	DCL01-C DCL23-C
31	Macro identifiers shall be distinct	Rule 5.4	DCL23-C
32	Identifiers shall be distinct from macro names	Rule 5.5	DCL23-C
33	A typedef name shall be a unique identifier	Rule 5.6	N/A
34	A tag name shall be a unique identifier	Rule 5.7	N/A
35	Identifiers that define objects or functions with external linkage shall be unique	Rule 5.8 example 1 Rule 5.8 example 2	N/A
36	Identifiers that define objects or functions with internal linkage should be unique	Rule 5.9 example 1 Rule 5.9 example 2	N/A
37	Bit-fields shall only be declared with an appropriate type	Rule 6.1	INT14-C
38	Single-bit named bit fields shall not be of a signed type	Rule 6.2	INT14-C
39	Octal constants shall not be used	Rule 7.1	DCL18-C
40	A u or U suffix shall be applied to all integer constants that are represented in an unsigned type	Rule 7.2	N/A
41	The lowercase character l shall not be used in a literal suffix	Rule 7.3	DCL16-C
42	A string literal shall not be assigned to an object unless the objects type is pointer to const-qualified char	Rule 7.4	N/A
43	Types shall be explicitly specified	Rule 8.1	DCL31-C

Zephyr rule	Description	MISRA-C 2012 reference	CERT C reference
136	The pointers returned by the Standard Library functions localeconv, getenv, setlocale or, strerror shall only be used as if they have pointer to const-qualified type	Rule 21.19	N/A
137	The pointer returned by the Standard Library functions asctime, ctime, gmtime, localtime, localeconv, getenv, setlocale or strerror shall not be used following a subsequent call to the same function	Rule 21.20	N/A
138	All resources obtained dynamically by means of Standard Library functions shall be explicitly released	Rule 22.1	N/A
139	A block of memory shall only be freed if it was allocated by means of a Standard Library function	Rule 22.2	N/A
140	The same file shall not be open for read and write access at the same time on different streams	Rule 22.3	N/A
141	There shall be no attempt to write to a stream which has been opened as read-only	Rule 22.4	N/A
142	A pointer to a FILE object shall not be dereferenced	Rule 22.5	N/A
143	The value of a pointer to a FILE shall not be used after the associated stream has been closed	Rule 22.6	N/A
144	The macro EOF shall only be compared with the unmodified return value from any Standard Library function capable of returning EOF	Rule 22.7	N/A
145	The value of errno shall be set to zero prior to a call to an errno-setting-function	Rule 22.8	N/A
146	The value of errno shall be tested against zero after calling an errno-setting-function	Rule 22.9	N/A
147	The value of errno shall only be tested when the last function to be called was an errno-setting-function	Rule 22.10	N/A

Additional rules

Rule A.1: Conditional Compilation

Severity
Required

Description
Do not conditionally compile function declarations in header files. Do not conditionally compile structure declarations in header files. You may conditionally exclude fields within structure definitions to avoid wasting memory when the feature they support is not enabled.

Rationale
Excluding declarations from the header based on compile-time options may prevent their documentation from being generated. Their absence also prevents use of `if (IS_ENABLED(CONFIG_FOO)) {}` as an alternative to preprocessor conditionals when the code path should change based on the selected options.

Rule A.2: Inclusive Language

Severity
Required

Description
Do not introduce new usage of offensive terms listed below. This rule applies but is not limited to source code, comments, documentation, and branch names. Replacement terms may vary by area or subsystem, but should aim to follow updated industry standards when possible.

Exceptions are allowed for maintaining existing implementations or adding new implementations of industry standard specifications governed externally to the Zephyr Project.

Existing usage is recommended to change as soon as updated industry standard specifications become available or new terms are publicly announced by the governing body, or immediately if no specifications apply.

Offensive Terms	Recommended Replacements
`{master,leader} / slave`	• `{primary,main} / {secondary,replica}` • `{initiator,requester} / {target,responder}` • `{controller,host} / {device,worker,proxy, target}` • `director / performer` • `central / peripheral`
`blacklist / whitelist`	• `denylist / allowlist` • `blocklist / allowlist` • `rejectlist / acceptlist`
`grandfather policy`	• `legacy`
`sanity`	• `coherence` • `confidence`

Rationale
Offensive terms do not create an inclusive community environment and therefore violate the Zephyr Project Code of Conduct. This coding rule was inspired by a similar rule in Linux.

Status
Related GitHub Issues and Pull Requests are tagged with the Inclusive Language Label.

Area	Selected Replacements	Status
Bluetooth	See Bluetooth Appropriate Language Mapping Tables	
CAN	This CAN in Automation Inclusive Language news post has a list of general recommendations. See CAN in Automation Inclusive Language for terms to be used in specification document updates.	
eSPI	• `master / slave => controller / target`	Refer to eSPI Specification for new terminology
gPTP	• `master / slave => TBD`	
Inter-Integrated Circuit (I2C) Bus	• `master / slave => controller / target`	Refer to I2C Specification for new terminology.
Inter-IC Sound (I2S) Bus	• `master / slave => controller / target`	Refer to I2S Specification for new terminology. The Zephyr I2S API was migrated to these terms in Zephyr 4.4; the former macro names are retained as deprecated aliases and will be removed in Zephyr 5.0.
SMP/A	• `master / slave => TBD`	
Serial Peripheral Interface (SPI) Bus	• `master / slave => controller / peripheral` • `MOSI / MISO / SS => SDO / SDI / CS`	The Open Source Hardware Association has selected these replacement terms. See OSHWA Resolution to Redefine SPI Signal Names. The Zephyr SPI API and tree were migrated to these terms in v4.5; the former names are retained as compatibility aliases, deprecated since v4.5 and scheduled for removal in v5.0.
Test Runner (Twiste	• `platform_whitelist => platform_allow` • `sanitycheck => twister`	

Rule A.3: Macro name collisions

Severity

Required

Description

Macros with commonly used names such as `MIN`, `MAX`, `ARRAY_SIZE`, must not be modified or protected to avoid name collisions with other implementations. In particular, they must not be prefixed to place them in a Zephyr-specific namespace, re-defined using `#undef`, or conditionally excluded from compilation using `#ifndef`. Instead, if a conflict arises with an existing definition originating from a *module*, the module's code itself needs to be modified (ideally upstream, alternatively via a change in Zephyr's own fork).

This rule applies to Zephyr as a project in general, regardless of the time of introduction of the macro or its current name in the tree. If a macro name is commonly used in several other well-known open source projects then the implementation in Zephyr should use that name. While there is a subjective and non-measurable component to what "commonly

used" means, the ultimate goal is to offer users familiar macros.

Finally, this rule applies to inter-module name collisions as well: in that case both modules, prior to their inclusion, should be modified to use module-specific versions of the macro name that collides.

Rationale

Zephyr is an RTOS that comes with additional functionality and dependencies in the form of modules. Those modules are typically independent projects that may use macro names that can conflict with other modules or with Zephyr itself. Since, in the context of this documentation, Zephyr is considered the central or main project, it should implement the non-namespaced versions of the macros. Given that Zephyr uses a fork of the corresponding upstream for each module, it is always possible to patch the macro implementation in each module to avoid collisions.

Rule A.4: C Standard Library Usage Restrictions in Zephyr Kernel

Severity

Required

Description

The use of the C standard library functions and macros in the Zephyr kernel shall be limited to the following functions and macros from the ISO/IEC 9899:2011 standard, also known as C11, and their extensions:

Table 2: List of allowed libc functions and macros in the Zephyr kernel

Function	Source
abort()	ISO/IEC 9899:2011
abs()	ISO/IEC 9899:2011
aligned_alloc()	ISO/IEC 9899:2011

vsnprintf()	ISO/IEC 9899:2011
vsprintf()	ISO/IEC 9899:2011

All of the functions listed above must be implemented by the *minimal libc* to ensure that the Zephyr kernel can build with the minimal libc.

In addition, any functions from the above list that are not part of the ISO/IEC 9899:2011 standard must be implemented by the *common libc* to ensure their availability across multiple C standard libraries.

Introducing new C standard library functions to the Zephyr kernel is allowed with justification given that the above requirements are satisfied.

Note that the use of the functions listed above are subject to secure and safe coding practices and it should not be assumed that their use in the Zephyr kernel is unconditionally permitted by being listed in this rule.

The “Zephyr kernel” in this context consists of the following components:

- Kernel (`kernel`)

- OS Library (`lib/os`)
- Architecture Port (`arch`)
- Logging Subsystem (`subsys/logging`)

Rationale

Zephyr kernel must be able to build with the *minimal libc*, a limited C standard library implementation that is part of the Zephyr RTOS and maintained by the Zephyr Project, to allow self-contained testing and verification of the kernel and core OS services.

In order to ensure that the Zephyr kernel can build with the minimal libc, it is necessary to restrict the use of the C standard library functions and macros in the Zephyr kernel to the functions and macros that are available as part of the minimal libc.

Rule A.5: C Standard Library Usage Restrictions in Zephyr Codebase

Severity

Required

Description

The use of the C standard library functions and macros in the Zephyr codebase shall be limited to the functions, excluding the Annex K "Bounds-checking interfaces", from the ISO/IEC 9899:2011 standard, also known as C11, unless exempted by this rule.

The "Zephyr codebase" in this context refers to all embedded source code files committed to the main Zephyr repository, except the Zephyr kernel as defined by the *Rule A.3: Macro name collisions*. With embedded source code we refer to code which is meant to be executed in embedded targets, and therefore excludes host tooling, and code specific for the native test targets.

The following non-ISO 9899:2011, hereinafter referred to as non-standard, functions and macros are exempt from this rule and allowed to be used in the Zephyr codebase:

Table 3: List of allowed non-standard libc functions

Function	Source
gmtime_r()	POSIX.1-2001
strnlen()	POSIX.1-2008
strtok_r()	POSIX.1-2001

All non-standard functions and macros listed above must be implemented by the *common libc* in order to make sure that these functions can be made available when using a C standard library that does not implement these functions.

Adding a new non-standard function from common C standard libraries to the above list is allowed with justification, given that the above requirement is satisfied. However, when there exists a standard function that is functionally equivalent, the standard function shall be used.

Rationale

Some C standard libraries, such as Newlib and Picolibc, include additional functions and macros that are defined by the standards and de-facto standards that extend the ISO C standard (e.g. POSIX, Linux).

The ISO/IEC 9899:2011 standard does not require C compiler toolchains to include the support for these non-standard functions, and therefore using these functions can lead to compatibility issues with the third-party toolchains that come with their own C standard libraries.

7.1.5 Coding Style Guidelines

Naming conventions

This section describes the naming conventions adopted by the Zephyr Project, for each individual programming language or tool used in it.

C Code naming conventions The naming conventions in this section apply to C source and header files, as stated in each individual sub-section.

Public symbol prefixes All *public APIs* introduced to Zephyr must be prefixed according to the area or subsystem they belong to. Examples of area or subsystem prefixes are provided below for reference.

- `k_` for the kernel
- `sys_` for system-wide code and features
- `net_` for the networking subsystem
- `bt_` for the Bluetooth subsystem
- `i2c_` for the I2C controller subsystem

C Code and General Style Guidelines

Coding style is enforced on any new or modified code, but contributors are not expected to correct the style on existing code that they are not modifying.

For style aspects where the guidelines don't offer explicit guidance or permit multiple valid ways to express something, contributors should follow the style of existing code in the tree, with higher importance given to "nearby" code (first look at the function, then the same file, then subsystem, etc).

In general, follow the Linux kernel coding style, with the following exceptions and clarifications:

- Tabs are 8 characters.
- Use snake case for code and variables.
- The line length is 100 columns or fewer. In the documentation, longer lines for URL references are an allowed exception.
- Add braces to every `if`, `else`, `do`, `while`, `for` and `switch` body, even for single-line code blocks.
- Use spaces instead of tabs to align comments after declarations, as needed.
- Use C89-style single line comments, `/* */`. The C99-style single line comment, `//`, is not allowed.
- Use `/** */` for doxygen comments that need to appear in the documentation.
- Avoid using binary literals (constants starting with `0b`).
- Avoid using non-ASCII symbols in code, unless it significantly improves clarity, avoid emojis in any case.
- Use proper capitalization of nouns in code comments (e.g. `UART` and not `uart`, `CMake` and not `cmake`).

Doxygen Style Guidelines

The Zephyr Project uses Doxygen to generate API documentation from source code comments. This guide defines the conventions for documenting Zephyr public APIs consistently.

All the Doxygen commands are available for use even if they don't explicitly appear in this document.

To build and preview Zephyr's Doxygen documentation locally, refer to *Documentation Generation*.

General Rules All *public header files and their public API symbols* (functions, structs, enums, unions, typedefs, macros, and global variables):

- Must be fully documented (see *Hiding internal details* for exceptions)
- Must belong to at least one Doxygen group (see *Groups*)

You must use the following syntax when documenting public APIs:

- Use `/**` to start a block comment and `*/` to end it.
- Use `/**<` for trailing comments on the same line as a symbol.
- Use `@` (not `\`) for Doxygen commands (e.g., `@param` not `\param`).
- The `@brief` command is optional. If not used, the first sentence (ending with a period) is treated as the brief description.

Constructs meant only for internal use must be hidden from the public documentation, as described in *Hiding internal details*.

What to document For any API element that accepts, returns, or stores a value (function parameters, return values, struct/union members, enum values, typedefs, and macros), their documentation must describe the following items when applicable:

Semantics
: What this element represents and how callers/users should interpret it. Don't restate the identifier or the C type.

  Example:

  - Avoid: `@param timeout Timeout value in ms.`
  - Prefer: `@param timeout Maximum time to wait before returning, in milliseconds.`

Valid values
: What values are accepted, and how they are interpreted. Specify one or more of the following:

  - Range: minimum/maximum values (for example, the type is `uint8_t` but only 0–100 are valid).
  - Discrete set: permitted values, when only a subset is allowed.
  - Enum: whether the value must be a valid member of a given enum (and whether all enumerators are allowed or only a subset).
  - Flags/bitmasks: which bits are valid and whether combinations are allowed.
  - Nullability: whether `NULL` is allowed for pointer values, and what it means.

Units
: When the value represents a quantity, specify the unit and reference (for example, milliseconds vs ticks, Hertz, bytes). Use SI unit symbols when applicable, and write a space between the number and the unit symbol (for example, `10 ms`).

Representation
: Any non-obvious encoding or scaling (for example, fixed-point scale, Q format, split integer and fractional fields, endianness requirements).

Ownership and lifetime
: For pointers/buffers, state who allocates/frees and how long the memory must remain valid. Note required size/alignment when relevant.

Writing style Brief descriptions should use the imperative mood (a verb phrase) rather than third-person prose. This keeps API summaries consistent and scannable.

- Avoid: “Transmits data through a pipe.”, “This function gets the device state.”.
- Prefer: “Transmit data through a pipe.”, “Get the device state.”, “Initialize the subsystem.”.

Parameter and member descriptions may be sentence fragments, but they should remain descriptive and avoid repeating the parameter/member name.

Groups Groups organize related symbols into a hierarchy that helps users navigate the API.

- Define each group once with `@defgroup`.
  - The provided title should be a short, descriptive name for the group. As groups inherently collapse various interfaces/API together, do *not* use “API” or “Interface” (or any other variant of these) terms in the title, as this would be redundant.
  - The brief description of the group should not paraphrase its title.
- Group names use snake_case.
- Use `@ingroup` to specify the parent group(s) a group belongs to.

Example:

```
/**
 * @defgroup mqtt_socket MQTT Client library
 * @ingroup networking
 * @since 1.14
 * @version 0.8.0
 * @{
 */

 /* documented contents of the MQTT header file */

 /** @} */
```

Note

A group may belong to multiple parent groups, so you may have multiple `@ingroup` commands. For example, device driver emulators typically appear both in “Emulator Interfaces” and “Device drivers” groups. See I2C Emulation Interface for an example.

Important

A group with no parent becomes a top-level entry of the *API Overview*, whose categories are deliberately few. Always give a new group a parent with `@ingroup`.

The top-level entries are allowlisted in doc/_doxygen/toplevel_groups.txt and enforced by scripts/ci/doxygen_toplevel_groups.py. Adding a new one requires documentation maintainer approval.

API Versioning Use `@since` and `@version` on group definitions (`@defgroup`) to document API history and maturity:

- `@since` indicates the Zephyr release when the API was introduced (e.g., `@since 3.7`)
- `@version` indicates the current API version, following semantic versioning

The version number reflects the API's maturity as defined in *API Overview*.

Example:

Listing 1: Example for an API introduced in Zephyr 1.14, with current version 0.8.0 (unstable).

```
/**
 * @defgroup mqtt_socket MQTT Client library
 * @ingroup networking
 * @since 1.14
 * @version 0.8.0
 * @{
 */

 /* documented contents of the MQTT header file */

 /** @} */
```

Files Each public header file must have an `@file` block at the top, appearing after the SPDX license and copyright notice.

The `@file` block must also belong to a Doxygen group, typically the one defined in the same header file. This allows users browsing by file to easily navigate to the associated group.

```
/**
 * @file
 * @brief Public API for the GPIO driver.
 * @ingroup gpio_interface
 */
```

Type Definitions Document `struct`, `enum`, `union`, and `typedef` definitions with a brief description.

Document each member (struct field, enum value, etc.) as well. It is recommended to use `/**<` trailing comments style when only a brief description is provided and it can fit on a single line.

Listing 2: Examples of fully documented enum, struct, and typedef.

```
/** @brief Parity modes */
enum uart_config_parity {
     UART_CFG_PARITY_NONE,    /**< No parity */
     UART_CFG_PARITY_ODD,     /**< Odd parity */
     UART_CFG_PARITY_EVEN,    /**< Even parity */
     UART_CFG_PARITY_MARK,    /**< Mark parity */
     UART_CFG_PARITY_SPACE,   /**< Space parity */
};

/**
 * GPIO pin configuration.
 *
 * Specifies direction, pull resistor, and interrupt settings.
```

(continues on next page)

(continued from previous page)

```
 */
struct gpio_config {
    uint32_t flags;    /**< Pin configuration flags. */
    gpio_pin_t pin;    /**< Pin number within the port. */
};

/**
 * @brief Identifies a set of pins associated with a port.
 *
 * The pin with index n is present in the set if and only if the bit
 * identified by (1U << n) is set.
 */
typedef uint32_t gpio_port_pins_t;
```

Functions

Parameters

- Document parameters with `@param` in declaration order
- Use `@param[out]` for pointers the function writes to.
- Use `@param[in,out]` for pointers the function both reads and writes.
- You may omit direction specifiers for const pointers and scalars (implicitly input-only).

Return Values

- Use `@return <description>` for general descriptions (e.g., boolean or computed values).
- Use `@retval <value> <description>` for specific, discrete return values (typically error codes), starting with the success case (when applicable). The `<value>` must be provided as the first word, followed by the description (e.g., `@retval -EINVAL Invalid arguments`, not `@retval -EINVAL if invalid arguments`).

> **Note**
>
> Since there might be multiple reasons for the same discrete value to be returned, it is allowed to use the same value in multiple `@retval` statements.

Example:

Listing 3: Examples of fully documented functions.

```
/**
 * @brief Write data to the TX queue from a provided buffer
 *
 * @param dev Pointer to the device structure for the driver instance.
 * @param buf Pointer to a buffer containing the data to transmit.
 * @param size Number of bytes to write. This value has to be equal or smaller
 *        than the size of the channel's TX memory block configuration.
 *
 * @retval 0 on success.
 * @retval -EIO The interface is not in READY or RUNNING state.
 * @retval -EBUSY Returned without waiting.
 * @retval -EAGAIN Waiting period timed out.
 * @retval -ENOMEM No memory in TX slab queue.
```

(continues on next page)

(continued from previous page)

```
 * @retval -EINVAL Size parameter larger than TX queue memory block.
 */
int i2s_buf_write(const struct device *dev, void *buf, size_t size);

/**
 * @brief Add an application callback.
 *
 * @param port Pointer to the device structure for the driver instance.
 * @param callback A valid application's callback structure pointer.
 *
 * @return 0 on success, negative errno value on failure.
 * @retval -ENOSYS Driver does not implement the operation.
 */
int gpio_add_callback(const struct device *port, struct gpio_callback *callback);

/**
 * @brief Helper function for converting struct sensor_value to float.
 *
 * @param val A pointer to a sensor_value struct.
 * @return The converted value.
 */
static inline float sensor_value_to_float(const struct sensor_value *val)
{
    return (float)val->val1 + (float)val->val2 / 1000000;
}
```

Macros For function-like macros, document parameters like you would for functions.

Listing 4: Example of a fully documented function-like macro.

```
/**
 * @brief Get a node's (only) register block size
 *
 * Equivalent to DT_REG_SIZE_BY_IDX(node_id, 0).
 *
 * @param node_id node identifier
 * @return node's only register block's size
 */
#define DT_REG_SIZE(node_id) DT_REG_SIZE_BY_IDX(node_id, 0)
```

Referencing the main documentation API documentation can reference content from the main, Sphinx-based documentation using the commands described below. In the generated API documentation pages, these references are rendered as hyperlinks pointing back to the corresponding page of the main documentation.

`@kconfig{<option>}`
: Reference a Kconfig option by its full name (including the `CONFIG_` prefix). This is the Doxygen counterpart of the *kconfig:option* role.

  Example: `@kconfig{CONFIG_GPIO}`

`@kconfig_regex{<regex>}`
: Reference all the Kconfig options matching a regular expression, as a link to the Kconfig search page with the pattern pre-filled. This is the Doxygen counterpart of the *kconfig:option-regex* role. As commas have a special meaning in Doxygen commands, they must be escaped with a backslash.

  Example: `@kconfig_regex{CONFIG_SECURE_STORAGE_ITS_.*_CUSTOM}`

`@dtcompatible{<compatible>}`
: Reference a Devicetree binding by its compatible string. This is the Doxygen counterpart of the *dtcompatible* role. As commas have a special meaning in Doxygen commands, they must be escaped with a backslash.

  Example: `@dtcompatible{zephyr\,input-longpress}`

`@rstref{<target>}` **or** `@rstref{<text> <target>}`
: Reference any documentation page or section by its reference label (or document name), similar to the Sphinx `ref` role. When no custom text is provided, the title of the referenced page or section is used as the link text.

  Example: `@rstref{zephyr_licensing}` or `@rstref{the licensing page <zephyr_licensing>}`

References are checked when the documentation is built: a reference to a Kconfig option, binding, or label that does not exist causes a documentation build warning.

Note

These commands expand to plain text when the Doxygen documentation is built standalone, i.e. without the rest of the documentation. See *Documentation Generation* for more details.

Referencing IETF RFCs

`@rfc{<number>}` **or** `@rfc{<number>,<anchor>}`
: Reference an IETF RFC by number, optionally pointing to an anchor within it. This is the Doxygen counterpart of the `rfc` role and renders as a hyperlink to the RFC on the IETF Datatracker.

  The anchor is passed through verbatim, so it can target anything the Datatracker defines for that RFC, such as `section-3.1`, `appendix-B.1.2`, `figure-2`, or `table-1`. Which anchors exist depends on the RFC: figures and tables are only anchored on RFCs rendered from their XML source.

  Do not put whitespace after the comma: Doxygen keeps it as part of the argument, where it ends up inside the URL fragment. The rendered link text still looks correct, so a broken anchor is only noticeable when following the link.

  Example: `@rfc{7519}`, `@rfc{8613,section-3.1}` or `@rfc{8613,appendix-B.1.2}`

Hiding internal details Use `@cond INTERNAL_HIDDEN` / `@endcond` to hide internal details from generated documentation.

You may still optionally document these internal symbols to provide a useful reference to internal users.

```
/** Timer structure.
 *
 * Opaque type for a timer object. All the fields in this structure are internal␣
↪and should not
 * be accessed outside of kernel code.
 */
struct k_timer {
    /** @cond INTERNAL_HIDDEN */

    /* ... internal members ... */

    /** @endcond */
};
```

Driver Backend API Driver subsystems expose a public API for applications and a "backend" API for driver implementers.

While the backend API is not intended to be used directly by applications, it still constitutes a public contract between the subsystem and driver implementers and must therefore be properly documented. It typically includes the driver operations structure, typedefs defining the signature of each operation, and, in some cases, additional helper types or macros that are useful for driver implementation.

Backend API Doxygen group Use `@def_driverbackendgroup` to create a subgroup that is a child of the main API group and that will contain all the symbols associated with the backend API. This command takes two arguments: a human-readable name for the backend API (typically the same as the parent group) and the parent group identifier.

```
/**
 * @def_driverbackendgroup{Haptics,haptics_interface}
 * @{
 */

/* callback typedefs, driver ops struct, helpers ... */

/** @} */
```

Driver operations typedefs Define a `typedef` for each driver operation. The detailed description may reference the corresponding public API function as it often has a similar signature.

```
/**
 * @brief Set the haptic device to stop output.
 * See haptics_stop_output() for argument description.
 */
typedef int (*haptics_stop_output_t)(const struct device *dev);
```

Driver operations structure Annotate the struct with `@driver_ops{Name}` (where *Name* matches the name passed to `@def_driverbackendgroup`). For each member, use `@driver_ops_mandatory` or `@driver_ops_optional` to indicate whether the driver must implement it, and `@copybrief` to inherit the brief from the public API function:

```
/**
 * @driver_ops{Haptics}
 */
__subsystem struct haptics_driver_api {
    /**
     * @driver_ops_mandatory @copybrief haptics_start_output
     */
    haptics_start_output_t start_output;
    /**
     * @driver_ops_mandatory @copybrief haptics_stop_output
     */
    haptics_stop_output_t stop_output;
    /**
     * @driver_ops_optional @copybrief haptics_register_error_callback
     */
    haptics_register_error_callback_t register_error_callback;
};
```

Conditional code To ensure conditionally-compiled code appears in documentation, use either of the following approaches:

1. Add the Kconfig macro (`CONFIG_...`) that is gating the code to the `PREDEFINED` list in doc/zephyr.doxyfile.in. This makes the code visible to Doxygen during documentation generation.
2. Alternatively, you can rely on the `__DOXYGEN__` macro being set to make the conditional code visible to Doxygen, as this macro is automatically defined by Doxygen.

```
struct coap_packet {
    uint8_t *data;  /**< User allocated buffer. */
#if defined(CONFIG_COAP_KEEP_USER_DATA) || defined(__DOXYGEN__)
    /**
     * Application-specific user data.
     * @kconfig_dep{CONFIG_COAP_KEEP_USER_DATA}
     */
    void *user_data;
#endif
};
```

Kconfig Dependencies The `@kconfig_dep` command can be used to document the Kconfig option(s) that are required in order for an API symbol to be available to the user. The command can be used with one, two or three Kconfig options.

For example, adding `@kconfig_dep{CONFIG_PM,CONFIG_SMP}` to the Doxygen documentation of an API symbol will cause the generated documentation to include a note reading: "Available only when the following Kconfig options are enabled: `CONFIG_PM`, `CONFIG_SMP`.".

You can see an example of `@kconfig_dep` usage in the documentation of `coap_packet`.

CMake Style Guidelines

A subset of these guidelines is enforced in CI by the `CMakeStyle` compliance check. You can run the same checks locally with `scripts/cmake/cmake_style.py` (a directory is searched recursively for `CMakeLists.txt` and `*.cmake` files):

```
pip install tree-sitter tree-sitter-cmake
./scripts/cmake/cmake_style.py path/to/CMakeLists.txt
./scripts/cmake/cmake_style.py drivers/
```

General Formatting

- **Indentation**: Use **2 spaces** for indentation. Avoid tabs to ensure consistency across different environments.
- **Line Length**: Limit line length to **100 columns** where possible.
- **Empty Lines**: Use empty lines to separate logically distinct sections within a CMake file.
- **No Space Before Opening Brackets**: Do not add a space between a command and the opening parenthesis. Use `if(...)` instead of `if (...)`.

  ```
  # Good:
  if(ENABLE_TESTS)
    add_subdirectory(tests)
  endif()

  # Bad:
  if (ENABLE_TESTS)
    add_subdirectory(tests)
  endif()
  ```

Commands and Syntax

- **Lowercase Commands**: Always use **lowercase** CMake commands (e.g., `add_executable`, `find_package`). This improves readability and consistency.

```
# Good:
add_library(my_lib STATIC src/my_lib.cpp)

# Bad:
ADD_LIBRARY(my_lib STATIC src/my_lib.cpp)
```

  Commands defined by CMake modules, and Zephyr or sysbuild extension commands that extend an existing mixed-case command, are an exception: they follow a mixed-case `Module_Action` naming convention and must be spelled with their canonical case (e.g. CMake's `ExternalProject_Add` extended by Zephyr's `ExternalZephyrProject_Add`). The `CMakeStyle` check exempts these from the lowercase rule. Extensions of a lowercase command stay lowercase (e.g. `add_dependencies` extended by sysbuild's `sysbuild_add_dependencies`).

- **One File Argument per Line**: Break the file arguments across multiple lines to make it easier to scan and identify each source file or item.

```
# Good:
target_sources(my_target PRIVATE
  src/file1.cpp
  src/file2.cpp
)

 # Bad:
target_sources(my_target PRIVATE src/file1.cpp src/file2.cpp)
```

Variable Naming

- **Use Uppercase for Cache Variables or variables shared across CMake files**: When defining cache variables using `option` or `set(... CACHE ...)`, use **UPPERCASE names**.

```
option(ENABLE_TESTS "Enable test suite" ON)
set(CMAKE_CXX_STANDARD 17 CACHE STRING "C++ standard version")
```

- **Use Lowercase for Local Variables**: For local variables within CMake files, use **lowercase** or **snake_case**.

```
set(output_dir "${CMAKE_BINARY_DIR}/output")
```

- **Consistent Prefixing**: Use consistent prefixes for variables to avoid name conflicts, especially in large projects.

```
set(MYPROJECT_SRC_DIR "${CMAKE_SOURCE_DIR}/src")
```

Quoting

- **Quote Strings and Variables**: Always quote string literals and variables to prevent unintended behavior, especially when dealing with paths or arguments that may contain spaces.

```
# Good:
set(my_path "${CMAKE_SOURCE_DIR}/include")

# Bad:
set(my_path ${CMAKE_SOURCE_DIR}/include)
```

- **Do Not Quote Boolean Values**: For boolean values (`ON`, `OFF`, `TRUE`, `FALSE`), avoid quoting them.

```
option(BUILD_SHARED_LIBS "Build shared libraries" OFF)
```

Avoid Hardcoding Paths

- Use CMake variables (`CMAKE_SOURCE_DIR`, `CMAKE_BINARY_DIR`, `CMAKE_CURRENT_SOURCE_DIR`) instead of hardcoding paths.

```
set(output_dir "${CMAKE_BINARY_DIR}/bin")
```

Conditional Logic

- Use `if`, `elseif`, and `else` with proper indentation, and close with `endif()`.

```
if(ENABLE_TESTS)
  add_subdirectory(tests)
endif()
```

Documentation

- Use comments to document complex logic in the CMake files.

```
# Find LlvmLld components required for building with llvm
find_package(LlvmLld 14.0.0 REQUIRED)
```

Devicetree Style Guidelines

- Indent with tabs.
- Tab size is 8 characters.
- Follow the Devicetree specification conventions and rules.
- If the Linux kernel rules in Devicetree Sources (DTS) Coding Style make a recommendation, it's the preferred style in Zephyr too.
- You can split related groups of properties into "paragraphs" by separating them with one empty line (two newline characters) if it aids readability.
- Use dashes (`-`) as word separators for node and property names.
- Use underscores (`_`) as word separators in node labels.
- Leave a single space on each side of the equal sign (`=`) in property definitions.
- Don't insert empty lines before a dedenting `};`.
- Insert a single empty line to separate nodes at the same hierarchy level.
- When splitting long property values across multiple lines, specify the first value on the same line as the opening bracket (`<` or `[`). Place the closing bracket and semicolon (`>;` or `];`) on the same line after the final value of the property.

Examples:

```
/dts-v1/;

/ {
        /* Node labels use the "_" separator, but node names use "-". */
        psa_rng: psa-rng {
```

(continues on next page)

(continued from previous page)

```
                compatible = "zephyr,psa-crypto-rng";
                status = "okay";
        };

        ramdisk0 {
                compatible = "zephyr,ram-disk";
                /* Property names use the "-" separator. */
                disk-name = "RAM";
                sector-size = <512>;
                sector-count = <128>;
        };

        periph0 {
                /* Wrap array values to conform with line lengths. Indent
                 * continuation so that values align.
                 */
                pinctrl-0 = <&periph0_siga_px0_default &periph0_sigb_py7_default
                             &periph0_sigc_pz1_default>;
                pinctrl-names = "default";
        };

        mipi-dbi {
                compatible = "zephyr,mipi-dbi-spi";

                lcd0: lcd@0 {
                        compatible = "sitronix,st7735r";
                        /* Split array values across multiple lines to help␣
↪readability. */
                        gamctrp1 = [10 0e 02 03
                                    0e 07 02 07
                                    0a 12 27 37
                                    00 0d 0e 10];
                        gamctrn1 = [10 0e 03 03
                                    0f 06 02 08
                                    0a 13 26 36
                                    00 0d 0e 10];
                };
        };
};
```

Kconfig Style Guidelines

This document provides style guidelines for writing Kconfig files in the Zephyr project. Following these guidelines ensures consistency and readability across the codebase, making it easier for developers to understand and maintain configuration options.

The following sections provide guidelines with examples to illustrate proper Kconfig formatting and naming conventions.

Basic Formatting Rules When writing Kconfig files, follow these basic formatting rules:

- **Line length**: Keep lines to 100 columns or fewer.
- **Indentation**: Use tabs for indentation, except for `help` entry text which should be placed at one tab plus two extra spaces.
- **Spacing**: Leave a single empty line between option declarations.

- **Comments**: Format comments as `# Comment` rather than `#Comment`.
- **Conditional blocks**: Insert an empty line before/after each top-level `if` and `endif` statement.
- **End of file**: End the file with exactly one newline.

For guidance on using statements like `select`, see *Kconfig - Tips and Best Practices* for more information.

These formatting rules are enforced in CI by the `KconfigFormat` compliance check. You can check your Kconfig files locally with the `scripts/kconfig/kconfig_style.py` script, which reports any style issues (a directory is searched recursively for Kconfig files):

```
./scripts/kconfig/kconfig_style.py path/to/Kconfig
./scripts/kconfig/kconfig_style.py drivers/sensor/
```

Symbol Naming and Structure The following examples demonstrate proper Kconfig symbol naming and structure:

```
# Symbol to enable/disable the feature ("enabling symbol")
config ADC_AD405X
        bool "AD405X ADC driver"
        depends on DT_HAS_ADI_AD4052_ADC_ENABLED || DT_HAS_ADI_AD4050_ADC_ENABLED
        select SPI
        default y
        help
          Enable ADC driver for AD405X.
```

```
# Symbol to enable/disable the feature ("enabling symbol")
menuconfig ADC_AD4114
        bool "AD4114 ADC driver"
        depends on DT_HAS_ADI_AD4114_ADC_ENABLED
        select SPI
        default y
        help
          Enable the AD4114 ADC driver.

if ADC_AD4114

# Symbol to configure the behavior of the feature ("config symbol")
config ADC_AD4114_ACQUISITION_THREAD_STACK_SIZE
        int "Stack size for the data acquisition thread"
        default 512
        help
          Size of the stack used for the internal data acquisition
          thread.

# Symbol to configure the behavior of the feature ("config symbol")
config ADC_AD4114_ACQUISITION_THREAD_PRIO
        int "Priority for the data acquisition thread"
        default 0
        help
          Priority level for the internal ADC data acquisition thread.

endif # ADC_AD4114
```

Naming Conventions

- As a general rule, symbols concerning the same component should be distinct from other symbols. This can usually be accomplished by using a common prefix. This prefix can be a simple keyword or, as in the case for drivers, several keywords for more precision.
- A common prefix usually indicates the subsystem or component the symbol belongs to.
- An enabling symbol name should consist of keywords to provide the context of the symbol in a scope from most general to most specific (e.g. *Driver Type -> Driver Name*).
- The prompt for an enabling symbol should use the same logic as the symbol name itself but use the keywords in reversed order.
  - Adhering to this style makes searching for symbols easier in the UI because one can filter by a scope keyword.
- When the enabling symbol is dependent on a devicetree node, consider depending on the *automatically created* `DT_HAS_<node>_ENABLED` symbol.
- When building complex expressions based on devicetree node compatibles, use the *automatically defined* `DT_COMPAT_VND_DEVICE` instead of defining a variable equal to *vnd*, *device* manually.

The specific formats by subtree:

- **Drivers (/drivers)**: Use the format `{Driver Type}_{Driver Name}` for symbols and `{Driver Name} {Driver Type} driver` for prompts.
- **Sensors (/drivers/sensors)**: Use the format `SENSOR_{Sensor Name}` for symbols and `{Sensor Name} {Sensor Type} sensor driver` for prompts.
- **Architecture (/arch)**: Many symbols are shared across architectures. Before creating new symbols, check if similar ones already exist in other architectures.
- **Samples (/samples)**: Use `SAMPLE_` for symbols, this is to prevent conflicts with external modules.
- **Tests (/tests)**: Use `TEST_` for symbols, this is to prevent conflicts with external modules.
- **Boards (/boards)**: Use `BOARD_` for symbols.
- **SoCs (/soc)**: Use the most appropriate base for symbols: `SOC_VENDOR_{SoC vendor}_` if it relates to several families from a SoC vendor, `SOC_FAMILY_{SoC family}_` if it relates to a whole SoC family, `SOC_SERIES_{SoC series}_` if it relates to a whole SoC series, or `SOC_{SoC}_` if it relates to a specific SoC - see *SoC Porting Guide* for details on these terms and where they must originate from. This is to prevent conflicts with other vendors and external modules.

Note

The following examples only show the symbol and prompt lines for brevity.

Examples **Driver Examples:**

```
config ADC_AD405X
        bool "AD405X ADC driver"

config CAN_MAX32
        bool "MAX32 CAN driver"

config I2C_EMUL
        bool "I2C emulator driver"
```

Sensor Examples:

```
config SENSOR_BMP581
        bool "BMP581 barometric pressure sensor driver"

config SENSOR_TMP007
        bool "TMP007 infrared thermopile sensor driver"

config SENSOR_LM75
        bool "LM75 temperature sensor driver"
```

Sample examples:

```
config SAMPLE_LOCK
        bool "Locking feature"

config SAMPLE_TEMPERATURE_READINGS
        bool "Fetch readings from temperature sensor"
```

Test examples:

```
config TEST_ITERATIONS
        int "Number of times test should run"
        default 3
```

SoC examples:

```
# This assumes the following soc.yml file for the vendor "hotel":
# family:
#   - name: alpha
#     series:
#       - name: foxtrot
#         socs:
#           - name: charlie

config SOC_VENDOR_HOTEL_FLASH_PREFETCH
        bool "Flash prefetch"

config SOC_FAMILY_ALPHA_JTAG_LOCK
        bool "Lock JTAG access"

config SOC_SERIES_FOXTROT_EMULATE_POWER_OFF
        bool "Emulate power off mode"

config SOC_CHARLIE_IMAGE_HEADER
        bool "Include image header"
```

Configuration Symbol Organization When a feature uses config symbols to configure its behavior:

- Use `menuconfig` instead of `config` to define the enabling feature (even when the config symbol has no prompt).
- Encapsulate the config symbols in an `if` statement to declare their dependency on the enabling symbol (this automatically groups these symbols under the enabling symbol in the UI).
- Prefix the config symbol with the enabling symbol's name for scope and context.
- In the prompt of the config symbol, describe what the symbol configures without repeating the scope keywords, because the grouping in the UI provides this context.

File Organization When organizing Kconfig files:

- Keep the Kconfig file close to the source files it configures.
- When dealing with large Kconfig files (e.g. with many config symbols), consider grouping (some of) them into a separate file and import it using the `source` directive to improve readability.

Python Style Guidelines

Python should be formatted in a PEP 8 compliant manner. Zephyr uses the ruff formatter to achieve this. This opinionated formatter aims for consistency, generality, readability and reducing git diffs.

To apply the formatter, run:

```
ruff check --select I --fix <file> # Sort imports
ruff format <file>
```

Ruff configuration A small set of options is applied on top of the defaults:

- Line length of 100 columns or fewer.
- Both single ' and double " quote styles are allowed.
- Line endings will be converted to `\n`. The default line ending on Unix.

Excluded files The formatter is enforced in CI, but only for newly added Python files, because the project already had a large Python codebase when this was introduced. The .ruff-excludes.toml file has a `[format]` section where all the files that are currently excluded are listed. It is encouraged for contributors, when changing an excluded file, to remove it from the list and format it in a separate commit.

Style Tools

Checkpatch The Linux kernel GPL-licensed tool `checkpatch` is used to check coding style conformity.

> **Note**
>
> checkpatch does not currently run on Windows.

Checkpatch is available in the scripts directory. To invoke it when committing code, make the file *$ZEPHYR_BASE/.git/hooks/pre-commit* executable and edit it to contain:

```
#!/bin/sh
set -e exec
exec git diff --cached | ${ZEPHYR_BASE}/scripts/checkpatch.pl -
```

Instead of running checkpatch at each commit, you may prefer to run it only before pushing on zephyr repo. To do this, make the file *$ZEPHYR_BASE/.git/hooks/pre-push* executable and edit it to contain:

```
#!/bin/sh
remote="$1"
url="$2"

z40=0000000000000000000000000000000000000000
```

(continues on next page)

(continued from previous page)

```
echo "Run push hook"

while read local_ref local_sha remote_ref remote_sha
do
    args="$remote $url $local_ref $local_sha $remote_ref $remote_sha"
    exec ${ZEPHYR_BASE}/scripts/series-push-hook.sh $args
done

exit 0
```

If you want to override checkpatch verdict and push you branch despite reported issues, you can add option –no-verify to the git push command.

A different way for running `checkpatch` is by using *check_compliance.py* script, which does additional style and compliance related checks.

clang-format The clang-format tool can be helpful to quickly reformat large amounts of new source code to our *Coding Style Guidelines* standards together with the `.clang-format` configuration file provided in the repository. `clang-format` is well integrated into most editors, but you can also run it manually like this:

```
clang-format -i my_source_file.c
```

`clang-format` is part of LLVM, which can be downloaded from the project releases page. Note that if you are a Linux user, `clang-format` will likely be available as a package in your distribution repositories.

When there are differences between the *Coding Style Guidelines* guidelines and the formatting generated by code formatting tools, the *Coding Style Guidelines* guidelines take precedence. If there is ambiguity between formatting tools and the guidelines, maintainers may decide which style should be adopted.

dts-linter The dts-linter can be helpful to quickly reformat large amounts of devicetree files to our *Coding Style Guidelines* standards. You can also run it manually like this:

For individual files

```
npx --ignore-scripts --prefix ./scripts/ci dts-linter --format --file board.dts --
↪file board_pinctrl.dtsi --patchFile diff.patch
git apply diff.patch
```

You can omit `--file` and this will format all files under the directory where the command has been called. Alternatively `--cwd` can also be passed set the base dir where the tool should look for files. This option is also used to make the paths relative in the patch file.

You can also fix in place with

```
npx --ignore-scripts --prefix ./scripts/ci dts-linter --formatFixAll
```

Editor Integration

- For VS Code: Install the extension from the VS Code Marketplace or Open VSIX
- For other editors with LSP Client support: Use the devicetree-language-server devicetree-language-server

Make sure you follow Devicetree Style Guidelines requirements to configure the editor correctly.

7.1.6 Proposals and RFCs

Many changes, including bug fixes and documentation improvements can be implemented and reviewed via the normal GitHub pull request workflow.

Many changes however are "substantial" and need to go through a design process and produce a consensus among the project stakeholders.

The "RFC" (request for comments) process is intended to provide a consistent and controlled path for new features to enter the project.

Contributors and project stakeholders should consider using this process if they intend to make "substantial" changes to Zephyr or its documentation. Some examples that would benefit from an RFC are:

- A new feature that creates new API surface area, and would require a feature flag if introduced.
- The modification of an existing stable API.
- The removal of features that already shipped as part of Zephyr.
- The introduction of new idiomatic usage or conventions, even if they do not include code changes to Zephyr itself.

The RFC process is a great opportunity to get more eyeballs on proposals coming from contributors before it becomes a part of Zephyr. Quite often, even proposals that seem "obvious" can be significantly improved once a wider group of interested people have a chance to weigh in.

The RFC process can also be helpful to encourage discussions about a proposed feature as it is being designed, and incorporate important constraints into the design while it's easier to change, before the design has been fully implemented.

For a Major Feature, first open an issue and outline your proposal so that it can be discussed. This will also allow us to better coordinate our efforts, prevent duplication of work, and help you to craft the change so that it is successfully accepted into the project. Providing the following information will increase the chances of your issue being dealt with quickly:

- Overview of the Proposal
- Motivation for or Use Case
- Design Details
- Alternatives
- Test Strategy

Some changes or contributions do not require an RFC, the rationale and details of the changes should however be part of the pull-request:

- Small enhancements and modifications to existing and established subsystems.
- Rephrasing, reorganizing or refactoring
- Addition or removal of warnings
- Addition of new boards, SoCs or drivers to existing subsystems
- …

The process in itself consists in creating a GitHub issue with the *RFC label* that documents the proposal thoroughly. You are encouraged to use the RFC form to make sure the proposal follows a template which project participants are already familiar with.

As with Pull Requests, RFCs might require discussion in the context of one of the Zephyr meetings in order to move it forward in cases where there is either disagreement or not enough voiced opinions in order to proceed. Make sure to either label it appropriately or include it in the corresponding GitHub project in order for it to be examined during the next meeting.

7.1.7 Modifying Contributions made by other developers

Scenarios

Zephyr contributors and collaborators are encouraged to assist as reviewers in pull requests, so that patches may be approved and merged to Zephyr's main branch as part of the original pull requests. The authors of the pull requests are responsible for amending their original commits following the review process.

There are occasions, however, when a contributor might need to modify patches included in pull requests that are submitted by other Zephyr contributors. For instance, this is the case when:

- a developer cherry-picks commits submitted by other contributors into their own pull requests in order to:
  - integrate useful content which is part of a stale pull request, or
  - get content merged to the project's main branch as part of a larger patch
- a developer pushes to a branch or pull request opened by another contributor in order to:
  - assist in updating pull requests in order to get the patches merged to the project's main branch
  - drive stale pull requests to completion so they can be merged

Accepted policies

A developer who intends to cherry-pick and potentially modify patches sent by another contributor shall:

- clarify in their pull request the reason for cherry-picking the patches, instead of assisting in getting the patches merged in their original pull request, and
- invite the original author of the patches to their pull request review.

A developer who intends to force-push to a branch or pull request of another Zephyr contributor shall clarify in the pull request the reason for pushing and for modifying the existing patches (e.g. stating that it is done to drive the pull request review to completion, when the pull request author is not able to do so).

> **Note**
>
> Developers should try to limit the above practice to pull requests identified as *stale*. Read about how to identify pull requests as stale in *development processes and tools*

If the original patches are substantially modified, the developer can either:

- (preferably) reach out to the original author and request them to acknowledge that the modified patches may be merged while having the original sign-off line and author identity, or
- submit the modified patches as their *own* work (i.e. with their *own* sign-off line and author identity). In this case, the developer shall identify in the commit message(s) the original source the submitted work is based on (mentioning, for example, the original PR number).

> **Note**
>
> Contributors should uncheck the box *"Allow Edits By Maintainers"* to indicate that they do not wish their patches to be amended, inside their original branch or pull request, by other Zephyr developers.

7.1.8 Pull Request Lifecycle Policy

This policy keeps the open pull request list focused on contributions that are actively progressing and have a realistic path to merge.

Goals

- Keep open pull requests manageable for contributors and maintainers.
- Prioritize review bandwidth for changes that are moving forward.
- Provide clear expectations for draft pull requests and inactive pull requests.

Scope

This policy applies to all pull requests in the repository, including draft pull requests.

Definitions

Active pull request
: A pull request with meaningful progress such as commits, review responses, or updates addressing requested changes.

Draft pull request
: A pull request opened for work in progress and early feedback.

Stalled pull request
: A pull request without meaningful activity inside the inactivity window.

Closed inactive pull request
: A pull request closed due to inactivity, supersession, or no clear merge path.

Draft Pull Request Expectations

- Draft pull requests should include a clear problem statement, current status, and known gaps.
- Draft pull requests should move to ready-for-review within 30 days.
- If a draft pull request is inactive for 30 days, it may be marked stale and a reminder is posted.
- If there is no meaningful progress for 7 additional days after stale notice, the pull request may be closed.

Ready-for-Review Pull Request Expectations

- Authors should respond to review feedback within 21 days.
- If a ready pull request has no meaningful activity for 30 days, it may be marked stale.
- If no meaningful update is made within 7 days after stale notice, the pull request may be closed.
- Pull requests with unresolved blocking feedback for more than 45 days may be closed if no concrete plan is provided.

What Counts as Meaningful Activity

Examples of meaningful activity include:

- New commits that address review feedback.
- Concrete technical responses and follow-up updates.

- Significant revision updates that materially change the pull request.

Examples that typically do not count as meaningful activity include:

- Ping-only comments with no technical update.
- Trivial rebases with no substantive change.

Exceptions

The following pull requests may be exempt from automatic inactive closure:

- Security-critical fixes.
- Release blockers.
- Pull requests explicitly waiting on an external dependency with a linked tracking item.

Exempt pull requests still need a status update at least every 30 days.

Superseded Pull Requests

When work is replaced by another pull request:

- Close the old pull request as superseded.
- Link the replacement pull request.
- Add a short summary comment preserving context.

Reopening Closed Inactive Pull Requests

Closing a pull request due to inactivity is an administrative step to keep the open list manageable. It is not a rejection of the contribution.

Closed inactive pull requests may be reopened when:

- The author posts an updated plan.
- Prior blocking feedback is addressed.
- Maintainers confirm that review can continue.

Contributors are encouraged to reopen at any time when they can provide meaningful updates.

Responsibilities

Contributors are expected to:

- Keep pull request descriptions up to date.
- Respond to review comments in a timely manner.
- Move draft pull requests to ready-for-review once they are reviewable.

Consult with the *contributor expectations* document for additional guidance.

Maintainers are expected to:

- Apply stale and closure decisions consistently.
- Provide clear blocking feedback.
- Close with explicit rationale and a reopen path.

Consult with the *maintainer responsibilities* document for additional guidance.

Contribution Guidelines
Learn about the overall process and guidelines for contributing to the Zephyr project.

This page is a mandatory read for first-time contributors as it contains important information on how to ensure your contribution can be considered for inclusion in the project and potentially merged.

Contributor Expectations
This document is another mandatory read that describes the expected behavior of *all* contributors to the project.

Reviewer Expectations
This document is another mandatory read that describes the expected behavior when reviewing contributions to the project.

Coding Guidelines
Code contributions are expected to follow a set of coding guidelines to ensure consistency and readability across the code base.

Coding Style Guidelines
Code contributions are expected to follow a set of style guidelines to ensure consistency and readability across the code base.

Proposals and RFCs
Learn when and how to submit RFCs (Request for Comments) for new features and changes to the project.

Modifying Contributions made by other developers
Guidelines for modifying contributions made by other developers and how to deal with stale pull requests.

Pull Request Lifecycle Policy
Policy for keeping open pull requests focused on work that is actively progressing and likely to merge.

7.2 Documentation

The Zephyr project thrives on good documentation. Whether it is as part of a code contribution or as a standalone effort, contributing documentation is particularly valuable to the project.

7.2.1 Documentation Guidelines

> **Note**
>
> For instructions on building the documentation, see *Documentation Generation*.

Zephyr Project content is written using the reStructuredText[2] markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted standalone website. Developers can view this content either in its raw form as .rst markup files, or (with Sphinx installed) they can *build the documentation* locally to generate the documentation in HTML or PDF format. The HTML content can then be viewed using a web browser. This same .rst content is served by the Zephyr documentation[4] website.

You can read details about reStructuredText[2] and about Sphinx extensions[1] from their respective websites.

[2] https://docutils.sourceforge.net/docs/ref/rst/restructuredtext.html
[4] https://docs.zephyrproject.org
[1] https://www.sphinx-doc.org/en/stable/contents.html

This document provides a quick reference for commonly used reST and Sphinx-defined directives and roles used to create the documentation you're reading.

For instructions regarding writing good C API documentation, see *Doxygen Style Guidelines*.

Content Structure

Tabs, spaces, and indenting Indenting is significant in reST file content, and using spaces is preferred. Extra indenting can (unintentionally) change the way content is rendered too. For lists and directives, indent the content text to the first non-white space in the preceding line. For example:

```
* List item that spans multiple lines of text
  showing where to indent the continuation line.

1. And for numbered list items, the continuation
   line should align with the text of the line above.

.. code-block::

   The text within a directive block should align with the
   first character of the directive name.
```

Refer to the Zephyr *Coding Style Guidelines* for additional requirements.

Headings While reST allows use of both an overline and matching underline to indicate a heading, we only use an underline indicator for headings.

- Document title (h1) use # for the underline character
- First section heading level (h2) use *
- Second section heading level (h3) use =
- Third section heading level (h4) use -

The heading underline must be the same length as the heading text.

For example:

```
This is a title heading
#######################

some content goes here

First section heading
*********************
```

Lists For bullet lists, place an asterisk (*) or hyphen (-) at the start of a paragraph and indent continuation lines with two spaces.

The first item in a list (or sublist) must have a blank line before it and should be indented at the same level as the preceding paragraph (and not indented itself).

For numbered lists start with a 1. or a. for example, and continue with autonumbering by using a # sign. Indent continuation lines with three spaces:

```
* This is a bulleted list.
* It has two items, the second
  item and has more than one line of reST text.  Additional lines
  are indented to the first character of the
```

(continues on next page)

(continued from previous page)

```
  text of the bullet list.

1. This is a new numbered list. If the wasn't a blank line before it,
   it would be a continuation of the previous list (or paragraph).
#. It has two items too.

a. This is a numbered list using alphabetic list headings
#. It has three items (and uses autonumbering for the rest of the list)
#. Here's the third item

#. This is an autonumbered list (default is to use numbers starting
   with 1).

   #. This is a second-level list under the first item (also
      autonumbered).  Notice the indenting.
   #. And a second item in the nested list.
#. And a second item back in the containing list.  No blank line
   needed, but it wouldn't hurt for readability.
```

Definition lists (with a term and its definition) are a convenient way to document a word or phrase with an explanation. For example this reST content:

```
The Makefile has targets that include:

html
   Build the HTML output for the project

clean
   Remove all generated output, restoring the folders to a
   clean state.
```

Would be rendered as:

The Makefile has targets that include:

html
: Build the HTML output for the project

clean
: Remove all generated output, restoring the folders to a clean state.

Multi-column lists If you have a long bullet list of items, where each item is short, you can indicate the list items should be rendered in multiple columns with a special `.. rst-class:: rst-columns` directive. The directive will apply to the next non-comment element (e.g., paragraph), or to content indented under the directive. For example, this unordered list:

```
.. rst-class:: rst-columns

* A list of
* short items
* that should be
* displayed
* horizontally
* so it doesn't
* use up so much
* space on
* the page
```

would be rendered as:

- A list of
- short items
- that should be
- displayed
- horizontally
- so it doesn't
- use up so much
- space on
- the page

A maximum of three columns will be displayed, and change based on the available width of the display window, reducing to one column on narrow (phone) screens if necessary. We've deprecated use of the `hlist` directive because it misbehaves on smaller screens.

Tables There are a few ways to create tables, each with their limitations or quirks. Grid tables offer the most capability for defining merged rows and columns, but are hard to maintain:

```
+------------------------+------------+----------+----------+
| Header row, column 1   | Header 2   | Header 3 | Header 4 |
| (header rows optional) |            |          |          |
+========================+============+==========+==========+
| body row 1, column 1   | column 2   | column 3 | column 4 |
+------------------------+------------+----------+----------+
| body row 2             | ...        | ...      | you can  |
+------------------------+------------+----------+ easily   +
| body row 3 with a two column span   | ...      | span     |
+------------------------+------------+----------+ rows     +
| body row 4             | ...        | ...      | too      |
+------------------------+------------+----------+----------+
```

This example would render as:

Header row, column 1 (header rows optional)	Header 2	Header 3	Header 4
body row 1, column 1	column 2	column 3	column 4
body row 2	...	...	you can easily span rows too
body row 3 with a two column span		...	
body row 4	...	...	

List tables are much easier to maintain, but don't support row or column spans:

```
.. list-table:: Table title
   :widths: 15 20 40
   :header-rows: 1

   * - Heading 1
     - Heading 2
     - Heading 3
   * - body row 1, column 1
     - body row 1, column 2
     - body row 1, column 3
```

(continues on next page)

(continued from previous page)

```
  * - body row 2, column 1
    - body row 2, column 2
    - body row 2, column 3
```

This example would render as:

Table 4: Table title

Heading 1	Heading 2	Heading 3
body row 1, column 1	body row 1, column 2	body row 1, column 3
body row 2, column 1	body row 2, column 2	body row 2, column 3

The `:widths:` parameter lets you define relative column widths. The default is equal column widths. If you have a three-column table and you want the first column to be half as wide as the other two equal-width columns, you can specify `:widths: 1 2 2`. If you'd like the browser to set the column widths automatically based on the column contents, you can use `:widths: auto`.

Tabbed Content As introduced in the *Getting Started Guide*, you can provide alternative content to the reader via a tabbed interface. When the reader clicks on a tab, the content for that tab is displayed, for example:

```
.. tabs::

   .. tab:: Apples

      Apples are green, or sometimes red.

   .. tab:: Pears

      Pears are green.

   .. tab:: Oranges

      Oranges are orange.
```

will display as:

Apples

Apples are green, or sometimes red.

Pears

Pears are green.

Oranges

Oranges are orange.

Tabs can also be grouped, so that changing the current tab in one area changes all tabs with the same name throughout the page. For example:

Linux

Linux Line 1

macOS

macOS Line 1

Windows

Windows Line 1

Linux

Linux Line 2

macOS

macOS Line 2

Windows

Windows Line 2

In this latter case, we're using `.. group-tab::` instead of simply `.. tab::`. Under the hood, we're using the sphinx-tabs extension that's included in the Zephyr setup. Within a tab, you can have most any content *other than a heading* (code-blocks, ordered and unordered lists, pictures, paragraphs, and such). You can read more about sphinx-tabs from the link above.

Text Formatting

ReSTructuredText supports a variety of text formatting options. This section provides a quick reference for some of the most commonly used text formatting options in Zephyr documentation. For an exhaustive list, refer to the reStructuredText Quick Reference[5], reStructuredText Interpreted Text Roles[6] as well as the additional roles provided by Sphinx[7].

Content Highlighting Some common reST inline markup samples:

- one asterisk: `*text*` for emphasis (*italics*),
- two asterisks: `**text**` for strong emphasis (**boldface**), and
- two backquotes: ``` ``text`` ``` for `inline code` samples.

If asterisks or backquotes appear in running text and could be confused with inline markup delimiters, you can eliminate the confusion by adding a backslash (\) before it.

File Names and Commands Sphinx extends reST by supporting additional inline markup elements (called "roles") used to tag text with special meanings and allow style output formatting. (You can refer to the Sphinx Inline Markup[3] documentation for the full list).

While double quotes can be used for rendering text as "code", you are encouraged to use the following roles for marking up file names, command names, and other "special" text.

- `file` for file names, e.g., ``:file:`CMakeLists.txt``` will render as `CMakeLists.txt`

> **Note**
>
> In case you want to indicate a "variable" file path, you may use curly braces to enclose the variable part of the path, e.g., ``:file:`{boardname}_defconfig``` will render as *boardname*`_defconfig`.

- `command` for command names, e.g., ``:command:`make``` will render as **make**
- `envvar` for environment variables, e.g., ``:envvar:`ZEPHYR_BASE``` will render as *ZEPHYR_BASE*

For creating references to files that are hosted in the Zephyr organization on GitHub, refer to *Cross-referencing files in the Zephyr tree* section below.

[5] https://docutils.sourceforge.io/docs/user/rst/quickref.html
[6] https://docutils.sourceforge.io/docs/ref/rst/roles.html
[7] https://www.sphinx-doc.org/en/master/usage/restructuredtext/roles.html
[3] https://sphinx-doc.org/markup/inline.html#inline-markup

User Interaction When documenting user interactions, such as key combinations or GUI interactions, use the following roles to highlight the commands in a meaningful way:

- `kbd` for keyboard input, e.g., `:kbd:`Ctrl-C`` will render as Ctrl-C
- `menuselection` for menu selections, e.g., `:menuselection:`File --> Open`` will render as *File ▸ Open*
- `guilabel` for GUI labels, e.g., `:guilabel:`Cancel`` will render as *Cancel*

Mathematical Formulas You can include mathematical formulas using either the `math` role or `math` directive. The directive provides more flexibility in case you have a more complex formula.

The input language for mathematics is LaTeX markup. Example:

```
The answer to life, the universe, and everything is :math:`30 + 2^2 + \sqrt{64} =␣
↪42`.
```

This would render as:

> The answer to life, the universe, and everything is $30 + 2^2 + \sqrt{64} = 42$.

Non-ASCII Characters Prefer plain ASCII unless a specific symbol is required for correctness or conventional typography (for example units like µ, or well-known marks like ™).

Avoid adding non-ASCII characters purely for aesthetic purposes.

The file doc/substitutions.txt contains some basic HTML substitution definitions for special formatting needs (e.g. to force line breaks), but Unicode characters can and should be used directly in the documentation source files.

Code Blocks and Command Examples Use the reST `code-block` directive to create a highlighted block of fixed-width text, typically used for showing formatted code or console commands and output. Smart syntax highlighting is also supported (using the Pygments package). You can also directly specify the highlighting language. For example:

```
.. code-block:: c

   struct k_object {
      char *name;
      uint8_t perms[CONFIG_MAX_THREAD_BYTES];
      uint8_t type;
      uint8_t flags;
      uint32_t data;
   } __packed;
```

Note the blank line between the `code-block` directive and the first line of the code-block body, and the body content is indented three spaces (to the first non-white space of the directive name).

This would be rendered as:

```
struct k_object {
   char *name;
   uint8_t perms[CONFIG_MAX_THREAD_BYTES];
   uint8_t type;
   uint8_t flags;
   uint32_t data;
} __packed;
```

Other languages are of course supported (see languages supported by Pygments[8]), and in particular, you are encouraged to make use of the following when appropriate:

[8] https://pygments.org/languages/

- `c` for C code
- `cpp` for C++ code
- `python` for Python code
- `console` for console output, i.e. interactive shell sessions where commands are prefixed by a prompt (ex. `$` for Linux, or `uart:~$` for Zephyr's shell), and where the output is also shown. The commands will be highlighted, and the output will not. What's more, copying code block using the "copy" button will automatically copy just the commands, excluding the prompt and the outputs of the commands.
- `shell` or `bash` for shell commands. Both languages get highlighted the same but you may use `bash` for conveying that the commands are bash-specific, and `shell` for generic shell commands.

Note

Do not use `bash` or `shell` if your code block includes a prompt, use `console` instead.

Reciprocally, do not use `console` if your code block does not include a prompt and is not showcasing an interactive session with command(s) and their output.

Table 5: When to use `bash`/`shell` vs. `console`

Use case	code-block snippet	Expected output

One or several commands, no output	`.. code-block:: shell`
	
	`echo "Hello World!"`
		`echo "Hello World!"`

An interactive shell session with command(s) and their output	`.. code-block:: console`
	
	`$ echo "Hello World!"`
	`Hello World!`
		`$ echo "Hello World!"`
		`Hello World!`

An interactive Zephyr shell session, with commands and their outputs	`.. code-block:: console`
	
	`uart:~$ version`
	`Zephyr version 3.5.99`
	`uart:~$ kernel uptime`
	`Uptime: 20970 ms`
		`uart:~$ version`
		`Zephyr version 3.5.99`
		`uart:~$ kernel uptime`
		`Uptime: 20970 ms`

- `bat` for Windows batch files
- `cfg` for config files with "KEY=value" entries (ex. Kconfig `.conf` files)
- `cmake` for CMake
- `devicetree` for Devicetree
- `kconfig` for Kconfig
- `yaml` for YAML
- `rst` for reStructuredText

When no language is specified, the language is set to `none` and the code block is not highlighted. You may also use `none` explicitly to achieve the same result; for example:

```
.. code-block:: none

   This would be a block of text styled with a background
   and box, but with no syntax highlighting.
```

Would display as:

```
This would be a block of text styled with a background
and box, but with no syntax highlighting.
```

There's a shorthand for writing code blocks too: end the introductory paragraph with a double colon (`::`) and indent the code block content that follows it by three spaces. On output, only one colon will be shown. The code block will have no highlighting (i.e. `none`). You may however use the `highlight` directive to customize the default language used in your document (see for example how this is done at the beginning of this very document).

Links and Cross-References

Cross-referencing internal content Traditional ReST links are only supported within the current file using the notation:

```
Refer to the `internal-linking`_ page
```

which renders as,

> Refer to the *internal-linking* page

Note the use of a trailing underscore to indicate an outbound link. In this example, the label was added immediately before a heading, so the text that's displayed is the heading text itself. You can change the text that's displayed as the link writing this as:

```
Refer to the `show this text instead <internal-linking_>`_ page
```

which renders as,

> Refer to the *show this text instead* page

Cross-referencing external content With Sphinx's help, we can create link-references to any tagged text within the Zephyr Project documentation.

Target locations in a document are defined with a label directive:

```
.. _my label name:

Heading
=======
```

Note the leading underscore indicating an inbound link. The content immediately following this label must be a heading, and is the target for a `:ref:`my label name`` reference from anywhere within the Zephyr documentation. The heading text is shown when referencing this label. You can also change the text that's displayed for this link, such as:

```
:ref:`some other text <my label name>`
```

To enable easy cross-page linking within the site, each file should have a reference label before its title so it can be referenced from another file. These reference labels must be unique across the whole site, so generic names such as "samples" should be avoided. For example the top of this document's .rst file is:

```
.. _doc_guidelines:

Documentation Guidelines for the Zephyr Project
###############################################
```

Other .rst documents can link to this document using the `:ref:`doc_guidelines`` tag and it will show up as *Documentation Guidelines*. This type of internal cross reference works across multiple files, and the link text is obtained from the document source so if the title changes, the link text will update as well.

You can also define links to any URL and then reference it in your document. For example, with this label definition in the document:

```
.. _Zephyr Wikipedia Page:
   https://en.wikipedia.org/wiki/Zephyr_(operating_system)
```

you can reference it with:

```
Read the `Zephyr Wikipedia Page`_ for more information about the
project.
```

Tip

When a document contains many external links, it can be useful to list them in a single "References" section at the end of the document. This can be done using the `target-notes` directive. Example:

```
References
==========

.. target-notes::

.. _external_link1: https://example.com
.. _external_link2: https://example.org
```

Cross-referencing C documentation

`:c:member:`

`:c:data:`

`:c:var:`

`:c:func:`

`:c:macro:`

`:c:struct:`

`:c:union:`

`:c:enum:`

`:c:enumerator:`

`:c:type:`

You may use these roles to cross-reference the Doxygen documentation of C functions, macros, types, etc.

They are rendered in the HTML output as links to the corresponding Doxygen documentation for the item. For example:

```
Check out :c:func:`gpio_pin_configure` for more information.
```

Will render as:

Check out `gpio_pin_configure()` for more information.

You may provide a custom link text, similar to the built-in `ref` role.

Cross-referencing CMake documentation You may use the following roles to cross-reference the documentation of Zephyr's CMake modules, commands, and variables.

`:cmake:module:`

This role is used to reference a CMake module. For example:

```
See :cmake:module:`extensions` for more information.
```

Will render as:

See *extensions* for more information.

`:cmake:command:`

This role is used to reference a CMake command. For example:

```
See :cmake:command:`yaml_load` for more information.
```

Will render as:

See *yaml_load()* for more information.

Commands documented by CMake itself are referenced through their fully qualified name, given as an explicit link target:

```
See :cmake:command:`target_sources <command:target_sources>` for more
↪information.
```

Will render as:

See `target_sources` for more information.

`:cmake:variable:`

This role is used to reference a CMake variable. For example:

```
See :cmake:variable:`CMAKE_C_COMPILER` for more information.
```

Will render as:

See `CMAKE_C_COMPILER` for more information.

Visual Elements

Images Images are included in the documentation by using an `image` directive:

```
.. image:: ../../../../images/doc-gen-flow.png
   :align: center
   :alt: alt text for the image
```

or if you'd like to add an image caption, use:

```
.. figure:: ../../../../images/doc-gen-flow.png
   :alt: image description

   Caption for the figure
```

The file name specified is relative to the document source file, and we recommend putting images into an `images` folder where the document source is found.

The usual image formats handled by a web browser are supported: WebP, PNG, GIF, JPEG, and SVG.

Keep the image size only as large as needed, generally at least 500 px wide but no more than 1000 px, and no more than 100 KB unless a particularly large image is needed for clarity.

Recommended image formats based on content

- **Screenshots**: WebP or PNG.
- **Diagrams**: Consider using Graphviz for simple diagrams (see dedicated section below. If using an external tool, SVG is preferred.
- **Photos** (ex. boards): WebP, no larger than 600 px on the largest dimension. Whenever the subject can be isolated from its background (typically the case for board photos), save the image with a transparent background so it blends in with both light and dark documentation themes.

  You can convert an existing image to a properly sized WebP using cwebp[9] or ImageMagick[10]. For example:

  ```
  # Using cwebp (resize width to 600 px, height auto, ~80% quality).
  # For a portrait image, use "-resize 0 600" to cap the height instead.
  cwebp -resize 600 0 board_name.png -o board_name.webp

  # Using ImageMagick
  magick board_name.png -resize 600x600 -quality 80 board_name.webp
  ```

  When the source already has a transparent background (e.g. a PNG with an alpha channel), both tools preserve transparency in the resulting WebP. The `-resize 600 0` / `600x600` arguments only scale the image down, preserving its aspect ratio.

Graphviz Graphviz[11] is a tool for creating diagrams specified in a simple text language. As it's important to allow for diagrams used in the documentation to be easily maintained, we encourage the use of Graphviz for creating diagrams. Graphviz is particularly well suited for creating state diagrams, flow charts, and other types of diagrams that can be expressed as a graph.

To include a Graphviz diagram in a document, use the `graphviz` directive. For example:

```
.. graphviz::
   :caption: An example graph using Graphviz

   digraph G {
      rankdir=LR;
      A -> B;
      B -> C;
      C -> D;
   }
```

Would render as:

Please refer to the Graphviz documentation[12] for more information on how to create diagrams using Graphviz's DOT language.

Mermaid Mermaid[13] is a tool for creating diagrams and visualizations using a simple text-based syntax. It is particularly well-suited for creating flowcharts, sequence diagrams, class diagrams, and state transition diagrams.

[9] https://developers.google.com/speed/webp/download
[10] https://imagemagick.org/
[11] https://graphviz.org
[12] https://graphviz.org/documentation
[13] https://mermaid.js.org/

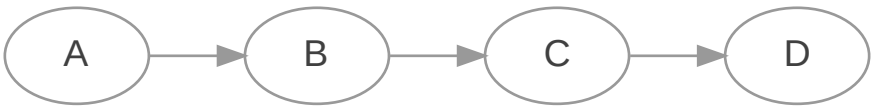

Fig. 1: An example graph using Graphviz

To include a mermaid diagram in a document, use the `mermaid` directive. For example:

```
.. mermaid::
   :caption: State transition diagram for a GPIO debounce
   :alt: GPIO debounce state diagram showing transitions between inactive and␣
↪active states
         through maybe_active and maybe_inactive intermediate states before each␣
↪state becomes
         stable.

   ---
   config:
     state:
       useMaxWidth: false
   ---
   stateDiagram-v2

       State inactive {
           [*] --> stable_inactive
           stable_inactive --> maybe_active : edge to active
           maybe_active --> stable_inactive : edge to inactive
       }

       State active {
           [*] --> stable_active
           stable_active --> maybe_inactive : edge to inactive
           maybe_inactive --> stable_active : edge to active
       }

       [*] --> inactive

       maybe_active --> active : After(x ms)
       maybe_inactive --> inactive : After(x ms)
```

Would render as:

Fig. 2: State transition diagram for a GPIO debounce

A diagram is drawn across the width of the page and its height follows from its aspect ratio, so a diagram that is taller than it is wide ends up much larger than it needs to be. Turning off `useMaxWidth`, as in the example above, keeps the diagram at the size Mermaid computed for it; it still shrinks to fit a narrow screen. The setting belongs to the diagram type, `state` here and `flowchart`, `sequence` or another type elsewhere.

For references about supported diagrams, syntax, and samples; please refer to the Mermaid doc-

umentation[14]. For fast iteration when creating or updating diagrams, you can use the Mermaid live editor[15].

Custom Sphinx Roles and Directives

The Zephyr documentation uses custom Sphinx roles and directives to provide additional functionality and to make it easier to write and maintain consistent documentation.

Application build commands

`.. zephyr-app-commands::`

Generate consistent documentation of the shell commands needed to manage (build, flash, etc.) an application

For example, to generate commands to build `samples/hello_world` for `qemu_x86` use:

```
.. zephyr-app-commands::
   :zephyr-app: samples/hello_world
   :board: qemu_x86
   :goals: build
```

This will render as:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
```

Options

`:tool: (string)`

Which tool to use. Valid options are currently `cmake`, `west` and `all`. The default is `west`.

`:app: (string)`

Path to the application to build.

`:zephyr-app: (string)`

Path to the application to build, this is an app present in the upstream zephyr repository. Mutually exclusive with `:app:`.

`:cd-into: (no value)`

If set, build instructions are given from within the `:app:` folder, instead of outside of it.

`:generator: (string)`

Which build system to generate.

Valid options are currently `ninja` and `make`. The default is `ninja`. This option is not case sensitive.

`:host-os:`

Which host OS the instructions are for.

Valid options are `unix`, `win` and `all`. The default is `all`.

`:board: (string)`

If set, build commands will target the given board.

[14] https://mermaid.js.org/intro/
[15] https://mermaid.live/

`:shield: (string)`
: If set, build commands will target the given shield.

  Multiple shields can be provided in a comma separated list.

`:conf:`
: If set, build commands will use the given configuration file(s).

  If multiple configuration files are provided, enclose the space-separated list of files with double quotes, e.g., *"a.conf b.conf"*.

`:gen-args: (string)`
: If set, indicates additional arguments to the CMake invocation.

`:build-args: (string)`
: If set, indicates additional arguments to the build invocation.

`:west-args: (string)`
: If set, additional arguments to the west invocation (ignored for `:tool: cmake`).

`:flash-args: (string)`
: If set, additional arguments to the flash invocation.

`:debug-args: (string)`
: If set, additional arguments to the debug invocation.

`:debugserver-args: (string)`
: If set, additional arguments to the debugserver invocation.

`:attach-args: (string)`
: If set, additional arguments to the attach invocation.

`:snippets: (string)`
: If set, indicates the application should be compiled with the listed snippets.

  Multiple snippets can be provided in a comma separated list.

`:build-dir: (string)`
: If set, the application build directory will *APPEND* this relative, Unix-separated, path to the standard build directory. This is mostly useful for distinguishing builds for one application within a single page.

`:build-dir-fmt: (string)`
: If set, assume that *west config build.dir-fmt‘* has been set to this path.

  Exclusive with `:build-dir:` and depends on `:tool: west`.

`:goals: (string)`
: A whitespace-separated list of what to do with the app (any of `build`, `flash`, `debug`, `debugserver`, `run`).

  Commands to accomplish these tasks will be generated in the right order.

`:maybe-skip-config: (no value)`
: If set, this indicates the reader may have already created a build directory and changed there, and will tweak the text to note that doing so again is not necessary.

`:compact: (no value)`
: If set, the generated output is a single code block with no additional comment lines.

Cross-referencing files in the Zephyr tree Special roles are available to reference files in the Zephyr tree. For example, referencing this very file can be done using the *zephyr_file* role.

`:zephyr_file:`

This role is used to reference a file in the Zephyr tree. For example:

```
Check out :zephyr_file:`doc/contribute/documentation/guidelines.rst` for more␣
↪information.
```

Will render as:

> Check out doc/contribute/documentation/guidelines.rst for more information.

You can reference specific lines or line ranges in a file by appending `#L`*line_number* or `#L`*start_line*`-L`*end_line* to the file path:

```
See :zephyr_file:`doc/contribute/documentation/guidelines.rst#L3` for the␣
↪main heading of
this document.
```

Will render as:

> See doc/contribute/documentation/guidelines.rst#L3 for the main heading of this document.

The role automatically verifies that the referenced file exists in the Zephyr tree and will generate a warning during documentation build if the file is not found.

> **Note**
>
> Use the line references sparingly as keeping them accurate over time can be challenging as the content of the linked file is subject to change.

You may use the *zephyr_raw* role instead if you want to reference the "raw" content.

`:zephyr_raw:`

This role is used to reference the raw content of a file in the Zephyr tree. For example:

```
Check out :zephyr_raw:`doc/contribute/documentation/guidelines.rst` for more␣
↪information.
```

Will render as:

> Check out doc/contribute/documentation/guidelines.rst for more information.

`:module_file:`

This role is used to reference a module in the Zephyr tree. For example:

```
Check out :module_file:`hal_stm32:CMakeLists.txt` for more information.
```

Will render as:

> Check out hal_stm32:CMakeLists.txt for more information.

Similar to *zephyr_file*, you can reference specific lines or line ranges in a file.

Cross-referencing GitHub issues and pull requests

`:github:`

This role is used to reference a GitHub issue or pull request.

For example, to reference issue #1234:

```
Check out :github:`1234` for more background about this known issue.
```

This will render as:

Check out GitHub #1234 for more background about this known issue.

Doxygen API documentation

`.. doxygengroup:: name`

This directive is used to output a short description of a Doxygen group and a link to the corresponding Doxygen-generated documentation.

All the code samples (declared using the *zephyr:code-sample* directive) indicating the group as relevant will automatically be list and referenced in the rendered output.

For example:

```
.. doxygengroup:: can_interface
```

Will render as:

CAN

Options

:project: (project name (optional))

Associated Doxygen project. This can be useful when multiple Doxygen projects are configured.

:c:group:

This role is used to reference a Doxygen group in the Zephyr tree. In the HTML documentation, they are rendered as links to the corresponding Doxygen-generated documentation for the group. For example:

```
Check out :c:group:`gpio_interface` for more information.
```

Will render as:

Check out GPIO for more information.

You may provide a custom link text, similar to the built-in `ref` role.

Kconfig options If you want to reference a Kconfig option from a document, you can use the *kconfig:option* role and provide the name of the option you want to reference. The role will automatically generate a link to the documentation of the Kconfig option when building HTML output.

Make sure to use the full name of the Kconfig option, including the `CONFIG_` prefix.

:kconfig:option:

This role is used to reference a Kconfig option in the Zephyr tree. For example:

```
Check out :kconfig:option:`CONFIG_GPIO` for more information.
```

Will render as:

Check out `CONFIG_GPIO` for more information.

:kconfig:option-regex:

This role is used to create links to regex searches for Kconfig options. It generates a link to the Kconfig search page with the provided regex pattern automatically filled in as the search query. It is useful for referencing multiple Kconfig options that share a common prefix, or belong to a common category. For example:

```
Check out␣
↪:kconfig:option-regex:`CONFIG_SECURE_STORAGE_ITS_(STORE|TRANSFORM)_.*_CUSTOM`␣
↪for
the various customization possibilities.
```

Will render as:

> Check out CONFIG_SECURE_STORAGE_ITS_(STORE|TRANSFORM)_.*_CUSTOM for the various customization possibilities.

It is encouraged to provide a custom link text to make the reference more readable. For example:

```
Check out the :kconfig:option-regex:`ITS Kconfig options
↪<CONFIG_SECURE_STORAGE_ITS_.*>`
for more information.
```

Will render as:

> Check out the ITS Kconfig options for more information.

Devicetree bindings If you want to reference a Devicetree binding from a document, you can use the *dtcompatible* role and provide the compatible string of the binding you want to reference. The role will automatically generate a link to the documentation of the binding when building HTML output.

`:dtcompatible:`

> This role can be used inline to make a reference to the generated documentation for the Devicetree compatible given as argument.
>
> There may be more than one page for a single compatible. For example, that happens if a binding behaves differently depending on the bus the node is on. If that occurs, the reference points at a "disambiguation" page which links out to all the possibilities, similarly to how Wikipedia disambiguation pages work. Example:

```
Check out :dtcompatible:`zephyr,input-longpress` for more information.
```

Will render as:

> Check out zephyr,input-longpress for more information.

Code samples

`.. zephyr:code-sample:: id`

> This directive is used to describe a code sample, including which noteworthy APIs it may be exercising.
>
> For example:

```
.. zephyr:code-sample:: blinky
   :name: Blinky
   :relevant-api: gpio_interface

   Blink an LED forever using the GPIO API.
```

> The content of the directive is used as the description of the code sample.

Options

`:name: (text)`

> Indicates the human-readable short name of the sample.

`:relevant-api: (text)`
: Optional space-separated list of Doxygen group names that correspond to the APIs exercised by the code sample.

`:zephyr:code-sample:`
: This role is used to reference a code sample described using *zephyr:code-sample*.

For example:

```
Check out :zephyr:code-sample:`blinky` for more information.
```

Will render as:

> Check out blinky for more information.

This can be used exactly like the built-in `ref` role, i.e. you may provide a custom link text. For example:

```
Check out :zephyr:code-sample:`blinky code sample <blinky>` for more
↪information.
```

Will render as:

> Check out blinky code sample for more information.

`.. zephyr:code-sample-category:: id`
: This directive is used to define a category for grouping code samples.

For example:

```
.. zephyr:code-sample-category:: gpio
   :name: GPIO
   :show-listing:

   Samples related to the GPIO subsystem.
```

The contents of the directive is used as the description of the category. It can contain any valid reStructuredText content.

Options

`:name: (text)`
: Indicates the human-readable name of the category.

`:show-listing: (flag)`
: If set, a listing of code samples in the category will be shown. The listing is automatically generated based on all code samples found in the subdirectories of the current document.

`:glob: (text)`
: A glob pattern to match the files to include in the listing. The default is */* but it can be overridden e.g. when samples may be found in directories not sitting directly under the category directory.

`:zephyr:code-sample-category:`
: This role is used to reference a code sample category described using *zephyr:code-sample-category*.

For example:

```
Check out :zephyr:code-sample-category:`cloud` samples for more information.
```

Will render as:

Check out cloud samples for more information.

`.. zephyr:code-sample-listing::`

This directive is used to show a listing of all code samples found in one or more categories.

For example:

```
.. zephyr:code-sample-listing::
   :categories: cloud
```

Will render as:

- AWS IoT Core MQTTConnect to AWS IoT Core and publish messages using MQTT.
- Microsoft Azure IoT Hub MQTTConnect to Azure IoT Hub and publish messages using MQTT.
- TagoIO HTTP PostSend random temperature values to TagoIO IoT Cloud Platform using HTTP.

Options

`:categories: (text)`

A space-separated list of category IDs for which to show the listing.

`:live-search: (flag)`

A flag to include a search box right above the listing. The search box allows users to filter the listing by code sample name/description, which can be useful for categories with a large number of samples. This option is only available in the HTML builder.

Boards

`.. zephyr:board:: name`

This directive is used at the beginning of a document to indicate it is the main documentation page for a board whose name is given as the directive argument.

For example:

```
.. zephyr:board:: wio_terminal
```

The metadata for the board is read from various config files and used to automatically populate some sections of the board documentation. A board documentation page that uses this directive can be linked to using the *zephyr:board* role.

`:zephyr:board:`

This role is used to reference a board documented using *zephyr:board*.

For example:

```
Check out :zephyr:board:`wio_terminal` for more information.
```

Will render as:

Check out wio_terminal for more information.

`.. zephyr:board-catalog::`

This directive is used to generate a catalog of Zephyr-supported boards that can be used to quickly browse the list of all supported boards and filter them according to various criteria.

`:zephyr:board-catalog:`

This role is used to reference the board catalog page, optionally with filter parameters. For example:

```
Check out :zephyr:board-catalog:`` for more information.
```

Will render as:

> Check out :zephyr:board-catalog:“ for more information.

This role can be used exactly like the built-in `ref` role, i.e. you may provide a custom link text. For example:

```
Check out the :zephyr:board-catalog:`boards using this compatible <
↪#compatibles=ti,hdc2080>`
for more information.
```

Will render as:

> Check out the boards using this compatible for more information.

`.. zephyr:board-supported-hw::`

This directive is used to show supported hardware features for all the targets of the board documented in the current page. The tables are automatically generated based on the board's Devicetree.

The directive must be used in a document that also contains a *zephyr:board* directive, as it relies on the board information to generate the table.

> **Note**
>
> This directive requires that the documentation is built with hardware features generation enabled (`zephyr_generate_hw_features` config option set to `True`). If disabled, a warning message will be shown instead of the hardware features tables.
>
> It is possible to limit the hardware features generation to boards from a specific list of vendors to speed up documentation builds without completely disabling the hardware features table. Set the config option `zephyr_hw_features_vendor_filter` to the list of vendors to generate features for. If the option is empty, hardware features are generated for all boards from all vendors.
>
> The config option `zephyr_hw_features_twister_extra_flags` can be used to provide additional flags to the twister command.

`.. zephyr:board-supported-runners::`

This directive is used to show the supported runners for the board documented in the current page, including which runner is the default for flashing and debugging.

The directive must be used in a document that also contains a *zephyr:board* directive, as it relies on the board information to generate the table.

> **Note**
>
> Similar to *zephyr:board-supported-hw*, this directive requires hardware features generation to be enabled (`zephyr_generate_hw_features` config option set to `True`) to produce a complete table. If disabled, a warning message will be shown instead of the runners tables.

Accessibility Guidelines

Accessibility is an important aspect of documentation, ensuring that all users, including those with disabilities, can access and understand the content.

When writing and maintaining Zephyr Project documentation, please follow these guidelines to improve accessibility for everyone.

Images and Figures All images and figures must include appropriate alternative text (alt text) to convey the meaning of the visual content to users who rely on screen readers or cannot view images.

- Use the `:alt:` attribute when including images using the `image` directive. Example:

```
.. image:: ../../../../contribute/documentation/image/doc-gen-flow.png
   :alt: Documentation generation process overview
```

- If the image contains text, ensure that the alt text includes this text verbatim.
- When using the `figure` directive, which allows for a caption, the `:alt:` text is still important. The alt text should describe the image itself, while the caption provides additional context or interpretation. Example:

```
.. figure:: ../../../../images/arch-diagram.png
   :alt: High-level overview of Zephyr OS architecture showing layers and␣
↪components.

   High-level overview of Zephyr OS architecture.
```

- Avoid using images as the sole method of conveying information that can be explained clearly with text.

Best Practices for writing alt text

- **Be Accurate and Equivalent**: Present the same essential information as the image.
- **Be Succinct**: Convey the core message of the image concisely.
- **Avoid Redundancy**: Do not use phrases like "Image of..." or "Picture of..." as screen readers typically announce the element as an image.
- **Describe, Don't Interpret**: Stick to describing what is visually present on the image.
- **Complex Images**: For charts, diagrams, or other complex visuals, provide a summary in the alt text. If a full understanding requires more detail, consider providing a more detailed description in the surrounding text or as part of the figure caption. Using text-based diagram tools like *Graphviz* can also improve accessibility.

Headings and Structure Use *headings* to structure your document logically. This allows users of assistive technologies to understand the document's organization and navigate it efficiently.

Tables Tables should be used only for tabular data and must be accessible to screen readers.

- Always define headers for rows and columns.
- Use the `list-table` directive when possible for better responsiveness and accessibility.
- Include a caption for tables where context is not immediately obvious. Example:

```
.. list-table:: GPIO Pin Configuration Options
   :widths: 15 30
   :header-rows: 1

   * - Field
     - Description
```

(continues on next page)

(continued from previous page)

```
  * - GPIO_INPUT
    - Configures pin as input
  * - GPIO_OUTPUT
    - Configures pin as output
```

7.2.2 Documentation Generation

These instructions will walk you through generating the Zephyr Project's documentation on your local system using the same documentation sources as we use to create the online documentation found at https://docs.zephyrproject.org

Documentation overview

Zephyr Project content is written using the reStructuredText markup language (.rst file extension) with Sphinx extensions, and processed using Sphinx to create a formatted stand-alone website. Developers can view this content either in its raw form as .rst markup files, or you can generate the HTML content and view it with a web browser directly on your workstation. This same .rst content is also fed into the Zephyr Project's public website documentation area (with a different theme applied).

You can read details about reStructuredText, and Sphinx from their respective websites.

The project's documentation contains the following items:

- ReStructuredText source files used to generate documentation found at the https://docs.zephyrproject.org website. Most of the reStructuredText sources are found in the `/doc` directory, but others are stored within the code source tree near their specific component (such as `/samples` and `/boards`)
- Doxygen-generated material used to create all API-specific documents also found at https://docs.zephyrproject.org
- Script-generated material for kernel configuration options based on Kconfig files found in the source code tree

The reStructuredText files are processed by the Sphinx documentation system, and make use of the doxygen-generated API material. Additional tools are required to generate the documentation locally, as described in the following sections.

Installing the documentation processors

Our documentation processing has been tested to run with:

- Doxygen version 1.17.0
- Graphviz 2.43
- Latexmk version 4.83
- All Python dependencies listed in the repository file `doc/requirements.txt`

In order to install the documentation tools, first install Zephyr as described in *Getting Started Guide*. Then install additional tools that are only required to generate the documentation, as described below:

[16] https://www.w3.org/WAI/standards-guidelines/wcag/

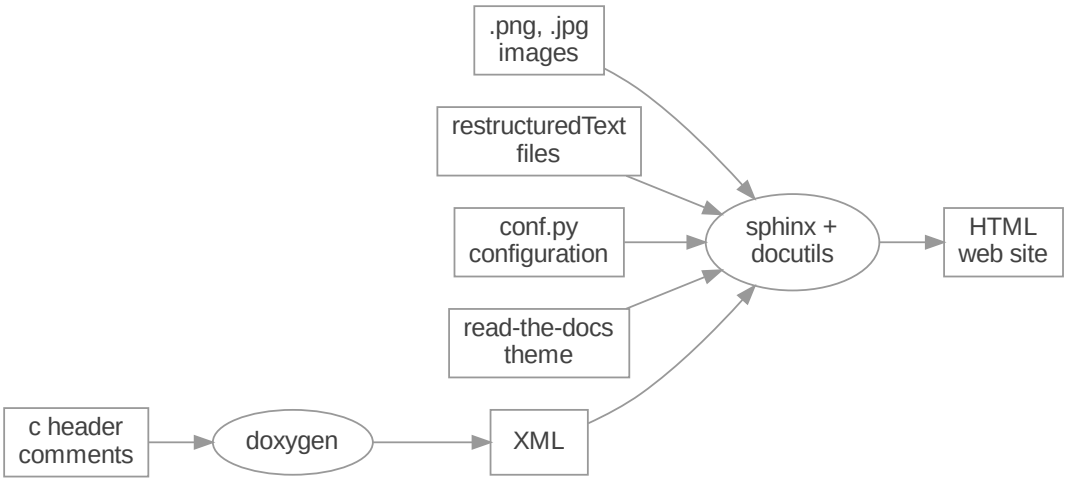

Fig. 3: Schematic of the documentation build process

Linux

Common to all Linux installations, install the Python dependencies required to build the documentation:

```
pip install -U -r ~/zephyrproject/zephyr/doc/requirements.txt
```

On Ubuntu Linux:

```
sudo apt-get install --no-install-recommends doxygen graphviz librsvg2-bin \
texlive-latex-base texlive-latex-extra latexmk texlive-fonts-recommended␣
↪imagemagick
```

On Fedora Linux:

```
sudo dnf install doxygen graphviz texlive-latex latexmk \
texlive-collection-fontsrecommended librsvg2-tools ImageMagick
```

On Clear Linux:

```
sudo swupd bundle-add texlive graphviz ImageMagick
```

On Arch Linux:

```
sudo pacman -S graphviz doxygen librsvg texlive-core texlive-bin \
texlive-latexextra texlive-fontsextra imagemagick
```

macOS

Install the Python dependencies required to build the documentation:

```
pip install -U -r ~/zephyrproject/zephyr/doc/requirements.txt
```

Use `brew` and `tlmgr` to install the tools:

```
brew install doxygen graphviz mactex librsvg imagemagick
tlmgr install latexmk
tlmgr install collection-fontsrecommended
```

Windows

Install the Python dependencies required to build the documentation:

```
pip install -U -r %HOMEPATH$\zephyrproject\zephyr\doc\requirements.txt
```

Open a `cmd.exe` window as **Administrator** and run the following command:

```
choco install doxygen.install graphviz strawberryperl miktex rsvg-convert␣
↪imagemagick
```

Note

On Windows, the Sphinx executable `sphinx-build.exe` is placed in the `Scripts` folder of your Python installation path. Depending on how you have installed Python, you might need to add this folder to your `PATH` environment variable. Follow the instructions in Windows Python Path to add those if needed.

Documentation presentation theme

Sphinx supports easy customization of the generated documentation appearance through the use of themes. Replace the theme files and do another `make html` and the output layout and style is changed. The `read-the-docs` theme is installed as part of the *Get Zephyr and install Python dependencies* step you took in the getting started guide.

Running the documentation processors

The `/doc` directory in your cloned copy of the Zephyr project git repo has all the .rst source files, extra tools, and Makefile for generating a local copy of the Zephyr project's technical documentation. Assuming the local Zephyr project copy is in a folder `zephyr` in your home folder, here are the commands to generate the html content locally:

```
# On Linux/macOS
cd ~/zephyrproject/zephyr/doc
# On Windows
cd %userprofile%\zephyrproject\zephyr\doc

# Use cmake to configure a Ninja-based build system:
cmake -GNinja -B_build .

# Enter the build directory
cd _build

# To generate HTML output, run ninja on the generated build system:
ninja html
# If you modify or add .rst files, run ninja again:
ninja html

# To generate PDF output, run ninja on the generated build system:
ninja pdf
```

Warning

The documentation build system creates copies in the build directory of every .rst file used to generate the documentation, along with dependencies referenced by those .rst files.

This means that Sphinx warnings and errors refer to the **copies**, and **not the version-controlled original files in Zephyr**. Be careful to make sure you don't accidentally edit the copy of the file in an error message, as these changes will not be saved.

Depending on your development system, it will take up to 15 minutes to collect and generate the HTML content. When done, you can view the HTML output with your browser started at `doc/_build/html/index.html` and if generated, the PDF file is available at `doc/_build/latex/zephyr.pdf`.

If you want to build the documentation from scratch just delete the contents of the build folder and run `cmake` and then `ninja` again.

Note

If you add or remove a file from the documentation, you need to re-run CMake.

On Unix platforms a convenience doc/Makefile can be used to build the documentation directly from there:

```
cd ~/zephyrproject/zephyr/doc

# To generate HTML output
make html

# To generate PDF output
make pdf
```

Developer-mode Document Building

When making and testing major changes to the documentation, we provide an option to temporarily stub-out the auto-generated Devicetree bindings documentation so the doc build process runs faster.

To enable this mode, set the following option when invoking cmake:

```
-DDT_TURBO_MODE=1
```

Another step that typically takes a long time is the generation of the list of supported features for each board. This can be disabled by setting the following option when invoking cmake:

```
-DHW_FEATURES_TURBO_MODE=1
```

Invoking **make** with the following target will build the documentation without either of the aforementioned features:

```
cd ~/zephyrproject/zephyr/doc

# To generate HTML output without detailed Devicetree bindings documentation
# and supported features index
make html-fast
```

For even faster iteration when working on narrative pages, additional `SKIP_*` options allow skipping entire categories of auto-generated content:

SKIP_DOXYGEN
: Skip running Doxygen and building the C API reference.

`SKIP_KCONFIG`
: Skip generating the Kconfig option reference and its search page.

`SKIP_EXTERNAL_CONTENT`
: Skip copying in the board, sample, and snippet pages that are maintained outside of the `doc/` folder (i.e. the contents of the boards, samples, and snippets folders).

Each option can be enabled individually:

```
make html SKIP_DOXYGEN=1
```

The **`make html-minimal`** target combines all of them on top of `html-fast`, making it the fastest way to preview a change to a narrative page:

```
make html-minimal
```

Warning

Content that a skipped generator would have produced is replaced with a placeholder, cross-references to it render as plain text, and the related warnings are suppressed. A build using any `SKIP_*` option is therefore only suitable for a local preview: it cannot be used to validate cross-references, and its output must not be published.

When working with documentation for boards from a specific vendor, it is also possible to limit generation of the list of supported features to subset of board vendors. This can be done by setting the following option when invoking cmake:

```
-DHW_FEATURES_VENDOR_FILTER=vendor1,vendor2
```

This option can also be used with the **`make`** wrapper:

```
cd ~/zephyrproject/zephyr/doc

# To generate HTML output with supported features limited to a subset of vendors
make html HW_FEATURES_VENDOR_FILTER=vendor1,vendor2
```

Viewing generated documentation locally

The generated HTML documentation can be hosted locally with python for viewing with a web browser:

```
$ python3 -m http.server -d _build/html
```

Note

WSL2 users may need to explicitly bind the address to `127.0.0.1` in order to be accessible from the host machine:

```
$ python3 -m http.server -d _build/html --bind 127.0.0.1
```

Alternatively, the documentation can be built with the `make html-live` (or `make html-live-fast`) command, which will build the documentation, host it locally, and watch the documentation directory for changes. When changes are observed, it will automatically rebuild the documentation and refresh the hosted files.

Building the Doxygen documentation standalone

The `doxygen` build target can be used to only build the Doxygen (API) documentation, which is much faster than building the full documentation set:

```
cd ~/zephyrproject/zephyr/doc
make doxygen
```

The output can be found in `_build/doxygen/html`.

The `doxygen-xml` target builds the same documentation with only the XML output enabled, in `_build/doxygen-xml/xml`.

In the regular documentation build, references made from Doxygen comments to the main documentation (e.g. `@kconfig{}`, `@dtcompatible{}` or `@rstref{}`, see *Referencing the main documentation*) are automatically resolved into hyperlinks. In a standalone Doxygen build, they are left as plain text since the rest of the documentation is not available.

Linking external Doxygen projects against Zephyr

External projects that build upon Zephyr functionality and wish to refer to Zephyr documentation in Doxygen (through the use of @ref), can utilize the tag file exported at zephyr.tag

Once downloaded, the tag file can be used in a custom `doxyfile.in` as follows:

```
TAGFILES = "/
↪path/to/zephyr.tag=https://docs.zephyrproject.org/latest/doxygen/html/"
```

For additional information refer to Doxygen External Documentation.

Documentation Guidelines
: This page provides some simple guidelines for writing documentation using the reSTructuredText (reST) markup language and Sphinx documentation generator.

Documentation Generation
: As you write documentation, it can be helpful to see how it will look when rendered.

  This page describes how to build the Zephyr documentation locally.

7.3 Dealing with external components

7.3.1 Contributing External Components

In some cases it is desirable to leverage existing, external source code in order to avoid re-implementing basic functionality or features that are readily available in other open source projects.

This section describes the circumstances under which external source code can be imported into Zephyr, and the process that governs the inclusion.

There are three main factors that will be considered during the inclusion process in order to determine whether it will be accepted. These will be described in the following sections.

Note that most of this page deals with external components that end up being compiled and linked into the final image, and programmed into the target hardware. For external tooling that is only used during compilation, code analysis, testing or simulation please refer to the *Contributing External Tooling* section at the end of the page.

Software License

> **Note**
>
> External source code licensed under the Apache-2.0 license is not subject to this section.

Integrating code into the Zephyr Project from other projects that use a license other than the Apache 2.0 license needs to be fully understood in context and approved by the Zephyr governing board, as described in the Zephyr project charter. The board will automatically reject licenses that have not been approved by the Open Source Initiative (OSI). See the *Submission and review process* section for more details.

By carefully reviewing potential contributions and also enforcing a *Developer Certification of Origin (DCO)* for contributed code, we ensure that the Zephyr community can develop products with the Zephyr Project without concerns over patent or copyright issues.

Merit

Just like with any other regular contribution, one that contains external code needs to be evaluated for merit. However, in the particular case of code that comes from an existing project, there are additional questions that must be answered in order to accept the contribution. More specifically, the following will be considered by the Technical Steering Committee and evaluated carefully before the external source code is accepted into the project:

- Is this the most optimal way to introduce the functionality to the project? Both the cost of implementing this internally and the one incurred in maintaining an externally developed codebase need to be evaluated.
- Is the external project being actively maintained? This is particularly important for source code that deals with security or cryptography.
- Have alternatives to the particular implementation proposed been considered? Are there other open source project that implement the same functionality?

Mode of integration

There are two ways of integrating external source code into the Zephyr Project, and careful consideration must be taken to choose the appropriate one for each particular case.

Integration in the main tree The first way to integrate external source code into the project is to simply import the source code files into the main `zephyr` repository. This automatically implies that the imported source code becomes part of the "mainline" codebase, which in turn requires that:

- The code is formatted according to the Zephyr *Coding Style Guidelines*
- The code adheres to the project's *Coding Guidelines*
- The code is subject to the same checks and verification requirements as the rest of the code in the main tree, including static analysis
- All files contain an SPDX tag if not already present
- If the source is not Apache 2.0 licensed, an `[[annotations]]` entry describing the component is added to the REUSE.toml file at the root of the repository. This is what the *licensing page* is generated from.

This mode of integration can be applicable to both small and large external codebases, but it is typically used more commonly with the former.

Integration as a module The second way of integrating external source code into the project is to import the whole or parts of the third-party open source project into a separate repository, and then include it under the form of a *module*. With this approach the code is considered as being developed externally, and thus it is not automatically subject to the requirements of the previous section.

Integration in main manifest file (west.yaml) Integrating external code into the main `west.yml` manifest file is limited to code that is used by a Zephyr subsystem (libraries), by a platform, drivers (HAL) or tooling needed to test or build Zephyr components.

The integration of modules in this group is validated by the Zephyr project CI, and verified to be working with each Zephyr release.

Integrated modules will not be removed from the tree without a detailed migration plan.

Integration as optional modules Standalone or loose integration of modules/projects without any incoming dependencies shall be made optional and shall be kept standalone. Optional projects that provide value to users directly and through a Zephyr subsystem or platform shall be added to an optional manifest file that is filtered by default. (`submanifests/optional.yml`).

Such optional projects might include samples and tests in their own repositories.

There shall not be any direct dependency added in the Zephyr code tree (Git repository) and all sample or test code shall be maintained as part of the module.

Note

This is valid for all new optional modules. Existing optional modules with samples and test code in the Zephyr Git repository will be transitioned out over time.

Integration as external modules Similar to optional modules, but added to the Zephyr project as an entry in the documentation using a pre-defined template. This type of modules exists outside the Zephyr project manifest with documentation instructing users and developers how to integrate the functionality.

Ongoing maintenance

Regardless of the mode of integration, external source code that is integrated in Zephyr requires regular ongoing maintenance. The submitter of the proposal to integrate external source code must therefore commit to maintain the integration of such code for the foreseeable future. This may require adding an entry in the `MAINTAINERS.yml` as part of the process.

Submission and review process

Before external source code can be included in the project, it must be reviewed and accepted by the Technical Steering Committee (TSC) and, in some cases, by the Zephyr governing board.

A request for external source code integration must be made by creating a new issue in the Zephyr project issue tracking system on GitHub with details about the source code and how it integrates into the project.

Follow the steps below to begin the submission process:

1. Make sure to read through the *Contributing External Components* section in detail, so that you are informed of the criteria used by the TSC and board in order to approve or reject a request
2. Use the New External Source Code Issue to open an issue

3. Fill out all required sections, making sure you provide enough detail for the TSC to assess the merit of the request. Optionally you can also create a Pull Request that demonstrates the integration of the external source code and link to it from the issue
4. Wait for feedback from the TSC, respond to any additional questions added as GitHub issue comments

If, after consideration by the TSC, the conclusion is that integrating external source code is the best solution, and the external source code is licensed under the Apache-2.0 license, the submission process is complete and the external source code can be integrated.

If, however, the external source code uses a license other than Apache-2.0, then these additional steps must be followed:

1. The TSC chair will forward the link to the GitHub issue created during the early submission process to the Zephyr governing board for further review
2. The Zephyr governing board has two weeks to review and ask questions:
   - If there are no objections, the matter is closed. Approval can be accelerated by unanimous approval of the board before the two weeks are up
   - If a governing board member raises an objection that cannot be resolved via email, the board will meet to discuss whether to override the TSC approval or identify other approaches that can resolve the objections
3. On approval of the Zephyr TSC and governing board the submission process is complete

The flowchart below shows an overview of the process:

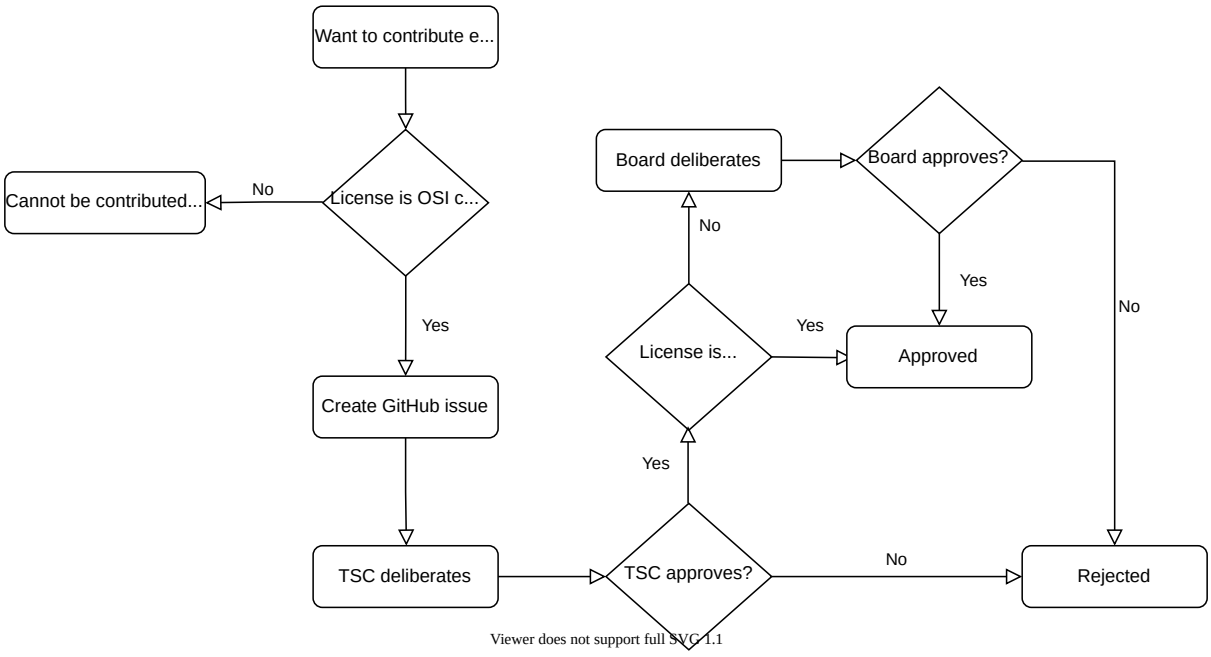

Fig. 4: Submission process

Contributing External Tooling

This section deals exclusively with the inclusion of external tooling in the Zephyr project, where tooling is defined as software that assists the compilation, testing or simulation processes but in no case ends up being part of the code compiled and linked into the final image. “Inclusion” in this context means becoming part of the Zephyr default distribution either in the main tree directly under the `scripts/` folder or indirectly as a west project in the main `west.yml` manifest.

Therefore, this section does not apply to 3rd-party tooling such as toolchains, simulators or others, which may still be referenced by the Zephyr build system or docs without being included in Zephyr.

Tooling components must be released under a license approved by the Open Source Initiative (OSI).

Just like with regular external components, tooling that is imported from another project can be integrated either in the main tree or as a *west project*. Note that in this case the corresponding west project will not be a *module*, because tooling does not make use of the Zephyr build system and does not need to be processed by it. Please see *Modules vs west projects* for additional information on the differences.

If the tool is integrated in the main tree it should be placed under the `scripts/` folder. If the tool is integrated as a west project, then the project repository can be hosted outside the zephyrproject-rtos GitHub organization, provided that the project is made optional via the `group-filter:` field in the main `west.yml` manifest. More info on optional projects can be found in *this section*.

The TSC must approve every Pull Request that introduces a new external tooling component. This will be done on a case-by-case, individual analysis of the proposed addition by the TSC representatives.

Additional considerations about the main manifest

In general, any additions or removals whatsoever to the `projects:` section of the main manifest file requires TSC approval. This includes, but is not limited to:

- Adding and removing groups and group filters
- Adding and removing projects
- Adding and removing `import` statements

7.3.2 Binary Blobs

In the context of an operating system that supports multiple architectures and many different IC families, some functionality may be unavailable without the help of executable code distributed in binary form. Binary blobs (or blobs for short) are files containing proprietary machine code or data in a binary format, e.g. without corresponding source code released under an OSI approved license.

Zephyr supports downloading and using third-party binary blobs via its built-in mechanisms, with some important caveats, described in the following sections. It is important to note that all the information in this section applies only to upstream (vanilla) Zephyr.

There are no limitations whatsoever (except perhaps license compatibility) in the support for binary blobs in forks or third-party distributions of Zephyr. In fact, Zephyr's build system supports arbitrary use cases related to blobs. This includes linking against libraries, flashing images to targets, etc. Users are therefore free to create Zephyr-based downstream software which uses binary blobs if they cannot meet the requirements described in this page.

Software license

Most binary blobs are distributed under proprietary licenses which vary significantly in nature and conditions. It is up to the vendor to specify the license as part of the blob submission process. Blob vendors may impose a click-through or other EULA-like workflow when users fetch and install blobs.

Hosting

Blobs must be hosted on the Internet and managed by third-party infrastructure. Two potential examples are Git repositories and web servers managed by individual hardware vendors.

The Zephyr Project does not host binary blobs in its Git repositories or anywhere else.

Fetching blobs

Blobs are fetched from official third-party sources by the *west blobs* command.

The blobs themselves must be specified in the *module.yml* files included in separate Zephyr *module repositories* maintained by their respective vendors. This means that in order to include a reference to a binary blob to the upstream Zephyr distribution, a module repository must exist first or be created as part of the submission process.

Each blob which may be fetched must be individually identified in the corresponding `module.yml` file. A specification for a blob must contain:

- An abstract description of the blob itself
- Version information
- A reference to vendor-provided documentation
- The blob's *type*, which must be one of the allowed types
- A checksum for the blob, which `west blobs` checks after downloading. This is required for reproducibility and to allow bisecting issues as blobs change using Git and west
- License text applicable to the blob or a reference to such text, in SPDX format

See the *corresponding section* for a more formal definition of the fields.

The *west blobs* command can be used to list metadata of available blobs and to fetch blobs from user-selected modules.

The `west blobs` command only fetches and stores the binary blobs themselves. Any accompanying code, including interface header files for the blobs, must be present in the corresponding module repository.

Tainting

Inclusion of binary blobs will taint the Zephyr build. The definition of tainting originates in the Linux kernel and, in the context of Zephyr, a tainted image will be one that includes binary blobs in it.

Tainting will be communicated to the user in the following manners:

- One or more Kconfig options `TAINT_BLOBS_*` will be set to `y`
- The Zephyr build system, during its configuration phase, will issue a warning. It will be possible to disable the warning using Kconfig
- The `west spdx` command will include the tainted status in its output
- The kernel's default fatal error handler will also explicitly print out the kernel's tainted status
- The boot banner prints the kernel's tainted status

Allowed types

The following binary blob types are acceptable in Zephyr:

- Precompiled libraries: Hardware enablement libraries, distributed in precompiled binary form, typically for SoC peripherals. An example could be an enablement library for a wireless peripheral
- Firmware images: An image containing the executable code for a secondary processor or CPU. This can be full or partial (typically delta or patch data) and is generally copied into

RAM or flash memory by the main CPU. An example could be the firmware for the core running a Bluetooth LE Controller

- Miscellaneous binary data files. An example could be pre-trained neural network model data

Hardware agnostic features provided via a proprietary library are not acceptable. For example, a proprietary and hardware agnostic TCP/IP stack distributed as a static archive would be rejected.

Note that just because a blob has an acceptable type does not imply that it will be unconditionally accepted by the project; any blob may be rejected for other reasons on a case by case basis (see library-specific requirements below). In case of disagreement, the TSC is the arbiter of whether a particular blob fits in one of the above types.

Precompiled library-specific requirements

This section contains additional requirements specific to precompiled library blobs.

Any person who wishes to submit a precompiled library must represent that it meets these requirements. The project may remove a blob from the upstream distribution if it is discovered that the blob fails to meet these requirements later on.

Interface header files The precompiled library must be accompanied by one or more header files, distributed under a non-copyleft OSI approved license, that define the interface to the library.

Allowed dependencies This section defines requirements related to external symbols that a library blob requires the build system to provide.

- The blob must not depend on Zephyr APIs directly. In other words, it must have been possible to build the binary without any Zephyr source code present at all. This is required for loose coupling and maintainability, since Zephyr APIs may change and such blobs cannot be modified by all project maintainers
- Instead, if the code in the precompiled library requires functionality provided by Zephyr (or an RTOS in general), an implementation of an OS abstraction layer (aka porting layer) can be provided alongside the library. The implementation of this OS abstraction layer must be in source code form, released under an OSI approved license and documented using Doxygen.

Toolchain requirements Precompiled library blobs must be in a data format which is compatible with and can be linked by a toolchain supported by the Zephyr Project. This is required for maintainability and usability. Use of such libraries may require special compiler and/or linker flags, however. For example, a porting layer may require special flags, or a static archive may require use of specific linker flags.

Limited scope Allowing arbitrary library blobs carries a risk of degrading the degree to which the upstream Zephyr software distribution is open source. As an extreme example, a target with a zephyr kernel clock driver that is just a porting layer around a library blob would not be bootable with open source software.

To mitigate this risk, the scope of upstream library blobs is limited. The project maintainers define an open source test suite that an upstream target must be able to pass using only open source software included in the mainline distribution and its modules. The open source test suite currently consists of:

- `samples/philosophers`
- `tests/kernel`

The scope of this test suite may grow over time. The goal is to specify tests for a minimal feature set which must be supported via open source software for any target with upstream Zephyr support.

At the discretion of the release team, the project may remove support for a hardware target if it cannot pass this test suite.

Support and maintenance

The Zephyr Project is not expected to be responsible for the maintenance and support of contributed binary blobs. As a consequence, at the discretion of the Zephyr Project release team, and on a case-by-case basis:

- GitHub issues reported on the zephyr repository tracker that require use of blobs to reproduce may not be treated as bugs
- Such issues may be closed as out of scope of the Zephyr project

This does not imply that issues which require blobs to reproduce will be closed without investigation. For example, the issue may be exposing a bug in a Zephyr code path that is difficult or impossible to trigger without a blob. Project maintainers may accept and attempt to resolve such issues.

However, some flexibility is required because project maintainers may not be able to determine if a given issue is due to a bug in Zephyr or the blob itself, may be unable to reproduce the bug due to lack of hardware, etc.

Blobs must have designated maintainers that must be responsive to issue reports from users and provide updates to the blobs to address issues. At the discretion of the Zephyr Project release team, module revisions referencing blobs may be removed from `zephyr/west.yml` at any time due to lack of responsiveness or support from their maintainers. This is required to maintain project control over bit-rot, security issues, etc.

The submitter of the proposal to integrate a binary blob must commit to maintain the integration of such blob for the foreseeable future.

Regarding Continuous Integration, binary blobs will **not** be fetched in the project's CI infrastructure that builds and optionally executes tests and samples to prevent regressions and issues from entering the codebase. This includes both CI ran when a new GitHub Pull Request is opened as well as any other regularly scheduled execution of the CI infrastructure.

Submission and review process

For references to binary blobs to be included in the project, they shall be submitted through the standard pull request (PR) workflow and do not require Technical Steering Committee (TSC) approval. Maintainers and reviewers are responsible for ensuring that all blob-related submissions conform to the documented criteria as defined in *Binary Blobs*.

The PR for initial integration with binary blobs shall include details about the blobs and the functionality they provide. The PR shall have the following information to support the review:

- Binary blob origin.
- Type of blob (precompiled library, firmware image).
- Zephyr module that the blob(s) will be referenced from.
- Brief description of what the blob(s) do.
- What other components do the blob(s) depend on, if any?
- License the blob(s) are distributed under.

If the initial integration PR receives the appropriate approvals the binary blob(s) can be integrated. The standard *PR escalation procedures* shall apply for any technical disagreements.

Subsequent updates to binary blobs follow the *module update procedure*.

Contributing External Components
: Basic functionality or features that would make useful addition to Zephyr might be readily available in other open source projects, and it is recommended and encouraged to reuse such code. This page describes in more details when and how to import external source code into Zephyr.

Contributing External Tooling
: Similarly, external tooling used during compilation, code analysis, testing or simulation, can be beneficial and is covered in this section.

Binary Blobs
: As some functionality might only be made available with the help of executable code distributed in binary form, this page describes the process and guidelines for *contributing binary blobs* to the project.

7.4 Need help along the way?

If you have questions related to the contribution process, the Zephyr community is here to help. You may join our Discord channel or use the Developer Mailing List.

Chapter 8

Project and Governance

8.1 Technical Steering Committee (TSC)

8.1.1 TSC Member Role

The TSC role and its responsibilities is defined in the Zephyr project charter.

Membership

A TSC member plays a pivotal role in shaping the technical direction of the Zephyr Project. TSC members work collaboratively with other TSC members, contributors, and stakeholders to ensure the project's success and sustainability.

By fulfilling the rights and responsibilities below, TSC members contribute to the overall success and growth of the Zephyr Project, ensuring that it remains a vibrant and thriving open-source community for years to come.

Rights

Decision Making
: Participate in key decisions related to the project's technical direction, including architectural changes, feature additions, and release planning.

Voting
: Exercise voting rights on important matters discussed within the TSC, including feature proposals, code contributions, and community initiatives.

Access
: Gain access to relevant project repositories, documentation, and communication channels to stay informed and contribute effectively.

Leadership
: Take on leadership roles within working groups or subcommittees dedicated to specific technical areas or initiatives.

Representation
: Act as a representative of the broader Zephyr community, advocating for the interests of contributors, users, and stakeholders.

Responsibilities TSC members are expected to fulfill the following responsibilities, though it is not mandatory to fulfill all:

Technical Oversight
: Provide guidance and oversight on technical matters, ensuring alignment with project

goals, standards, and best practices through active participation as core members in working groups and committees.

Code Review
Participate in code reviews to maintain code quality, consistency, and compatibility with project standards.

Community Engagement
Engage with the community through forums, mailing lists, conferences, and other channels to foster collaboration, address concerns, and gather feedback.

Documentation
Contribute to the development and maintenance of project documentation, including technical guides, API references, and best practices.

Release Management
Collaborate with the release manager and other stakeholders to plan and coordinate project releases, ensuring timely delivery and quality assurance.

Contributor Support
Support and mentor new contributors, helping them navigate the project's codebase, processes, and community norms.

Issue Triage
Assist in triaging and prioritizing issues reported by users and contributors, facilitating timely resolution and communication.

Compliance and Licensing
Ensure compliance with project licensing requirements and open-source best practices, addressing any licensing-related issues that may arise.

Conflict Resolution
Facilitate constructive discussions and resolution of technical disagreements or conflicts within the community, promoting a healthy and inclusive environment.

Continuous Improvement
Continuously seek opportunities to improve project governance, processes, and infrastructure, driving innovation and sustainability.

Appointed TSC Members

See Zephyr project charter for more details.

- Appointed TSC members have no term limits besides the term of their employment at the organization they represent or their organization's membership in the Zephyr Project.
- Appointed TSC members can select an Alternate from the same organization.

Elected TSC Members

Per the Zephyr project charter, TSC members can nominate representatives from the technical community at the rate of no more than one per quarter.

- Majority vote is required to confirm a candidate.
- Once elected, a TSC member serves for 2 years.
- Elected TSC members do not have the right to appoint an Alternate.
- To ensure continuity of the TSC, at the end of the 2 year term, the TSC is required to reconfirm the membership of elected members. If the elected member declines a new term or if the TSC fails to reconfirm the term, the seat will be open for new nominations.
- If an elected TSC member resigns before the end of the 2 year term, their spot will be open for new members outside of the quarterly nomination limit. The elected member will serve a 2 year term.

- The TSC has the right to terminate elected members who become inactive and are not fulfilling the responsibilities of TSC members as described in this document.
- The number of elected members shall not exceed 20% of the total of appointed members.
- Existing TSC members who were elected before May 2024 shall be re-confirmed after completing the 2 year term since they were first elected.

Suspensions

As noted under Section 8b of the Project Charter, voting rights for a representative who misses three consecutive meetings are subject to suspension and suspended representatives do not count towards the quorum requirement.

A representative's suspension will end and voting rights be restored at the start of the next attended meeting. The TSC enforces the suspension policy for voting members who miss three consecutive TSC weekly meetings.

Multi-day meetings (F2F events) are counted as "one" meeting. The TSC voted on February 16, 2022 to discontinue default enforcement of the suspension policy. The TSC voted on January 18, 2023 to re-enact default enforcement of the suspension policy.

Notice of suspension will be sent to representatives who miss three consecutive meetings, noting that rights will be restored upon next attendance of a TSC meeting.

Note

As per Section 4b of the Project Charter, Platinum and Silver Members may choose to opt out of a voting seat on the TSC.

Members who opt out and then wish to reclaim their seat later will have their voting rights restored at the start of the second consecutive meeting attended following notification to the TSC Chair.

Voting

Voting in the Zephyr Project is defined under Section 8 of the Project Charter.

Additional points of clarity / TSC interpretation have been added below. The Governing Board may opt to update the Charter to include the below refinements. Until then, additional clarifications (if/where needed) will be discussed in the Process Working Group, and approved in the TSC.

- TSC In-Meeting Voting For items requesting an in-meeting vote of the Zephyr Technical Steering Committee (TSC), assuming quorum requirements have been met, the default voting mechanism will be a verbal motion to determine if there is general consensus.
- If there are no objections to a motion being brought forward, general consensus is assumed and the motion passes.
- Should there be any objections raised, the vote will move to email, and be executed using the Voting Guidelines outlined in Section 8 of the Project Charter.
- Should a motion be deemed urgent by the TSC Chair, and assuming quorum requirements have been met, the Chair may call for a roll call vote in-meeting.

Voting Options

- Voting Options are:
  - "Yes",
  - "No" or

– “Abstain”

Abstention Abstentions do not count in tallying the vote negatively or positively; when members abstain, they are in effect attending only to contribute to a quorum.

Abstentions do not impact the number of votes needed to decide a vote.

Quorum Quorum for TSC meetings shall require 60% of the voting representatives… (ref 8b of the Charter)

Decisions Decisions by vote shall be based on a majority vote, provided that at least sixty percent (60%) of the **TSC** representatives must be either present or participating electronically or by written action in order to conduct a valid vote. (ref 8c of the Charter)

Example A:

> 40 eligible TSC voters. 3 abstain from a vote on a motion. 12 vote Yes. 11 vote No.
>
> Quorum reached: 26 votes cast (quorum = 60% of 40 = 24) Majority vote: 12 Yes vs. 11 No. Yes wins. Motion adopted.

Example B:

> 40 eligible TSC voters. 5 abstain from a vote on a motion. 12 vote Yes. 6 vote No. Quorum reached? 23 votes cast (quorum = 60% of 40 = 24)
>
> Vote is not valid. Quorum not reached.

Example C:

> 40 eligible TSC voters. 21 abstain from a vote on a motion. 2 vote Yes. 1 votes No. Quorum reached? 24 votes cast (quorum = 60% of 40 = 24)
>
> Majority vote: 2 Yes vs. 1 No. Yes wins.

Immutable Votes

Votes are considered immutable once cast. A voter may not change their vote, once cast, between the time a Motion is brought forth and the time at which results are announced.

8.2 TSC Project Roles

8.2.1 Project Roles

You can participate in the Zephyr Project as a *Contributor*, *Collaborator*, or *Maintainer*.

Contributor: Any community member who contributes code, documentation, or other assets to the project.

Collaborator: An active Contributor who is involved in one or more areas of the project.

Maintainer: A lead Collaborator responsible for a specific area or subsystem within the project. Maintainers also serve as representatives for their area on the Technical Steering Committee (TSC) as needed.

Areas in this context refer to specific subsystems, components, or modules within the Zephyr Project codebase. Examples of areas include, but are not limited to, networking, file systems, device drivers, architecture support, and board support packages (boards and SoC definitions).

Areas in the project should at least have one Maintainer and may have multiple Collaborators. Depending on the size and complexity of the area, there may be multiple Maintainers as well, however, the number of maintainers should be kept to a practical minimum to ensure effective management and decision-making.

Contributor

A *Contributor* is a developer who wishes to contribute to the project, at any level.

Contributors are granted the following rights and responsibilities:

- Right to contribute code, documentation, translations, artwork, etc.
- Right to report defects (bugs) and suggestions for enhancement.
- Right to participate in the process of reviewing contributions by others.
- Right to participate in the feature development process.
- Responsibility to abide by decisions, once made. They are welcome to provide new, relevant information to reopen decisions.
- Responsibility for issues and bugs introduced by one's own contributions.
- Responsibility to respect the rules of the community.
- Responsibility to provide constructive advice whenever participating in discussions and in the review of contributions.
- Responsibility to follow the project's code of conduct (https://github.com/zephyrproject-rtos/zephyr/blob/main/CODE_OF_CONDUCT.md)

Zephyr Contributor Badge When your first contribution to the Zephyr project gets merged, you'll become eligible to claim your Zephyr Contributor Badge. This digital badge can be displayed on your website, blog, social media profile, etc. It will allow you to showcase your involvement in the Zephyr project and help raise its awareness.

You may apply for your Contributor Badge by filling out the Zephyr Contributor Badge form.

Collaborator

A *Collaborator* is a Contributor who is also participating in the maintenance of Zephyr source code. Their input weighs more when decisions are made, in a fully meritocratic fashion.

You become a collaborator by showing consistent involvement in the project, including making significant contributions to the project over a period of time and by participating in the development and review of at least one area.

To request to become a Collaborator, submit a pull request adding yourself to the `collaborators` section of an area in the *MAINTAINERS File* and notify the maintainers of that area. The addition needs to be approved by the maintainers of that area.

Collaborators have the following rights and responsibilities, in addition to those listed for Contributors:

- Right to participate in setting goals for the short and medium terms for the area being maintained, alongside the maintainers of that area.
- Responsibility to participate in the feature development process.
- Responsibility to review relevant code changes within reasonable time.
- Responsibility to ensure the quality of the code to expected levels.
- Responsibility to participate in community discussions.
- Responsibility to mentor new contributors when appropriate
- Responsibility to participate in the quality verification and release process, when those happen.

Collaborator change requests on pull requests should be addressed by the original submitter. In cases where the changes requested do not follow the *expectations* and the guidelines of the

project or in cases of disagreement, it is the responsibility of the assignee to advance the review process and resolve any disagreements.

Collaborator approval of pull requests are counted toward the minimum required approvals needed to merge a PR. Other criteria for merging may apply.

Maintainer

A *Maintainer* is a Collaborator who is also responsible for knowing, directing and anticipating the needs of a given zephyr source code area.

An individual may become a maintainer of a given area by demonstrating sustained and meaningful contributions over time. This includes:

- Making significant technical contributions to the area.
- Actively participating in the development process, including code reviews and design discussions.
- Establishing familiarity with the architecture, constraints, and evolution of the area.

Maintainer status may also be granted when introducing a new area or subsystem to the project as its original author while demonstrating recognized expertise and long-term commitment to the area.

In all cases, maintainership reflects both technical ownership and ongoing engagement with the community supporting that area.

To request to become a Maintainer, submit a pull request adding yourself to the `maintainers` section of an area in the *MAINTAINERS File* and notify the existing maintainers of that area. The addition needs to be approved by the maintainers of that area.

Usually, there's only one maintainer but depending on the area, there may be multiple maintainers sharing the responsibility.

Maintainers have the following rights and responsibilities, in addition to those listed for Contributors and Collaborators:

- Right to set the overall architecture of the relevant subsystems or areas of involvement.
- Right to make decisions in the relevant subsystems or areas of involvement, in conjunction with the collaborators and submitters. See *PR Technical Escalation*.
- Responsibility to convey the direction of the relevant subsystem or areas to the TSC
- Responsibility to ensure all contributions of the project have been reviewed within reasonable time.
- Responsibility to enforce the Code of Conduct. As leaders in the community, maintainers are expected to be role models in upholding the project's code of conduct and creating a welcoming and inclusive environment for everyone.
- Responsibility to triage static analysis issues in their code area. See *Static Code Analysis*.

Maintainer approval of pull requests are counted toward the minimum required approvals needed to merge a PR. Other criteria for merging may apply.

8.2.2 Teams and Supporting Activities

Assignee

An *Assignee* is one of the maintainers of an area being changed in a pull request.

Assignees are set automatically based on the code being changed. Other Maintainers or the Release Engineering team can set assignees when the latter is not possible, or when another assignee is more appropriate, in this last case documenting in a comment the motivation for the change.

- Responsibility to drive the pull request to a mergeable state
- Right to dismiss stale and unrelated reviews or reviews not following *expectations* from reviewers and seek reviews from additional maintainers, developers and contributors
- Right to block pull requests from being merged until issues or changes requested are addressed
- Responsibility to re-assign a pull request if they are the original submitter of the code
- Solicit approvals from maintainers of the subsystems affected
- Responsibility to drive the *PR Technical Escalation* process

Static Analysis Audit Team

The Static Analysis Audit team works closely with the release engineering team to ensure that static analysis defects opened during a release cycle are properly addressed. The team has the following rights and responsibilities:

- Right to revert any triage in a static analysis tool (e.g: Coverity) that does not follow the project expectations.
- Responsibility to inform code owners about improper classifications.
- Responsibility to alert TSC if any issues are not adequately addressed by the responsible code owners.

Joining the Static Analysis Audit team

- Contributors highly involved in the project with some expertise in static analysis.

Release Engineering Team

A team of active Maintainers involved in multiple areas.

- The members of the Release Engineering team are expected to fill the Release Manager role based on a defined cadence and selection process.
- The cadence and selection process are defined by the Release Engineering team and are approved by the TSC.
- The team reports directly into the TSC.

Release Engineering team has the following rights and responsibilities:

- Right to merge code changes to the zephyr tree following the project rules.
- Right to revert any changes that have broken the code base
- Right to close any stale changes after <N> months of no activity
- Responsibility to take directions from the TSC and follow them.
- Responsibility to coordinate code merges with maintainers.
- Responsibility to merge all contributions regardless of their origin and area if they have been approved by the respective maintainers and follow the merge criteria of a change.
- Responsibility to keep the Zephyr code base in a working and passing state (as per CI)

Joining the Release Engineering team

- Maintainers highly involved in the project may be nominated by a TSC voting member to join the Release Engineering team. Nominees may become members of the team by approval of the existing TSC voting members.

- To ensure a functional Release Engineering team the TSC shall periodically review the team's followed processes, the appropriate size, and the membership composition (ensure, for example, that team members are geographically distributed across multiple locations and time-zones).

Release Manager

A *Maintainer* responsible for driving a specific release to completion following the milestones and the roadmap of the project for this specific release.

- TSC has to approve a release manager.

A Release Manager is a member of the Release Engineering team and has the rights and responsibilities of that team in addition to the following:

- Right to manage and coordinate all code merges after the code freeze milestone (M3, see program management overview.)
- Responsibility to drive and coordinate the triaging process for the release
- Responsibility to create the release notes of the release
- Responsibility to notify all stakeholders of the project, including the community at large about the status of the release in a timely manner.
- Responsibility to coordinate with QA and validation and verify changes either directly or through QA before major changes and major milestones.

Roles / Permissions

Table 1: Project Roles vs GitHub Permissions

		Admin	**Merge Rights**	Member	Owner	Collaborator
Main Roles	Contributor					x
	Collaborator			x		
	Maintainer			x		
Supportive Roles	QA/Validation			x		x
	DevOps	**x**				
	System Admin	**x**			x	
	Release Engineering		**x**	x		

8.2.3 Role Retirement

Individuals approved by the TSC or representatives of the TSC to fill a project role who are no longer actively fulfilling the rights and responsibilities associated with their role may be requested by the TSC to retire from that role.

Retirements of inactive maintainers or collaborators are reflected by removing the individual's GitHub user name from the relevant sections of the *MAINTAINERS File* in the Zephyr repository and may be initiated by the TSC, representatives of the TSC or by the individuals themselves. Maintainers may also initiate the removal of inactive collaborators in their area.

A maintainer may object to being retired, and request a decision by the TSC.

8.2.4 MAINTAINERS File

The following guidelines apply to the structure, scope, and maintenance of the MAINTAINERS file.

- The MAINTAINERS file shall have designated individuals responsible for the accuracy, structure, and upkeep of the file, in accordance with the Zephyr Project Charter. These individuals shall be appointed by the TSC.
- The granularity of maintainership should remain practical and manageable.
- The TSC, in collaboration with existing maintainers and contributors, should actively identify and encourage contributors to step up as maintainers for orphaned areas of the codebase and should facilitate the assignment of maintainers to those components.
- Unmaintained areas shall be clearly marked as such in the MAINTAINERS file.
- Updates to the MAINTAINERS file should:
  - Generally be included as standalone commits when introducing new files or directories.
  - Major changes, including the addition of new areas and new maintainers, should be submitted as separate pull requests, requiring approval by the MAINTAINERS file's maintainers. Such activities might be the result of splitting existing large areas into smaller ones or merging smaller areas.

Guidelines for assigning maintainers to different areas of the codebase:

Architectures, core components, subsystems, samples, and tests:
Each area shall have an explicitly assigned maintainer.

Boards (including related samples and tests) and SoCs (including DTS definitions)
Each board and SoC should have an explicitly assigned maintainer through a platform area covering the boards, SoCs, and their related components and drivers.

Drivers / Backends
The area of the API level shall have a maintainer and specific driver implementations or backends shall also be covered through a platform area covering the driver implementation. The driver area or the subsystem maintainers are assigned in case of changes to driver instances or backends.

8.3 TSC Working Groups

8.3.1 Overview

The TSC, at its discretion, may establish working groups or subcommittees to serve as focused teams dedicated to specific technical areas, initiatives, or tasks.

8.3.2 Membership

Working Group Membership Eligibility

- Each Working group (WG) shall determine its own membership eligibility, in consultation with the TSC.
- Each working group shall have a team of members who are actively involved in its activities and decision-making processes.
- It is expected that WG membership shall be **open to all** Zephyr project *Collaborators*; however, working groups may impose restrictions such as the number of participants from a single company.
- All TSC members are eligible to join a working group as members, part of the responsibilities being a TSC member.
- The minimal number of members may vary depending on the complexity of the tasks and the breadth of expertise required to address them effectively.

- A working group should aim to have at least five to seven members to ensure diversity of perspectives, collaboration, and continuity.
- The structure of each working group within the Zephyr Project should be designed to ensure effectiveness, productivity, and inclusivity. While the optimal size of a working group can vary depending on the specific context and scope of its activities.
- Participation in WG meetings and discussions is open to all project *contributors*.

Working Group Chair / Co-chair

Each working group may elect a Chair and optionally a Co-Chair who is responsible for leading meetings and representing the working group to the TSC.

Working Group Chair / Co-Chair Elections

- The Chair and Co-Chair shall be elected by the members of the working group
- Any member of the working group has the right to nominate themselves for the chair/co-chair positions.
- The term for the chair/co-chair is one year
- If a chair/co-chair resigns from the position before the end of the term, a vote is to be held to elect a new chair/co-chair.

Working Group Voter Eligibility

- Voting for a Chair or Co-Chair is open to the members of the working group.
- Only 1 working group member from each company may vote in the election.
- The Chair and Co-Chair shall be members of the working group.

Working Group Election Confirmation

- The elected Chair (and/or Co-Chair) is submitted to the TSC for confirmation.
- The TSC decides to accept the outcome or requests a new voting.

8.3.3 Advisory role

- Working Groups are advisory in nature. They provide advice to the projects and to the TSC.
- Working groups operate on a rough consensus basis. If the working group is unable to reach consensus on what advice to offer, the working group Chair shall raise the issue with the TSC or the relevant committee (Safety and Security), where a formal vote can be taken, or advise the project that the working group cannot reach consensus.
- Working groups shall keep track of discussions and record any votes, decisions, or recommendations made and share results with the community and the TSC.
- Working group meetings and offline discussions shall be captured in a standalone document with all supporting details such as attendance, quorum, actions to be taken, and next steps.
- Decisions made within a working group are non-binding and are only considered ratified after communicating decisions and outcomes to the TSC.
- Lacking any objections from the TSC within 1 week after the communication or report of any results, decisions of a working group are considered confirmed and ratified.

8.3.4 TSC Working Group Lifecycle

Creation of a TSC working group

In order to create a TSC working group, a TSC member shall make a proposal to the TSC (via TSC email list) that shall cover at least the following:

- TSC working group name.
- TSC working group purpose
- TSC working group expected deliverables
- TSC working group starting participants with at least one TSC member acting as a sponsor.
- Optionally TSC working group definition of done

Update of a TSC working group

The TSC can modify a TSC working group via a TSC decision. To request such a modification, a request is made to the TSC email list.

Conclusion of a TSC working group

The TSC decides the termination of the TSC working group in accordance with the TSC decision procedure. The submission of a request to terminate the TSC working group should cover:

- TSC working group name
- TSC working group deliveries
- Motivation for termination of the TSC working group

8.4 Release Process

The Zephyr project releases on a time-based cycle, rather than a feature-driven one. Zephyr releases represent an aggregation of the work of many contributors, companies, and individuals from the community.

A time-based release process enables the Zephyr project to provide users with a balance of the latest technologies and features and excellent overall quality. A roughly 6-month release cycle allows the project to coordinate development of the features that have actually been implemented, allowing the project to maintain the quality of the overall release without delays because of one or two features that are not ready yet.

8.4.1 Release Phases Overview

Each release cycle consists of a *development phase* followed by a *stabilization phase*. Release candidates will be created during the stabilization phase.

During the development phase, all sorts of changes can be merged. This is called the *merge window* for the main branch for this reason. During the stabilization phase, the project and its maintainers focus on fixing bugs and documenting the release. During this time, new features are generally not accepted. The main branch is in *feature freeze* during the stabilization phase.

The milestones for the current major version can be found on the Official GitHub Wiki. Information on previous releases can be found here.

Note

After each stable release is made, a new “release branch” for that release is created.

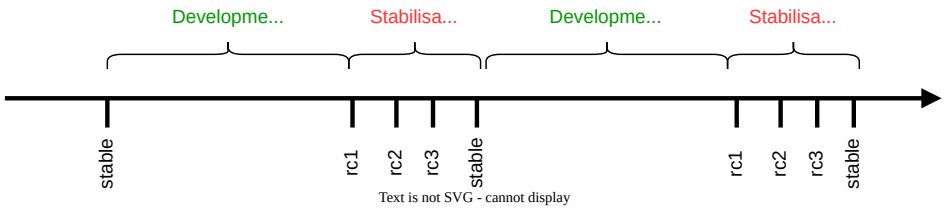

Fig. 1: Release Cycle

For example, after Zephyr stable release v4.4.0 was announced, a new branch `v4.4-branch` was created. Commits intended for v4.4.x point releases (v4.4.1, v4.4.2, etc.) should be proposed with that branch as a target.

This page currently does not document the point release process in detail.

Merge Window (Development Phase)

After tagging a release, the release managers open the main branch for development for the next release cycle. We call this time the *merge window* or the *development phase* for each release. During the merge window, any code which meets the *Pull Request Merge Criteria* can be merged into the main branch. Most changes for each release are made during its merge window.

Each release's merge window lasts approximately five months.

After the merge window, the release team tags the first *release candidate* for the upcoming release. At that point, the main branch is closed for most feature development, and the project is in *feature freeze* for the next release. Feature freeze is described in the next section.

Here is an example timeline for a merge window:

- the merge window opened when v4.3.0 was tagged on 13 November 2025. At this point, the main branch was open for merges for the next release, which was v4.4.0.
- the merge window for v4.4.0 closed when v4.4.0-rc1 was tagged on 24 March 2026. At this time, the project entered feature freeze for the v4.4.0 release.

Feature Freeze (Stabilization Phase)

When the first release candidate is tagged, the release's merge window is closed. This is called the *feature freeze* or *stabilization phase* for that release. During feature freeze, no new features will be merged for that release without a *Technical Steering Committee (TSC)* approved exception.

Please be patient during the stabilization phase while waiting for pull request review for new features.

As mentioned, the exception process for merging features during the feature freeze requires TSC approval and a justification. As a general rule, if your pull request is not yet merged and feature freeze is declared, the best thing to do is to wait for the next *merge window* to open.

If you believe your feature merits an exception and should be merged during feature freeze, contact the TSC. See the TSC wiki page for general contact information.

Here is an example timeline for a feature freeze:

- The feature freeze for v4.4.0 began when v4.4.0-rc1 was tagged on 24 March 2026. At that time, new features required a TSC exception in order to be merged to the main branch.
- The feature freeze for v4.4.0 ended when v4.4.0 was tagged on 14 April 2026. At that time, the main branch was open again for the next release's *merge window*.

The following sections describe the feature freeze in more detail.

Allowed Changes After feature freeze, **only** stabilization-related changes **shall** be accepted:

- Bug fixes addressing functional defects
- Stabilization fixes improving reliability, build stability, or test behavior
- Documentation updates (clarifications, corrections, improvements)
- Tests for existing functionality (no new feature enablement)

For more details on when certain changes are accepted, see *table*.

Exceptions to these allowed changes are rare and require both explicit justification and TSC approval. As a general rule, if a feature misses the development phase window, it should wait for the next development cycle.

Disallowed Changes The following changes **shall not** be accepted after feature freeze:

- New features or feature enhancements
- API changes, unless required to resolve a critical defect
- Refactoring not directly tied to a bug fix or stabilization effort
- New subsystems, drivers, boards, or architectural changes

8.4.2 Issue Tracking during Feature Freeze

Referencing a GitHub issue in a pull request is **recommended** but **not required** during feature freeze.

Pull requests **must** include a clear description of:

- The issue being addressed
- The impact of the issue
- How the change resolves the issue

Maintainers and release engineers **may** request additional clarification when the intent or scope of a pull request is not clear.

Mandatory Issue Usage

A GitHub issue **shall** be required in the following cases:

- Release blockers
- Fixes targeting maintenance of already released branches

Review and Approval

All pull requests **shall** follow the standard review and approval process.

Maintainers **shall** ensure that:

- Changes comply with this policy
- Scope is minimal and focused on stabilization
- Risk is appropriate for the release phase

Release engineers **may**:

- Reject or defer changes based on risk assessment
- Request changes or additional justification

Risk Expectations

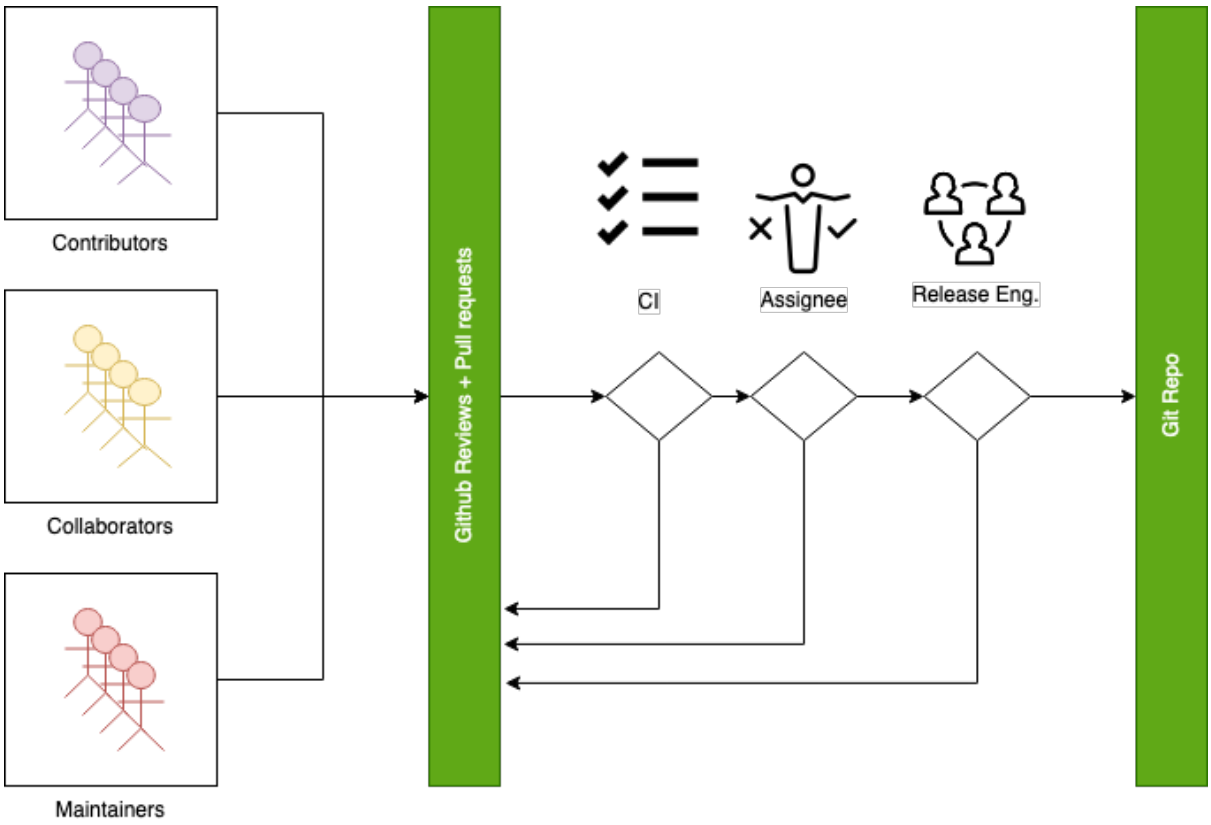
Changes accepted during stabilization **shall** be:

- Minimal in scope
- Low risk
- Adequately tested

Changes introducing significant risk **may** be deferred to a future release, even if they qualify as bug fixes.

8.4.3 Pull Request Merge Criteria

The following criteria apply during all release phases.



- All *PR Requirements* must be met.
- Minimal of 2 approvals, including an approval by the designated assignee.
- Pull requests should be reviewed by at least a maintainer or collaborator of each affected area; Unless the changes to a given area are considered trivial enough, in which case approvals by other affected subsystems maintainers/collaborators would suffice.
- Four eye principle on the organisation level. We already require at least 2 approvals (basic four eye principle), however, such reviews and approvals might be unintentionally biased in the case where the submitter is from the same organisation as the approvers. To allow for project wide review and approvals, the merge criteria is extended with the guidelines below:
  - Changes or additions to common and shared code shall have approvals from different organisations (at least one approval from an organisation different than the submitters'). Common and shared code is defined as anything that does not fall under `soc`, `boards` and `drivers/*/*`.

  - Changes or additions to hardware support (driver, SoC, boards) shall at least have the merger be from a different organisation. This applies only to implementation of an API supporting vendor specific hardware and not the APIs.
  - Release engineers may make exceptions for areas with contributions primarily coming from one organisation and where reviews from other organisations are not possible, however, merges shall be completed by a person from a different organisation. In such cases, the minimum review period of at least 2 days shall be strictly followed to allow for additional reviews.
  - Release engineers shall not merge code changes originating and reviewed only by their own organisation. To be able to merge such changes, at least one review shall be from a different organisation.
- A minimum review period of 2 business days, 4 hours for trivial changes (see *Give reviewers time to review before code merge*).
- Hotfixes can be merged at any time after CI has passed and are excluded from most of the conditions listed above.
- All required checks are passing:
  - Device Tree
  - Documentation
  - Code linters (Gitlint, Pylint, Ruff, Sphinx, etc.)
  - Identity/Emails
  - Kconfig
  - License checks
  - Checkpatch (Coding Style)
  - Integration Tests (Via twister) on emulation/simulation platforms
  - Simulated Bluetooth Tests

8.4.4 Release Quality Criteria

The main motivation is to clearly have the criteria in place that must be met for a release. This will help define when a release is "done" in terms that most people can understand and in ways that help new people to understand the process and participate in creating successful releases:

- The release criteria documents all the requirements of our target audience for each Zephyr release
- The target audiences for each release can be different, and may overlap
- The criteria at any given time are not set in stone: there may be requirements that have been overlooked, or that are new, and in these cases, the criteria should be expanded to ensure all needs are covered.

Below is the high level criteria to be met for each release:

- No blocker bugs / blocking issues
- All relevant tests shall pass on `Tier 0` platforms
- All relevant tests shall pass on Tier 0 and 1 platforms (at least 1 per architecture/architecture variant/Hardware features)
- All applicable samples/tests shall build on Tiers 0, 1 and 2
- All high and critical static analysis and security issues addressed
- Release Notes are up-to-date.

Blocker Bugs

Blocker bug process kicks in during the release process and is in effect after the feature freeze milestone. An issue labeled as a blocker practically blocks a release from happening. All blocker bugs shall be resolved before a release is created.

A fix for a bug that is granted `blocker` status can be merged to 'main' and included in the release all the way until the final release date.

Bugs of moderate severity and higher that have impact on all users are typically the candidates to be promoted to blocker bugs

Contributors and member of the release engineering team shall follow these guidelines for release blocker bugs:

- Only mark bugs as blockers if the software (Zephyr) must not be released with the bug present.
- All collaborators can add or remove blocking labels.
- Evaluate bugs as potential blockers based on their severity and prevalence.
- Provide detailed rationale whenever adding or removing a blocking label.
- Ensure all blockers have the milestone tagged.
- Release managers have final say on blocking status; contact them with any questions.

8.4.5 Release Milestones

This table documents milestones associated with each release.

Table 2: Release Milestones

Timeline	Checkpoint	Description	Owner
T-5M	Planning	Finalize dates for release, Assign release owner and agree on project wide goals for this release.	TSC
T-7W	Review target milestones	Finalize target milestones for features in flight.	Release Engineering
T-5W	Release Announcement	Release owner announces feature freeze and timeline for release.	Release Manager
T-4W	Release Timeline reminder	Release owner sends a reminder of the feature freeze and timeline for release.	Release Manager
T-3W	Feature Freeze (RC1)	After RC1, no new features may be introduced. Only stabilization, cosmetic updates, bug fixes, documentation improvements, and new tests for existing features are permitted.	Release Engineering
T-2W	2nd Release Candidate	No new features after RC2, ONLY stabilization and cosmetic changes, bug and doc fixes are allowed.	Release Manager
T-1W	Hard Freeze (RC3)	Only blocker bug fixes after RC3, documentation improvements and changes to release notes are allowed. Release notes need to be complete by this checkpoint. Release Criteria is met.	Release Manager
T-0W	Release		Release Manager

8.4.6 Long Term Support (LTS) Releases

Long-term support releases are designed to be supported and maintained for an extended period and are the recommended release for products and the auditable branch used for certification.

An LTS release is defined as:

- **Product focused**
- **Extended Stabilisation period**: Allow for more testing and bug fixing
- **Stable APIs**
- **Quality Driven Process**
- **Long Term**: Maintained for an extended period of time (at least 5 years).

Product Focused

Zephyr LTS is the recommended release for product makers with an extended support and maintenance which includes general stability and bug fixes, security fixes.

An LTS includes both mature and new features. API and feature maturity is documented and tracked. The footprint and scope of mature and stable APIs expands as we move from one LTS to the next giving users access to bleeding edge features and new hardware while keeping a stable foundation that evolves over time.

Extended Stabilisation Period

Zephyr LTS development cycle differs from regular releases and has an extended stabilization period. Feature freeze of regular releases happens 3-4 weeks before the scheduled release date. The stabilization period for LTS is extended by 3 weeks with the feature freeze occurring 6-7 weeks before the anticipated release date. The time between code freeze and release date is extended in this case.

Stable APIs

Zephyr LTS provides a stable and long-lived foundation for developing products. To guarantee stability of the APIs and the implementation of such APIs it is required that any release software that makes the core of the OS went through the Zephyr API lifecycle and stabilized over at least 2 releases. This guarantees that we release many of the highlighted and core features with mature and well-established implementations with stable APIs that are supported during the lifetime of the release LTS.

- API Freeze (LTS - 2)
  - All stable APIs need to be frozen 2 releases before an LTS. APIs can be extended with additional features, but the core implementation is not modified. This is valid for the following subsystems for example:
    - Device Drivers (i2c.h, spi.h)...
    - Kernel (k_*):
    - OS services (logging,debugging, ..)
    - DTS: API and bindings stability
    - Kconfig
  - New APIs for experimental features can be added at any time as long as they are standalone and documented as experimental or unstable features/APIs.
- Feature Freeze (LTS - 1) - No new features or overhaul/restructuring of code covering major LTS features.
  - Kernel + Base OS

  - Additional advertised LTS features
  - Auxiliary features on top of and/or extending the base OS and advertised LTS features can be added at any time and should be marked as experimental if applicable

Quality Driven Process

The Zephyr project follows industry standards and processes with the goal of providing a quality oriented releases. This is achieved by providing the following products to track progress, integrity and quality of the software components provided by the project:

- Compliance with published coding guidelines, style guides and naming conventions and documentation of deviations.
- Static analysis reports
  - Regular static analysis on the complete tree using available commercial and open-source tools, and documentation of deviations and false positives.
- Documented components and APIS
- Requirements Catalog
- Verification Plans
- Verification Reports
- Coverage Reports
- Requirements Traceability Matrix (RTM)
- SPDX License Reports

Each release is created with the above products to document the quality and the state of the software when it was released.

Long Term Support and Maintenance

LTS releases are published every 2.5 to 3 years and are branched and maintained independently from the main tree for approximately 5 years after they were released.

Support is provided in three main phases:

- **Phase 1 (first 2 years):** General bug fixes and security fixes, including platform and driver fixes.
- **Phase 2 (following 3+ years):** Security and OS stability fixes only.
- **Phase 3:** Extended support may be available through third parties (details to be determined).

Support for a given LTS release (LTS *N*) continues until the initial release of the LTS two versions ahead (LTS *N+2*). A final release of LTS *N* occurs shortly after the initial release of LTS *N+2*.

The list of currently supported LTS releases and their EOL dates can be found here.

Fig. 2: Long Term Support Release

Changes and fixes flow in both directions. However, changes from main branch to an LTS branch will be limited to fixes that apply to both branches and for existing features only.

All fixes for an LTS branch that apply to the mainline tree shall be submitted to mainline tree as well.

Auditable Code Base

An auditable code base is to be established from a defined subset of Zephyr OS features and will be limited in scope. The LTS, development tree, and the auditable code bases shall be kept in sync after the audit branch is created, but with a more rigorous process in place for adding new features into the audit branch used for certification.

This process will be applied before new features move into the auditable code base.

The initial and subsequent certification targets will be decided by the Zephyr project governing board.

Processes to achieve selected certification will be determined by the Security and Safety Working Groups and coordinated with the TSC.

8.4.7 Host Tools Support Policy

This section documents policies related to host tools required to develop zephyr applications.

Python Version Policy

Zephyr tracks the Python upstream release schedule when determining its minimum supported Python version.

The minimum supported version is selected to balance long-term support and practical availability in mainstream, actively supported Linux distributions (e.g. current Ubuntu LTS and Debian Stable releases).

A Python version is considered for removal when:

- It is approaching or has reached upstream end-of-life (EOL), and
- Newer Python versions are broadly available in current, actively supported major Linux distributions.

8.4.8 Hardware Support Tiers

This section documents a rough set of tiers associated with hardware platforms. These criteria are not currently formally enforced or evaluated at a board, architecture, or SoC level.

Tier 0: Emulation Platforms

- Tests are both built and run in these platforms in CI, and therefore runtime failures can block Pull Requests.
- Supported by the Zephyr project itself, commitment to fix bugs in releases.
- One Tier 0 platform is required for each new architecture.
- Bugs reported against platforms of this tier are to be evaluated and treated as a general bug in Zephyr and should be dealt with the highest priority.

Tier 1: Supported Platforms

- Commitment from a specific team to run tests using twister device testing for the “Zephyr compatibility test suite” (details TBD) on a regular basis using open-source and publicly available drivers.
- Commitment to fix bugs in time for releases. Not supported by “Zephyr Project” itself.
- General availability for purchase
- Bugs reported against platforms of this tier are to be evaluated and treated as a general bug in Zephyr and should be dealt with medium to high priority.

Tier 2: Community Platforms

- Platform implementation is available in upstream, no commitment to testing, may not be generally available.
- Has a dedicated maintainer who commits to respond to issues / review patches.
- Bugs reported against platforms of this tier are NOT considered as a general bug in Zephyr.

Tier 3: Deprecated and unsupported Platforms

- Platform implementation is available, but no owner or unresponsive owner.
- No commitment to support is available.
- May be removed from upstream if no one works to bring it up to tier 2 or better.
- Bugs reported against platforms of this tier are NOT considered as a general bug in Zephyr.

8.4.9 Release Procedure

This section documents the Release manager responsibilities so that it serves as a knowledge repository for Release managers.

Release Checklist

Each release has a GitHub issue associated with it that contains the full checklist. After a release is complete, a checklist for the next release is created.

Tagging

The following syntax should be used for releases and tags in Git:

- Release [Major].[Minor].[Patch Level]
- Release Candidate [Major].[Minor].[Patch Level]-rc[RC Number]
- Tagging:
  - v[Major].[Minor].[Patch Level]-rc[RC Number]
  - v[Major].[Minor].[Patch Level]
  - v[Major].[Minor].99 - A tag applied to main branch to signify that work on v[Major].[Minor+1] has started. For example, v1.7.99 will be tagged at the start of v1.8 process. The tag corresponds to VERSION_MAJOR/VERSION_MINOR/PATCHLEVEL macros as defined for a work-in-progress main branch version. Presence of this tag allows generation of sensible output for "git describe" on main branch, as typically used for automated builds and CI tools.

The final release and each release candidate shall be tagged using the following steps:

> **Note**
>
> Tagging needs to be done via explicit git commands and not via GitHub's release interface. The GitHub release interface does not generate annotated tags (it generates 'lightweight' tags regardless of release or pre-release). You should also upload your gpg public key to your GitHub account, since the instructions below involve creating signed tags. Alternatively, if you don't have a gpg key, you can also use your ssh key for signing.

Release Candidate

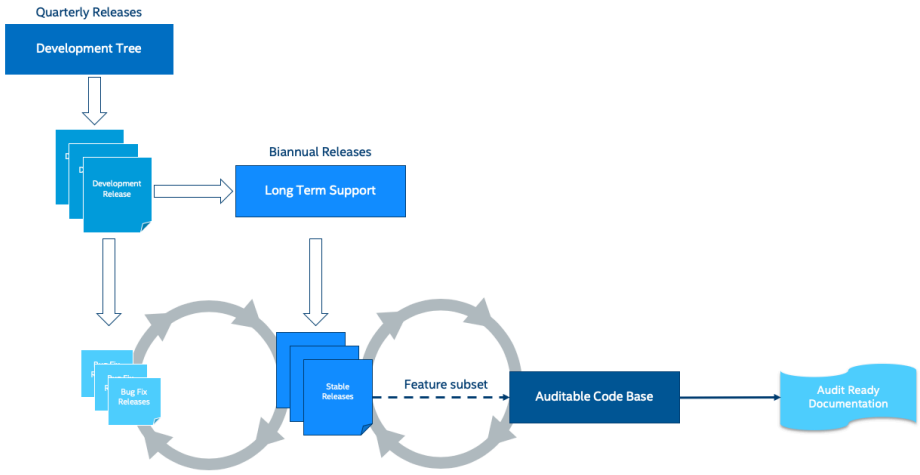


Fig. 3: Zephyr Code and Releases

Note

This section uses tagging 1.11.0-rc1 as an example, replace with the appropriate release candidate version.

1. Update the version variables in the VERSION file located in the root of the Git repository to match the version for this release candidate. The `EXTRAVERSION` variable is used to identify the rc[RC Number] value for this candidate:

   ```
   EXTRAVERSION = rc1
   ```

2. Post a PR with the updated VERSION file using `release: Zephyr 1.11.0-rc1` as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using an annotated tag:

   ```
   $ git pull
   $ git tag -s -m "Zephyr 1.11.0-rc1" v1.11.0-rc1
   ```

4. Verify that the tag has been signed correctly, `git show` for the tag must contain a signature (look for the `BEGIN PGP SIGNATURE` or `BEGIN SSH SIGNATURE` marker in the output):

   ```
   $ git show v1.11.0-rc1
   ```

5. Push the tag:

   ```
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0-rc1
   ```

6. Send an email to the mailing lists (`announce` and `devel`) with a link to the release

Final Release

Note

This section uses tagging 1.11.0 as an example, replace with the appropriate final release version.

When all final release criteria has been met and the final release notes have been approved and merged into the repository, the final release version will be set and repository tagged using the following procedure:

1. Update the version variables in the VERSION file located in the root of the Git repository. Set `EXTRAVERSION` variable to an empty string to indicate final release:

   ```
   EXTRAVERSION =
   ```

2. Post a PR with the updated VERSION file using `release: Zephyr 1.11.0` as the commit subject. Merge the PR after successful CI.

3. Tag and push the version, using two annotated tags:

   ```
   $ git pull
   $ git tag -s -m "Zephyr 1.11.0" v1.11.0
   ```

4. Verify that the tag has been signed correctly, `git show` for the tag must contain a signature (look for the `BEGIN PGP SIGNATURE` or `BEGIN SSH SIGNATURE` marker in the output):

   ```
   $ git show v1.11.0
   ```

5. Push the tag:

   ```
   $ git push git@github.com:zephyrproject-rtos/zephyr.git v1.11.0
   ```

6. Find the new `v1.11.0` tag at the top of the releases page and edit the release with the `Edit tag` button with the following:

   - Copy the overview of `docs/releases/release-notes-1.11.rst` into the release notes textbox and link to the full release notes file on docs.zephyrproject.org.

7. Send an email to the mailing lists (`announce` and `devel`) with a link to the release

8.5 Feature Tracking

To propose something new to the Zephyr Project:

1. Start by searching existing issues to see if there is prior work on the area.
2. If not, feel free to create a new issue of the appropriate type (Enhancement, RFC/Proposal, etc.)

You should contact an assigned owner if you'd like to discuss or contribute to an existing issue's implementation.

> **Note**
>
> Previously, the project used GitHub labels to track feature-related work. You may find issues with labels like "Feature" or "Enhancement".
>
> These labels are deprecated for new issues, which should be of the appropriate type instead. For example, create an issue of type Enhancement instead of adding the Enhancement label to a new issue.

8.5.1 Roadmap and Release Plans

Project roadmaps and release plans are both important tools for the project, but they have very different purposes and should not be confused. A project roadmap communicates the high-level overview of a project's strategy, while a release plan is a tactical document designed to capture and track the features planned for upcoming releases.

- The project roadmap communicates the why; a release plan details the what
- A release plan spans only a few months; a product roadmap might cover a year or more

Project Roadmap

The project roadmap should serve as a high-level, visual summary of the project's strategic objectives and expectations.

If built properly, the roadmap can be a valuable tool for several reasons. It can help the project present its plan in a compelling way to existing and new stakeholders, to help recruit new members and it can be a helpful resource the team and community can refer to throughout the project's development, to ensure they are still executing according to plan.

As such, the roadmap should contain only strategic-level details, major project themes, epics, and goals.

Release Plans

The release plan comes into play when the project roadmap's high-level strategy is translated into an actionable plan built on specific features, enhancements, and fixes that need to go into a specific release or milestone.

The release plan communicates those features and enhancements slated for your project' next release (or the next few releases). So it acts as more of a project plan, breaking the big ideas down into smaller projects the community and main stakeholders of the project can make progress on.

8.6 Code Flow and Branches

8.6.1 Introduction

The zephyr Git repository has three types of branches:

main
: Which contains the latest state of development

collab-*
: Collaboration branches that are used for shared development of new features to be introduced into the main branch when ready. Creating a new collaboration branch requires a justification and TSC approval. Collaboration branches shall be based off the main branch and any changes developed in the collab branch shall target the main development branch. For released versions of Zephyr, the introduction of fixes and new features, if approved by the TSC, shall be done using backport pull requests.

vx.y-branch
: Branches which track maintenance releases based on a major release

Development in collaboration branches before features go to mainline allows teams to work independently on a subsystem or a feature, improves efficiency and turnaround time, and encourages collaboration and streamlines communication between developers.

Changes submitted to a collaboration branch can evolve and improve incrementally in a branch, before they are submitted to the mainline tree for final integration.

By dedicating an isolated branch to complex features, it's possible to initiate in-depth discussions around new additions before integrating them into the official project.

Collaboration branches are ephemeral and shall be removed once the collaboration work has been completed. When a branch is requested, the proposal should include the following:

- Define exit criteria for merging the collaboration branch changes back into the main branch.
- Define a timeline for the expected life cycle of the branch. It is recommended to select a Zephyr release to set the timeline. Extensions to this timeline requires TSC approval.

8.6.2 Roles and Responsibilities

Collaboration branch owners have the following responsibilities:

- Use the infrastructure and tools provided by the project (GitHub, Git)
- All changes to collaboration branches shall come in form of github pull requests.
- Force pushing a collaboration branch is only allowed when rebasing against the main branch.
- Review changes coming from team members and request review from branch owners when submitting changes.
- Keep the branch in sync with upstream and update on a regular basis.
- Push changes frequently to upstream using the following methods:
  - GitHub pull requests: for example, when reviews have not been done in the local branch (one-man branch).
  - Merge requests: When a set of changes has been done in a local branch and has been reviewed and tested in a collaboration branch.

8.7 Development Environment and Tools

8.7.1 Code Review

GitHub is intended to provide a framework for reviewing every commit before it is accepted into the code base. Changes, in the form of Pull Requests (PR) are uploaded to GitHub but don't actually become a part of the project until they've been reviewed, passed a series of checks (CI), and are approved by maintainers. GitHub is used to support the standard open source practice of submitting patches, which are then reviewed by the project members before being applied to the code base.

Pull requests should be appropriately *labeled*, and linked to any relevant *bug or feature tracking issues* .

The Zephyr project uses GitHub for code reviews and Git tree management. When submitting a change or an enhancement to any Zephyr component, a developer should use GitHub. GitHub Actions automatically assigns a responsible reviewer on a component basis, as defined in the MAINTAINERS.yml file stored with the code tree in the Zephyr project repository. A limited set of release managers are allowed to merge a pull request into the main branch once reviews are complete.

Give reviewers time to review before code merge

The Zephyr project is a global project that is not tied to a certain geography or timezone. We have developers and contributors from across the globe. When changes are proposed using pull request, we need to allow for a minimal review time to give developers and contributors the opportunity to review and comment on changes. There are different categories of changes and we know that some changes do require reviews by subject matter experts and owners of the subsystem being changed. Many changes fall under the "trivial" category that can be addressed with general reviews and do not need to be queued for a maintainer or code-owner review. Additionally, some changes might require further discussions and a decision by the TSC or the Security working group. To summarize the above, the diagram below proposes minimal review times for each category:

Workflow

- An author of a change can suggest in his pull-request which category a change should belong to. A project maintainers or TSC member monitoring the inflow of changes can change

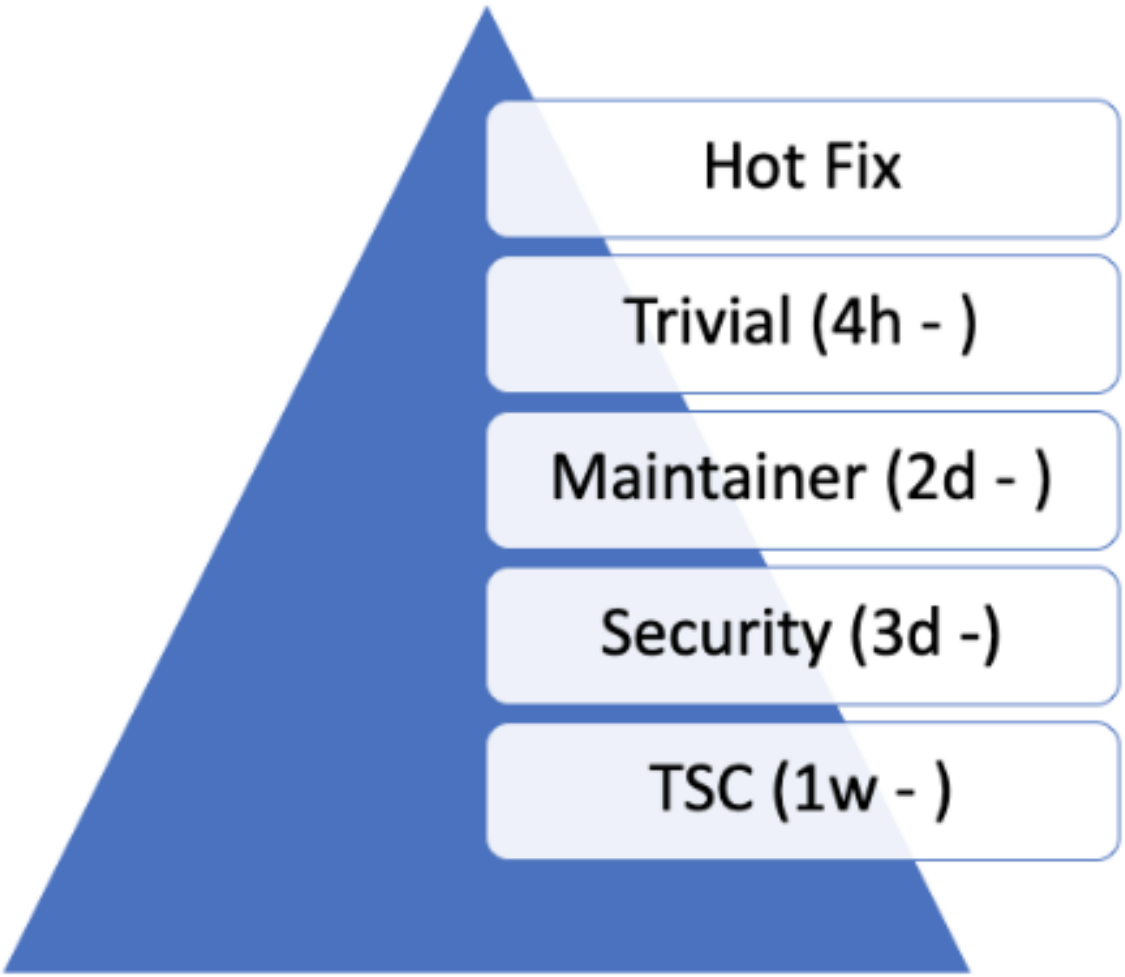

Fig. 4: Pull request classes

the label of a pull request by adding a comment justifying why a change should belong to another category.

- The project will use the label system to categorize the pull requests.
- Changes should not be merged before the minimal time has expired.

Categories/Labels

Hotfix
: Any change that is a fix to an issue that blocks developers from doing their daily work, for example CI breakage, Test breakage, Minor documentation fixes that impact the user experience.

  Such fixes can be merged at any time after they have passed CI checks. Depending on the fix, severity, and availability of someone to review them (other than the author) they can be merged with justification without review by one of the project owners.

Trivial
: Trivial changes are those that appear obvious enough and do not require maintainer or code-owner involvement. Such changes should not change the logic or the design of a subsystem or component. For example a trivial change can be:

  - Documentation changes
  - Configuration changes
  - Minor Build System tweaks
  - Minor optimization to code logic without changing the logic
  - Test changes and fixes
  - Sample modifications to support additional configuration or boards etc.

Maintainer
: Any changes that touch the logic or the original design of a subsystem or component will need to be reviewed by the code owner or the designated subsystem maintainer. If the code changes is initiated by a contributor or developer other than the owner the pull request needs to be assigned to the code owner who will have to drive the pull request to a mergeable state by giving feedback to the author and asking for more reviews from other developers.

Security
: Changes that appear to have an impact to the overall security of the system need to be reviewed by a security expert from the security working group.

TSC and Working Groups
: Changes that introduce new features or functionality or change the way the overall system works need to be reviewed by the TSC or the responsible Working Group. For example for *breaking API changes*, the proposal needs to be presented in the Architecture meeting so that the relevant stakeholders are made aware of the change.

A Pull-Request should have an Assignee

- An assignee to a pull request should not be the same as the author of the pull-request
- An assignee to a pull request is responsible for driving the pull request to a mergeable state
- An assignee is responsible for dismissing stale reviews and seeking reviews from additional developers and contributors
- Pull requests should not be merged without an approval by the assignee.

Pull Request should not be merged by author without review

All pull requests need to be reviewed and should not be merged by the author without a review. The following exceptions apply:

- Hot fixes: Fixing CI issues, reverts, and system breakage
- Release related changes: Changing version file, applying tags and release related activities without any code changes.

Developers and contributors should always seek review, however there are cases when reviewers are not available and there is a need to get a code change into the tree as soon as possible.

Reviewers shall not 'Request Changes' without comments or justification

Any change requests (-1) on a pull request have to be justified. A reviewer should avoid blocking a pull-request with no justification. If a reviewer feels that a change should not be merged without their review, then: Request change of the category: for example:

- Trivial -> Maintainer
- Assign Pull Request to yourself, this will mean that a pull request should not be merged without your approval.

Pull Requests should have at least 2 approvals before they are merged

A pull-request shall be merged only with two positive reviews (approval). Beside the person merging the pull-request (merging != approval), two additional approvals are required to be able to merge a pull request. The person merging the request can merge without approving or approve and merge to get to the 2 approvals required.

Reviewers should keep track of pull requests they have provided feedback to

If a reviewer has requested changes in a pull request, he or she should monitor the state of the pull request and/or respond to mention requests to see if his feedback has been addressed. Failing to do so, negative reviews shall be dismissed by the assignee or an owner of the repository. Reviews will be dismissed following the criteria below:

- The feedback or concerns were visibly addressed by the author
- The reviewer did not revisit the pull request after 2 week and multiple pings by the author
- The review is unrelated to the code change or asking for unjustified structural changes such as:
  - Split the PR
  - Can you fix this unrelated code that happens to appear in the diff
  - Can you fix unrelated issues
  - Etc.

Closing Stale Issues and Pull Requests

- The Pull requests and issues sections on Github are NOT discussion forums. They are items that we need to execute and drive to closure. Use the mailing lists for discussions.
- In case of both issues and pull-requests the original poster needs to respond to questions and provide clarifications regarding the issue or the change. After one week without a response to a request, a second attempt to elicit a response from the contributor will be made. After one more week without a response the item may be closed (draft and DNM tagged pull requests are excluded).

8.7.2 Continuous Integration

All changes submitted to GitHub are subject to tests that are run on emulated platforms and architectures to identify breakage and regressions that can be immediately identified. Testing using Twister additionally performs build tests of all boards and platforms. Documentation changes are also verified through review and build testing to verify doc generation will be successful.

Any failures found during the CI test run will result in a negative review assigned automatically by the CI system. Developers are expected to fix issues and rework their patches and submit again.

The CI infrastructure currently runs the following tests:

- Run `checkpatch` for code style issues (can vote -1 on errors; see note)
- Gitlint: Git commit style based on project requirements
- License Check: Check for conflicting licenses
- Run `twister` script
  - Run kernel tests in QEMU (can vote -1 on errors)
  - Build various samples for different boards (can vote -1 on errors)
- Verify documentation builds correctly.

Note

`checkpatch` is a Perl script that uses regular expressions to extract information that requires a C language parser to process accurately. As such it sometimes issues false positives. Known cases include constructs like:

```
static uint8_t __aligned(PAGE_SIZE) page_pool[PAGE_SIZE * POOL_PAGES];
IOPCTL_Type *base = config->base;
```

Both lines produce a diagnostic regarding spaces around the `*` operator: the first is misidentified as a pointer type declaration that would be correct as `PAGE_SIZE *POOL_PAGES` while the second is misidentified as a multiplication expression that would be correct as `IOPCTL_Type * base`.

Maintainers can override the -1 in cases where the CI infrastructure gets the wrong answer.

8.7.3 Labeling issues and pull requests in GitHub

The project uses GitHub issues and pull requests (PRs) to track and manage daily and long-term work and contributions to the Zephyr project. We use GitHub **labels** to classify and organize these issues and PRs by area, type, priority, and more, making it easier to find and report on relevant items.

All GitHub issues or pull requests must be appropriately labeled. Issues and PRs often have multiple labels assigned, to help classify them in the different available categories. When reviewing a PR, if it has missing or incorrect labels, maintainers shall fix it.

This saves us all time when searching, reduces the chances of the PR or issue being forgotten, speeds up reviewing, avoids duplicate issue reports, etc.

These are the labels we currently have, grouped by applicability:

Labels applicable to issues only

Label	Description
priority: {high|medium|low}	To classify the impact and importance of a bug. Note: Issue priorities are generally set or changed during the bug-triage or TSC meetings.
Regression	Something, which was working, but does not anymore (bug subtype).
Duplicate	This issue is a duplicate of another issue (please specify).
Good first issue	Good for a first time contributor to take.
Release Notes	Issues that need to be mentioned in release notes as known issues with additional information.

Labels applicable to pull requests only

The issue or PR describes a change to a stable API.

Label	Description
Hotfix	Fix for an issue blocking development.
Trivial	Simple changes that can have shorter review time and be reviewed by anyone, i.e. typos, straightforward one-liner bug fixes, etc.
Maintainer	Maintainer review required.
Security Review	To be reviewed by a security expert.
DNM	This PR should not be merged (Do Not Merge). For work in progress, GitHub “draft” PRs are preferred.
Needs review	The PR needs attention from the maintainers.
Backport	The PR is a backport or should be backported.
Licensing	The PR has licensing issues which require a licensing expert to review it.

Note

For all labels applicable to PRs: Please note that the label, together with PR complexity, affects how long a merge should be held to ensure proper review. See *review process* for details.

Labels applicable to both pull requests and issues

Label	Description
area: {area-name}	Indicates Zephyr subsystems (e.g, *area: Kernel*, *area: I2C*, *area: Memory Management*), project functions (e.g., *area: Debugging*, *area: Documentation*, *area: Process*), or other categories (e.g., *area: Coding Style*, *area: MISRA-C*) affected by the bug or the pull request. An area maintainer should be able to filter by an area label and find all issues and PRs which relate to that area.
platform: {platform name}	An issue or PR which affects only a particular platform.
TSC	TSC stands for Technical Steering Committee. The issue is to be discussed in the following TSC meeting if time permits.
Breaking API Change	The issue or PR describes a breaking change to a stable API. See additional information in *Introducing breaking API changes*.
bug	The issue is a bug, or the PR is fixing a bug.
Coverity	A Coverity detected issue or its fix.
Waiting for response	The Zephyr developers are waiting for the submitter to respond to a question, or address an issue.
Blocked	Blocked by another PR or issue.
Stale	An issue or a PR which seems abandoned, and requires attention by the author.
In progress	For PRs: is work in progress and should not be merged yet. For issues: Is being worked on.
RFC	The author would like input from the community. For a PR it should be considered a draft.
LTS	Long term release branch related.
EXT	Related to an external component.

8.8 Bug Reporting

To maintain traceability and relation between proposals, changes, features, and issues, it is recommended to cross-reference source code commits with the relevant GitHub issues and vice versa. Any changes that originate from a tracked feature or issue should contain a reference to the feature by mentioning the corresponding issue or pull-request identifiers.

At any time it should be possible to establish the origin of a change and the reason behind it by following the references in the code.

8.8.1 Reporting a regression issue

It could happen that the issue being reported is identified as a regression, as the use case is known to be working on earlier commit or release. In this case, providing directly the guilty commit when submitting the bug gains a lot of time in the eventual bug fixing.

To identify the commit causing the regression, several methods could be used, but tree bisecting method is an efficient one that doesn't require deep code expertise and can be used by every

one.

For this, git bisect is the recommended tool.

Recommendations on the process:

- Run `west update` on each bisection step.
- Once the bisection is over and a culprit identified, verify manually the result.

8.9 Communication and Collaboration

The Zephyr Discord Server is the primary chat forum used by Zephyr developers, contributors, and users.

The Zephyr project mailing lists are used as an additional communication tool by project members, contributors, and the community. There are specialized mailing lists for specific interests. Several lists are public and open. Mailing lists are always available for use in situations where Discord is unavailable or an unsuitable forum.

In general, bug reports and other issues should be reported as GitHub Issues and not broadcasted to the mailing list. The same applies to code reviews.

8.10 Code Documentation

8.10.1 API Documentation

Well documented APIs enhance the experience for developers and are an essential requirement for defining an API's success. Doxygen is a general purpose documentation tool that the zephyr project uses for documenting APIs. It generates either an on-line documentation browser (in HTML) and/or provides input for other tools that is used to generate a reference manual from documented source files. In particular, doxygen's XML output is used as an input when producing the Zephyr project's online documentation.

8.10.2 Reference to Requirements

APIs for the most part document the implementation of requirements or advertised features and can be traced back to features. We use the API documentation as the main interface to trace implementation back to documented features. This is done using doxygen's native requirements traceability commands (`@satisfies` and `@verifies`) that reference requirements maintained somewhere else in a requirement catalogue.

8.10.3 Test Documentation

To help understand what each test does and which functionality it tests we also document all test code using the same tools and in the same context and generate documentation for all unit and integration tests maintained in the same environment. Tests are documented using references to the APIs or functionality they validate by creating a link back to the APIs and by adding a reference to the original requirements.

8.10.4 Documentation Guidelines

Test Code

The Zephyr project uses several test methodologies, the most common being the *Ztest framework*. Test documentation should only be done on the entry test functions (usually prefixed with test_) and those that are called directly by the Ztest framework. Those tests are going to appear in test reports and using their name and identifier is the best way to identify them and trace back to them from requirements.

Test documentation should not interfere with the actual API documentation and needs to follow a new structure to avoid confusion. Using a consistent naming scheme and following a well-defined structure we will be able to group this documentation in its own module and identify it uniquely when parsing test data for traceability reports. Here are a few guidelines to be followed:

- All test code documentation should be grouped under the `all_tests` doxygen group
- All test documentation should be under doxygen groups that are prefixed with tests_

Documenting a Requirement

A requirement is documented with the doxygen `@requirement` command, which takes a unique identifier and an optional title. Doxygen collects all requirements on a single page and allows them to be referenced from anywhere by their identifier. Use a comment block dedicated to the requirement, typically maintained in the requirement catalogue:

```
/**
* @requirement ZEPH-015 (Give a semaphore)
*
* The kernel shall provide a mechanism to give a semaphore, increasing its
* count up to its configured maximum.
*/
```

The identifier used here (for example `ZEPH-015`) is the same one referenced by the `@satisfies` and `@verifies` commands below, which is what links the implementation and tests back to the requirement.

The doxygen `@verifies` command signifies that a test verifies a requirement:

```
/**
* @brief Tests for the Semaphore kernel object
* @defgroup kernel_semaphore_tests Semaphore
* @ingroup all_tests
* @{
*/

...
/**
* @brief A brief description of the tests
* Some details about the test
* more details
*
* @verifies ZEPH-015
*/
void test_sema_thread2thread(void)
{
...
}
...

/**
* @}
*/
```

To get coverage of how an implementation or a piece of code satisfies a requirement, we use the doxygen `@satisfies` command:

```
/**
* @brief Give a semaphore.
```

(continues on next page)

(continued from previous page)

```
*
* This routine gives @a sem, unless the semaphore is already at its maximum
* permitted count.
*
* @note Can be called by ISRs.
*
* @param sem Address of the semaphore.
*
* @satisfies ZEPH-015
*/
__syscall void k_sem_give(struct k_sem *sem);
```

To generate the matrix, you will first need to build the documentation, specifically you will need to build the doxygen XML output:

```
$ make doxygen
```

Parse the generated XML data from doxygen to generate the traceability matrix.

The Zephyr project defines a development process workflow using GitHub **Issues** to track feature, enhancement, and bug reports together with GitHub **Pull Requests** (PRs) for submitting and reviewing changes. Zephyr community members work together to review these Issues and PRs, managing feature enhancements and quality improvements of Zephyr through its regular releases, as described in *Release Process*.

We can only manage the volume of Issues and PRs, by requiring timely reviews, feedback, and responses from the community and contributors, both for initial submissions and for followup questions and clarifications. Read about the project's *development processes and tools* and specifics about *review timelines* to learn about the project's goals and guidelines for our active developer community.

TSC Project Roles describes in detail the Zephyr project roles and associated permissions with respect to the development process workflow.

8.11 Terminology

- mainline: The main tree where the core functionality and core features are being developed.
- subsystem/feature branch: is a branch within the same repository. In our case, we will use the term branch also when referencing branches not in the same repository, which are a copy of a repository sharing the same history.
- upstream: A parent branch the source code is based on. This is the branch you pull from and push to, basically your upstream.
- LTS: Long Term Support

Chapter 9

Security

These documents describe the requirements, processes, and developer guidelines for ensuring security is addressed within the Zephyr project.

9.1 Zephyr Security Overview

9.1.1 Introduction

This document outlines the steps of the Zephyr Security Subcommittee towards a defined security process that helps developers build more secure software while addressing security compliance requirements. It presents the key ideas of the security process and outlines which documents need to be created. After the process is implemented and all supporting documents are created, this document is a top-level overview and entry point.

Overview and Scope

We begin with an overview of the Zephyr development process, which mainly focuses on security functionality.

In subsequent sections, the individual parts of the process are treated in detail. As depicted in Figure 1, these main steps are:

1. **Secure Development:** Defines the system architecture and development process that ensures adherence to relevant coding principles and quality assurance procedures.
2. **Secure Design:** Defines security procedures and implement measures to enforce them. A security architecture of the system and relevant sub-modules is created, threats are identified, and countermeasures designed. Their correct implementation and the validity of the threat models are checked by code reviews. Finally, a process shall be defined for reporting, classifying, and mitigating security issues.
3. **Security Certification:** Defines the certifiable part of the Zephyr RTOS. This includes an evaluation target, its assets, and how these assets are protected. Certification claims shall be determined and backed with appropriate evidence.

Intended Audience

This document is a guideline for the development of a security process by the Zephyr Security Subcommittee and the Zephyr Technical Steering Committee. It provides an overview of the Zephyr security process for (security) engineers and architects.

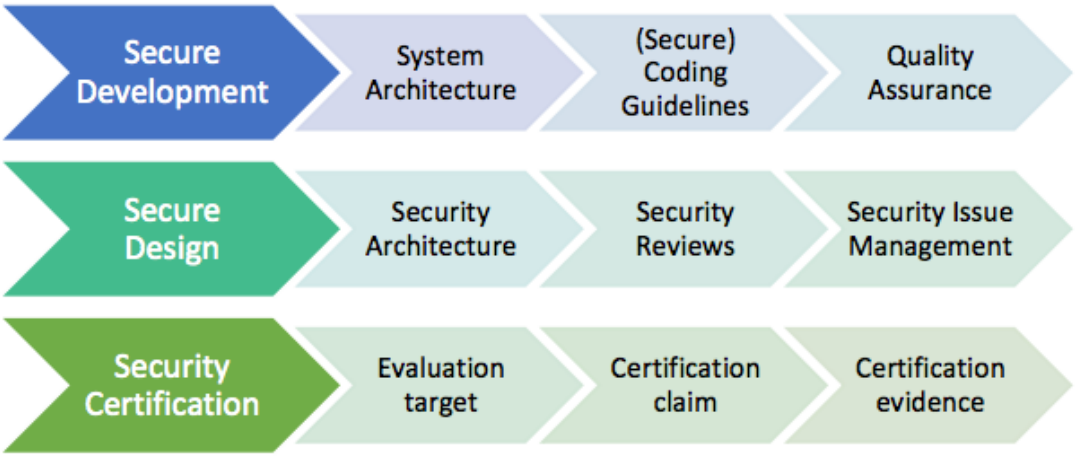

Fig. 1: Figure 1. Security Process Steps

Nomenclature

In this document, the keywords “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” are to be interpreted as described in **[?]**.

These words are used to define absolute requirements (or prohibitions), highly recommended requirements, and truly optional requirements. As noted in RFC-2119, “These terms are frequently used to specify behavior with security implications. The effects on security of not implementing a MUST or SHOULD, or doing something the specification says MUST NOT or SHOULD NOT be done may be very subtle. Document authors should take the time to elaborate the security implications of not following recommendations or requirements as most implementers will not have had the benefit of the experience and discussion that produced the specification.”

Security Document Update

This document is a living document. As new requirements, features, and changes are identified, they will be added to this document through the following process:

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Security Subcommittee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

9.1.2 Current Security Definition

This section recapitulates the current status of secure development within the Zephyr RTOS. Currently, focus is put on functional security and code quality assurance, although additional security features are scoped.

The three major security measures currently implemented are:

- **Security Functionality** with a focus on cryptographic algorithms and protocols. Support for cryptographic hardware is scoped for future releases. The Zephyr runtime architecture is a monolithic binary and removes the need for dynamic loaders, thereby reducing the exposed attack surface.

- **Quality Assurance** is driven by using a development process that requires all code to be reviewed before being committed to the common repository. Furthermore, the reuse of proven building blocks such as network stacks increases the overall quality level and guarantees stable APIs. Static code analyses provide additional quality checks.
- **Execution Protection** including thread separation, stack and memory protection is currently available in the upstream Zephyr RTOS starting with version 1.9.0 (stack protection). Memory protection and thread separation were added in version 1.10.0 for X86 and in version 1.11.0 for ARM and ARC.

These topics are discussed in more detail in the following subsections.

Security Functionality

The security functionality in Zephyr hinges mainly on the inclusion of cryptographic algorithms, and on its monolithic system design.

The cryptographic features are provided through PSA Crypto, with Mbed TLS as the underlying implementation. Applications leverage PSA Crypto APIs, ensuring a standardized and secure approach to cryptographic operations. Mbed TLS, as the implementation of PSA Crypto, supports a wide range of cryptographic algorithms, making it suitable for various application requirements.

APIs for vendor specific cryptographic IPs in both hardware and software are planned, including secure key storage in the form of secure access modules (SAMs), Trusted Platform Modules (TPMs), and Trusted Execution Environments (TEEs).

The security architecture is based on a monolithic design where the Zephyr kernel and all applications are compiled into a single static binary. System calls are implemented as function calls without requiring context switches. Static linking eliminates the potential for dynamically loading malicious code.

Additional protection features are available in later releases. Stack protection mechanisms are provided to protect against stack overruns. In addition, applications can take advantage of thread separation features to split the system into privileged and unprivileged execution environments. Memory protection features provide the capability to partition system resources (memory, peripheral address space, etc.) and assign resources to individual threads or groups of threads. Stack, thread execution level, and memory protection constraints are enforced at the time of context switch.

Quality Assurance

The Zephyr project uses an automated quality assurance process. The goal is to have a process including mandatory code reviews, feature and issue management/tracking, and static code analyses.

Code reviews are documented and enforced using a voting system before getting checked into the repository by the responsible subsystem's maintainer. The main goals of the code review are:

- Verifying correct functionality of the implementation
- Increasing the readability and maintainability of the contributed source code
- Ensuring appropriate usage of string and memory functions
- Validation of the user input
- Reviewing the security relevant code for potential issues

The current coding principles focus mostly on coding styles and conventions. Functional correctness is ensured by the build system and the experience of the reviewer. Especially for security relevant code, concrete and detailed guidelines need to be developed and aligned with the developers (see: *Secure Coding*).

Static code analyses are run on the Zephyr code tree on a regular basis, see *Static Code Analysis*.

Bug and issue tracking and management is performed using Github. The term “survivability” was coined to cover pro-active security tasks such as security issue categorization and management. A problem identified as vulnerability is managed within Github security advisories.

Issues determined by static analyses should have more stringent reviews before they are closed as non-issues (at least another person educated in security processes need to agree on non-issue before closing).

A security subcommittee has been formed to develop a security process in more detail; this document is part of that process.

Execution Protection

Execution protection is supported and can be categorized into the following tasks:

- **Memory separation:** Memory will be partitioned into regions and assigned attributes based on the owner of that region of memory. Threads will only have access to regions they control.
- **Stack protection:** Stack guards would provide mechanisms for detecting and trapping stack overruns. Individual threads should only have access to their own stacks.
- **Thread separation:** Individual threads should only have access to their own memory resources. As threads are scheduled, only memory resources owned by that thread will be accessible. Topics such as program flow protection and other measures for tamper resistance are currently not in scope.

System Level Security (Ecosystem, ...)

System level security encompasses a wide variety of categories. Some examples of these would be:

- Secure/trusted boot
- Over the air (OTA) updates
- External Communication
- Device authentication
- Access control of onboard resources
  - Flash updating
  - Secure storage
  - Peripherals
- Root of trust
- Reduction of attack surface

Some of these categories are interconnected and rely on multiple pieces to be in place to produce a full solution for the application.

9.1.3 Secure Development Process

The development of secure code shall adhere to certain criteria. These include coding guidelines and development processes that can be roughly separated into two categories related to software quality and related to software security. Furthermore, a system architecture document shall be created and kept up-to-date with future development.

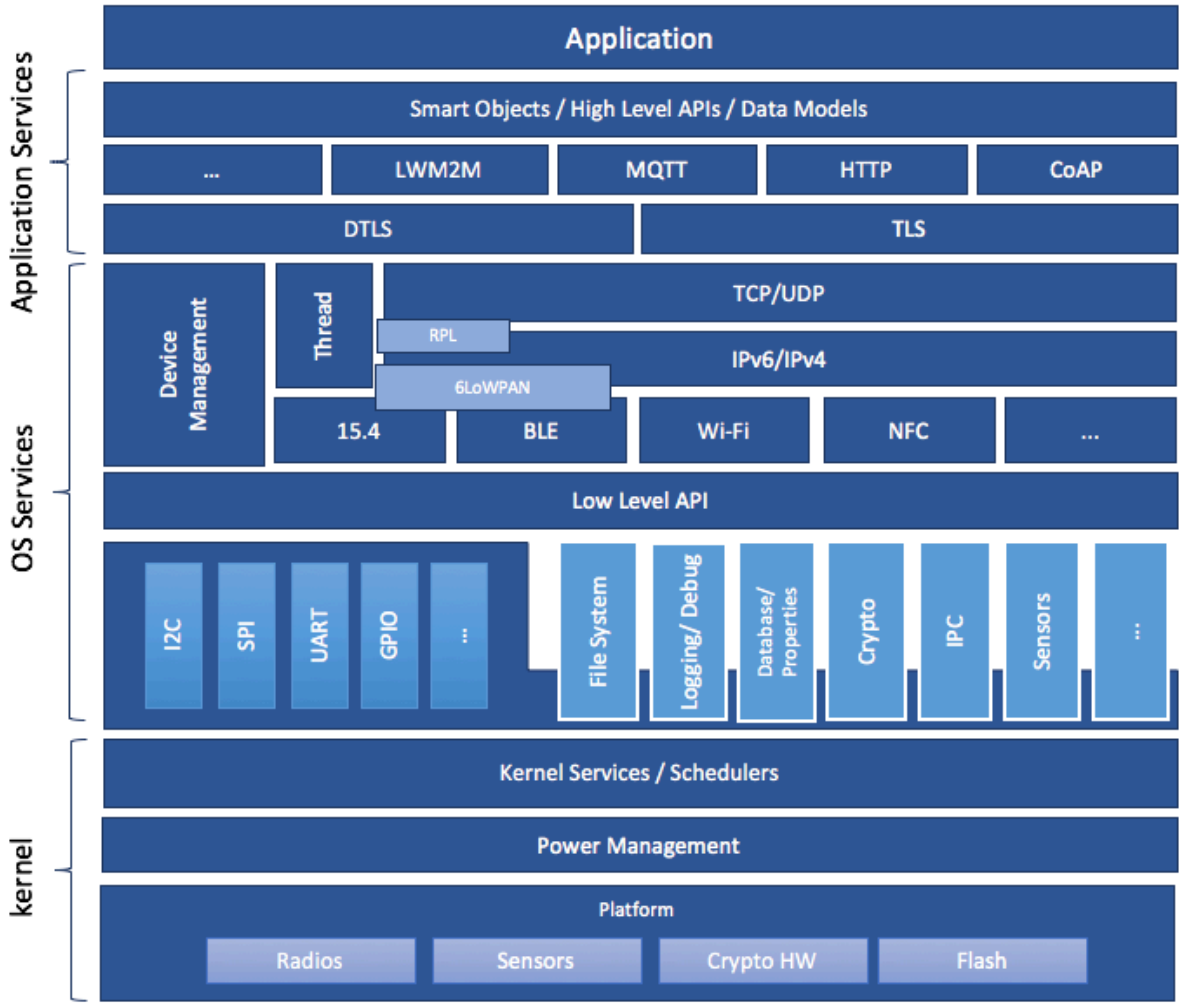

Fig. 2: Figure 2: Zephyr System Architecture

System Architecture

A high-level schematic of the Zephyr system architecture is given in Figure 2. It separates the architecture into an OS part (*kernel + OS Services*) and a user-specific part (*Application Services*). The OS part itself contains low-level, platform specific drivers and the generic implementation of I/O APIs, file systems, kernel-specific functions, and the cryptographic library.

A document describing the system architecture and design choices shall be created and kept up to date with future development. This document shall include the base architecture of the Zephyr OS and an overview of important submodules. For each of the modules, a dedicated architecture document shall be created and evaluated against the implementation. These documents shall serve as an entry point to new developers and as a basis for the security architecture. Please refer to the *Zephyr subsystem documentation* for detailed information.

Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. These standards are included in the Zephyr Project documentation, specifically in its *Secure Coding* section. In [**?**], the following, widely accepted principles for protection mechanisms are defined to prevent security violations and limit their impact:

- **Open design** as a design principle incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.
- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [**?**] and abstracted APIs.
- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.
- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [**?**].
- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [**?**].
- **Least privilege** describes an access model in which each user, program and thread shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.
- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [**?**] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.
- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure its usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth:** do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [**?**] paradigm shall be used.
- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely

used (a threshold of 80% is given in [**?**]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.

- **Change management:** to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

Based on these design principles and commonly accepted best practices, a secure development guide shall be developed, published, and implemented into the Zephyr development process. Further details on this are given in the *Secure Design* section.

Quality Assurance

The quality assurance part encompasses the following criteria:

- **Adherence to the Coding Conventions** with respect to coding style, naming schemes of modules, functions, variables, and so forth. This increases the readability of the Zephyr code base and eases the code review. These coding conventions are enforced by automated scripts prior to check-in.
- **Adherence to Deployment Guidelines** is required to ensure consistent releases with a well-documented feature set and a trackable list of security issues.
- **Code Reviews** ensure the functional correctness of the code base and shall be performed on each proposed code change prior to check-in. Code reviews shall be performed by at least one independent reviewer other than the author(s) of the code change. These reviews shall be performed by the subsystem maintainers and developers on a functional level and are to be distinguished from security reviews as laid out in the *Secure Design* section. Refer to the *Project and Governance* documentation for more information.
- **Static Code Analysis** tools efficiently detect common coding mistakes in large code bases. All code shall be analyzed using an appropriate tool prior to merges into the main repository. This is not per individual commit, but is to be run on some interval on specific branches. It is mandatory to remove all findings or waive potential false-positives before each release. Waivers shall be documented centrally and in the form of a comment inside the source code itself. The documentation shall include the employed tool and its version, the date of the analysis, the branch and parent revision number, the reason for the waiver, the author of the respective code, and the approver(s) of the waiver. This shall as a minimum run on the main release branch and on the security branch. It shall be ensured that each release has zero issues with regard to static code analysis (including waivers). Refer to the *Project and Governance* documentation for more information.
- **Complexity Analyses** shall be performed as part of the development process and metrics such as cyclomatic complexity shall be evaluated. The main goal is to keep the code as simple as possible.
- **Automation:** the review process and checks for coding rule adherence are a mandatory part of the precommit checks. To ensure consistent application, they shall be automated as part of the precommit procedure. Prior to merging large pieces of code in from subsystems, in addition to review process and coding rule adherence, all static code analysis must have been run and issues resolved.

Release and Lifecycle Management

Lifecycle management contains several aspects:

- **Device management** encompasses the possibility to update the operating system and/or security related sub-systems of Zephyr enabled devices in the field.
- **Lifecycle management:** system stages shall be defined and documented along with the transactions between the stages in a system state diagram. For security reasons, this shall include locking of the device in case an attack has been detected, and a termination if the end of life is reached.
- **Release management** describes the process of defining the release cycle, documenting releases, and maintaining a record of known vulnerabilities and mitigations. Especially for certification purposes the integrity of the release needs to be ensured in a way that later manipulation (e.g., inserting of backdoors, etc.) can be easily detected.
- **Rights management and NDAs:** if required by the chosen certification, the confidentiality and integrity of the system needs to be ensured by an appropriate rights management (e.g., separate source code repository) and non-disclosure agreements between the relevant parties. In case of a repository shared between several parties, measures shall be taken that no malicious code is checked in.

These points shall be evaluated with respect to their impact on the development process employed for the Zephyr project.

9.1.4 Secure Design

In order to obtain a certifiable system or product, the security process needs to be clearly defined and its application needs to be monitored and driven. This process includes the development of security related modules in all of its stages and the management of reported security issues. Furthermore, threat models need to be created for currently known and future attack vectors, and their impact on the system needs to be investigated and mitigated. Please refer to the *Secure Coding* outlined in the Zephyr project documentation for detailed information.

The software security process includes:

- **Adherence to the Secure Development Coding** is mandatory to avoid that individual components breach the system security and to minimize the vulnerability of individual modules. While this can be partially achieved by automated tests, it is inevitable to investigate the correct implementation of security features such as countermeasures manually in security-critical modules.
- **Security Reviews** shall be performed by a security architect in preparation of each security-targeted release and each time a security-related module of the Zephyr project is changed. This process includes the validation of the effectiveness of implemented security measures, the adherence to the global security strategy and architecture, and the preparation of audits towards a security certification if required.
- **Security Issue Management** encompasses the evaluation of potential system vulnerabilities and their mitigation as described in *Security Issue Management*.

These criteria and tasks need to be integrated into the development process for secure software and shall be automated wherever possible. On system level, and for each security related module of the secure branch of Zephyr, a directly responsible security architect shall be defined to guide the secure development process.

Security Architecture

The general guidelines above shall be accompanied by an architectural security design on system- and module-level. The high level considerations include

- The identification of **security and compliance requirements**
- **Functional security** such as the use of cryptographic functions whenever applicable
- Design of **countermeasures** against known attack vectors

- Recording of security relevant **auditable events**
- Support for **Trusted Platform Modules (TPM)** and **Trusted Execution Environments (TEE)**
- Mechanisms to allow for **in-the-field updates** of devices using Zephyr
- Task scheduler and separation

The security architecture development is based on assets derived from the structural overview of the overall system architecture. Based on this, the individual steps include:

1. **Identification of assets** such as user data, authentication and encryption keys, key generation data (obtained from RNG), security relevant status information.
2. **Identification of threats** against the assets such as breaches of confidentiality, manipulation of user data, etc.
3. **Definition of requirements** regarding security and protection of the assets, e.g., countermeasures or memory protection schemes.

The security architecture shall be harmonized with the existing system architecture and implementation to determine potential deviations and mitigate existing weaknesses. Newly developed sub-modules that are integrated into the secure branch of the Zephyr project shall provide individual documents describing their security architecture. Additionally, their impact on the system level security shall be considered and documented.

Security Vulnerability Reporting

Please see *Security Vulnerability Reporting* for information on reporting security vulnerabilities.

Threat Modeling and Mitigation

The modeling of security threats against the Zephyr RTOS is required for the development of an accurate security architecture and for most certification schemes. The first step of this process is the definition of assets to be protected by the system. The next step then models how these assets are protected by the system and which threats against them are present. After a threat has been identified, a corresponding threat model is created. This model contains the asset and system vulnerabilities, as well as the description of the potential exploits of these vulnerabilities. Additionally, the impact on the asset, the module it resides in, and the overall system is to be estimated. This threat model is then considered in the module and system security architecture and appropriate countermeasures are defined to mitigate the threat or limit the impact of exploits.

In short, the threat modeling process can be separated into these steps (adapted from **[?]**):

1. Definition of assets
2. Application decomposition and creation of appropriate data flow diagrams (DFDs)
3. Threat identification and categorization using the **[?]** and **[?]** approaches
4. Determination of countermeasures and other mitigation approaches

This procedure shall be carried out during the design phase of modules and before major changes of the module or system architecture. Additionally, new models shall be created, or existing ones shall be updated whenever new vulnerabilities or exploits are discovered. During security reviews, the threat models and the mitigation techniques shall be evaluated by the responsible security architect.

From these threat models and mitigation techniques tests shall be derived that prove the effectiveness of the countermeasures. These tests shall be integrated into the continuous integration workflow to ensure that the security is not impaired by regressions.

Vulnerability Analyses

In order to find weak spots in the software implementation, vulnerability analyses (VA) shall be performed. Of special interest are investigations on cryptographic algorithms, critical OS tasks, and connectivity protocols.

On a pure software level, this encompasses

- **Penetration testing** of the RTOS on a particular hardware platform, which involves testing the respective Zephyr OS configuration and hardware as one system.
- **Side channel attacks** (timing invariance, power invariance, etc.) should be considered. For instance, ensuring **timing invariance** of the cryptographic algorithms and modules is required to reduce the attack surface. This applies to both the software implementations and when using cryptographic hardware.
- **Fuzzing tests** shall be performed on both exposed APIs and protocols.

The list given above serves primarily illustration purposes. For each module and for the complete Zephyr system (in general on a particular hardware platform), a suitable VA plan shall be created and executed. The findings of these analyses shall be considered in the security issue management process, and learnings shall be formulated as guidelines and incorporated into the secure coding guide.

If possible (as in case of fuzzing analyses), these tests shall be integrated into the continuous integration process.

9.1.5 Security Certification

One goal of creating a secure branch of the Zephyr RTOS is to create a certifiable system or certifiable submodules thereof. The certification scope and scheme are yet to be decided. However, many certifications such as Common Criteria [**?**] require evidence that the evaluation claims are indeed fulfilled, so a general certification process is outlined in the following. Based on the final choices for the certification scheme and evaluation level, this process needs to be refined.

Generic Certification Process

In general, the steps towards a certification or precertification (compare [**?**]) are:

1. The **definition of assets** to be protected within the Zephyr RTOS. Potential candidates are confidential information such as cryptographic keys, user data such as communication logs, and potentially IP of the vendor or manufacturer.
2. Developing a **threat model** and **security architecture** to protect the assets against exploits of vulnerabilities of the system. As a complete threat model includes the overall product including the hardware platform, this might be realized by a split model containing a precertified secure branch of Zephyr which the vendor could use to certify their Zephyr-enabled product.
3. Formulating an **evaluation target** that includes the **certification claims** on the security of the assets to be evaluated and certified, as well as assumptions on the operating conditions.
4. Providing **proof** that the claims are fulfilled. This includes consistent documentation of the security development process, etc.

These steps are partially covered in previous sections as well. In contrast to these sections, the certification process only requires to consider those components that shall be covered by the certification. The security architecture, for example, considers assets on system level and might include items not relevant for the certification.

Certification Options

For the security certification as such, the following options can be pursued:

1. **Abstract precertification of Zephyr as a pure software system:** this option requires assumptions on the underlying hardware platform and the final application running on top of Zephyr. If these assumptions are met by the hardware and the application, a full certification can be more easily achieved. This option is the most flexible approach but puts the largest burden on the product vendor.
2. **Certification of Zephyr on specific hardware platform without a specific application in mind:** this scenario describes the enablement of a secure platform running the Zephyr RTOS. The hardware manufacturer certifies the platform under defined assumptions on the application. If these are met, the final product can be certified with little effort.
3. **Certification of an actual product:** in this case, a full product including a specific hardware, the Zephyr RTOS, and an application is certified.

In all three cases, the certification scheme (e.g., FIPS 140-2 [**?**] or Common Criteria [**?**]), the scope of the certification (main-stream Zephyr, security branch, or certain modules), and the certification/assurance level need to be determined.

In case of partial certifications (options 1 and 2), assumptions on hardware and/or software are required for certifications. These can include [**?**]

- **Appropriate physical security** of the hardware platform and its environment.
- **Sufficient protection of storage and timing channels** on the hardware platform itself and all connected devices. (No mentioning of remote connections.)
- Only **trusted/assured applications** running on the device
- The device and its software stack is configured and operated by **properly trained and trusted individuals** with no malicious intent.

These assumptions shall be part of the security claim and evaluation target documents.

9.2 Security Vulnerability Reporting

9.2.1 Introduction

Vulnerabilities in the Zephyr project should preferably be reported by opening a draft security advisory on the Zephyr repository's security advisories page. Alternatively, reports may be submitted to the project security incident response team via email to vulnerabilities@zephyrproject.org. These reports will be acknowledged and analyzed by the security response team within 1 week.

All vulnerabilities are tracked and managed through the Zephyr project's security advisories page on GitHub, where the original submitter will be granted access to view the issues that they have reported.

9.2.2 Vulnerability Reporting Guidelines

Security research and vulnerability reporting are valued contributions to the Zephyr project. To keep this process safe and productive for everyone, all reports and related activities must comply with the Zephyr project Code of Conduct.

The guidelines below describe what is expected when researching and reporting security vulnerabilities in Zephyr.

Reporting expectations

To help the security response team triage and resolve issues efficiently, a report should:

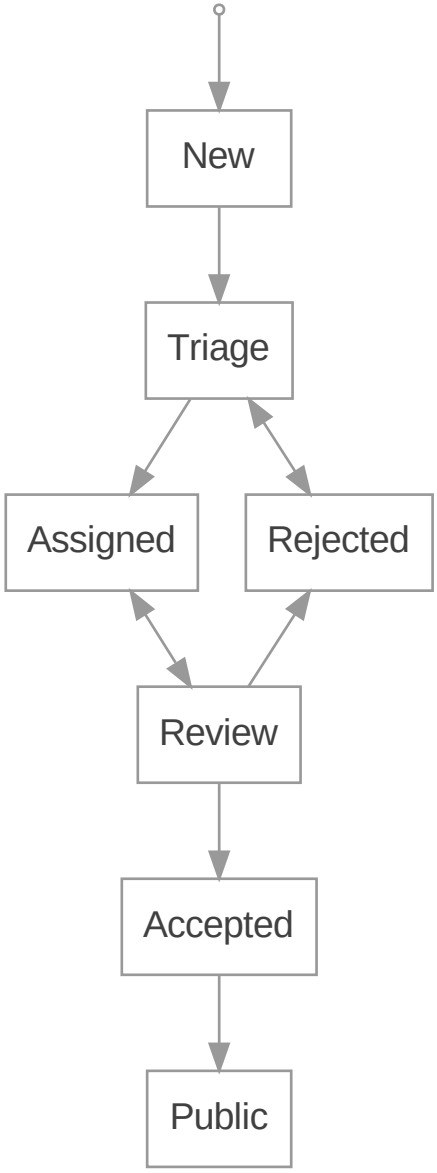
- Describe the affected component, version, board or platform, and configuration needed to reproduce the issue.

- Include clear, step-by-step reproduction instructions and a minimal proof-of-concept where possible.
- Explain the security impact (for example, loss of confidentiality, integrity, or availability) and any known mitigations.
- Avoid including destructive payloads or components that could cause harm to users or systems if the report were inadvertently disclosed.

Reporters are expected to make a good-faith effort to give the project a reasonable opportunity to investigate and remediate the issue before any public disclosure, consistent with the embargo and disclosure process described in the following sections.

9.2.3 Security Issue Management

Issues within this bug tracking system will transition through a number of states according to this diagram:



- New: This state represents new reports that have been entered directly by a reporter. When entered by the response team in response to an email, the issue shall be transitioned directly to Triage.
- Triage: This issue is awaiting Triage by the response team. The response team will analyze the issue, determine a responsible entity, assign it to that individual, and move the issue to the Assigned state. Part of triage will be to set the issue's priority.
- Assigned: The issue has been assigned, and is awaiting a fix by the assignee.
- Review: Once there is a Zephyr pull request for the issue, the PR link will be added to a comment in the issue, and the issue moved to the Review state.
- Accepted: Indicates that this issue has been merged into the appropriate branch within Zephyr.
- Public: The embargo period has ended. The issue will be made publicly visible, the associ-

ated CVE updated, and the vulnerabilities page in the docs updated to include the detailed information.

The security advisories created are kept private, due to the sensitive nature of security reports. The issues are only visible to certain parties:

- Members of the PSIRT mailing list
- the reporter
- others, as proposed and ratified by the Zephyr Security Subcommittee. In the general case, this will include:
  - The code owner responsible for the fix.
  - The Zephyr release owners for the relevant releases affected by this vulnerability.

The Zephyr Security Subcommittee shall review the reported vulnerabilities during any meeting with more than three people in attendance. During this review, they shall determine if new issues need to be embargoed.

The guideline for embargo will be based on: 1. Severity of the issue, and 2. Exploitability of the issue. Issues that the subcommittee decides do not need an embargo will be reproduced in the regular Zephyr project bug tracking system.

Security sensitive vulnerabilities shall be made public after an embargo period of at most 90 days. The intent is to allow 30 days within the Zephyr project to fix the issues, and 60 days for external parties building products using Zephyr to be able to apply and distribute these fixes.

Fixes to the code shall be made through pull requests PR in the Zephyr project github. Developers shall make an attempt to not reveal the sensitive nature of what is being fixed, and shall not refer to CVE numbers that have been assigned to the issue. The developer instead should merely describe what has been fixed.

The security subcommittee will maintain information mapping embargoed CVEs to these PRs (this information is within the Github security advisories), and produce regular reports of the state of security issues.

Each issue that is considered a security vulnerability shall be assigned a CVE number. As fixes are created, it may be necessary to allocate additional CVE numbers, or to retire numbers that were assigned.

9.2.4 Vulnerability Notification

Each Zephyr release shall contain a report of CVEs that were fixed in that release. Because of the sensitive nature of these vulnerabilities, the release shall merely include a list of CVEs that have been fixed. After the embargo period, the vulnerabilities page shall be updated to include additional details of these vulnerabilities. The vulnerability page shall give credit to the reporter(s) unless a reporter specifically requests anonymity.

The Zephyr project shall maintain a vulnerability-alerts mailing list. This list will be seeded initially with a contact from each project member. Additional parties can request to join this list by filling out the form at the Vulnerability Registry. These parties will be vetted by the project director to determine that they have a legitimate interest in knowing about security vulnerabilities during the embargo period.

Periodically, the security subcommittee will send information to this mailing list describing known embargoed issues, and their backport status within the project. This information is intended to allow them to determine if they need to backport these changes to any internal trees.

When issues have been triaged, this list will be informed of:

- The Zephyr Project security advisory link (GitHub).
- The CVE number assigned.
- The subsystem involved.

- The severity of the issue.

After acceptance of a PR fixing the issue (merged), in addition to the above, the list will be informed of:

- The association between the CVE number and the PR fixing it.
- Backport plans within the Zephyr project.

9.2.5 Backporting of Security Vulnerabilities

Each security issue fixed within zephyr shall be backported to the following releases:

- The current Long Term Stable (LTS) release.
- The most recent two releases.

The developer of the fix shall be responsible for any necessary backports, and apply them to any of the above listed release branches, unless the fix does not apply (the vulnerability was introduced after this release was made). All recommendations for *vulnerability fixes* apply for backport pull requests (and associated issues). Additionally, it is recommended that the developer privately informs the responsible release manager that the backport pull request and issue are addressing a vulnerability.

Backports will be tracked on the security advisory.

9.2.6 Need to Know

Due to the sensitive nature of security vulnerabilities, it is important to share details and fixes only with those parties that have a need to know. The following parties will need to know details about security vulnerabilities before the embargo period ends:

- Maintainers will have access to all information within their domain area only.
- The current release manager, and the release manager for historical releases affected by the vulnerability (see backporting above).
- The Project Security Incident Response (PSIRT) team will have full access to information. The PSIRT is made up of representatives from platinum members, and volunteers who do work on triage from other members.
- As needed, release managers and maintainers may be invited to attend additional security meetings to discuss vulnerabilities.

9.3 Secure Coding

Traditionally, microcontroller-based systems have not placed much emphasis on security. They have usually been thought of as isolated, disconnected from the world, and not very vulnerable, just because of the difficulty in accessing them. The Internet of Things has changed this. Now, code running on small microcontrollers often has access to the internet, or at least to other devices (that may themselves have vulnerabilities). Given the volume they are often deployed at, uncontrolled access can be devastating[1].

This document describes the requirements and process for ensuring security is addressed within the Zephyr project. All code submitted should comply with these principles.

Much of this document comes from [**?**].

[1] An attack resulted in a significant portion of DNS infrastructure being taken down.

9.3.1 Introduction and Scope

This document covers guidelines for the Zephyr Project, from a security perspective. Many of the ideas contained herein are captured from other open source efforts.

We begin with an overview of secure design as it relates to Zephyr. This is followed by a section on *Secure development knowledge*, which gives basic requirements that a developer working on the project will need to have. This section gives references to other security documents, and full details of how to write secure software are beyond the scope of this document. This section also describes vulnerability knowledge that at least one of the primary developers should have. This knowledge will be necessary for the review process described below this.

Following this is a description of the review process used to incorporate changes into the Zephyr codebase. This is followed by documentation about how security-sensitive issues are handled by the project.

Finally, the document covers how changes are to be made to this document.

9.3.2 Secure Coding

Designing an open software system such as Zephyr to be secure requires adhering to a defined set of design standards. In [**?**], the following, widely accepted principles for protection mechanisms are defined to help prevent security violations and limit their impact:

- **Open design** as a design guideline incorporates the maxim that protection mechanisms cannot be kept secret on any system in widespread use. Instead of relying on secret, custom-tailored security measures, publicly accepted cryptographic algorithms and well established cryptographic libraries shall be used.
- **Economy of mechanism** specifies that the underlying design of a system shall be kept as simple and small as possible. In the context of the Zephyr project, this can be realized, e.g., by modular code [**?**] and abstracted APIs.
- **Complete mediation** requires that each access to every object and process needs to be authenticated first. Mechanisms to store access conditions shall be avoided if possible.
- **Fail-safe defaults** defines that access is restricted by default and permitted only in specific conditions defined by the system protection scheme, e.g., after successful authentication. Furthermore, default settings for services shall be chosen in a way to provide maximum security. This corresponds to the “Secure by Default” paradigm [**?**].
- **Separation of privilege** is the principle that two conditions or more need to be satisfied before access is granted. In the context of the Zephyr project, this could encompass split keys [**?**].
- **Least privilege** describes an access model in which each user, program, and thread, shall have the smallest possible subset of permissions in the system required to perform their task. This positive security model aims to minimize the attack surface of the system.
- **Least common mechanism** specifies that mechanisms common to more than one user or process shall not be shared if not strictly required. The example given in [**?**] is a function that should be implemented as a shared library executed by each user and not as a supervisor procedure shared by all users.
- **Psychological acceptability** requires that security features are easy to use by the developers in order to ensure their usage and the correctness of its application.

In addition to these general principles, the following points are specific to the development of a secure RTOS:

- **Complementary Security/Defense in Depth**: do not rely on a single threat mitigation approach. In case of the complementary security approach, parts of the threat mitigation are performed by the underlying platform. In case such mechanisms are not provided by the platform, or are not trusted, a defense in depth [**?**] paradigm shall be used.

- **Less commonly used services off by default**: to reduce the exposure of the system to potential attacks, features or services shall not be enabled by default if they are only rarely used (a threshold of 80% is given in [**?**]). For the Zephyr project, this can be realized using the configuration management. Each functionality and module shall be represented as a configuration option and needs to be explicitly enabled. Then, all features, protocols, and drivers not required for a particular use case can be disabled. The user shall be notified if low-level options and APIs are enabled but not used by the application.
- **Change management**: to guarantee a traceability of changes to the system, each change shall follow a specified process including a change request, impact analysis, ratification, implementation, and validation phase. In each stage, appropriate documentation shall be provided. All commits shall be related to a bug report or change request in the issue tracker. Commits without a valid reference shall be denied.

9.3.3 Secure development knowledge

Secure designer

The Zephyr project must have at least one primary developer who knows how to design secure software.

This requires understanding the following design principles, including the 8 principles from [**?**]:

- economy of mechanism (keep the design as simple and small as practical, e.g., by adopting sweeping simplifications)
- fail-safe defaults (access decisions shall deny by default, and projects' installation shall be secure by default)
- complete mediation (every access that might be limited must be checked for authority and be non-bypassable)
- open design (security mechanisms should not depend on attacker ignorance of its design, but instead on more easily protected and changed information like keys and passwords)
- separation of privilege (ideally, access to important objects should depend on more than one condition, so that defeating one protection system won't enable complete access. For example, multi-factor authentication, such as requiring both a password and a hardware token, is stronger than single-factor authentication)
- least privilege (processes should operate with the least privilege necessary)
- least common mechanism (the design should minimize the mechanisms common to more than one user and depended on by all users, e.g., directories for temporary files)
- psychological acceptability (the human interface must be designed for ease of use - designing for "least astonishment" can help)
- limited attack surface (the set of the different points where an attacker can try to enter or extract data)
- input validation with allowlists (inputs should typically be checked to determine if they are valid before they are accepted; this validation should use allowlists (which only accept known-good values), not blocklists (which attempt to list known-bad values)).

Vulnerability Knowledge

A "primary developer" in a project is anyone who is familiar with the project's code base, is comfortable making changes to it, and is acknowledged as such by most other participants in the project. A primary developer would typically make a number of contributions over the past year (via code, documentation, or answering questions). Developers would typically be considered primary developers if they initiated the project (and have not left the project more than three years ago), have the option of receiving information on a private vulnerability reporting channel

(if there is one), can accept commits on behalf of the project, or perform final releases of the project software. If there is only one developer, that individual is the primary developer.

At least one of the primary developers **must** know of common kinds of errors that lead to vulnerabilities in this kind of software, as well as at least one method to counter or mitigate each of them.

Examples (depending on the type of software) include SQL injection, OS injection, classic buffer overflow, cross-site scripting, missing authentication, and missing authorization. See the CWE/SANS top 25 or OWASP Top 10 for commonly used lists.

A free class from the nonprofit OpenSecurityTraining2 for C/C++ developers is available at OST2_1001. It teaches how to prevent, detect, and mitigate linear stack/heap buffer overflows, non-linear out of bound writes, integer overflows, and other integer issues. The follow-on class, OST2_1002, covers uninitialized data access, race conditions, use-after-free, type confusion, and information disclosure vulnerabilities.

Zephyr Security Subcommittee

There shall be a "Zephyr Security Subcommittee", responsible for enforcing this guideline, monitoring reviews, and improving these guidelines.

This team will be established according to the Zephyr Project charter.

9.3.4 Code Review

The Zephyr project shall use a code review system that all changes are required to go through. Each change shall be reviewed by at least one primary developer that is not the author of the change. This developer shall determine if this change affects the security of the system (based on their general understanding of security), and if so, shall request the developer with vulnerability knowledge, or the secure designer to also review the code. Any of these individuals shall have the ability to block the change from being merged into the mainline code until the security issues have been addressed.

9.3.5 Issues and Bug Tracking

The Zephyr project shall have an issue tracking system (such as GitHub) that can be used to record and track defects that are found in the system.

Because security issues are often sensitive, this issue tracking system shall have a field to indicate a security issue. Setting this field shall result in the issue only being visible to the Zephyr Security Subcommittee. In addition, there shall be a field to allow the Zephyr Security Subcommittee to add additional users that will have visibility to a given issue.

This embargo, or limited visibility, shall only be for a fixed duration, with a default being a project-decided value. However, because security considerations are often external to the Zephyr project itself, it may be necessary to increase this embargo time. The time necessary shall be clearly annotated in the issue itself.

The list of issues shall be reviewed at least once a month by the Zephyr Security Subcommittee. This review should focus on tracking the fixes, determining if any external parties need to be notified or involved, and determining when to lift the embargo on the issue. The embargo should **not** be lifted via an automated means, but the review team should avoid unnecessary delay in lifting issues that have been resolved.

9.3.6 Modifications to This Document

Changes to this document shall be reviewed by the Zephyr Security Subcommittee, and approved by consensus.

9.4 Sensor Device Threat Model

This document describes a threat model for an IoT sensor device. Spelling out a threat model helps direct development effort, and can be used to help prioritize these efforts as well.

This device contains a sensor of some type (for example temperature, or a pressure in a pipe), which sends this data to an SoC running a microcontroller. This microcontroller connects to a cloud service, and relays this sensor data to this service. The cloud service is also able to send configuration data to the device, as well as software update images. A general diagram can be seen in Figure 1:

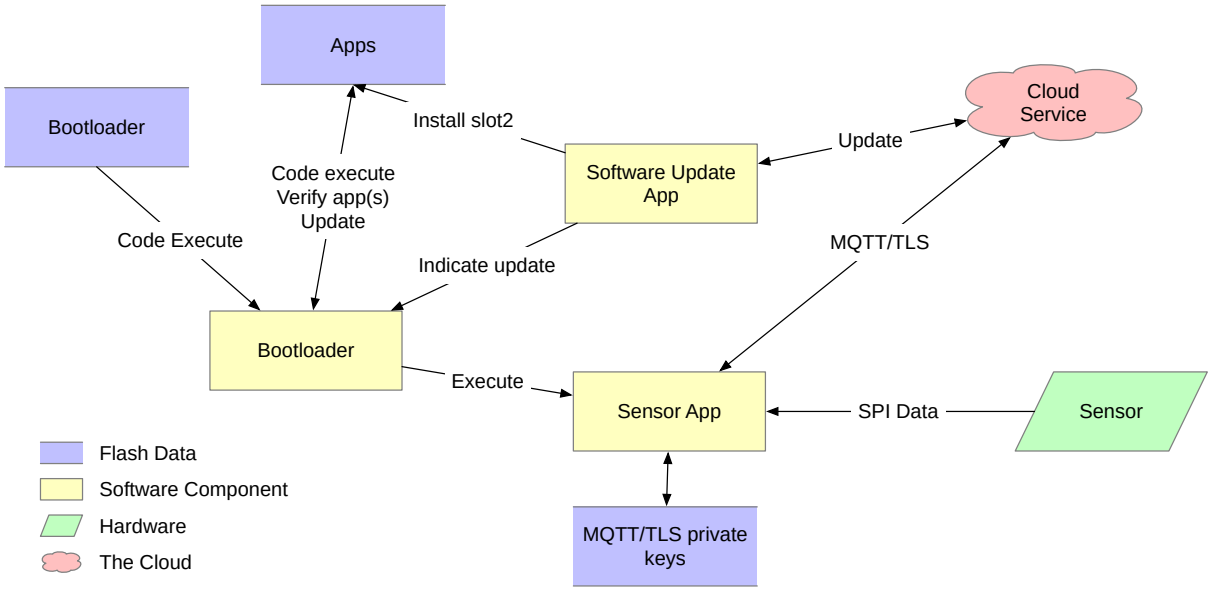


Fig. 3: Figure 1. Sensor General Diagram

In this sensor device, the sensor connects with the SoC via an SPI bus, and the SoC has a network interface that it uses to communicate with the cloud service. The particulars of these interfaces can impact the threat model in unexpected ways, and variants on this will need to be considered (for example, using a separate network interface SoC connected via some type of bus).

This model also focuses on communicating via the MQTT-over-TLS protocol, as this seems to be in wide use[1].

9.4.1 Assets

One aspect of the threat model to consider are assets involved in the operation of the device. The following list enumerates the assets included in this model:

1. **The bootloader**. This is a small code/data image contained in on-device flash that is the first code to run. In order to establish a root of trust, this image must be immutable. This model assumes that the SoC provides a mechanism to protect a region of the flash from future writes, and that this will be done after this image is programmed into the device, early in production [th-imboot].
2. **The application firmware image**. This asset consists of the remainder of the firmware run by the microcontroller. The distinction is made because this part of the image will need to be updated periodically as security vulnerabilities are discovered. Requirements for updates to this image are:
    a. The image shall only be replaced with an authorized image [th-authrepl].

[1] See https://www.slideshare.net/kartben/iot-developer-survey-2018. As of this writing, the three major cloud IoT service providers, AWS IoT, Google Cloud IoT, and Microsoft Azure IoT all provide MQTT over TLS. Some feedback has suggested that some find difficulty with UDP protocols and routing issues on various networks.

   b. When an authorized replacement image is available, the update shall be done in a timely manner [th-timely-update].

   c. The image update shall be seen as atomic, meaning that when the image is run, the flash shall contain either the update image in its entirety, or the old image in its entirety [th-atomic-update].

3. **Root certificate list**. In order to authenticate the cloud service (server), the IoT device must have a list of root certificates that are allowed to sign the certificate on the server. For cloud-provider based services, this list will generally be provided by the service provider. Because the root certificates can expire, and possibly be revoked, this list will need to be periodically updated [th-root-certs], [th-root-check].

4. **Client secrets**. To authenticate the client to the service, the client must possess some kind of secret. This is generally a private key, usually either an RSA key or an EC private key. When establishing communication with the server, the device will use this secret either as part of the TLS establishment, or to sign a message used in the communication.

   This secret is generally generated by the service provider, or by software running elsewhere, and must be securely installed on the device. Policy may dictate that this secret be replaced periodically, which will require a way to update the client secret. Typically, the service will allow two or three active keys to allow this update to proceed while the old key is used.

   These secrets must be protected from read, and the smallest amount of code necessary shall have access to them. [th-secret-storage]

5. **Current date/time**. TLS certificate verification requires knowledge of the current date and time in order to determine if the current time falls within the certificate's current validity time. Also, token based client authentication will generally require the client to sign a message containing a time window that the token is valid. Certificate validation requires the device's notion of date and time to be accurate within a day or so. Token generation generally requires the time to be accurate within 5-10 minutes.

   It may be possible to approximate secure time by querying an external time server. Secure NTP is possibly beyond the capabilities of an IoT device. The main risks of having incorrect time are denial of service (the device rejects valid certificates), and the generation of tokens with invalid times. It could be possible to trick the device into generating tokens that are valid in the future, but the attacker would also have to spoof the server's certificate to be able to intercept this. [th-time]

6. **Sensor data**. The data received from the sensor itself, and delivered to the service shall be delivered without modification or tampering.

7. **Device configuration**. Various configuration data, such as the hostname of the service to connect to, the address of a time server, frequency and parameters of when sensor data is sent to the service, and other need to be kept by the device. This configuration data will need to be updated periodically as the configuration changes. Updates should be allowed only from authorized parties. [th-conf]

8. **Logs**. In order to assist with analysis of security issues, the device shall log information about security-pertinent events. IoT devices generally have limited storage, and as such, these logs need to be carefully selected. It may also be possible to send these log events to the cloud service where they can be stored in a more resource-available environment. Types of events that should be logged include:

   a. **Firmware image updates**. The system should log the download of new images, and when an image is successfully updated.

   b. **Client secret changes**. Changes and new client secrets should be logged.

   c. **Changes to the device configuration**.

   [th-logs]

9.4.2 Communication

In addition to assets, the threat model also considers the locations where data or assets are communicated between entities of the system.

1. **Flash contents**. The flash device contains several regions. The contents of flash can be modified programmatically by the SoC's CPU.

   a. **The bootloader**. As described in the Assets section, the bootloader is a small section of the flash device containing the code initially run. This section shall be written early in the lifecycle of the device, and the flash device then configured to permanently disallow modification of this section. This configuration should also prevent modification via external interfaces, such as JTAG or SWD debuggers.

      The bootloader is responsible for verifying the signature of the application image as well as updating the application image from the update image when an update is needed.

      The bootloader shall verify the signature of the update image before installing it.

      The bootloader shall only accept an update image with a newer version number than the current image.

   b. **The application image**. The application image contains the code executed during normal operation of the device. Before running this image, the bootloader shall verify a digital signature of the image, to avoid running an image that has been tampered with. The flash/system shall be configured such that after the bootloader has completed, the CPU will be unable to write to the application image.

   c. **The update image**. This is an area of flash that holds a new version of the application image. This image will be downloaded and stored by the application during normal operation. When this has completed, the application can trigger a reboot, and the bootloader can install the new image.

   d. **Secret storage**. An area of the flash will be used to store client secrets. This area is written and read by a subset of the application image. The application shall be configured to protect this area from both reads and writes by code that does not need to have access to it, giving consideration to possible exploits found within a majority of the application code. Revealing the contents of the secrets would allow the attacker to spoof this device.

      Initial secrets shall be placed in the device during a provisioning activity, distinct from normal operation of the device. Later updates can be made under the direction of communication received over a secured channel to the service.

   e. **Configuration storage**. There shall be an area to store other configuration information. On resource-constrained devices, it is allowed for this to be stored in the same region as the secret storage, however, this adds additional code that has access to the secret storage area, and as such, more code that must be scrutinized.

   f. **Log storage**. The device may have an area of flash where log events can be written.

2. **Sensor/Actuator interface**. In this design, the sensor or actuator communicates with the SoC via a bus, such as SPI. The hardware design shall be made to make intercepting this bus difficult for an attack. Required techniques depend on the sensitivity and use of the sensor data, and can range from having the sensor mounted on the same PCB as the MCU to epoxy potting the entire device.

3. **Communication with cloud service**. Communication between the device, and the cloud service will be done over the general internet. As such, it shall be assumed that an attacker can arbitrarily intercept this channel and, for example, return spoofed DNS results or attempt man-in-the-middle attacks against communication with cloud services.

   The device shall use TLS for all communication with the cloud service [th-all-tls]. The TLS

stack shall be configured to use only cipher suites that are generally considered secure[2], including forward secrecy. The communication shall be secured by the following:

a. **Cipher suite selection**. The device shall only allow communication with generally agreed secure cipher suites [th-tls-ciphers].

b. **Server certificate verification**. The server presented by the server shall be verified [th-root-check].

   i. **Naming**. The certificate shall name the host and service the cloud service server is providing. **RFC 6125** describes best practices for this. It is permissible for the device to require the certificate to be more restrictive than as described in this RFC, provided the service can use a certificate that can comply.

   ii. **Path validation**. The device shall verify that the certificate chain has a valid signature path from a root certificate contained within the device, to the certificate presented by the service. **RFC 4158** describes this in general. The device is permitted to require a more restricted path, provided the server certificate used complies with this restriction.

   iii. **Validity period**. The validity period of all presented certificates shall be checked against the device's best notion of the current time.

c. **Client authentication**. The client shall authenticate itself to the service using a secret known only to that particular device. There are several options, and the technique used is generally mandated by the particular service provider being used [th-tls-client-auth].

   i. **TLS client certificates**. The TLS protocol allows the client to present a certificate, and assert its knowledge of the secret described by that certificate. Generally, these certificates will be stored within the service provider. These certificates can be self-signed, or signed by a CA. Since the service provider maintains a list of valid certificates (mapping them to a device identity), having these certificates signed by a CA does not add any additional security, but may be useful in the management of these certificates.

   ii. **Token-based authentication**. It is also possible for the client to authenticate itself using the *password* field of the MQTT CONNECT packet. However, the secret itself must not be transmitted in this packet. Instead, a token-based protocol, such as **RFC 7519**'s JSON Web Token (JWT) can be used. These tokens will generally have a small validity period (e.g. 1 hour), to prevent them from being reused if they are intercepted. The token shall not be sent until the device has verified the identity of the server.

d. **Random/Entropy source**. Cryptographic communication requires the generation of secure pseudorandom numbers. The device shall use a modern, accepted cryptographic random-bit generator to generate these random numbers. It shall use either a Non-Deterministic Random Bit Generator (True RBG) implemented in hardware within the SoC, or a Deterministic Random Bit Generator (Pseudo RBG) seeded by an entropy source within the SoC. Please see NIST SP 800-90A for information on approved RBGs and NIST SP 800-90B for information on testing a device's entropy source [th-entropy].

4. **Communication with the time service**. Ideally, the device shall contain hardware that maintains a secure time. However, most SoCs in use do not have support for this, and it will be necessary to consult an external time service. **RFC 4330** and referenced RFCs describe the Simple Network Time Protocol that can be used to query the current time from a network time server.

5. **Device lifecycle**. An IoT device will have a lifecycle from production to destruction and

[2] As new exploits are discovered, what is considered secure can change. Organizations such as https://www.ssllabs.com/ provide information on current ideas of how TLS must be configured to be secure.

disposal of the device. Aspects of this lifecycle that impact security include initial provisioning, normal operation, re-provisioning, and destruction.

a. **Initial provisioning**. During the initial provisioning stage, it is necessary to program the bootloader, an initial application image, a device secret, and initial configuration data [th-initial-provision]. In addition, the bootloader flash protection shall be installed. Of this information, only the device secret needs to differ per device. This secret shall be securely maintained, and destroyed in all locations outside of the device once it has been programmed [th-initial-secret].

b. **Normal operation**. Normal operation includes the behavior described by the rest of this document.

c. **Re-provisioning**. Sometimes it is necessary to re-provision a device, such as for a different application. One way to do this is to keep the same device secret, and replace the configuration data, as well as the cloud service data associated with the device. It is also possible to program a new device secret, but if this is done it shall be done securely, and the new secret destroyed externally once programmed into the device [th-reprovision].

d. **Destruction**. To prevent the device secret from being used to spoof the device, upon decommissioning, the secret for a particular device shall be rendered ineffective [th-destruction]. Possibilities include:

   i. Hardware destruction of the device.

   ii. Securely wiping the flash area containing the secret[3].

   iii. Removing the device identity and certificate from the service.

9.4.3 Other Considerations

In addition to the above, network connected devices generally will need a way to configure them to connect to the network environment they are placed in. There are numerous ways of doing this, and it is important for these configuration methods to not circumvent the security requirements described above.

9.4.4 Threats

9.4.5 Notes

9.5 Hardening Tool

Before launching a product, it's crucial to ensure that your software is as secure as possible. This process, known as "hardening", involves strengthening the security of a system to protect it from potential threats and vulnerabilities.

At a high-level, hardening a Zephyr application can be seen as a two-fold process:

1. Disabling features and compilation flags that might lead to security vulnerabilities (ex. making sure that no "experimental" features are being used, disabling features typically used for debugging purposes such as assertions, shell, etc.).
2. Enabling optional features that can lead to improve security (ex. stack sentinel, hardware stack protection, etc.). Some of these features might be hardware-dependent.

To simplify this process, Zephyr offers a **hardening tool** designed to analyze an application's configuration against the **hardening database**, a set of recommendations curated by the Zephyr **Security Working Group**. The tool looks at the Kconfig options in the build target and provides tailored suggestions and recommendations to adjust security-related options, along with the rationale behind each recommendation.

[3] Note that merely erasing this flash area is unlikely to be sufficient.

9.5.1 Usage

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t hardenconfig
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild hardenconfig
```

The output should be similar to the table below. For each configuration option set to a value that could lead to a security vulnerability, the table will propose a recommended value that should be used instead, together with the reason the option matters.

```
Hardening report for profile: strict

|                              |           |               |                |␣
↪switches, catching overflows on hardware without |
|                              |           |               |                |␣
↪MPU/MMU stack protection.                        |
+------------------------------+-----------+---------------+----------------+--------------------
```

Options that are not applicable to the current target (for example, MPU-based protections on hardware without an MPU, or options with no visible prompt in the current configuration) are not reported.

In addition to the database-driven checks, the tool flags any enabled option that is marked in Kconfig itself as experimental, deprecated or not secure (i.e. options selecting `CONFIG_EXPERIMENTAL`, `CONFIG_DEPRECATED` or `CONFIG_NOT_SECURE`).

9.5.2 Profiles

Recommendations are grouped into **profiles**. Two profiles are provided in-tree:

`base`
: Baseline hardening every production build should satisfy: enable available memory-protection and exploit-mitigation features, and disable inherently insecure options.

`strict` **(default)**
: Everything in `base`, plus removal of debugging, tracing and observability features (logging, shell, assertions, etc.) that enlarge the attack surface or disclose internal state. Some products legitimately keep a subset of these enabled — if that is your case, check against the `base` profile instead:

```
west build -t hardenconfig -- -DHARDENCONFIG_PROFILE=base
```

9.5.3 Configuration options

The tool is controlled through CMake cache variables (passed after `--` on the `west build` command line, as above) or environment variables of the same name:

Option	Effect
`HARDENCONFIG_PROFILE`	Hardening profile to check against. Default: `strict`.
`HARDENCONFIG_SHOW_ALL`	When set, also list passing and non-applicable options instead of only failures.
`HARDENCONFIG_STRICT`	When set, exit with a non-zero code if any check fails. Useful to gate CI pipelines or release processes on a clean hardening report.
`HARDENCONFIG_JSON`	Path to a file where results are additionally written as JSON, for consumption by scripts and dashboards.
`HARDENCONFIG_EXTRA_SOURCE`	Semicolon-separated list of additional hardening database files (see below).

9.5.4 The hardening database

The database is distributed so that each rule lives with the code it hardens and is reviewed by that code's maintainers:

- scripts/kconfig/hardening.yaml — the central file, owned by the Security Working Group. It defines the hardening **profiles**, plus rules for symbols defined in the top-level Kconfig files.
- `hardening.yaml` **fragments** next to the Kconfig files they relate to (for example subsys/bluetooth/hardening.yaml or arch/x86/hardening.yaml), containing rules only. Fragments are discovered automatically under `arch/`, `boards/`, `drivers/`, `kernel/`, `lib/`, `modules/`, `share/`, `soc/` and `subsys/`. Defining the same symbol in two files is an error, as is defining profiles in a fragment.

All files use the same JSON schema, scripts/schemas/hardening-schema.yaml. Each rule is keyed by the Kconfig symbol it applies to and recommends either an exact value or an integer constraint:

```
rules:
  BOOT_BANNER:
    value: n
    rationale: |
      The boot banner prints the exact Zephyr version to the console,
      letting anyone with console access fingerprint the firmware and
      match it against known vulnerabilities for that release.
    references: [CWE-200]

  STACK_POINTER_RANDOM:
```

(continues on next page)

(continued from previous page)

```
    min: 100
    rationale: |
      Randomizing each thread's initial stack pointer makes stack
      addresses unpredictable. The offset is taken out of the thread's
      own stack, which keeps the recommended value small.
    references: [CWE-121]
```

Contributing a new rule means adding it to the `hardening.yaml` fragment next to the relevant Kconfig file (creating the fragment if the subsystem does not have one yet) and requires a `rationale` — that requirement is enforced by the schema. Continuous integration additionally verifies that every file parses and matches the schema, that every rule references an existing Kconfig symbol with a value coherent with the symbol's type, that no rule is defined twice, and that no file looks like a misnamed fragment — so entries cannot silently go stale or silently fail to load.

The `rationale` is what the report shows the reader, wrapped into a narrow column, and is usually all they have to go on. State the security consequence of the option in one or two sentences, present tense, with the feature as the subject:

`value: n`
: The exposure enabling it creates and, where it matters, who can reach it: "Verbose modem logging dumps all data exchanged with the modem, which can include credentials such as APN settings, PINs and server addresses."

`value: y`
: The attack it defeats, or what leaving it off permits, whichever reads better.

`value: 0`, `min` **and** `max`
: What the other values emit or fail to prevent, and what the boundary value itself does.

Do not:

- Say where the option belongs. The profile is what decides whether a product should accept the consequence; write "…discloses internal transfer state and addresses", not "…and belongs only in development builds".
- Claim an effect that is not complete without further action. For example, an option may enable the generation of a stripped binary, but making sure that is the one deployed is up to the user.
- Restate a column the report already shows. In "0 disables randomization entirely; at least 100 bytes of random offset is recommended", the second half is the Recommended column.
- Repeat another rule's wording. Two rules that can fail in the same report should read differently enough for the reader to tell them apart.

Do not add an `n` rule for an option that can only be enabled while another `n` rule covering at least the same profiles is already violated; for example, a rule for a shell command module is redundant once `CONFIG_SHELL` itself is flagged, and CI rejects it. A rule for an option that merely `selects` a flagged one is not redundant: it names what the user must actually change.

Rules do not carry applicability conditions: whether a recommendation applies to a given target is already encoded in Kconfig itself (dependencies, hardware support), and the tool reports options that are not applicable to the current target as not applicable rather than as failures.

9.5.5 Extending the database out of tree

Product teams can layer their own recommendations on top of the in-tree database with `HARDENCONFIG_EXTRA_SOURCES`. Each additional file uses the same schema and may define new profiles (optionally extending in-tree ones) and new rules, as well as override in-tree rules. Redefining an existing profile is rejected, so an in-tree profile keeps the meaning documented here whatever a product layers on top of it:

```yaml
profiles:
  acme-production:
    extends: strict
    description: ACME product security policy.

rules:
  MY_VENDOR_DEBUG_INTERFACE:
    value: n
    profiles: [acme-production]
    rationale: |
      The vendor debug interface bypasses the product's authentication.
```

```
west build -t hardenconfig -- \
  -DHARDENCONFIG_EXTRA_SOURCES=/path/to/acme-hardening.yaml \
  -DHARDENCONFIG_PROFILE=acme-production
```

9.6 Control Flow Integrity

Control Flow Integrity (CFI) is a security feature that ensures that the control flow of a program follows a predefined path, preventing attackers from diverting execution to malicious code. CFI is particularly useful in defending against control flow hijacking attacks, such as return-oriented programming (ROP) and jump-oriented programming (JOP).

CFI works by validating the control flow of a program at runtime, ensuring that function calls and returns are made to legitimate targets. This is typically achieved through instrumentation of the code, which adds checks to verify that the control flow adheres to the expected paths defined by the program's control flow graph.

9.6.1 Forward and return edges

In the context of CFI, control flow edges can be categorized into two types:

1. **Forward edges**: These represent the flow of control from one function to another, such as a function call. Forward edges are typically validated to ensure that the target of a call is a legitimate function within the program.
2. **Return edges**: These represent the return from a function back to the caller. Return edges are validated to ensure that the return address is legitimate and corresponds to a valid call site.

Forward edges can be supported by compiler instrumentation, which adds checks to verify that the target of a function call is valid. Return edges can be supported by maintaining a shadow stack or using other mechanisms to ensure that return addresses are legitimate.

Zephyr does support maintaining a shadow stack which can be enabled via `CONFIG_HW_SHADOW_STACK`. Then, the kernel will use macros like `K_THREAD_HW_SHADOW_STACK_DEFINE`, in tandem with other thread stack related macros, to provide the area for shadow stacks used by threads. Usually, applications only need to enable `CONFIG_HW_SHADOW_STACK` (and related ones, such as `CONFIG_HW_SHADOW_STACK_PERCENTAGE_SIZE` and `CONFIG_HW_SHADOW_STACK_MIN_SIZE`) to enable shadow stack support. The kernel will then automatically manage the shadow stack for each thread.

Implementation details

The `K_THREAD_HW_SHADOW_STACK*` family of macros does a minimal setup of the shadow stack parameters. Then, they invoke arch-specific `ARCH_THREAD_HW_SHADOW_STACK*` macros to perform the actual setup.

9.6.2 Hardware support

While CFI can be implemented in software, hardware support can significantly enhance its effectiveness and performance. Currently, Zephyr supports Intel Control-flow Enforcement Technology (CET), which provides hardware-based support for CFI.

Intel CET

Intel Control-flow Enforcement Technology (CET) is a set of hardware features that enhance the security of applications by providing support for CFI. CET includes two main components:

1. **Shadow Stack**: This feature maintains a separate stack for return addresses, ensuring that return addresses cannot be tampered with. When a function returns, the return address is popped from the shadow stack and compared to that of the regular stack, providing an additional layer of protection against control flow hijacking.
2. **Indirect Branch Tracking (IBT)**: This feature tracks indirect branches (such as function pointers) and ensures that they only target valid locations in the code. It prevents attackers from redirecting execution to arbitrary code through techniques like ROP.

These two features proved the return and forward edge validation, respectively. To enable shadow stack support in Zephyr, on supported hardware, you can use the `CONFIG_HW_SHADOW_STACK` Kconfig option. To enable IBT, use `CONFIG_X86_CET_IBT`.

As IBT is effectively implemented by the compiler, toolchain support is necessary. Currently, Zephyr SDK x86 toolchain can be used to build applications with IBT support. However, their precompiled artifacts, such as `libc` and `libgcc`, do not have IBT enabled. Therefore, for `libc`, one needs to build it as a module, for example, by using `CONFIG_PICOLIBC_USE_MODULE`. For other bits, one would need a custom toolchain.

Intel CET Limitations Currently, the shadow stacks that are created behind the scenes live on the global namespace. Thus, one *cannot* reuse thread stack names, even across different compilation units.

ARM Pointer Authentication and Branch Target Identification

ARM platforms provide hardware-based CFI features through Pointer Authentication (PAC) and Branch Target Identification (BTI), available on both Cortex-M and ARM64 (Cortex-A/R) architectures:

1. **Pointer Authentication (PAC)**: Signs return addresses and other pointers using cryptographic signatures. When a return address is pushed to the stack, it is signed with a key unique to each thread. Before returning, the signature is verified, ensuring the return address has not been tampered with. This protects against Return-Oriented Programming (ROP) attacks. Available in ARMv8.1-M Mainline (Cortex-M) and ARMv8.3-A and later (ARM64).
2. **Branch Target Identification (BTI)**: Marks legitimate indirect branch targets with special BTI landing pad instructions. The processor verifies that indirect branches land only on valid targets marked with BTI instructions. This protects against Jump-Oriented Programming (JOP) attacks. Available in ARMv8.1-M Mainline (Cortex-M) and ARMv8.5-A and later (ARM64).

These features provide return and forward edge validation, respectively. PAC and BTI can be enabled via the `ARM_PACBTI` menu. Available options include `CONFIG_ARM_PACBTI_STANDARD` (both PAC and BTI), `CONFIG_ARM_PACBTI_PACRET` (PAC only), `CONFIG_ARM_PACBTI_BTI` (BTI only), and other variants. Both features can be used independently or combined for comprehensive control flow integrity.

Like x86 CET IBT, these features require compiler support and proper C library instrumentation. PAC requires that functions use the appropriate signing and verification instructions, while BTI

requires that all legitimate branch targets include BTI landing pad instructions. Precompiled C libraries from toolchains typically lack this instrumentation.

For BTI support, the C library must be compiled with `-mbranch-protection` flags to include BTI landing pads in all functions. Therefore, when using any option that enables BTI, only `CONFIG_MINIMAL_LIBC` or picolibc built as a module via `CONFIG_PICOLIBC_USE_MODULE` can be used. Newlib from toolchains is not supported with BTI.

PAC has less strict requirements as it primarily affects function prologues and epilogues, but for optimal security, building the C library with PAC support is recommended.

9.7 Vulnerabilities

This page collects all of the vulnerabilities that are discovered and fixed in each release. It will also often have more details than is available in the releases. Some vulnerabilities are deemed to be sensitive, and will not be publicly discussed until there is sufficient time to fix them. Because the release notes are locked to a version, the information here can be updated after the embargo is lifted.

Vulnerabilities from previous years are collected on separate pages:

9.7.1 CVE-2017

CVE 2017-14199

Buffer overflow in `getaddrinfo()`.

- Zephyr project bug tracker ZEPSEC-12
- PR6158 fix for 1.11.0

CVE 2017-14201

The shell DNS command can cause unpredictable results due to misuse of stack variables.

Use After Free vulnerability in the Zephyr shell allows a serial or telnet connected user to cause denial of service, and possibly remote code execution.

This has been fixed in release v1.14.0.

- Zephyr project bug tracker ZEPSEC-17
- PR13260 fix for v1.14.0

CVE 2017-14202

The shell implementation does not protect against buffer overruns resulting in unpredictable behavior.

Improper Restriction of Operations within the Bounds of a Memory Buffer vulnerability in the shell component of Zephyr allows a serial or telnet connected user to cause a crash, possibly with arbitrary code execution.

This has been fixed in release v1.14.0.

- Zephyr project bug tracker ZEPSEC-18
- PR13048 fix for v1.14.0

9.7.2 CVE-2019

CVE 2019-9506

The Bluetooth BR/EDR specification up to and including version 5.1 permits sufficiently low encryption key length and does not prevent an attacker from influencing the key length negotiation. This allows practical brute-force attacks (aka “KNOB”) that can decrypt traffic and inject arbitrary ciphertext without the victim noticing.

- Zephyr project bug tracker ZEPSEC-20
- PR18702 fix for v1.14.0
- PR18659 fix for v2.0.0

9.7.3 CVE-2020

CVE 2020-10019

Buffer Overflow vulnerability in USB DFU of zephyr allows a USB connected host to cause possible remote code execution.

This has been fixed in releases v1.14.2, v2.2.0, and v2.1.1.

- Zephyr project bug tracker ZEPSEC-25
- PR23460 fix for 1.14.x
- PR23457 fix for 2.1.x
- PR23190 fix in 2.2.0

CVE 2020-10021

Out-of-bounds write in USB Mass Storage with unaligned sizes

Out-of-bounds Write in the USB Mass Storage memoryWrite handler with unaligned Sizes.

See NCC-ZEP-024, NCC-ZEP-025, NCC-ZEP-026

This has been fixed in releases v1.14.2, and v2.2.0.

- Zephyr project bug tracker ZEPSEC-26
- PR23455 fix for v1.14.2
- PR23456 fix for the v2.1 branch
- PR23240 fix for v2.2.0

CVE 2020-10022

UpdateHub Module Copies a Variable-Size Hash String Into a Fixed-Size Array

A malformed JSON payload that is received from an UpdateHub server may trigger memory corruption in the Zephyr OS. This could result in a denial of service in the best case, or code execution in the worst case.

See NCC-ZEP-016

This has been fixed in the below pull requests for main, branch from v2.1.0, and branch from v2.2.0.

- Zephyr project bug tracker ZEPSEC-28
- PR24154 fix for main
- PR24065 fix for branch from v2.1.0
- PR24066 fix for branch from v2.2.0

CVE 2020-10023

Shell Subsystem Contains a Buffer Overflow Vulnerability In shell_spaces_trim

The shell subsystem contains a buffer overflow, whereby an adversary with physical access to the device is able to cause a memory corruption, resulting in denial of service or possibly code execution within the Zephyr kernel.

See NCC-ZEP-019

This has been fixed in releases v1.14.2, v2.2.0, and in a branch from v2.1.0,

- Zephyr project bug tracker ZEPSEC-29
- PR23646 fix for v1.14.2
- PR23649 fix for branch from v2.1.0
- PR23304 fix for v2.2.0

CVE 2020-10024

ARM Platform Uses Signed Integer Comparison When Validating Syscall Numbers

The arm platform-specific code uses a signed integer comparison when validating system call numbers. An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0,

- Zephyr project bug tracker ZEPSEC-30
- PR23535 fix for v1.14.2
- PR23498 fix for branch from v2.1.0
- PR23323 fix for v2.2.0

CVE 2020-10027

ARC Platform Uses Signed Integer Comparison When Validating Syscall Numbers

An attacker who has obtained code execution within a user thread is able to elevate privileges to that of the kernel.

See NCC-ZEP-001

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0.

- Zephyr project bug tracker ZEPSEC-35
- PR23500 fix for v1.14.2
- PR23499 fix for branch from v2.1.0
- PR23328 fix for v2.2.0

CVE 2020-10028

Multiple Syscalls In GPIO Subsystem Performs No Argument Validation

Multiple syscalls with insufficient argument validation

See NCC-ZEP-006

This has been fixed in releases v1.14.2, and v2.2.0, and in a branch from v2.1.0.

- Zephyr project bug tracker ZEPSEC-32

- PR23733 fix for v1.14.2
- PR23737 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (gpio patch)

CVE 2020-10058

Multiple Syscalls In kscan Subsystem Performs No Argument Validation

Multiple syscalls in the Kscan subsystem perform insufficient argument validation, allowing code executing in userspace to potentially gain elevated privileges.

See NCC-ZEP-006

This has been fixed in a branch from v2.1.0, and release v2.2.0.

- Zephyr project bug tracker ZEPSEC-34
- PR23748 fix for branch from v2.1.0
- PR23308 fix for v2.2.0 (kscan patch)

CVE 2020-10059

UpdateHub Module Explicitly Disables TLS Verification

The UpdateHub module disables DTLS peer checking, which allows for a man in the middle attack. This is mitigated by firmware images requiring valid signatures. However, there is no benefit to using DTLS without the peer checking.

See NCC-ZEP-018

This has been fixed in a PR against Zephyr main.

- Zephyr project bug tracker ZEPSEC-36
- PR24954 fix on main (to be fixed in v2.3.0)
- PR24954 fix v2.1.0
- PR24954 fix v2.2.0

CVE 2020-10060

UpdateHub Might Dereference An Uninitialized Pointer

In updatehub_probe, right after JSON parsing is complete, objects[1] is accessed from the output structure in two different places. If the JSON contained less than two elements, this access would reference uninitialized stack memory. This could result in a crash, denial of service, or possibly an information leak.

Recommend disabling updatehub until such a time as a fix can be made available.

See NCC-ZEP-030

This has been fixed in a PR against Zephyr main.

- Zephyr project bug tracker ZEPSEC-37
- PR27865 fix on main (to be fixed in v2.4.0)
- PR27865 fix for v2.3.0
- PR27865 fix for v2.2.0
- PR27865 fix for v2.1.0

CVE 2020-10061

Error handling invalid packet sequence

Improper handling of the full-buffer case in the Zephyr Bluetooth implementation can result in memory corruption.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- Zephyr project bug tracker ZEPSEC-75
- PR23516 fix for v2.3 (split driver)
- PR23517 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23547 fix for branch from v2.2.0

CVE 2020-10062

Packet length decoding error in MQTT

CVE: An off-by-one error in the Zephyr project MQTT packet length decoder can result in memory corruption and possible remote code execution. NCC-ZEP-031

The MQTT packet header length can be 1 to 4 bytes. An off-by-one error in the code can result in this being interpreted as 5 bytes, which can cause an integer overflow, resulting in memory corruption.

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-84
- commit 11b7a37d for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE 2020-10063

Remote Denial of Service in CoAP Option Parsing Due To Integer Overflow

A remote adversary with the ability to send arbitrary CoAP packets to be parsed by Zephyr is able to cause a denial of service.

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-55
- PR24435 fix in main for v2.3
- PR24531 fix for branch from v2.2
- PR24535 fix for branch from v2.1
- PR24530 fix for branch from v1.14
- NCC-ZEP report (NCC-ZEP-032)

CVE 2020-10064

Improper Input Frame Validation in ieee802154 Processing

- Zephyr project bug tracker ZEPSEC-65
- PR24971 fix for v2.4
- PR33451 fix for v1.4

CVE 2020-10065

OOB Write after not validating user-supplied length (<= 0xffff) and copying to fixed-size buffer (default: 77 bytes) for HCI_ACL packets in bluetooth HCI over SPI driver.

- Zephyr project bug tracker ZEPSEC-66
- This issue has not been fixed.

CVE 2020-10066

Incorrect Error Handling in Bluetooth HCI core

In hci_cmd_done, the buf argument being passed as null causes nullpointer dereference.

- Zephyr project bug tracker ZEPSEC-67
- PR24902 fix for v2.4
- PR25089 fix for v1.4

CVE 2020-10067

Integer Overflow In is_in_region Allows User Thread To Access Kernel Memory

A malicious userspace application can cause a integer overflow and bypass security checks performed by system call handlers. The impact would depend on the underlying system call and can range from denial of service to information leak to memory corruption resulting in code execution within the kernel.

See NCC-ZEP-005

This has been fixed in releases v1.14.2, and v2.2.0.

- Zephyr project bug tracker ZEPSEC-27
- PR23653 fix for v1.14.2
- PR23654 fix for the v2.1 branch
- PR23239 fix for v2.2.0

CVE 2020-10068

Zephyr Bluetooth DLE duplicate requests vulnerability

In the Zephyr project Bluetooth subsystem, certain duplicate and back-to-back packets can cause incorrect behavior, resulting in a denial of service.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- Zephyr project bug tracker ZEPSEC-78
- PR23707 fix for v2.3 (split driver)
- PR23708 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23964 fix for v2.2.0

CVE 2020-10069

Zephyr Bluetooth unchecked packet data results in denial of service

An unchecked parameter in bluetooth data can result in an assertion failure, or division by zero, resulting in a denial of service attack.

This has been fixed in branches for v1.14.0, v2.2.0, and will be included in v2.3.0.

- Zephyr project bug tracker ZEPSEC-81
- PR23705 fix for v2.3 (split driver)
- PR23706 fix for v2.3 (legacy driver)
- PR23091 fix for branch from v1.14.0
- PR23963 fix for branch from v2.2.0

CVE 2020-10070

MQTT buffer overflow on receive buffer

In the Zephyr Project MQTT code, improper bounds checking can result in memory corruption and possibly remote code execution. NCC-ZEP-031

When calculating the packet length, arithmetic overflow can result in accepting a receive buffer larger than the available buffer space, resulting in user data being written beyond this buffer.

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-85
- commit 0b39cbf3 for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE 2020-10071

Insufficient publish message length validation in MQTT

The Zephyr MQTT parsing code performs insufficient checking of the length field on publish messages, allowing a buffer overflow and potentially remote code execution. NCC-ZEP-031

This has been fixed in main for v2.3.

- Zephyr project bug tracker ZEPSEC-86
- commit 989c4713 fix for v2.3
- NCC-ZEP report (NCC-ZEP-031)

CVE 2020-10072

All threads can access all socket file descriptors

There is no management of permissions to network socket API file descriptors. Any thread running on the system may read/write a socket file descriptor knowing only the numerical value of the file descriptor.

- Zephyr project bug tracker ZEPSEC-87
- PR25804 fix for v2.4
- PR27176 fix for v1.4

CVE 2020-10136

IP-in-IP protocol routes arbitrary traffic by default zephyrproject

- Zephyr project bug tracker ZEPSEC-64

CVE 2020-13598

FS: Buffer Overflow when enabling Long File Names in FAT_FS and calling fs_stat

Performing fs_stat on a file with a filename longer than 12 characters long will cause a buffer overflow.

- Zephyr project bug tracker ZEPSEC-88
- PR25852 fix for v2.4
- PR28782 fix for v2.3
- PR33577 fix for v1.4

CVE 2020-13599

Security problem with settings and littlefs

When settings is used in combination with littlefs all security related information can be extracted from the device using MCUmgr and this could be used e.g in bt-mesh to get the device key, network key, app keys from the device.

- Zephyr project bug tracker ZEPSEC-57
- PR26083 fix for v2.4

CVE 2020-13600

Malformed SPI in response for eswifi can corrupt kernel memory

- Zephyr project bug tracker ZEPSEC-91
- PR26712 fix for v2.4

CVE 2020-13601

Possible read out of bounds in dns read

- Zephyr project bug tracker ZEPSEC-92
- PR27774 fix for v2.4
- PR30503 fix for v1.4

CVE 2020-13602

Remote Denial of Service in LwM2M do_write_op_tlv

In the Zephyr LwM2M implementation, malformed input can result in an infinite loop, resulting in a denial of service attack.

- Zephyr project bug tracker ZEPSEC-56
- PR26571 fix for v2.4
- PR33578 fix for v1.4

CVE 2020-13603

Possible overflow in mempool

- Zephyr offers pre-built ‘malloc’ wrapper function instead.
- The ‘malloc’ function is wrapper for the ‘sys_mem_pool_alloc’ function
- sys_mem_pool_alloc allocates ‘size + WB_UP(sizeof(struct sys_mem_pool_block))’ in an unsafe manner.

- Asking for very large size values leads to internal integer wrap-around.
- Integer wrap-around leads to successful allocation of very small memory.
- For example: calling malloc(0xffffffff) leads to successful allocation of 7 bytes.
- That leads to heap overflow.
- Zephyr project bug tracker ZEPSEC-111
- PR31796 fix for v2.4
- PR32808 fix for v1.4

9.7.4 CVE-2021

CVE 2021-3319

DOS: Incorrect 802154 Frame Validation for Omitted Source / Dest Addresses

Improper processing of omitted source and destination addresses in ieee802154 frame validation (ieee802154_validate_frame)

This has been fixed in main for v2.5.0

- Zephyr project bug tracker GHSA-94jg-2p6q-5364
- PR31908 fix for main

CVE 2021-3320

Mismatch between validation and handling of 802154 ACK frames, where ACK frames are considered during validation, but not during actual processing, leading to a type confusion.

- PR31908 fix for main

CVE 2021-3321

Incomplete check of minimum IEEE 802154 fragment size leading to an integer underflow.

- Zephyr project bug tracker ZEPSEC-114
- PR33453 fix for v2.4

CVE 2021-3323

Integer Underflow in 6LoWPAN IPHC Header Uncompression

This has been fixed in main for v2.5.0

- Zephyr project bug tracker GHSA-89j6-qpxf-pfpc
- PR 31971 fix for main

CVE 2021-3430

Assertion reachable with repeated LL_CONNECTION_PARAM_REQ.

This has been fixed in main for v2.6.0

- Zephyr project bug tracker GHSA-46h3-hjcq-2jjr
- PR 33272 fix for main
- PR 33369 fix for 2.5
- PR 33759 fix for 1.14.2

CVE 2021-3431

BT: Assertion failure on repeated LL_FEATURE_REQ

This has been fixed in main for v2.6.0

- Zephyr project bug tracker GHSA-7548-5m6f-mqv9
- PR 33340 fix for main
- PR 33369 fix for 2.5

CVE 2021-3432

Invalid interval in CONNECT_IND leads to Division by Zero

This has been fixed in main for v2.6.0

- Zephyr project bug tracker GHSA-7364-p4wc-8mj4
- PR 33278 fix for main
- PR 33369 fix for 2.5

CVE 2021-3433

BT: Invalid channel map in CONNECT_IND results to Deadlock

This has been fixed in main for v2.6.0

- Zephyr project bug tracker GHSA-3c2f-w4v6-qxrp
- PR 33278 fix for main
- PR 33369 fix for 2.5

CVE 2021-3434

L2CAP: Stack based buffer overflow in le_ecred_conn_req()

This has been fixed in main for v2.6.0

- Zephyr project bug tracker GHSA-8w87-6rfp-cfrm
- PR 33305 fix for main
- PR 33419 fix for 2.5
- PR 33418 fix for 1.14.2

CVE 2021-3435

L2CAP: Information leakage in le_ecred_conn_req()

This has been fixed in main for v2.6.0

- Zephyr project bug tracker GHSA-xhg3-gvj6-4rqh
- PR 33305 fix for main
- PR 33419 fix for 2.5
- PR 33418 fix for 1.14.2

CVE 2021-3436

Bluetooth: Possible to overwrite an existing bond during keys distribution phase when the identity address of the bond is known

During the distribution of the identity address information we don't check for an existing bond with the same identity address.This means that a duplicate entry will be created in RAM while the newest entry will overwrite the existing one in persistent storage.

This has been fixed in main for v2.6.0

CVE 2021-3510

Zephyr JSON decoder incorrectly decodes array of array

When using JSON_OBJ_DESCR_ARRAY_ARRAY, the subarray is has the token type JSON_TOK_LIST_START, but then assigns to the object part of the union. arr_parse then takes the offset of the array-object (which has nothing todo with the list) treats it as relative to the parent object, and stores the length of the subarray in there.

This has been fixed in main for v2.7.0

- PR 36340 fix for main

- PR 37816 fix for 2.6

CVE 2021-3581

HCI data not properly checked leads to memory overflow in the Bluetooth stack

In the process of setting SCAN_RSP through the HCI command, the Zephyr Bluetooth protocol stack did not effectively check the length of the incoming HCI data. Causes memory overflow, and then the data in the memory is overwritten, and may even cause arbitrary code execution.

CVE 2025-7403

Bluetooth: bt_conn_tx_processor unsafe handling

Unsafe handling in bt_conn_tx_processor causes a use-after-free, resulting in a write-before-zero. The written 4 bytes are attacker-controlled, enabling precise memory corruption.

- Zephyr project bug tracker GHSA-9r46-cqqw-6j2j

This has been fixed in main for v4.2.0

- PR 90975 fix for main

CVE 2025-10456

Bluetooth: Semi-Arbitrary ability to make the BLE Target send disconnection requests

A vulnerability was identified in the handling of Bluetooth Low Energy (BLE) fixed channels (such as SMP or ATT). Specifically, an attacker could exploit a flaw that causes the BLE target (i.e., the device under attack) to attempt to disconnect a fixed channel, which is not allowed per the Bluetooth specification. This leads to undefined behavior, including potential assertion failures, crashes, or memory corruption.

- Zephyr project bug tracker GHSA-hcc8-3qr7-c9m8

This has been fixed in main for v4.2.0

- PR 93576 fix for main
- PR 100474 fix for 3.7

CVE 2025-10457

Bluetooth: Out-Of-Context le_conn_rsp handling

The function responsible for handling BLE connection responses does not verify whether a response is expected—that is, whether the device has initiated a connection request. Instead, it relies solely on identifier matching.

- Zephyr project bug tracker GHSA-xqj6-vh76-2vv8

This has been fixed in main for v4.2.0

- PR 94080 fix for main

CVE 2025-10458

Bluetooth: le_conn_rsp does not sanitize CID, MTU, MPS values

Parameters are not validated or sanitized, and are later used in various internal operations.

- Zephyr project bug tracker GHSA-vmww-237q-2fwp

This has been fixed in main for v4.2.0

- PR 93174 fix for main

CVE 2025-9408

Userspace privilege escalation vulnerability on Cortex M

System call entry on Cortex M (and possibly R and A, but I think not) has a race which allows very practical privilege escalation for malicious userspace processes.

9.7.9 CVE-2026

CVE 2026-0849

crypto: ATAES132A response length allows stack buffer overflow

Malformed ATAES132A responses with an oversized length field overflow a 52-byte stack buffer in the Zephyr crypto driver, allowing a compromised device or bus attacker to corrupt kernel memory and potentially hijack execution.

- Zephyr project bug tracker GHSA-ff4p-3ggg-prp6

This has been fixed in main for v4.4.0

- PR 103163 fix for main

CVE 2026-1677

net: TLS 1.2 connections allowed on TLS 1.3 sockets

Zephyr sockets created with `IPPROTO_TLS_1_3` can still negotiate a TLS 1.2 connection when both TLS versions are enabled in Kconfig, because the socket-level protocol selection is not propagated to mbedTLS (e.g. via `mbedtls_ssl_conf_min_tls_version`). The ClientHello advertises both versions and the peer can establish TLS 1.2, so applications that assumed `IPPROTO_TLS_1_3` enforces TLS 1.3 may silently use TLS 1.2 and remain exposed to TLS 1.2-specific weaknesses.

CVE 2026-1678

dns: memory-safety issue in the DNS name parser

`dns_unpack_name()` caches the buffer tailroom once and reuses it while appending DNS labels. As the buffer grows, the cached size becomes incorrect, and the final null terminator can be written past the buffer. With assertions disabled (default), a malicious DNS response can trigger an out-of-bounds write when `CONFIG_DNS_RESOLVER` is enabled.

CVE 2026-1681

net: Stack Overflow with Ping (to own IP Address) via Shell

Issuing an ICMP ping via the `net ping` shell command to a device's own IPv4 address causes the network stack to recursively re-enter the input path on the same system work-queue stack. Because the destination is recognized as a local address, both the echo request and the resulting echo reply are processed inline before the current frame returns. The nested input-path frames exceed the work-queue stack and trigger a stack overflow.

CVE 2026-5066

net: sockets: tls: Potential out-of-bounds write/read in socket_op_vtable::connect function

A potential out-of-bounds write/read exists in the TLS socket connect path of the network sockets subsystem (`subsys/net/lib/sockets/sockets_tls.c`). When the TLS session cache is enabled, `tls_session_store()` and `tls_session_restore()` `memcpy` the caller-supplied address into a fixed-size buffer using the caller-controlled `addrlen` value without validating it against the destination size. Since `struct net_sockaddr` is an opaque type, an application can pass an `addrlen` larger than `sizeof(struct net_sockaddr)` (for example 128 bytes into a 24-byte stack buffer), causing the `memcpy` to read and write past the end of the address memory used by the TLS session cache. This can lead to a crash and denial of service, and potentially to arbitrary code execution.

CVE 2026-5067

Out-of-bounds read/write in HTTP WebSocket upgrade via non-null-terminated Sec-WebSocket-Key

A remote, unauthenticated attacker can trigger memory corruption in Zephyr's HTTP server WebSocket upgrade path by sending a crafted `Sec-WebSocket-Key` header that is copied without guaranteed NUL termination and then passed to `strlen()`. This can cause out-of-bounds read and out-of-bounds write on stack memory, leading to a crash (denial of service) and potentially code execution. The path is reachable when `CONFIG_HTTP_SERVER_WEBSOCKET` is enabled.

CVE 2026-5068

Bluetooth: L2CAP LE CoC: remote out-of-bounds write via segmentation counter stored in net_buf user_data

A remote, unauthenticated BLE peer can trigger a 2-byte out-of-bounds write in the Bluetooth host during L2CAP LE CoC SDU reassembly. When the application enables segmentation (via `chan_ops.alloc_buf`) and the chosen RX pool has a `user_data_size` smaller than 2 bytes, the segmentation counter stored in the `net_buf` user_data area is written out of bounds in `l2cap_chan_le_recv_seg` (`subsys/bluetooth/host/l2cap.c`). This can lead to heap corruption and a fatal error.

CVE 2026-5589

Bluetooth: Mesh: Out-of-bounds write caused by an integer underflow

An integer underflow in `bt_mesh_sol_recv()` in the Bluetooth Mesh solicitation handling (`subsys/bluetooth/mesh/solicitation.c`) leads to an out-of-bounds write. When `CONFIG_BT_MESH_OD_PRIV_PROXY_SRV` is enabled, the function parses solicitation PDUs from raw BLE advertising payloads. The AD parsing loop reads an attacker-controlled length byte and computes `reported_len - 3` without checking that `reported_len` is at least 3. When the value is smaller, the signed subtraction yields a negative number that bypasses the length guard and is then implicitly converted to a very large `size_t`, advancing the buffer pointer far out of bounds so that subsequent reads dereference invalid memory. A nearby BLE device can trigger this with a non-connectable advertisement carrying a UUID16 AD structure and a crafted length byte, with no pairing or prior association required, potentially leading to denial of service or arbitrary code execution.

CVE 2026-8718

Out-of-bounds write in DTLS peer Connection ID getsockopt (`TLS_DTLS_PEER_CID_VALUE`) in Zephyr net sockets/TLS

`tls_opt_dtls_peer_connection_id_value_get()` in `subsys/net/lib/sockets/sockets_tls.c`, which handles `getsockopt(SOL_TLS, TLS_DTLS_PEER_CID_VALUE)`, passed the caller-supplied `optval` directly to `mbedtls_ssl_get_peer_cid()` without verifying the buffer was at least `MBEDTLS_SSL_CID_OUT_LEN_MAX` (default 32) bytes. `mbedtls_ssl_get_peer_cid()` copies the peer-negotiated DTLS Connection ID (length 1..`MBEDTLS_SSL_CID_OUT_LEN_MAX`) into that buffer without a destination-size parameter, so a caller-supplied `optlen` smaller than the CID causes a write of up to 31 bytes past the buffer end.

In `CONFIG_USERSPACE` builds the getsockopt syscall verifier (`z_vrfy_zsock_getsockopt`) bounce-buffers the user's `optval` into a kernel allocation of exactly `optlen` bytes (`k_usermode_alloc_from_copy -> z_thread_malloc`), so an unprivileged user thread that passes a small `optlen` on a connected DTLS socket with Connection ID enabled induces a kernel-heap buffer overflow, with the overflowing content being the remote peer's CID.

The defect requires `CONFIG_MBEDTLS_SSL_DTLS_CONNECTION_ID`, an established DTLS session with a negotiated peer CID, and (for the kernel-crossing case) `CONFIG_USERSPACE`. Introduced when the `TLS_DTLS_CID` option was added (v3.5.0).

The fix rejects callers whose `optlen` is below `MBEDTLS_SSL_CID_OUT_LEN_MAX` with -EINVAL.

CVE 2026-9263

Out-of-bounds read in Bluetooth Controller ISOAL framed RX reassembly leaks adjacent memory into host HCI ISO packets

The Zephyr Bluetooth controller ISO Adaptation Layer (`subsys/bluetooth/controller/ll_sw/isoal.c`) fails to validate the length field of a framed ISO PDU start segment. Per the Bluetooth specification a start segment (`sc=0`) always carries a 3-byte `time_offset`, so its segment-header `len` must be at least `PDU_ISO_SEG_TIMEOFFSET_SIZE` (3). `isoal_check_seg_header()` accepted start segments with `len < 3` as valid, and `isoal_rx_framed_consume()` then computed `length = seg_hdr->len - 3` in a `uint8_t`, underflowing to 253-255 when `len` is 0-2. That oversized length is passed to `isoal_rx_append_to_sdu()`, whose copy is clamped only against the destination SDU buffer size, not the source PDU length, so up to ~255 bytes of controller memory beyond the received PDU are copied (via `sink_sdu_write_hci()`/`net_buf_add_mem`) into an HCI

ISO data packet and delivered to the host. The PDU and its segment headers are entirely attacker-controlled and arrive over the air, reachable through both the CIS and BIS-sync HCI data paths (`hci_driver.c`) and the vendor data path (`ull_iso.c`), so a remote CIS peer or a broadcaster the device is synced to can trigger an out-of-bounds read causing information disclosure to the host and potential denial of service (faults or malformed oversized HCI ISO packets). The flaw affects all Zephyr releases since framed ISO reception was introduced in v3.0.0. The fix rejects `sc=0` segments with `len` < 3 in `isoal_check_seg_header()` and adds a guard before the subtraction in `isoal_rx_framed_consume()`.

CVE 2026-10593

Remotely triggerable NULL-pointer dereference in Bluetooth LE Audio BAP unicast client QoS-state handling

The Zephyr Bluetooth LE Audio Basic Audio Profile (BAP) unicast client mishandles peer-supplied ASE state notifications. In `unicast_client_ep_qos_state()` (`subsys/bluetooth/audio/bap_unicast_client.c`), the handler writes attacker-controlled QoS fields (`interval`, `framing`, `phy`, `sdu`, `rtn`, `latency`, `pd`) through the `stream->qos` pointer with only a `stream != NULL` guard. `stream->qos` is `NULL` for any stream that has been codec-configured via `bt_bap_stream_config()` but not yet added to a unicast group (it is set only by `unicast_group_add_stream()`).

A malicious or buggy remote ASCS server, to which the local device is connected as a BAP unicast client, can send a GATT notification announcing the ASE has entered the QoS Configured state while the local endpoint is still in the Codec Configured state — a transition the dispatcher explicitly permits — during that window, causing a write through a NULL pointer and a crash (denial of service). The data written is itself remote-controlled.

The defect shipped in v4.3.0 and v4.4.0 (and earlier). The fix re-points all BAP QoS storage to the always-valid embedded `ep->qos` struct, eliminating the NULL dereference.

CVE 2026-10634

Use-after-free in Zephyr native TCP `net_tcp_foreach()` due to dropping `tcp_lock` during the callback

Zephyr's native TCP stack iterates the global connection list in `net_tcp_foreach()` (`subsys/net/ip/tcp.c`) using the `SYS_SLIST_FOR_EACH_CONTAINER_SAFE` macro, which caches a pointer to the next list node. Prior to this fix the function released `tcp_lock` while invoking the per-connection callback and re-acquired it afterwards. During that window a concurrent `tcp_conn_release()`, running on the dedicated TCP work-queue thread when a connection's reference count drops to zero (e.g. a remote peer closing or resetting the connection), can remove and `k_mem_slab_free()` the cached next connection. When the iterator advances it dereferences the freed (and possibly reallocated) slab memory — a use-after-free that can crash the system (denial of service) and, if

the slot has been reused, cause the callback to operate on an attacker-influenced object (potential information disclosure or further fault). `net_tcp_foreach()` is reached in production via the `net conn` network shell command and via `net_tcp_close_all_for_iface()` on interface-down; the freeing side is driven by ordinary TCP traffic. The fix moves the connection/context teardown in `tcp_conn_release()` inside the `tcp_lock` critical section and keeps `tcp_lock` held across the callback in `net_tcp_foreach()`. The defect was introduced with the modern (TCP2) stack in 2020 and affects releases up to and including v4.4.0.

CVE 2026-10635

Dangling memory-domain pointer (use-after-free) in Xtensa MMU page-table code on memory-domain de-init

On Xtensa targets with `CONFIG_USERSPACE` and `CONFIG_XTENSA_MMU`, the page-table code (`arch/xtensa/core/ptables.c`) maintains a global list, `xtensa_domain_list`, of active memory domains using a list node embedded inside the caller-owned `struct k_mem_domain`. When a domain is destroyed via `k_mem_domain_deinit()` -> `arch_mem_domain_deinit()`, the page tables are torn down and `domain->arch.ptables` is set to `NULL`, but the domain's node was not removed from `xtensa_domain_list`. The freed/deinitialized domain therefore remained linked into the global list as a dangling pointer into caller-owned storage that may then be freed or reused.

Any subsequent `arch_mem_map()`/`arch_mem_unmap()` operation (widely invoked by kernel memory-mapping and demand-paging code) traverses the stale node and dereferences `domain->ptables`: at minimum a NULL pointer dereference causing a fatal MMU exception (denial of service), and if the `k_mem_domain` storage has been freed or reused, a use-after-free in which a stale/controlled `ptables` value is dereferenced and written through during the page-table walk (`l2_page_table_map` writes `l1_table[...]` and `l2_table[...]`, and `xtensa_mmu_compute_domain_regs` writes into the domain struct and the L1 table), yielding page-table memory corruption that can undermine userspace isolation.

The vulnerable path is reachable only from privileged kernel/supervisor code (`k_mem_domain_deinit` is not a syscall), not directly from unprivileged user threads or remotely. Affected: Zephyr v4.4.0 (the Xtensa memory-domain de-initialization feature was introduced in commit 3032b58f52d and first shipped in v4.4.0); fixed on `main` by adding `sys_slist_find_and_remove()` in `arch_mem_domain_deinit()`. The Xtensa MPU path is unaffected.

CVE 2026-10636

Use-after-free in Zephyr IPv4 IGMP send path (`igmp_send`)

In Zephyr's IPv4 IGMP implementation, `igmp_send()` in `subsys/net/ip/igmp.c` read the network interface back out of the packet via `net_pkt_iface(pkt)` after the packet had been handed to `net_send_data()`. On the successful-send path the packet's last reference may already have

been released by the L2 driver or by the network stack's TX handling (synchronously in the default NET_TC_TX_COUNT=0 immediate-transmit configuration), returning the net_pkt slab block to its free list. The subsequent net_pkt_iface(pkt) dereferences the freed packet, a use-after-free read; with CONFIG_NET_STATISTICS_PER_INTERFACE the resulting dangling interface pointer is further dereferenced for a statistics-counter write. The IGMP send path is reachable without authentication from inbound IPv4 IGMP membership queries addressed to 224.0.0.1 (net_ipv4_igmp_input -> send_igmp_report/send_igmp_v3_report -> igmp_send), as well as from local multicast join/leave/rejoin operations. Realistic impact is undefined behavior and potential denial of service (sporadic crash or stats corruption); a controllable write requires the asynchronous TX path plus a concurrent slab reuse. The flaw was introduced with IGMPv2 support and affects releases from v2.6.0 through v4.4.0. The fix caches the interface pointer before sending. Note the analogous IPv6 MLD path (mld_send in subsys/net/ip/ipv6_mld.c) retains the same unfixed pattern.

CVE 2026-10637

Use-after-free of net_pkt in IPv6 MLD send path triggerable by a link-local MLD Query

subsys/net/ip/ipv6_mld.c:mld_send() read the packet interface via net_pkt_iface(pkt) after net_send_data(pkt) returned successfully. Per the network stack's ownership contract (include/zephyr/net/net_core.h, and the explicit warning in subsys/net/ip/net_core.c:453-460 'do not use pkt after that call'), a successful send transfers ownership of the net_pkt and the L2 driver frees it (e.g. ethernet_send() unrefs the packet on success, subsys/net/l2/ethernet/ethernet.c:790), returning it to its k_mem_slab. The subsequent net_pkt_iface(pkt) is therefore a read of a freed object; the recovered interface pointer is then dereferenced and incremented by the per-interface statistics path (net_stats.h UPDATE_STAT/SET_STAT) when CONFIG_NET_STATISTICS_PER_INTERFACE is enabled. If the freed slot is concurrently reallocated, pkt->iface may read back as NULL (NULL-pointer dereference / crash) or as a stale/garbage pointer (stray increment write / memory corruption). The path is reachable remotely on the local link without authentication: handle_mld_query() (registered for NET_ICMPV6_MLD_QUERY) responds to a valid MLDv2 General Query (unspecified multicast address, hop limit 1) by calling send_mld_report() -> mld_send(). The result is a remotely triggerable denial of service of the networking stack, with a narrow possibility of memory corruption. The fix caches the interface in a local before sending and no longer touches the packet after net_send_data(). The IPv4/IGMP sibling (igmp_send) already used the corrected pattern.

CVE 2026-10638

Use-after-free in Zephyr ICMPv6 RX path when updating statistics after sending an echo reply or error

subsys/net/ip/icmpv6.c reads the network interface from a net_pkt after that packet has been handed to net_try_send_data(). In icmpv6_handle_echo_request() and net_icmpv6_send_error(), the post-send statistics update calls net_pkt_iface(reply)/net_pkt_iface(pkt) on the just-sent packet. The send path (net_try_send_data -> net_if_tx) unreferences and may free the packet back to its memory slab before returning — synchronously in the RX thread when no TX queue is configured (CONFIG_NET_TC_TX_COUNT == 0), and asynchronously the driver/L2 may already have freed it otherwise. net_pkt_iface() therefore dereferences a freed (and possibly reused) net_pkt; with CONFIG_NET_STATISTICS_PER_INTERFACE the stale iface pointer is further dereferenced and written through (iface->stats.icmp.sent++), turning the use-after-free read into a write through an attacker-influenceable pointer. The core stack already documents this hazard in net_core.c ("do not use pkt after that call") and caches iface before sending; the ICMPv6 callers did not. An unauthenticated remote attacker triggers the flaw simply by sending an ICMPv6 Echo Request (ping) or an IPv6 packet that elicits an ICMPv6 error (unknown next header, fragment reassembly timeout, destination unreachable), leading to denial of service via crash and potential memory corruption. Affected: Zephyr networking with CONFIG_NET_NATIVE_IPV6, roughly v4.2.0 through v4.4.0. The fix caches the interface pointer before sending and uses it for all statistics updates; the sibling commit 86e21665d46 fixes the identical bug in ICMPv4.

CVE 2026-10639

Use-after-free reading net_pkt_iface() of a sent ICMPv4 echo-reply packet in icmpv4_handle_echo_request()

In Zephyr's native IPv4 stack, icmpv4_handle_echo_request() in subsys/net/ip/icmpv4.c builds an echo-reply packet (reply), hands it to net_try_send_data(), and then, on success, calls net_stats_update_icmp_sent(net_pkt_iface(reply)). net_try_send_data() transfers ownership of reply to the TX path (net_if_try_queue_tx -> net_if_tx -> L2/driver send, or the asynchronous net_if_tx_thread), which can unref it to refcount 0 and return the struct net_pkt to its slab (net_pkt_unref -> k_mem_slab_free) before the stats line runs. net_core.c documents this exact contract ('the pkt might contain garbage already ... do not use pkt after that call').

The post-send net_pkt_iface(reply) therefore reads reply->iface out of a freed (and possibly already reallocated) net_pkt, a use-after-free read; with CONFIG_NET_STATISTICS_PER_INTERFACE the stats macro additionally increments a counter through that value, i.e. a dereference/write through a stale or recycled-slot pointer.

The path is reached unauthenticated by any remote host that pings the device (net_icmpv4_input -> net_icmp_call_ipv4_handlers -> icmpv4_handle_echo_request) and is gated on CONFIG_NET_STATISTICS_ICMP. Impact is a probabilistic read of recycled packet memory plus a possible wild-pointer write under a timing race, leading most likely to corrupted interface statistics or a remotely triggerable crash (DoS).

The defect was introduced in 2019 (v1.14) and is present through v4.4.0. The companion change in net_icmpv4_send_error() is not a use-after-free because it reads net_pkt_iface(orig), the caller-owned received packet, which stays alive across the send. The fix caches the interface pointer from the live received packet before sending and uses it for the post-send stats updates.

CVE 2026-10640

Use-after-free reading `net_pkt iface` after send in IPv6 Neighbor Discovery (`ipv6_nbr.c`)

Zephyr's IPv6 Neighbor Discovery send paths (`net_ipv6_send_na`, `net_ipv6_send_ns`, `net_ipv6_send_rs` in `subsys/net/ip/ipv6_nbr.c`) updated the per-interface ICMP- sent statistics by calling `net_pkt_iface(pkt)` after `net_send_data(pkt)` had already returned successfully. On the success path the network stack owns and releases the packet's reference (the L2/driver send unrefs it, e.g. `ethernet_send` -> `net_pkt_unref`), so for a freshly allocated packet with refcount 1 the `net_pkt` slab block can be freed before the statistics line runs (synchronously when no TX queue thread is configured, or via a concurrent TX thread otherwise).

The subsequent `net_pkt_iface(pkt)` reads `pkt->iface` from the freed slab block, and with `CONFIG_NET_STATISTICS_PER_INTERFACE` enabled that loaded pointer is dereferenced to increment `iface->stats.icmp.sent`, a use-after-free (CWE-416). If the slab block was reallocated in the meantime the read/increment targets unrelated or attacker-influenced memory, yielding corrupted statistics, a fault/crash (denial of service), or potential limited memory corruption.

The vulnerable Neighbor Advertisement path is reachable by any unauthenticated on-link node simply by sending ICMPv6 Neighbor Solicitations to a Zephyr node with native IPv6 enabled (`handle_ns_input` -> `net_ipv6_send_na`).

Affected from v3.3.0 through v4.4.0; the fix uses the already-available `iface` argument instead of touching the sent packet. Configurations without per-interface statistics dereference only a global counter and are not affected by the memory-safety aspect.

CVE 2026-10641

Out-of-bounds write in Bluetooth HFP Hands-Free CIND indicator parsing (cind_handle_values)

Zephyr's Bluetooth Classic Hands-Free Profile (HFP) Hands-Free role parser (subsys/bluetooth/host/classic/hfp_hf.c) contains an out-of-bounds write. During Service Level Connection setup the HF sends AT+CIND=? and parses the AG's +CIND: response in cind_handle(), which assigns a per-entry counter `index` and calls cind_handle_values() for each list element. cind_handle_values() then wrote `hf->ind_table[index] = i` without verifying that `index` is within the 20-element int8_t ind_table[] array of struct bt_hfp_hf. Because the parser places no cap on the number of +CIND: list entries, a remote Attendant Gateway (a malicious, compromised, or spoofed peer the device connects to over Bluetooth) can send a response with more than 20 recognized indicator entries and drive `index` arbitrarily large, writing a small attacker-positioned value past the array into adjacent struct fields (feature masks, SDP/version state, the calls[] array, work/atomic bookkeeping) and potentially beyond the static connection pool slot. This yields memory corruption and at least denial of service of the Bluetooth host, triggered by a single malformed AT response with no user interaction. The sibling consumer ag_indicator_handle_values() already performed the equivalent bounds check; this commit adds the same `index >= ARRAY_SIZE(hf->ind_table)` guard to close the gap. Affects builds

with CONFIG_BT_HFP_HF enabled; introduced with the original HFP HF CIND parser (~v1.7) and present through v4.4.0.

CVE 2026-10642

Unbounded TX busy-loop DoS in Zephyr PL011 UART driver under CTS hardware flow control

The Zephyr PL011 UART driver (`drivers/serial/uart_pl011.c`) contains an unbounded software loop in `pl011_irq_tx_enable()` that repeatedly invokes the interrupt-driven application callback while the TX interrupt mask bit (`PL011_IMSC_TXIM`) is set, to work around the controller's level-transition TX-interrupt behavior.

When CTS hardware flow control is enabled (devicetree `hw-flow-control` or runtime `UART_CFG_FLOW_CTRL_RTS_CTS`) and the wired serial peer de-asserts CTS, the controller stops draining the TX FIFO; `pl011_fifo_fill()` then returns 0 on every call while the application still has pending data and therefore never disables the TX interrupt. The loop condition never clears, so the thread that called `uart_irq_tx_enable()` (e.g. `h4_send()` in the Bluetooth HCI H4 driver) spins indefinitely, hanging the executing context and stalling the transport — a denial of service (CWE-835).

An attacker controlling the device attached to the UART's CTS line can trigger the hang by withholding CTS during transmission. Because that peer is the device wired to the UART — which may be a removable or external module (e.g. an off-board Bluetooth controller on the HCI H4 link) rather than a permanently-bonded on-PCB part — the attack vector is scored Adjacent (AV:A) rather than Physical; the security subcommittee should confirm the vector against the specific deployment. Impact is availability only; there is no memory-safety, confidentiality, or integrity consequence.

The vulnerable loop was introduced in commit b783bc8448ef (Feb 2025) and shipped in releases v4.1.0 through v4.4.0. The fix breaks out of the loop when CTS is blocking and arms the CTS modem-status interrupt to resume transmission when CTS re-asserts.

CVE 2026-10643

Out-of-bounds heap write in Zephyr `recvmsg()` ancillary-data path (`insert_pktinfo` undersizes the control-buffer capacity check)

Zephyr's IP socket `recvmsg()` implementation (`subsys/net/lib/sockets/sockets_inet.c`, `insert_pktinfo()`) validated the user-supplied ancillary (`msg_control`) buffer using only the payload length (`msg->msg_controllen < pktinfo_len`) before writing a full control message consisting of an aligned cmsg header plus the payload. Because the check omitted the cmsg header size, a control buffer whose length falls in the under-checked window (e.g. 16-27 bytes for IPv4 `IP_PKTINFO` on a 64-bit target, where a single element actually occupies 28 bytes) passes the guard

yet causes a fixed-size out-of-bounds write of up to one cmsg header (~12 bytes) past the end of the buffer.

Under CONFIG_USERSPACE the recvmsg verifier allocates a kernel-heap copy of the control buffer sized to msg_controllen and runs the implementation against it, so the overflow corrupts kernel heap memory and is triggerable from an unprivileged userspace thread; in supervisor mode it corrupts the caller's buffer.

The path is reachable on a UDP/IP socket with IP_PKTINFO/IPV6_RECVPKTINFO (or hoplimit/timestamping) enabled when the application calls recvmsg() with an undersized control buffer and a datagram is received; part of the overwritten bytes (the destination IP in ipi_addr) is influenced by the received packet.

The fix makes the capacity check use NET_CMSG_SPACE(pktinfo_len) (aligned header + aligned data) and returns -ENOMEM when the buffer is too small. Affected: v3.6.0 through v4.4.0.

CVE 2026-10644

Out-of-bounds write in Microchip SERCOM-G1 (PIC32CM-JH) async UART RX with 1-byte buffer

The Microchip SERCOM-G1 UART driver (drivers/serial/uart_mchp_sercom_g1.c), used by the PIC32CM-JH SoC family, contains an out-of-bounds write in its asynchronous (DMA) receive path. When uart_rx_enable() is invoked with a one-byte receive buffer (len == 1) and CONFIG_UART_MCHP_ASYNC is enabled, the RX-complete ISR starts a single-beat DMA transfer while a received byte is already pending in the SERCOM DATA register. On this SoC the peripheral-triggered DMA start sequencing then writes one byte past the end of the caller-supplied buffer (CWE-787).

The overflowed byte's value is the UART RX data supplied by the connected serial peer (adjacent attacker), while its size and location are fixed at one byte immediately after the buffer.

Exploitation requires the async UART config (not enabled by default on the in-tree PIC32CM-JH boards) and a consumer that enables RX with a one-byte buffer; impact is limited single-byte memory corruption adjacent to the RX buffer (possible crash / denial of service).

The defect shipped in v4.4.0. The fix reads the first byte with the CPU and, for one-byte buffers, performs no DMA at all; for larger buffers it sizes the DMA for the remaining len-1 bytes.

CVE 2026-10645

Out-of-bounds read in Zephyr ext2 directory entry traversal from a crafted filesystem image

The Zephyr ext2 filesystem driver (subsys/fs/ext2) trusted the on-disk directory entry fields de_rec_len and de_name_len when walking a directory block. ext2_fetch_direntry() guarded only with de_name_len > EXT2_MAX_FILE_NAME, but de_name_len is a uint8_t and EXT2_MAX_FILE_NAME is 255, so the check is always false; the function then memcpy'd up to 255 name bytes and the lookup/readdir paths advanced traversal by an unvalidated de_rec_len.

Each directory block is read into a `block_size`-sized slab buffer, and `block_off` can be driven near the block end by preceding entries' `rec_len`, so the 8-byte header read and the subsequent name `memcpy` can read up to ~263 bytes past the end of the block buffer into adjacent heap/slab memory. On the readdir path those bytes are returned to the caller in `fs_dirent.name`, leaking adjacent kernel heap memory; a `de_rec_len` of 0 also causes a zero-progress infinite loop (denial of service), and the unlink path's `memmove(de, next, next_reclen)` over unvalidated records is an additional OOB read/write source. The defect is reached by any path-based operation (open, stat, unlink, rename, mkdir) or directory listing on a mounted ext2 volume, so a crafted or corrupted ext2 image on attacker-supplied storage (SD card, USB mass storage, or otherwise mounted image) triggers it. Affected: Zephyr ext2 from its introduction in v3.5.0 through v4.4.0. The fix validates `rec_len` and `name_len` in the parser and rejects entries whose header does not fit the remaining block or whose `rec_len` crosses the block boundary in every traversal caller.

CVE 2026-10646

Use-after-return in `zsock_getaddrinfo()` when a timed-out DNS query is retried without cancellation

Zephyr's BSD-sockets `getaddrinfo()` implementation (`subsys/net/lib/sockets/getaddrinfo.c`) passes a pointer to a stack-allocated state object (`struct getaddrinfo_state ai_state`) as the `user_data` of an asynchronous DNS resolver query. The socket layer waits on a semaphore with a timeout deliberately set slightly longer than the resolver's own per-query timeout. When that semaphore wait nonetheless times out (`-EAGAIN`) - which can occur when the resolver's timeout work is delayed by workqueue contention, or in the documented multi-retry configuration where `CONFIG_NET_SOCKETS_DNS_TIMEOUT` exceeds `CONFIG_NET_SOCKETS_DNS_BACKOFF_INTERVAL` - the pre-fix code retries the query (`goto again`) without cancelling the previous one and without resetting the semaphore.

The previous query slot remains active in the resolver with its callback and the stack pointer as `user_data`, and `ai_state->dns_id` is overwritten so the stale query can no longer be cancelled. A subsequent DNS response delivered over UDP and matched by its 16-bit transaction id (in `dispatcher_cb()`/`dns_read()`), or the resolver's own delayed query-timeout work, then invokes `dns_resolve_cb()` against the now out-of-scope stack frame, writing through the stale pointer (`state->status`, `state->idx`, `state->ai_arr[]`, and `k_sem_give()`).

Because the triggering response is network-delivered and its 16-bit id is spoofable/replayable by an on- or off-path attacker, this is a network-influenceable use-after-return that can corrupt reused stack memory, leading to crashes/denial of service or memory corruption.

The fix cancels the timed-out query by name and type before retrying and resets the local semaphore, eliminating the stale callback path. Affected: Zephyr v4.0.0 through v4.4.0.

CVE 2026-10647

Deadlock denial of service in USB CDC-NCM device class on TX enqueue failure

The USB CDC-NCM device class (`subsys/usb/device_next/class/usbd_cdc_ncm.c`) ignores the return value of `usbd_ep_enqueue()` in its ethernet transmit callback `cdc_ncm_send()`. When the enqueue fails, the function still calls `k_sem_take(&data->sync_sem, K_FOREVER)`, blocking on a completion semaphore that is only ever signaled from the bulk-IN transfer-completion callback. Because nothing was enqueued, that callback never fires and the calling thread — a shared network traffic-class TX thread — deadlocks permanently while holding the interface TX lock, halting transmission until reboot (and leaking the transmit buffer).

The enqueue fails under conditions controlled by the attached USB host: `usbd_ep_enqueue()` returns `-EPERM` whenever the bus is suspended (a standard, persistent host operation), and the underlying `udc_ep_enqueue()` returns `-EPERM`/`-ENODEV` on disconnect, bus reset, or endpoint disable. The `cdc_ncm_send()` guard only checks the `DATA_IFACE_ENABLED` and `IFACE_UP` flags, not the suspended state, so a packet transmitted while the host holds the bus suspended reaches the failing enqueue and deadlocks the TX path.

The realistic trigger is a bus suspend that occurs while the exported network interface is active and has traffic to send — host sleep, USB selective/auto-suspend, or hub power management — after which any device-originated packet deadlocks the path, recoverable only by reboot. The impact is a persistent loss of the virtual network connection between the host's NCM interface and the Zephyr device; because the deadlocked thread is a shared traffic-class TX thread, egress on other network interfaces can stall as well. There is no memory corruption or information disclosure.

The defect was introduced with the CDC-NCM driver and shipped in releases through v4.4.0; it is fixed by checking the `usbd_ep_enqueue()` return value and freeing the buffer before the blocking wait.

CVE 2026-10648

NULL-pointer dereference in MCUmgr serial/console SMP transport on buffer-pool exhaustion

`mcumgr_serial_process_frag()` in `subsys/mgmt/mcumgr/transport/src/serial_util.c` calls `net_buf_reset()` on the result of `smp_packet_alloc()` before checking it for `NULL`. `smp_packet_alloc()` uses `net_buf_alloc(K_NO_WAIT)` against the shared MCUmgr packet pool (`CONFIG_MCUMGR_TRANSPORT_NETBUF_COUNT`, default 4), which returns `NULL` when the pool is exhausted. In default builds the `__ASSERT_NO_MSG` in `net_buf_reset` is a no-op, so `net_buf_simple_reset` writes through the `NULL` pointer (`buf->len = 0; buf->data = buf->__buf`), causing a fault/crash.

The fragment data reaches this code from attacker-controlled bytes on the MCUmgr serial/UART/shell-console transports (`smp_uart.c`, `smp_raw_uart.c`, `smp_shell.c`), and a fresh buffer is allocated at the start of essentially every new packet. An attacker on the serial/console link can flood the transport to drive the 4-entry buffer pool to exhaustion and induce the `NULL` dereference, crashing the device (denial of service).

The defect was introduced after the original MCUmgr rework and shipped in Zephyr v4.4.0. The fix moves the `NULL` check ahead of `net_buf_reset`.

CVE 2026-10651

Out-of-bounds read in Bluetooth Classic SDP attribute parsing (`bt_sdp_parse_attribute`)

`bt_sdp_parse_attribute()` in `subsys/bluetooth/host/classic/sdp.c` validated only that the SDP record buffer held the type-marker byte plus the 2-byte attribute ID (a check of `buf->len < 3`) but then read a fourth byte, the data-element descriptor (`type`), via `net_buf_simple_pull_u8()`. Because `net_buf_simple_pull_u8()` dereferences `buf->data[0]` before its only bounds guard (an `__ASSERT_NO_MSG` that compiles out when `CONFIG_ASSERT` is disabled, the production default), a record of exactly three bytes (0x09 followed by a 2-byte attribute ID) causes a one-byte read past the end of the logical buffer. The parser is reachable from inbound, remote-controlled data: a Bluetooth BR/EDR peer acting as an SDP server returns discovery-response records that are stored verbatim in the client receive buffer and parsed via the public `bt_sdp_get_attr()`/`bt_sdp_has_attr()`/`bt_sdp_record_parse()` helpers. The over-read is bounded to a single byte that is used only as an internal length selector and is never leaked to the attacker; subsequent length checks then reject the malformed record. Realistic impact is therefore limited to an edge-case denial of service (a fault only if the record ends exactly at a mapped-memory boundary, or a deterministic assert panic when `CONFIG_ASSERT=y`). Affects Zephyr v4.3.0 and v4.4.0; fixed by adding `sizeof(type)` to the length check.

CVE 2026-10652

Out-of-bounds read in Zephyr DNS resolver TXT/SRV record parsing (unvalidated `rdlength`)

Zephyr's DNS resolver (`subsys/net/lib/dns`) parses resource records from DNS responses in `dns_unpack_answer()`, which validated only the fixed RR header (type, class, TTL, `rdlength`) and accepted any attacker-declared `rdlength`, including one extending past the end of the received datagram. The TXT and SRV consumers in `dns_validate_record()` (`resolve.c`) then read up to `rdlength` bytes (clamped only to a record-type maximum such as `DNS_MAX_TEXT_SIZE`, default 64, not to the packet) from the receive buffer via `memcpy` without their own bounds check, and pass the result to the application's resolve callback. A malicious or spoofed DNS server, an on-path attacker forging UDP DNS replies, or (with mDNS/LLMNR enabled) any LAN node can craft a truncated TXT or SRV response that causes an out-of-bounds read of adjacent receive-pool memory; the disclosed stale bytes (residual contents of prior DNS packets / uninitialized pool memory) are returned to the application as TXT/SRV record contents, an information leak, and may in some configurations cross the allocation boundary and fault, causing a denial of service. The read is bounded (~64 bytes for TXT, ~6 for SRV) and read-only (no write). The fix rejects any record whose declared rdata extends past `dns_msg->msg_size` at the single chokepoint in `dns_unpack_answer()`. Affected: v4.3.0 and v4.4.0.

CVE 2026-10653

Non-atomic net_buf reference counts cause double-free / free-list corruption under concurrent unref

The Zephyr net_buf library (lib/net_buf/buf.c) manipulated both of its reference counts – the per-header buf->ref and the per-data-block ref_count at the start of each variable/heap data allocation – with plain non-atomic C operators (buf->ref++, if (--buf->ref > 0), if (--(*ref_count))).

The API is documented as self-synchronizing: callers may share one buffer across threads (e.g. via k_fifo) and each holder independently calls net_buf_unref() with no surrounding lock. Under true concurrency (SMP, or single-core preemption between the non-atomic load and store while another context unrefs the same buffer), two holders can both observe the same prior reference value and both conclude they are the last reference.

For heap/variable-data pools (mem_pool_data_unref/heap_data_unref, used by zbus message subscribers, the IP stack RX/TX buffers when CONFIG_NET_BUF_FIXED_DATA_SIZE=n, capture, wireguard, ISO-TP and usbip) this produces a double k_heap_free()/k_free() of the same block – heap-metadata corruption and a use-after-free on the heap-hardening poison pattern.

For the per-header refcount the buffer is returned to the pool free LIFO twice for any pool type (including fixed-data pools used by Bluetooth and networking), corrupting the free list so a later allocation hands the same buffer to two owners.

The fix converts both refcounts to atomic_inc/atomic_dec (overlaying buf->ref in an atomic_t-sized union and changing the data-block refcount from uint8_t to atomic_t).

Impact is gated on genuine concurrency and on an application architecture that shares one buffer among multiple independent unref'ers; the trigger is a refcount/timing race rather than packet content, so an external attacker has at most weak indirect influence over the race window. Affects all Zephyr releases through v4.4.0.

CVE 2026-10654

RFCOMM session-disconnect race leaks session/L2CAP and denies further RFCOMM service in Zephyr Bluetooth Classic

A race condition in the Zephyr Bluetooth Classic RFCOMM host stack (subsys/bluetooth/host/classic/rfcomm.c) mishandles a simultaneous bidirectional session disconnect. When the local device has initiated a session teardown (state BT_RFCOMM_STATE_DISCONNECTING, DISC sent, RTX timer armed) and the connected peer concurrently sends its own DISC frame for dlci 0, rfcomm_handle_disc() invokes rfcomm_session_disconnected(), which unconditionally forced the session to BT_RFCOMM_STATE_DISCONNECTED without ever calling bt_l2cap_chan_disconnect().

Because the recovery timer was also cancelled and a later UA is ignored in the DISCONNECTED state, the session becomes permanently wedged: the underlying L2CAP channel is never released and the session slot in the fixed bt_rfcomm_pool[CONFIG_BT_MAX_CONN] array is never reclaimed (its conn pointer stays set).

Subsequent bt_rfcomm_dlc_connect() calls on that connection fail with -EINVAL due to the invalid session state, so RFCOMM service is denied for that peer, and repeated occurrences can exhaust the session pool. The DISC frame is peer-controlled over the air, but exploitation requires the peer's DISC to collide with a local-initiated disconnect (a high-complexity timing race).

Impact is availability/resource-leak only; there is no memory-safety, confidentiality, or integrity consequence. The defect shipped in released versions (present in v4.4.0 and earlier).

The fix only transitions to DISCONNECTED when the session is not already in DISCONNECTING, preserving the proper L2CAP teardown path.

CVE 2026-10655

Use-after-free race in SNTP async client when closing the socket while the socket service is still polling it

The asynchronous SNTP client in Zephyr (`subsys/net/lib/sntp/sntp.c`, `sntp_close_async`) closed the UDP socket file descriptor directly from the calling thread immediately after detaching it from the network socket service, without synchronizing with the socket-service poll thread.

The socket service thread polls each socket via `zvfs_poll`, which (in `zsock_poll_prepare_ctx`) registers a `k_poll_event` pointing into the socket's `net_context` (`&ctx->recv_q`) and then blocks in `k_poll` without holding a reference or lock. `net_context` objects are allocated from a fixed pool (`contexts[CONFIG_NET_MAX_CONTEXTS]`) and reused after close.

When `sntp_close_async` is invoked from a different thread than the poll thread (in the in-tree consumer `subsys/net/lib/config/init_clock_sntp.c`, the SNTP timeout handler runs on the system workqueue while the socket service thread is blocked in poll on the same fd), the close frees and may reuse the `net_context` while the poll thread still has a poller node linked into the freed object, resulting in a use-after-free / object confusion of kernel poll structures.

The SNTP timeout path is the normal no-response failure mode, so a network peer or off-path attacker who drops or delays the SNTP/NTP response can drive the racing close repeatedly (and periodically with `NET_CONFIG_SNTP_INIT_RESYNC`). The most likely consequence is a crash of the networking thread (denial of service), with potential memory corruption when the freed context slot is reallocated.

The fix defers the close to the socket service thread itself via `net_socket_service_close` (`NET_SOCKET_SERVICE_CLOSE_SOCKETS`), so the same thread that polls performs the close, eliminating the race. Affected releases: v4.2.0 through v4.4.0.

CVE 2026-10656

NULL-pointer dereference DoS in MAX32 USB device controller transfer-completion handlers

The MAX32xxx USB device controller driver (`drivers/usb/udc/udc_max32.c`, compatible `adi_max32_usbhs`) dereferenced an endpoint buffer in its OUT and IN transfer-completion handlers without checking it for `NULL`. `udc_event_xfer_out_done()` called `net_buf_add(buf, ep_request->actlen)` immediately after `buf = udc_buf_get(ep_cfg)`, where `udc_buf_get()` returns `NULL` when the endpoint FIFO is empty.

A transfer-completion event is queued from interrupt context and processed asynchronously by the driver thread; between queuing and processing, the endpoint FIFO can be drained by host-controlled control flow — in particular `udc_setup_received()` drains the EP0 OUT/IN FIFOs whenever a new SETUP packet arrives, and dequeue/disable/purge paths drain it likewise.

A USB host that aborts an in-flight EP0 control transfer with a new SETUP packet (legal USB behavior) can therefore cause a stale `XFER_OUT_DONE` event to be processed against an empty FIFO, producing `net_buf_add(NULL, ...)`, a near-NULL pointer dereference that faults and crashes the device. No authentication is required; the attacker is the USB host the device is connected to (physical bus access). Impact is denial of service (device crash).

The defect was introduced when the MAX32 UDC driver was added and shipped in Zephyr v4.4.0. The fix adds NULL-buffer checks that return early with `UDC_EVT_ERROR`/-ENOBUFS in both the OUT-done and IN-done handlers.

CVE 2026-10657

Out-of-bounds read in Zephyr DNS resolver mDNS suffix check (memcmp past string NUL)

Zephyr's DNS resolver detects mDNS (.local) queries in `dns_resolve_name_internal()` (`subsys/net/lib/dns/resolve.c`) with `memcmp(strrchr(query, '.'), ".local", 7)`, which always reads a fixed 7 bytes from the suffix pointer. When the resolved hostname's final label is shorter than 7 bytes (e.g. names ending in .org, .com, .net, .io, or a trailing dot), the comparison reads 1-2 bytes past the string's NUL terminator.

The hostname (`query`) is the caller-supplied name passed through the standard `getaddrinfo()`/`dns_get_addr_info()`/`dns_resolve_name()` path and is influenceable by operators or remote inputs (server names from configuration, parsed URLs, or app-facing interfaces).

On a tightly-sized buffer with no slack (for example a userspace `getaddrinfo` call where the hostname is copied with `k_usermode_string_alloc_copy` to exactly `strlen+1` bytes), the over-read crosses the allocation boundary; if that boundary is unmapped (guard page, memory-domain boundary under MPU, or an address sanitizer) the over-read faults, causing a denial of service. The over-read bytes are never returned, so there is no information disclosure.

The flaw is compiled only when `CONFIG_MDNS_RESOLVER` is enabled, exists since v1.10.0, and is fixed by replacing the fixed-length `memcmp` with a NUL-safe `strcmp(ptr, ".local")`.

CVE 2026-10658

Out-of-bounds access in Bluetooth ISO receive (`bt_iso_recv`) due to missing SDU-header length validation

`bt_iso_recv()` in `subsys/bluetooth/host/iso.c` pulled the ISO SDU header (4 bytes) or, when the timestamp flag is set, the timestamped SDU header (8 bytes) from the inbound HCI ISO Data buffer via `net_buf_pull_mem()` without first checking `buf->len`. The upstream

hci_iso() handler enforces buf->len == the controller-declared ISO Data_Load length, so a malicious or buggy controller / adjacent BLE peer on an established CIS/BIS can present a first-fragment (BT_ISO_START) or single (BT_ISO_SINGLE) PDU shorter than the SDU header. Because net_buf_simple_pull_mem only guards length with __ASSERT_NO_MSG (compiled out when CONFIG_ASSERT is disabled, the production default), the pull underflows buf->len (uint16_t, e.g. 0 - 8 = 0xFFF8) and advances buf->data past valid data: the subsequent reads of hdr->slen and hdr->sn are out-of-bounds reads of adjacent pool memory. For the multi-fragment (START) case the corrupted buffer is retained as iso->rx, and a following CONT/END fragment's net_buf_tailroom() guard underflows to a near-SIZE_MAX value, defeating the bounds check and causing net_buf_add_mem() to memcpy attacker-supplied fragment data far past the RX pool buffer (out-of-bounds write). The flaw affects ISO receive builds (CONFIG_BT_ISO_RX, selected by the default-off LE Audio options BT_ISO_PERIPHERAL/BT_ISO_CENTRAL/BT_ISO_SYNC_RECEIVER) and has existed since the ISO subsystem was introduced (v2.6.0) through v4.4.0. The fix adds explicit buf->len < sizeof(*ts_hdr) and buf->len < sizeof(*hdr) checks that drop the buffer before pulling.

CVE 2026-10659

NULL pointer dereference in Zephyr Dhara FTL disk driver on flash read error during journal resume

The Dhara flash translation layer disk driver (drivers/disk/ftl_dhara.c) implemented the dhara_nand_* callbacks so that, on a flash error, the error code was written unconditionally through the caller-supplied dhara_error_t *err pointer (e.g. *err = DHARA_E_ECC in dhara_nand_read, and similar in dhara_nand_erase/prog/copy).

The upstream Dhara library calls these callbacks with err == NULL along its journal-resume binary search: find_last_checkblock() invokes find_checkblock(j, mid, &found, NULL), which forwards the NULL pointer into dhara_nand_read(). This path runs during disk_ftl_access_init() -> dhara_map_resume() whenever the FTL disk is mounted/initialised.

If a flash read error (uncorrectable ECC, bad block, controller error) occurs on one of the probed checkpoint pages, the driver dereferences and writes to NULL, faulting the kernel (denial of service). The trigger is conditioned on the NAND medium content/health, which can be influenced by media wear, induced faults, or a corrupted/crafted on-flash image.

The fix routes all error assignments through the library's NULL-safe dhara_set_error() helper. Affects Zephyr v4.4.0, where the driver was introduced.

CVE 2026-10660

Shared reassembly buffer in Bluetooth BAP Broadcast Assistant enables cross-connection memory corruption

The Bluetooth BAP Broadcast Assistant GATT client in subsys/bluetooth/audio/bap_broadcast_assistant.c reassembled remote Broadcast Receive State data into a single file-static net_buf_simple (att_buf, BT_ATT_MAX_ATTRIBUTE_LEN = 512 bytes) shared by all connection instances, while the BUSY flag, long-read handle, and reset/offset state were per-connection.

When the device acts as a Broadcast Assistant connected to multiple Scan Delegator peripherals, notification and long-read callbacks from different connections interleave on the shared buffer: the append in notify_handler (net_buf_simple_add_mem at the not-busy branch) performs no tailroom check, so receive-state notifications from two or more delegators accumulate on the same 512-byte buffer and, with a sufficiently large configured ATT MTU (BT_L2CAP_TX_MTU up to 2000) and two-to-three concurrent connections, write past the buffer into adjacent .bss (net_buf_simple_add only asserts in debug builds).

Even below the overflow threshold, one connection's net_buf_simple_reset zeroes the shared length while another connection's reassembly and GATT read offset are in flight, mixing one peer's data into another's parse. A malicious or compromised Scan Delegator (or two colluding peers) over BLE can trigger this, causing out-of-bounds writes (memory corruption / denial of service) and cross-connection data corruption.

The fix moves the buffer into the per-connection instance struct so each connection reassembles into its own buffer. Affects Zephyr releases shipping the Broadcast Assistant with the shared buffer, including v4.4.0 and earlier.

CVE 2026-10663

Use-after-free / double-free of the root USB device in the experimental USB host stack

In Zephyr's experimental USB host stack (CONFIG_USB_HOST_STACK), usbh_device_disconnect() (subsys/usb/host/usbh_device.c) freed the root usb_device slab object without clearing the cached pointer ctx->root. The bus removal handler dev_removed_handler() (subsys/usb/host/usbh_core.c) decides what to tear down solely from ctx->root, checking only that it is non-NULL.

Because UHC controller drivers (e.g. uhc_max3421e, uhc_mcux_common) synthesize UHC_EVT_DEV_REMOVED directly from physical bus line state with no debounce or state guard, an attacker with physical USB access (or a rogue device that bounces its connection) can deliver a second device-removed event after a root device disconnect. The handler then re-enters usbh_device_disconnect() with the dangling pointer, locking a mutex inside the freed object (use-after-free), removing the freed node from the device list, and calling k_mem_slab_free() on the already-freed block (double-free). If the slab block has been reissued to a newly attached device in between, this corrupts a live object.

Impact is denial of service (crash) and memory corruption; the attack vector is physical/local. The flaw was introduced in v4.4.0 by the connect/disconnect refactor and is fixed by clearing ctx->root in usbh_device_disconnect() before freeing.

CVE 2026-10664

Out-of-bounds write in nRF70 Wi-Fi driver power-save event handler (unbounded TWT flow count)

The nRF70 Wi-Fi driver's power-save event handler `nrf_wifi_event_proc_get_power_save_info()` in `drivers/wifi/nrf_wifi/src/wifi_mgmt.c` copied TWT (Target Wake Time) flow entries from an `nrf_wifi_umac_event_power_save_info` event into the fixed-size `twt_flows[WIFI_MAX_TWT_FLOWS]` (8-element) array of a caller-supplied `struct wifi_ps_config`, looping over event-provided `num_twt_flows` without validating it against `WIFI_MAX_TWT_FLOWS` or checking `event_len`. When `num_twt_flows` exceeds 8, the handler writes past the destination array (which is typically on the caller's stack, e.g. the `wifi ps` shell command) – an out-of-bounds write of ~40-byte TWT entries – and reads `twt_flow_info[i]` past the event buffer. The event is delivered by the nRF70 co-processor firmware in response to a host-initiated power-save GET, so reaching the overflow requires the firmware to emit a malformed or out-of-range event; the trust boundary is host-to-trusted-coprocessor rather than a direct remote-AP write, with over-the-air influence on the flow count being indirect and bounded by the 3-bit TWT flow-id space. Affected: builds with `CONFIG_NRF70_STA_MODE` on releases through v4.4.0. The fix rejects events with `num_twt_flows > WIFI_MAX_TWT_FLOWS` or with `event_len` shorter than the claimed entries, and adds a NULL check on the caller buffer.

CVE 2026-10665

Heap buffer overflow on WireGuard receive path via unbounded incoming packet length

In Zephyr's WireGuard subsystem (`subsys/net/lib/wireguard`), `wg_process_data_message()` in `wg_crypto.c` linearizes an inbound transport-data payload into a fixed pool buffer of `CONFIG_WIREGUARD_BUF_LEN` bytes before decryption. The call `net_buf_linearize(buf->data, data_len, pkt->buffer, ..., data_len)` passed the attacker-derived `data_len` as both the destination capacity and the copy length, defeating the function's internal `len = min(len, dst_len)` bound. `data_len` is derived from the received UDP datagram length and is only lower-bounded by `wg_ctrl_recv()` (no upper bound). When `data_len` exceeds `CONFIG_WIREGUARD_BUF_LEN` — e.g. when the buffer length is lowered below the link MTU, on links with MTU above the buffer size, or via reassembled IPv4/IPv6 fragments that exceed it — the underlying `memcpy` writes past the end of the pool buffer, an out-of-bounds write (CWE-787). The overflow occurs before the Poly1305 authentication check, so it requires only a valid receiver session index rather than a valid authenticator, and is reachable by a malicious or compromised peer (or an on-path attacker driving an established session) over the network, yielding remote memory corruption and at minimum a reliable denial of service. The defect was present in the WireGuard implementation shipped in Zephyr 4.4.0. The fix adds an explicit `data_len > CONFIG_WIREGUARD_BUF_LEN` rejection and corrects the linearize call to pass `net_buf_max_len(buf)` as the destination capacity.

CVE 2026-10667

SMP use-after-free in Zephyr `CONFIG_USERSPACE` dynamic kernel-object tracking, reachable from unprivileged user threads

Zephyr's dynamic kernel-object tracking (kernel/userspace/userspace.c, formerly kernel/userspace.c) maintains a doubly-linked list (obj_list) of dynamically allocated kernel objects. Iteration over this list in k_object_wordlist_foreach() was performed under lists_lock using the SAFE iterator (which caches the next node), but list removal and freeing of nodes was performed under different, disjoint spinlocks: objfree_lock in k_object_free() and obj_lock in unref_check(). On an SMP system, while one CPU iterated obj_list under lists_lock, another CPU could unlink and k_free() the dyn_obj node that the iterator had cached as its next pointer, causing the iterator to dereference freed kernel memory (use-after-free / dangling list traversal). All of the racing operations are reachable from unprivileged user-mode threads via system calls: k_object_alloc/k_object_alloc_size and k_object_release drive removals through unref_check() (under obj_lock), while k_thread_abort and thread creation drive the iteration through k_thread_perms_all_clear()/k_thread_perms_inherit() (under lists_lock). A deprivileged user thread on a CONFIG_SMP + CONFIG_USERSPACE build can therefore corrupt the kernel's object-tracking structures across the userspace security boundary, yielding kernel memory corruption (potential privilege escalation) or a kernel crash (denial of service). The fix removes objfree_lock and serializes every obj_list modification under lists_lock, including holding it across find+remove in k_object_free() and around unref_check() in k_thread_perms_clear(). Affects CONFIG_SMP``+``CONFIG_USERSPACE``+``CONFIG_DYNAMIC_OBJECTS configurations; the defect dates to the 2019 spinlockification (commit 8a3d57b6cc6, first released in v1.14.0) and shipped through v4.4.0.

CVE 2026-10668

Host-triggerable control-endpoint wedge (DoS) in Nuvoton NuMaker HSUSBD UDC driver

The Nuvoton NuMaker HSUSBD USB device-controller driver (drivers/usb/udc/udc_numaker.c) armed the control Data IN stage unconditionally (base->CEPTXCNT = len in numaker_hsusbd_ep_trigger). Because the HSUSBD hardware cannot disarm a control Data IN already armed for a previous transfer, a USB host that cancels an in-flight control transfer (timeout) and then issues a new SETUP packet can drive the driver out of sync: stale data may be transmitted in the new transfer and the control endpoint can become permanently stuck NAK'ing every subsequent control transfer.

A malicious or buggy host (physical/adjacent attacker driving the bus) can repeatedly cancel-and-re-SETUP to wedge the device's USB control endpoint, denying service to the device's USB function (the device stops enumerating/responding on the control pipe) until a USB reset or replug. The flaw is an availability-only denial of service; the FIFO copy loops (bounded by net_buf length and the hardware BUFFULL flag) and the net_buf lifecycle are independent of the arming desync, so there is no out-of-bounds access, use-after-free, or information leak.

The fix monitors the IN-token and new-SETUP events (k_event) and only arms control Data IN when an IN token is present and no new SETUP has arrived, cancelling the current transfer on a new SETUP. Affects boards using the Nuvoton NuMaker HSUSBD controller (CONFIG_UDC_NUMAKER with DT_HAS_NUVOTON_NUMAKER_HSUSBD_ENABLED); shipped in v4.4.0.

CVE 2026-10669

Xtensa MPU `arch_buffer_validate()` integer-overflow lets a user thread bypass syscall pointer validation

On Xtensa SoCs built with `CONFIG_XTENSA_MPU` and `CONFIG_USERSPACE`, `arch_buffer_validate()` in `arch/xtensa/core/mpu.c` — the architecture hook that verifies a user-mode-supplied buffer is accessible to the calling user thread with the requested permission — defaulted its return value to 0 (access permitted) and only set a denial result inside its per-MPU-region probe loop. When the rounded extent of the buffer wraps the 32-bit address space (size + alignment offset near `SIZE_MAX`, or `ROUND_UP(size + offset)` overflowing to 0), the loop executes zero iterations and the function returns 0 = permitted without probing any MPU region.

The syscall-layer pre-checks (`K_SYSCALL_MEMORY_SIZE_CHECK` / `Z_DETECT_POINTER_OVERFLOW`) only catch a raw `addr+size` wrap and do not cover the `ROUND_UP`-induced wrap, and the string path (`arch_user_string_nlen` -> `arch_buffer_validate`) has no syscall-layer guard at all.

An unprivileged user-mode thread can therefore pass a crafted `(addr, size)` to any syscall that validates user buffers via `k_usermode_from_copy/to_copy` or `k_usermode_string_copy` and have validation succeed for memory it must not access; the kernel then reads from (disclosure) or, with `write=1`, writes to (corruption) attacker-chosen kernel or other-partition memory on the thread's behalf, enabling information disclosure, memory corruption, privilege escalation, and denial of service.

Affected from v3.7.0 (when Xtensa MPU userspace support was added) through v4.4.0. The fix changes the default to `-EINVAL` (deny by default), adds an explicit `size_add_overflow` check, and sets the success value only after the full range has been validated.

CVE 2026-10670

User-triggerable kernel NULL-pointer dereference (DoS) in `k_thread_name_copy()` syscall verifier

The `CONFIG_USERSPACE` verification handler for the `k_thread_name_copy()` system call (`z_vrfy_k_thread_name_copy()` in `kernel/thread.c`) calls `k_object_find()` on the caller-supplied thread pointer and then dereferences the returned `struct k_object` without checking it for `NULL`. `k_object_find()` returns `NULL` whenever the supplied pointer is not a registered (static or dynamic) kernel object.

The pre-fix guard tested `thread == NULL` instead of `ko == NULL`, so an unprivileged user-mode thread that invokes `k_thread_name_copy()` with any non-NULL but unregistered pointer (e.g. an arbitrary address) passes the NULL test, after which the verifier reads `ko->type` through a NULL pointer.

Because the syscall verifier runs in supervisor mode, this NULL dereference is a kernel-mode fault that halts or reboots the system, allowing untrusted user code to crash the kernel across the userspace security boundary (denial of service). The marshaller passes the thread argument to the verifier without any prior `K_SYSCALL_OBJ` validation, so the bad pointer reaches the defect directly.

The flaw affects builds with `CONFIG_USERSPACE` and `CONFIG_THREAD_NAME` enabled and has been present since the special-case lookup was introduced around v2.0.0; it is present in v4.4.0 and

earlier. The fix changes the guard to check the k_object_find() return value (ko == NULL) before dereferencing it.

CVE 2026-10671

User thread can re-initialize an in-use k_pipe, corrupting kernel wait queues (CONFIG_USERSPACE)

In Zephyr's kernel pipe implementation, the userspace syscall verifier z_vrfy_k_pipe_init() in kernel/pipe.c used K_SYSCALL_OBJ() (which requires the kernel object to already be initialized) instead of K_SYSCALL_OBJ_NEVER_INIT() (which rejects an already-initialized object). As a result, on CONFIG_USERSPACE builds an unprivileged user thread that has been granted access to a k_pipe object can invoke the k_pipe_init syscall to re-initialize a pipe that is already in use.

z_impl_k_pipe_init() unconditionally resets the ring buffer, sets pipe->waiting to 0, and re-initializes both wait queues (z_waitq_init on pipe->data and pipe->space) without waking or accounting for threads currently blocked on the pipe. Any thread already pended in k_pipe_read()/k_pipe_write() is left orphaned: still marked pending with pended_on pointing at the cleared wait queue and with stale qnode_dlist links into the (now re-initialized) embedded list head.

When such an orphaned waiter is later timed out or woken, the scheduler calls sys_dlist_remove() on its stale node, writing through dangling prev/next pointers into kernel wait-queue/scheduler structures, causing list corruption (an attacker-driven invalid kernel write), lost wakeups, indefinitely blocked threads, and silent data loss. The flaw lets a deprivileged user thread corrupt the state of a kernel object shared with other threads/partitions.

The fix switches the verifier to K_SYSCALL_OBJ_NEVER_INIT(), matching the existing k_msgq_init verifier, so a user thread can no longer re-initialize a live pipe. The vulnerable code shipped in v4.1.0 and remained through v4.4.0.

CVE 2026-10672

Unterminated URI buffer causes out-of-bounds read in LwM2M firmware pull (Package URI)

subsys/net/lib/lwm2m/lwm2m_pull_context.c copied the firmware-update Package URI into a fixed static buffer (context.uri, size CONFIG_LWM2M_SWMGMT_PACKAGE_URI_LEN, default 128) with memcpy(context.uri, uri, LWM2M_PACKAGE_URI_LEN), copying exactly the destination size with no length validation. The Firmware-Update object stores the server-supplied Package URI (/5/0/1) in a 255-byte buffer, so a LwM2M management server (or an on-path attacker on a session lacking strong DTLS) can WRITE a URI of 128-254 characters; only the first 128 bytes are then copied into context.uri with no NUL terminator. That buffer is subsequently consumed as a C string by http_parser_parse_url(context.uri, strlen(context.uri), ...), strlen-based CoAP URI-path/PROXY-URI option appends, and lwm2m_parse_peerinfo(), causing

an out-of-bounds read of adjacent static memory. The over-read bytes are appended to outbound CoAP requests (information disclosure of adjacent device memory to the server/proxy) and can crash the device (denial of service). The vulnerable copy was introduced by the pull-context refactor (first released in v3.0.0) and is present through v4.4.0; the default-on `CONFIG_LWM2M_FIRMWARE_UPDATE_PULL_SUPPORT` path is affected. The fix adds a `strlen(uri) >= sizeof(context.uri)` check returning `-ENOMEM` and switches to `strcpy()`, guaranteeing a bounded, NUL-terminated buffer.

CVE 2026-10674

DoS (hard fault) in NXP LPUART driver: unsupported runtime UART config leaves clocks disabled

The NXP LPUART serial driver (`drivers/serial/uart_mcux_lpuart.c`), when `CONFIG_UART_USE_RUNTIME_CONFIGURE` is enabled, called `LPUART_Deinit()` at the start of `mcux_lpuart_configure()`, which disables the LPUART peripheral clocks. The requested configuration is validated only afterwards (in `mcux_lpuart_configure_basic`), and unsupported parity/data-bit/stop-bit/flow-control values return `-ENOTSUP` before the clock is re-enabled.

As a result, a `uart_configure()` request with an unsupported configuration left the LPUART in a clock-disabled state; any subsequent access to LPUART registers (`poll_out`/`poll_in`, interrupt handling, or a later reconfigure) faults on the gated peripheral and escalates to a hard fault, crashing the system.

`uart_configure()` is a Zephyr syscall whose verifier (`z_vrfy_uart_configure`) only checks that `cfg` is readable user memory and forwards the caller-supplied configuration unchanged, so an unprivileged userspace thread with access to an LPUART device can deterministically trigger the fault, a persistent system-wide denial of service.

Introduced in v2.5.0 and present in all subsequent releases until this fix, which removes the `LPUART_Deinit()` call and instead only disables the transmitter/receiver, leaving the clock running.

CVE 2026-10675

Bluetooth Mesh PB-ADV: invalidated provisioning link kept alive indefinitely, blocking (re)provisioning (DoS)

In Zephyr's Bluetooth Mesh PB-ADV provisioning bearer (`subsys/bluetooth/mesh/pb_adv.c`), `prov_msg_recv()` rescheduled the provisioning protocol watchdog timer unconditionally at the top of the function, before the FCS check and before the `ADV_LINK_INVALID` check. Once a provisioning attempt fails, `prov_failed()` sets `ADV_LINK_INVALID` and the only recovery path is the

protocol timer firing (`protocol_timeout -> prov_link_close -> close_link -> reset_adv_link` and re-enabling of scanning and the unprovisioned device beacon).

A remote, unauthenticated attacker on the BLE advertising channel can first induce a provisioning failure (e.g. with a malformed generic-provisioning PDU) and then transmit any FCS-valid PB-ADV transaction PDU on the same link ID more often than once per protocol timeout (60 s, or 120 s for OOB input/output). Because each such packet reset the timer even on an invalidated link, `protocol_timeout` never fired, the dead link was never torn down, and the device remained pinned in an un-provisionable state with its unprovisioned beacon disabled and new Link Open requests rejected.

PB-ADV PDUs are processed without authentication and the FCS is a keyless CRC, so no pairing or prior trust is required and the attacker chooses the link ID itself. The impact is a persistent denial of provisioning/re-provisioning service; there is no memory-safety, confidentiality, or integrity impact.

The vulnerable code shipped in releases through v4.4.1. The fix moves the timer reschedule to after the `ADV_LINK_INVALID` check (and the FCS check before the reset) so an invalidated link can no longer be kept alive by incoming packets.

CVE 2026-10677

Kernel heap memory leak in `z_vrfy_k_poll()` lets an unprivileged user thread exhaust the kernel resource pool

The `CONFIG_USERSPACE` syscall verifier `z_vrfy_k_poll()` in `kernel/poll.c` allocates a kernel-side copy of the user-supplied `k_poll_event[]` via `z_thread_malloc()` and then validates each event's object handle. Before this fix, validation used `K_OOPS(K_SYSCALL_OBJ(...))` inline inside the loop, which kills the calling thread without freeing `events_copy`.

A user thread can pass `num_events >= 1` with a forged object handle to leak the allocation; because newly spawned user threads inherit the parent's `resource_pool` (`kernel/thread.c`), an attacker spawns sacrificial threads to repeat the leak until the shared kernel heap is exhausted. Once depleted, legitimate kernel allocations from that pool (`k_queue` alloc nodes, `k_msgq` buffers, future `k_poll` calls, etc.) fail, causing a system-level denial of service.

The fix replaces each inline `K_OOPS` with a conditional `goto oops_free` so the buffer is freed before the thread is killed. Affects Zephyr releases from v1.12.0 (when `k_poll` was first exposed to user mode) through v4.4.1.

CVE 2026-10678

NULL-pointer / out-of-bounds write in Zephyr MCTP I2C+GPIO target binding driven by an unauthenticated I2C controller

The MCTP-over-I2C+GPIO target binding in Zephyr (`subsys/pmci/mctp/mctp_i2c_gpio_target.c`) processes pseudo-register writes from an I2C bus master byte-by-byte in `mctp_i2c_gpio_target_write_received()` without validating the order or the receive buffer. In the affected versions the `MCTP_I2C_GPIO_RX_MSG_ADDR` (data) handler dereferences and writes through `b->rx_pkt` without checking that the receive buffer was allocated: a controller that selects the data register and writes a byte without first sending the length register (which is what allocates the buffer) causes a write of an attacker-chosen byte through a NULL/unallocated `mctp_pktbuf` pointer (i.e. into a small attacker-advanceable offset above address 0), producing memory corruption or a hard fault.

The same handler also performs a write-then-check bounds test, allowing a one-byte heap overflow at `data[255]` when more than 255 data bytes are sent.

Because the I2C target callback is invoked with raw bytes supplied by whatever device is the bus master and the binding performs no authentication, a malicious or malfunctioning controller on the bus can trigger these without any prior protocol state, leading to memory corruption and/or denial of service on the target device.

The vulnerable code was introduced when the I2C+GPIO target binding was added and shipped in Zephyr v4.3.0 and v4.4.0. The fix defers allocation to the first data byte with a NULL check, treats a missing length as a zero-sized packet rejected by libmctp, and moves the bounds check before the store.

CVE 2026-10679

Divide-by-zero in DesignWare SPI driver reachable from spi_transceive syscall (local DoS)

The DesignWare SPI driver (`drivers/spi/spi_dw.c`) computed the SPI BAUDR clock divider as `info->clock_frequency / config->frequency` without validating `config->frequency`.

`spi_transceive` is a Zephyr `__syscall` and its verify handler (`drivers/spi/spi_handlers.c`) copies the caller-supplied `spi_config` from userspace without checking the frequency field, so a userspace thread that has been granted access to a DesignWare SPI device kernel object can pass `frequency = 0` and trigger an unsigned integer divide-by-zero in `spi_dw_configure()`.

On Cortex-M Mainline (`SCB->CCR.DIV_0_TRP` is set in `z_arm_fault_init()`) and on ARC (a dedicated `__ev_div_zero` vector) this raises a CPU exception, resulting in a kernel fault and local denial of service.

The fix rejects zero frequency and frequencies above `clock_frequency / 2` (the DesignWare SSI databook minimum SCKDIV of 2) with `-EINVAL`. The defect affects all Zephyr releases up to and including v4.4.0; exploitation requires `CONFIG_USERSPACE=y` and an unprivileged thread already granted SPI driver permission. There is no memory-corruption or information-disclosure impact.

CVE 2026-10680

Out-of-bounds access in Zephyr BR/EDR L2CAP configuration request handling via `uint16_t` length underflow

The Classic (BR/EDR) L2CAP signaling handlers `l2cap_br_conf_req()` and `l2cap_br_conf_rsp()` in `subsys/bluetooth/host/classic/l2cap_br.c` validated the minimum command size against `buf->len` (the bytes remaining in the whole received PDU) instead of `len` (the per-command data length from the L2CAP signaling header). Because multiple signaling commands can be packed into one PDU, `buf->len` may exceed a command's `len`. An attacker can send a `CONF_REQ` command with a header length smaller than the configuration-request structure (e.g. 0), followed by another command so that `buf->len` still satisfies the check. The check then passes incorrectly and `opt_len = len - sizeof(*req)` underflows the `uint16_t` to a near-0xFFFF value. The configuration-option loop, which lacks an `opt_len`-versus-`buf->len` guard, then walks far past the end of the pooled ACL receive buffer using `net_buf` pull primitives that perform no runtime bounds check, producing an out-of-bounds read of host memory and, when the out-of-bounds option bytes encode an MTU or flush-timeout option, an out-of-bounds write. The BR/EDR signaling channel is processed before pairing/encryption and an L2CAP channel to an L0 service such as SDP can be opened without pairing, so an unauthenticated peer within radio range that can establish an ACL connection can trigger the flaw, leading to memory corruption and denial of service (host/device crash). The defect is present in released versions including v4.4.0. The fix validates against `len` instead of `buf->len` in both handlers.

CVE 2026-10681

SMP race in `thread_idx_alloc()` lets concurrent `k_object_alloc(K_OBJ_THREAD)` callers share a kernel-object permission slot

In Zephyr's userspace dynamic-objects subsystem, `thread_idx_alloc()` in `kernel/userspace/userspace.c` allocated a new thread permission index from the global `_thread_idx_map[]` bitmap without holding `lists_lock`.

On SMP systems, two user-mode threads invoking the `k_object_alloc(K_OBJ_THREAD)` syscall concurrently can both observe the same low free bit, perform the same non-atomic RMW to clear it, and return the identical `tidx`.

The two newly created `K_OBJ_THREAD` objects are then assigned the same `thread_id`, so the two user threads alias a single bit position in every kernel object's `perms[]` bitfield: any subsequent grant of access on a kernel object to one thread is implicitly a grant to the other, defeating userspace ACL isolation. A secondary lost-update window between the unlocked `&=~BIT()` in alloc and the locked `|= BIT()` in `thread_idx_free()` can also leak entries from the thread-index pool.

The defect is reachable from any user-mode thread via the unrestricted `__syscall k_object_alloc` and is gated on `CONFIG_USERSPACE`, `CONFIG_DYNAMIC_OBJECTS`, and `CONFIG_SMP`. The flaw was introduced when the per-thread permission index was added in 2018 and is present in every release up to and including v4.4.0. Fixed by holding `lists_lock` across the bitmap RMW and the permissions clear (and inlining the `obj_list` traversal that previously took the lock itself).

CVE 2026-10682

Out-of-bounds write in Zephyr `log_filter_set` syscall verifier reachable from userspace

The userspace verifier `z_vrfy_log_filter_set()` for the `log_filter_set` syscall in `subsys/logging/log_mgmt.c` performed a signed comparison against the `int16_t src_id` parameter: `src_id < (int16_t)log_src_cnt_get(domain_id)`. Any negative value for `src_id` (e.g. -1) trivially satisfied this check and was forwarded into `z_impl_log_filter_set`, where it propagated to `filter_set()` and ultimately to `get_dynamic_filter()`, which uses `source_id` as an unsigned index into the linker-section array `&TYPE_SECTION_START(log_dynamic)[source_id].filters`.

After implicit conversion through `uint32_t`, an `int16_t` -1 becomes 0xFFFFFFFF, indexing `log_dynamic` far out of bounds and causing the kernel to perform an OOB read and an OOB read-modify-write (`LOG_FILTER_SLOT_GET/SET`) against memory adjacent to the `log_dynamic` section.

The written value is a constrained 3-bit log level slot within the targeted 32-bit word, but the target address is attacker-chosen (a small negative offset from `log_dynamic`) and the write occurs in supervisor mode following a syscall from an unprivileged user thread, providing a kernel memory-corruption / privilege-escalation primitive.

The defect is reachable on any build with `CONFIG_USERSPACE=y` and `CONFIG_LOG_RUNTIME_FILTERING=y`. Present from Zephyr v3.3.0 through v4.4.1. The fix replaces the signed bound check with an unsigned comparison: `(uint32_t)src_id < log_src_cnt_get(domain_id)`, which correctly rejects negative inputs.

CVE 2026-10683

DesignWare I2C target driver can be wedged into a permanent stuck state by an on-bus master (DoS)

In the Synopsys DesignWare I2C driver (`drivers/i2c/i2c_dw.c`) operating in target/slave mode, the `rx_full` interrupt handler gates the `write_requested()` callback on `dw->state != CMD_SEND`, and `dw->state` is only reset to READY on a STOP interrupt. The `START_DET` interrupt, whose handler in `i2c_dw_slave_read_clear_intr_bits()` would reset the state on every (re)START, was never added to the enabled interrupt mask in `i2c_dw_slave_register()`, so that recovery path was dead code.

As a result, if the STOP interrupt is lost (bus glitch/reset, or a concurrent master driving STOP) or the bus master issues a legal WRITE-repeated-START-WRITE sequence with the same direction, the driver remains in `CMD_SEND` permanently and never invokes `write_requested()` again for the life of the target.

An I2C master on the same physical bus can deliberately trigger this, causing the I2C target function to malfunction for all subsequent write transactions and desynchronizing consumer framing state (e.g. MCTP-over-I2C), a recoverable-by-reset denial of service of the target peripheral.

The fix unmasks `START_DET` so the state is reset at every bus (re)START. Impact is availability-only over a local board-level bus; no memory corruption results in the in-tree consumer, whose per-byte buffer write is independently bounds-checked.

CVE 2026-10684

Out-of-bounds read in coredump shell when printing stored-dump target code

In `subsys/debug/coredump/coredump_shell.c`, `print_coredump_hdr()` used the 16-bit `tgt_code` field of a stored Zephyr coredump header directly as an index into `coredump_target_code2str[]`, a fixed 7-element array of string pointers, with no bounds check.

A stored coredump whose `tgt_code` is >= 7 causes an out-of-bounds read of a `char*` up to ~64K entries past the array; that value is passed as the `%s` argument to `shell_print`, which dereferences and walks it as a string. The result is either disclosure of device memory contents to the shell user or a crash when the out-of-bounds pointer is unmapped.

The defect is reached via the `coredump print` shell command (`cmd_coredump_print_stored_dump` -> `pretty_print_coredump` -> `parse_and_print_coredump` -> `print_coredump_hdr`). The `tgt_code` field is device-generated and in-range during normal crash handling, so triggering requires local shell access plus the ability to stage or corrupt the stored coredump in the flash/in-memory backend.

Introduced in v4.2.0 (commit 13abd7fe730) and present through v4.4.0; fixed by clamping out-of-range codes to the 'unknown' (index 0) entry.

CVE 2026-10685

Use-after-free of GATT subscribe params in Bluetooth host CCC-write response handler

The Zephyr Bluetooth GATT client CCC-write response handler `gatt_write_ccc_rsp()` in `subsys/bluetooth/host/gatt.c` invoked the application's `params->subscribe()` callback after it had already called `params->notify(conn, params, NULL, 0)`.

Per the public GATT API, a notify callback with `NULL` data is the documented signal that the subscription has terminated and the `bt_gatt_subscribe_params` struct may be freed or reused by the application; calling `subscribe()` on the struct afterwards is a use-after-free, including an indirect call through the freed `params->subscribe` function pointer.

The error branch is remotely (adjacent) reachable: a Zephyr device acting as a GATT client that calls `bt_gatt_subscribe()` can be driven into this ordering when a connected GATT server peer answers the CCC write with an ATT Error Response (the peer-supplied error code flows through `att_error_rsp` -> `att_handle_rsp` into `gatt_write_ccc_rsp`).

For applications that free or recycle subscription parameters in their notification-termination handler, this results in memory corruption, a crash (denial of service), or potentially attacker-influenced control flow. The fix reorders the handler so the `subscribe()` callback runs before the terminating `notify(NULL)` in both the error and unsubscribe paths.

CVE 2026-10686

Missing hop-limit decrement on IPv6 forwarding path allows unbounded packet looping (DoS) in Zephyr routers

Zephyr's IPv6 forwarding path re-sent routed unicast packets without ever decrementing the IPv6 hop limit. Both routing branches of `ipv6_route_packet()` (`subsys/net/ip`) were affected: the explicit-route path (`net_route_packet()`) and the on-link cross-interface path (`net_route_packet_if()`). Each set the packet forwarding flag and called `net_send_data()` with the hop limit untouched and no expiry check.

Per RFC 8200 the hop-limit decrement is the mechanism that bounds packet lifetime and terminates routing loops; without it, a device acting as an IPv6 router relays looping packets indefinitely. An on-path attacker who can induce or exploit a transient L3 loop turns it into a permanent forwarding storm, causing CPU/bandwidth resource exhaustion (availability DoS) on the forwarder and adjacent links; path-discovery and loop diagnostics that rely on hop-limit expiry are also defeated.

Affected configurations. In every affected release the forwarding path is reached via `CONFIG_NET_ROUTE` (enabled by default when `CONFIG_NET_IPV6_NBR_CACHE` is set), together with `CONFIG_NET_ROUTING` for cross-interface routing. Note that `CONFIG_NET_IPV6_FORWARDING` and `CONFIG_NET_IPV4_FORWARDING` — which appear in the fix and in this advisory's evidence notes — were introduced *after* v4.4.0, when the routing options were split and renamed; they do not exist in any affected release. When auditing a v4.4.1-or-earlier configuration, look for `CONFIG_NET_ROUTE` and `CONFIG_NET_ROUTING`.

IPv4 is not affected in any release. The IPv4 forwarding path (`net_route_ipv4_packet()` in `route_ipv4.c`) was added after v4.4.0 and has never shipped in a release. Its TTL decrement and IPv4 header-checksum recomputation landed on `main` as part of the same fix, so the evidence notes below discuss it, but no released version is reachable by way of IPv4.

Affected releases are v1.8.0 through v4.4.1: v1.8.0 introduced `net_route_packet()` and v2.2.0 added `net_route_packet_if()`, and neither decremented the hop limit. v4.3.1 carries the explicit-route fix but not the on-link one, so it is affected as well. Fixed on `main` by 7d8f1afa7345 (explicit-route path) and 589eadc74efa (on-link path).

CVE 2026-10773

Out-of-bounds read in DHCPv4 client message-type name lookup (net_dhcpv4_msg_type_name)

The DHCPv4 client helper `net_dhcpv4_msg_type_name()` in `subsys/net/lib/dhcpv4/dhcpv4.c` indexes a static 8-element `const char *` name table after a faulty bounds check. The guard used `msg_type <= sizeof(name)` instead of `msg_type <= ARRAY_SIZE(name)`; `sizeof` returns the byte size of the pointer array (32 on 32-bit, 64 on 64-bit targets) rather than the element count of 8, so message-type values from 9 up to that byte size pass the check and cause `name[msg_type - 1]` to read past the end of the array.

The `msg_type` value originates from the DHCP MESSAGE TYPE option, which is read as an unchecked raw byte from a received packet (`net_pkt_read_u8`) and passed unmodified into the lookup. A DHCP server, or any host able to inject a spoofed DHCP reply onto the client's link, can therefore drive the index out of bounds. The out-of-range slot yields a garbage `const char *` that is then dereferenced by a `%s` log conversion.

The lookup is reached only from a debug log statement (`NET_DBG` / `LOG_DBG`), so the out-of-bounds read is triggerable only when the DHCPv4 log module is built at DEBUG level (`CONFIG_NET_DHCPV4_LOG_LEVEL_DBG`), which is not the default configuration. When that condition holds, the result is an out-of-bounds read and a wild-pointer dereference: most likely a crash of the DHCP client (denial of service) and potentially disclosure of an adjacent pointer's contents through the log output. The fix replaces `sizeof` with `ARRAY_SIZE`, restoring the correct 1..8 acceptance window.

CVE 2026-10774

PSA key-slot leak in Bluetooth Mesh subnet deletion leading to resource-exhaustion DoS

Zephyr's Bluetooth Mesh subnet key management leaks one PSA Crypto key slot on every subnet-key teardown. In `subsys/bluetooth/mesh/subnet.c`, `net_keys_create()` imports the Private Beacon Key into a PSA key slot under `CONFIG_BT_MESH_PRIV_BEACONS` (enabled by default), but `subnet_keys_destroy()` guarded the matching `psa_destroy_key()` with `CONFIG_BT_MESH_V1d1`. That Kconfig symbol was removed when explicit Mesh 1.0.1 support was dropped, so the destroy branch became permanently dead code and the import is never balanced by a destroy.

The imbalanced teardown is reached every time subnet keys are destroyed: deleting a subnet (Config Server NetKey Delete), completing a Key Refresh Procedure (which retires the old key set), and resetting/re-provisioning the node. The over-the-air triggers are processed only under the node's device key, so they are exercisable by the provisioner or network administrator that owns the node, reachable over the Bluetooth Mesh network.

With the default `CONFIG_MBEDTLS_PSA_KEY_SLOT_COUNT` of 16, repeated add/delete or key-refresh cycles exhaust the shared PSA key-slot pool after roughly a dozen rounds. Once exhausted, `bt_mesh_private_beacon_key()` and thus subnet creation fail: the node can no longer add subnets or complete key refresh, and other PSA crypto consumers on the device may be

starved, until the device is rebooted. The fix aligns the destroy guard with the import guard (CONFIG_BT_MESH_PRIV_BEACONS) so each slot is freed.

CVE 2026-10848

Out-of-bounds read in Zephyr OCPP 1.6 RPC message parser (parse_rpc_msg)

The OCPP 1.6 client in subsys/net/lib/ocpp parsed inbound WAMP RPC frames in parse_rpc_msg() (subsys/net/lib/ocpp/ocpp_j.c) using a hand-rolled helper, extract_string_field(), that copied the message's uid and action fields with strncpy(out_buf, token + 1, outlen - 1) and then scanned the result with strchr(out_buf, '"'). Because strncpy does not NUL-terminate the destination when the source is at least outlen - 1 (127) bytes long, the subsequent strchr reads past the 128-byte destination buffer into adjacent stack memory; if a " byte is found beyond the buffer, a one-byte out-of-bounds NUL write also occurs. A related defect in extract_payload() runs strchr/strrchr over the receive buffer, which may not be NUL-terminated when a maximal-length frame fills it.

The parsed bytes come directly from the OCPP central-system server over a websocket: the reader thread fills recv_buf via websocket_recv_msg() and calls parse_rpc_msg() on each inbound DATA frame (subsys/net/lib/ocpp/ocpp.c). A malicious or compromised central server, or an on-path attacker (OCPP is commonly deployed over plain ws://), can send an RPC frame whose uid or action field is 127+ bytes with no closing quote, triggering the out-of-bounds access.

The primary impact is a remotely triggerable denial of service: the unbounded scan can fault on an unmapped page, and the stray NUL write can corrupt adjacent stack state. The over-read data is not reflected to the peer, so disclosure is limited. The feature is EXPERIMENTAL and must be explicitly enabled (CONFIG_OCPP). The fix replaces the manual parser with the bounds-respecting json_mixed_arr_parse() and copies the extracted uid with an explicitly NUL-terminated buffer, eliminating both over-reads.

CVE 2026-10849

Heap out-of-bounds write in Zephyr hawkBit OTA client when terminating server response body

The hawkBit device management client in subsys/mgmt/hawkbit accumulates the body of an HTTP response from the update server into a heap buffer in response_json_cb() (subsys/mgmt/hawkbit/hawkbit.c). The buffer is sized to hold the received body bytes but reserves no space for a terminating NUL. When the full response has arrived, the code writes response_data[downloaded_size] = '\0' — and whenever the accumulated body length equals the allocation, that terminator lands one byte past the end of the heap object (a heap-based out-of-bounds write, CWE-122 / CWE-787).

The body length and fragmentation are taken directly from the parsed HTTP response (rsp->body_frag_start / rsp->body_frag_len) and are fully controlled by the remote hawkBit server, which chooses its own response length. The precise trigger depends on how the

buffer grows, and both forms are remotely reachable. Since v4.0.0 the reallocation is sized to exactly `downloaded_size + body_len`, so **any** response body larger than the 1100-byte initial buffer makes the out-of-bounds write deterministic; such response sizes are normal for hawkBit deployment metadata. Before v4.0.0 the buffer grew by doubling and the growth check (`(downloaded_size + body_len) > response_buffer_size`) is false at equality, so a response body whose length is exactly the current allocation — 1100 bytes with the default initial buffer — skips the reallocation entirely and writes the terminator at `response_data[1100]` of an 1100-byte object. The HTTP length-mismatch check does not catch this, because the declared and received lengths genuinely agree. Either form is reachable by a malicious, compromised, or man-in-the-middle update server (TLS is optional and, when enabled, does not protect against a hostile server), with no authentication of response content and no client-side length cap protecting the write.

The out-of-bounds write is a fixed single NUL byte immediately following the allocation, corrupting adjacent allocator metadata or the next allocation. The practical impact is heap corruption leading to denial of service (fault on a subsequent allocation or free), with the bounded, allocator-dependent possibility of further corruption. The fix sizes the buffer to the body length plus one and copies with `memcpy`, ensuring the terminator always lands within the allocation.

CVE 2026-11368

Use-after-free in Bluetooth host ATT TX completion on disconnect mid-transfer

The Bluetooth host ATT layer (`subsys/bluetooth/host/att.c`) associates each in-flight ATT TX buffer with its owning channel via the static `tx_meta_data_storage[]` array (`data->att_chan = chan`). When a buffer's last reference is dropped, its net-buf destroy callback defers the completion handling to the system workqueue (`att_tx_destroy -> att_tx_destroy_work_handler -> att_on_sent_cb -> bt_att_sent`), where `bt_att_sent` dereferences the channel and its ATT context (`sys_slist_get(&att->reqs)`).

When a peer disconnects while an ATT PDU (a server notification/indication or any response) is still in flight in the controller TX path, L2CAP tears the channel down in `l2cap_chan_del()`: it runs the disconnected callback and then the released callback (`bt_att_released`), which frees the channel slab slot. Because the in-flight buffer is held by the connection TX path rather than the channel's own queue, its deferred destroy work can run after the channel has been freed. The `att_on_sent_cb` guard intended to drop the stale callback itself dereferences `meta->att_chan`, which is now a dangling pointer into a freed (and possibly reused) slab slot.

A remote peer with an ATT connection can drive this by disconnecting during routine ATT traffic; no pairing or user interaction is required to reach the ATT bearer. The result is a use-after-free read/write of freed channel memory, reliably crashing the Bluetooth host (denial of service) and, because the channel slab slot may be reused, potentially corrupting live memory.

The fix makes `bt_att_released()` `NULL` the `att_chan` field of every `tx_meta_data_storage[]` entry still referencing the channel before freeing it, so the deferred guard observes a `NULL` pointer and drops the callback. Teardown and the destroy work both run on the cooperative system workqueue, so the array update is serialized and needs no lock.

CVE 2026-11742

Use-after-free race in kernel `k_queue_peek_head/tail` due to missing spinlock

The kernel queue helper `z_queue_node_peek()` in `kernel/queue.c` dereferences a node taken from a queue's `data_q` list, reading the node's flag byte and, for items enqueued via `k_queue_alloc_append/alloc_prepend`, the data pointer of an internally allocated `alloc_node` struct. The implementations of `z_impl_k_queue_peek_head()` and `z_impl_k_queue_peek_tail()` performed this read-and-dereference without holding the queue's spinlock, while every other accessor of the same list — including `k_queue_get()`, which unlinks a node and `k_free()`s its backing `alloc_node` — operates under that lock.

Because peek was unsynchronized, a concurrent `k_queue_get()` on the same queue (on an SMP build, or under preemption/ISR concurrency) can free the node between the moment peek obtains the node pointer and the moment it dereferences it. The peek then reads flag bits and a data pointer out of freed, potentially re-allocated heap memory and returns a stale or dangling pointer to its caller. `k_fifo` and `k_lifo` are thin wrappers over `k_queue`, so this affects buffer queues used throughout the `net_buf`, Bluetooth, USB, and networking subsystems; the peek operations are also system calls reachable from `CONFIG_USERSPACE` threads.

The consequences are a use-after-free read that can leak stale heap contents (one pointer word) and, when the returned dangling pointer is subsequently consumed as a live buffer, a dereference that can crash the system or corrupt memory. Exploitation requires winning a small race window with local access (e.g. a userspace process racing `k_queue_peek_*` against `k_queue_get` on a shared queue, or two CPUs), so practical impact is bounded and of low severity.

The fix wraps both peek implementations with `k_spin_lock/k_spin_unlock` on the queue lock, making the read-and-dereference atomic with respect to the concurrent unlink-and-free and bringing peek into line with the rest of the queue's locking discipline.

CVE 2026-11743

Missing negative-offset/overflow check in SF32LB MPI QSPI NOR flash driver allows out-of-bounds read and write

The SF32LB MPI QSPI NOR flash driver (drivers/flash/flash_sf32lb_mpi_qspi_nor.c) validated the flash offset and length on its read and write paths with the test `(offset + size) > data->size`. Because `offset` is a signed `off_t` while `size` is unsigned, a negative offset is converted to a large unsigned value and the addition can wrap to a small result that passes the check. The read path then performs `memcpy(dst, (void *)(data->base + offset), size)` and the write path programs flash at `offset` and cache-invalidates `data->base + offset`, in both cases accessing memory outside the mapped flash window. The driver's erase path already rejected negative offsets, but read and write did not.

In builds with `CONFIG_USERSPACE`, `flash_read` and `flash_write` are syscalls whose verifiers validate the device object and the caller's buffer but deliberately delegate offset bounds checking to the driver. An unprivileged thread that has been granted access to this flash device can therefore call the syscall with a crafted negative offset and a buffer valid in its own memory domain, and reach the unchecked access.

The most direct impact is on the read path: by choosing a negative offset and matching size, an attacker slides the memcpy source below the flash base and copies arbitrary CPU-addressable memory into its own buffer, disclosing memory it is not authorized to read. The write path additionally allows programming flash at an out-of-range address and invalidating an attacker-chosen cache range, affecting integrity and availability. Reachability requires userspace to be enabled and the raw flash device object to be granted to an untrusted thread.

The fix replaces the check with `qspi_nor_range_is_valid()`, which rejects negative offsets and performs the bound comparison in overflow-safe 64-bit arithmetic on both paths, and additionally adds an SRAM DMA bounce buffer plus source/destination overlap rejection to prevent a separate DMA bus-hang condition.

CVE 2026-11809

UpdateHub probe: uninitialized-heap out-of-bounds read of network-supplied metadata

The UpdateHub OTA client in `subsys/mgmt/updatehub/updatehub.c` contains an out-of-bounds / uninitialized-memory read in `z_impl_updatehub_probe()`. The probe response from the UpdateHub server is copied into a heap buffer (`metadata`) that is correctly NUL-terminated, but a second buffer (`metadata_copy`) is allocated with `k_malloc` (unzeroed) and filled with `memcpy(metadata_copy, metadata, strlen(metadata))`, which omits the terminating NUL. Everything after the copied content remains uninitialized heap.

When the first `json_obj_parse()` over the array descriptor fails, the code falls back to `json_obj_parse(metadata_copy, strlen(metadata_copy), ...)`. The `strlen()` call scans past the copied bytes through uninitialized heap and, if no zero byte is found before the end of the allocation, reads beyond the buffer; the resulting over-long length is then parsed as JSON. The probe payload is fully controlled by the (malicious, compromised, or — without the optional `CONFIG_UPDATEHUB_DTLS` — on-path) UpdateHub server, which can craft a large payload that fails the first parse to drive this path.

The consequence is a read of uninitialized heap, with a worst case of an out-of-bounds read past the `metadata_copy` allocation that can fault and crash the update thread/device, producing a network-triggerable denial of service. The over-read data is consumed only internally to evaluate the update and is not returned to the attacker, so there is no direct information disclosure and no out-of-bounds write.

The fix zeroes `metadata_copy` with `memset` before the copy, guaranteeing NUL termination and bounding `strlen()` within the allocation.

CVE 2026-11810

NULL-pointer dereference in UpdateHub OTA agent on empty inner metadata array (remote DoS)

The UpdateHub firmware-update agent's probe handler (`z_impl_updatehub_probe()` in `subsys/mgmt/updatehub/updatehub.c`) parses the JSON metadata returned by the update server into a fixed two-level nested-array struct. After parsing it validates only the outer array length (`objects_len != 2`) and then dereferences `objects[1].objects[0].objects.sha256sum` via `strlen()` without checking that the inner object array of element `[1]` is non-empty.

The metadata is attacker-influenceable network input: the agent fetches it over CoAP from the configured UpdateHub server during its routine OTA probe. A malicious or compromised update server (or, when DTLS is disabled, a network man-in-the-middle) can return a response whose second outer object array is empty. Because the parse target is zero-initialised, the corresponding `objects[1].objects[0].objects.sha256sum` pointer is NULL, and the subsequent `strlen()` dereferences address zero. The same defect exists in both the 'any boards' and 'some boards' metadata layouts.

The resulting CPU fault is fatal under Zephyr's default error handling, halting or resetting the device, so the flaw is a remotely triggerable denial of service. Impact is limited to availability; it is a read from NULL with no out-of-bounds write, memory corruption, or information disclosure. The fix rejects metadata whose inner object array is empty before any dereference, on both layouts.

CVE 2026-11811

Socket file-descriptor leak in UpdateHub OTA client start_coap_client() leading to resource-exhaustion DoS

The UpdateHub over-the-air update client's `start_coap_client()` in `subsys/mgmt/updatehub/updatehub.c` leaks the CoAP/DTLS socket descriptor on its connection-setup failure paths. The shared `error:` cleanup gated socket closing on a `ret > 0` flag, but `ret` was set to `-1` immediately after the socket was created, so when `zsock_setsockopt()` (DTLS) or `zsock_connect()` subsequently failed the gate was false and `cleanup_connection()` was never called. The open descriptor in the global `ctx.sock` was then overwritten by the next attempt, permanently leaking it from the socket / net_context pool until reboot.

The failing setup path is reached every time the OTA client tries to contact the UpdateHub server and the connection cannot be established — driven automatically by the periodic `autohandler()` poll (and on demand via the `updatehub_probe()`/`updatehub_update()` API or the `updatehub run` shell command). The DTLS handshake/connect outcome is influenceable by a network or on-path attacker who drops, resets, or otherwise disrupts traffic to the server, and also fails naturally whenever the server is unreachable.

Each failed attempt permanently leaks one descriptor; once the shared socket pool is exhausted, networking degrades device-wide until the device is rebooted, a denial-of-service condition. Severity is low because the leak rate is bounded by the configured OTA poll interval (default once per 24 hours), the effect is gradual and recovered by reboot, and only builds with the UpdateHub client enabled are affected. There is no memory-corruption, information-disclosure, or authentication impact.

CVE 2026-11812

UpdateHub: race condition on shared context causes out-of-bounds write and DoS

The UpdateHub management subsystem (subsys/mgmt/updatehub/updatehub.c) drives every update operation through a single file-scope `ctx` structure that holds the CoAP block context, payload buffer, status code, socket, and a one-element poll-fd array `fds[1]`. Access to `ctx` was not serialized, and `prepare_fds()` wrote `ctx.fds[ctx.nfds]` and incremented `ctx.nfds` with no bounds check.

Two independent paths mutate `ctx` concurrently: the background autohandler running on the system workqueue, and user-triggered operations reached through the `updatehub run` shell command, direct API calls, or — since the operations are exposed as syscalls — userspace threads. When a second flow enters `prepare_fds()` while `ctx.nfds` is already 1, the write lands one element past the array; by struct layout it overlaps the adjacent `ctx.sock`/`ctx.nfds` members. More broadly, the unsynchronized sharing lets two flows interleave connection setup and teardown, double-closing a socket descriptor or scribbling the shared buffers.

The result is corruption of the update subsystem's internal state and denial of service of the firmware-update path; the out-of-bounds write is contained within the `ctx` structure and there is no demonstrated path to memory outside it or to code execution. Triggering requires a local actor able to invoke update operations (or, with CONFIG_USERSPACE, an unprivileged userspace thread) and to win a timing race against the background handler; remote peers cannot control the race timing. The fix serializes the entry points with a mutex and adds a bounds check to `prepare_fds()`.

CVE 2026-11893

Double free / use-after-free in Bouffalo Lab HCI driver send() error paths (hci_bflb)

The Bluetooth HCI driver for Bouffalo Lab on-chip BLE controllers (BL60x/BL70x/BL61x), `bt_bflb_send()` in `drivers/bluetooth/hci/hci_bflb.c`, violates the `bt_hci_driver_api.send()` buffer-ownership contract. That contract (documented at `include/zephyr/drivers/bluetooth.h`) requires the buffer reference to be consumed only on success; on error the caller still owns the reference and unrefs it. The driver instead routed all error paths through a shared label that unconditionally called `net_buf_unref(buf)` before returning the error code, consuming the buffer on failure as well.

When `send()` returns an error, the host TX path (`send_buf()` in `subsys/bluetooth/host/conn.c`) unrefs the same buffer again, believing it still owns it. This double-unref over-decrements the net_buf reference count. Because the buffer is a TX fragment whose destroy callback also decrements its still-queued parent buffer, the parent is freed prematurely while reachable on the connection TX queue, producing a use-after-free and corruption of the shared net_buf pool rather than a benign leak.

The error conditions are on the host-to-controller transmit path (controller send failure, or an unsupported H:4 packet type), so they are not driven directly by attacker-supplied radio bytes; a

remote/adjacent peer can influence them only indirectly, e.g. by inducing controller TX failures under heavy link load. The consequence when reached is BLE-stack denial of service (crash / pool corruption) with possible further memory corruption, bounded to devices using one of these Bouffalo Lab on-chip controllers.

- Zephyr project bug tracker GHSA-ph42-6rqx-728c

This has been fixed in main for v4.5.0

CVE 2026-11894

Double-free / use-after-free in Realtek BEE Bluetooth HCI driver `send()` error paths

The Realtek BEE Bluetooth HCI driver's send callback, `bt_hci_bee_send()` in `drivers/bluetooth/hci/hci_bee.c`, violated the `bt_hci_driver_api` buffer-ownership contract. That contract requires the driver to consume (unref) the transmit `net_buf` only on success; on an error return the host caller retains ownership and unrefs the buffer itself. The pre-fix code routed all error paths through a shared cleanup label that unconditionally called `net_buf_unref(buf)` before returning the error code.

Because the host TX paths (in `subsys/bluetooth/host/hci_core.c`) unref the buffer again after `send()` returns an error, the buffer is freed twice: the driver returns it to its `net_buf` pool and the host then unrefs the already-freed buffer, corrupting the shared pool / underflowing the reference count (CWE-415). The same error branch additionally dereferenced `buf->len` inside a `LOG_ERR` call after the buffer had already been unref'd, a read of freed memory (CWE-416) that is compiled in at the default error log level.

The failing edges are reached when the controller's host-to-controller buffer allocation fails or the controller send fails (resource-exhaustion / IO conditions). A remote Bluetooth peer can push the device toward these conditions indirectly by driving heavy host transmit activity, at which point the double-free corrupts the host `net_buf` pool and most likely crashes the device, with residual potential for further memory corruption. The impact is confined to builds using this specific Realtek BEE HCI driver.

The fix returns early from each error path without unreffing and unrefs the buffer only on the success path, restoring the ownership contract and eliminating both the double-free and the use-after-free read.

CVE 2026-11985

Cross-thread FPU register leak on ARM when FPU enabled without register sharing

On the Zephyr ARM port, enabling the hardware FPU (`CONFIG_FPU`) forces the "Floating point ABI" choice, which defaults to `CONFIG_FP_HARDABI`. Both `FP_HARDABI` and `FP_SOFTABI` permit the compiler to emit hardware FP instructions in any function, even code that never uses floating-point types. However, the callee-saved FP registers (s16-s31 / d8-d15) are only saved and restored across a context switch when `CONFIG_FPU_SHARING` is enabled (`arch/arm/core/cortex_m/swap_helper.S` and `arch/arm/core/cortex_a_r/swap_helper.S`), and prior to this fix selecting an ABI did not enable FPU register sharing, which defaults off.

In a build that enables the FPU with the default ABI but leaves `CONFIG_FPU_SHARING` disabled, the kernel preserves no callee-saved FP register state across thread switches. The documented

precondition for this “unshared” mode — that only a single thread ever executes FP instructions — is silently violated because the compiler may generate FP instructions in every thread.

Under CONFIG_USERSPACE, where threads are mutually isolated, this becomes an information-disclosure boundary crossing: a victim thread can leave secret-derived values in s16-s31, and a co-resident unprivileged thread can read those registers directly (FP register access is not privilege-gated), recovering data left behind by another thread. Without userspace the same defect causes cross-thread FP state corruption (a correctness fault). The leak is bounded to the 16 callee-saved single-precision registers and is opportunistic, so impact is low.

The fix makes FP_HARDABI and FP_SOFTABI select CONFIG_FPU_SHARING and tags every thread with K_FP_REGS at creation, so callee-saved FP state is always preserved across context switches whenever the compiler may emit FP instructions.

CVE 2026-12051

NULL pointer dereference in USB DFU device_next download handler (handle_download)

The USB DFU class implementation in Zephyr’s new (experimental) device_next USB device stack contains a NULL pointer dereference in handle_download() (subsys/usb/device_next/class/usbd_dfu.c). The handler computes MIN(setup->wLength, buf->len) and passes buf->data to the image write callback without checking that the buf net_buf pointer is non-NULL.

The handler is reached over the USB control endpoint, driven by the USB host. For a DFU_DNLOAD (download) request with no Data OUT stage — notably the zero-length terminating download that the DFU protocol uses to end a firmware transfer — the USB core invokes the class handler with a NULL buffer. After the device has been advanced to the DFU_DNLOAD_IDLE state (by sending one valid download block and a GET_STATUS), a zero-length DFU_DNLOAD reaches handle_download() with buf == NULL, dereferencing it.

The result is a NULL+offset read that triggers a fatal CPU fault, i.e. a denial of service (device crash/reset). The attacker is whatever controls the USB host the device is attached to; DFU download support must be enabled with a registered image. There is no memory corruption or information disclosure — impact is limited to availability. The fix adds an explicit if (buf != NULL) guard so the callback receives a zero-length, NULL-data transfer instead of crashing.

CVE 2026-12052

Out-of-bounds write in USB CDC NCM control handler when host wLength is smaller than the response

The USB device-side CDC NCM class control-to-host handler usbd_cdc_ncm_cth in subsys/usb/device_next/class/usbd_cdc_ncm.c builds a fixed-size response for the GET_NTB_PARAMETERS (28-byte struct ntb_parameters) and GET_NTB_INPUT_SIZE (8-byte struct ntb_input_size)

class requests and copies the whole structure into the control DATA IN buffer with `net_buf_add_mem(buf, ..., sizeof(...))`, ignoring the host-supplied `wLength`.

The control DATA IN buffer is allocated by the USB stack with a capacity of exactly `wLength` bytes (`usbd_ep_ctrl_data_in_alloc -> udc_ctrl_data_alloc -> net_buf_alloc_len(&udc_ep_pool, wLength)`; no round-up is applied for the IN endpoint). Because `net_buf_add_mem`/`net_buf_simple_add` only bounds the copy with an `__ASSERT_NO_MSG`, which is compiled out in production builds, a host that issues one of these standard CDC NCM control requests with a `wLength` smaller than the response structure (e.g. `wLength = 1`) causes the handler to `memcpy` up to 27 bytes past the end of the allocated pool buffer.

The request fields come straight from the USB SETUP packet, so any host (or USB interposer) the Zephyr device enumerates against can trigger the overflow with no authentication once an image built with the device_next USB stack and the CDC NCM class is connected. The out-of-bounds write corrupts adjacent allocations and metadata in the shared `udc_ep_pool`, primarily causing memory corruption and denial of service of the USB stack; the overflow length is bounded (<= 27 bytes) and the written content is fixed device constants, and the bug reads nothing back so there is no information disclosure. The fix clamps the copy with `MIN(sizeof(...), setup->wLength)`, matching the existing CDC ACM handler.

CVE 2026-12232

Out-of-bounds read via unvalidated stream_id in Intel ALH DAI get_properties

The Intel ALH digital-audio-interface driver function `dai_alh_get_properties()` in `drivers/dai/intel/alh/alh.c` used a caller-supplied `int stream_id` with no range validation. The value indexes the fixed-size `static const uint8_t alh_handshake_map[64]` array and scales a FIFO register address, so an out-of-range `stream_id` produces an out-of-bounds read of one byte at an attacker-chosen signed offset from the array. That byte is written into `prop->dma_hs_id` and the resulting `struct dai_properties` is copied back to the caller, leaking it.

`dai_get_properties_copy()` is a Zephyr `__syscall`, and its verifier `z_vrfy_dai_get_properties_copy()` (`drivers/dai/dai_handlers.c`) validates only the device-object permission and the destination buffer, not `stream_id`. A user-mode thread that has been granted access to the ALH DAI device object can therefore call the syscall with an arbitrary `stream_id`, crossing the userspace/kernel sandbox boundary.

The impact is a one-byte-per-call arbitrary-offset kernel information disclosure (and leakage of a computed kernel address via `fifo_address`); a `stream_id` that resolves to an unmapped page faults in kernel context, giving a local denial of service. Exploitation requires `CONFIG_USERSPACE` and device access, making this a local, moderate-severity issue. The fix rejects negative and too-large `stream_id` values up front and returns NULL, which the copy wrapper maps to `-ENOENT`.

CVE 2026-12233

Uninitialized mutex in TLS trusted-credential backend causes kernel NULL-deref DoS under contention

The PSA Protected Storage credential backend (subsys/net/lib/tls_credentials/tls_credentials_trusted.c) declared its credential-store mutex as a plain zero-filled `static struct k_mutex credential_lock;` and never called `k_mutex_init()` on it. A statically zero-filled `k_mutex` has an uninitialized wait queue (its dlist head/tail are NULL instead of the self-referential sentinels that `k_mutex_init`/`K_MUTEX_DEFINE` install). The uncontended lock path does not touch the wait queue, so the defect is latent and serialized use behaves correctly.

When two execution contexts contend on the lock, `k_mutex_lock()` pends the blocking thread on the wait queue via `z_pend_curr()`, which calls `sys_dlist_append()` on the zeroed list and dereferences a NULL tail pointer (`tail->next = node`), faulting the kernel. The lock is held during TLS handshake credential loading and by all credential add/get/delete operations, so a deployment performing concurrent TLS handshakes (for example a server handling multiple simultaneous connections from a remote peer) or a credential-management operation concurrent with a handshake can trigger the dereference.

The impact is a denial of service: a deterministic kernel panic / device reset on the first contention. There is no memory corruption beyond the NULL dereference and no confidentiality or integrity impact; mutual exclusion on the fast path remains correct. Exposure is limited to builds with `CONFIG_TLS_CREDENTIALS_BACKEND_PROTECTED_STORAGE` enabled (PSA Protected Storage / TF-M platforms); the default volatile RAM backend initializes its lock correctly and is unaffected.

The fix initializes the mutex statically with `K_MUTEX_DEFINE(credential_lock)`, providing a valid wait queue so the contended path no longer touches a NULL list.

CVE 2026-12234

TOCTOU double-fetch in `zsock_sendmsg`/`recvmsg` userspace verifiers allows kernel-heap out-of-bounds write

The userspace syscall verifiers `z_vrfy_zsock_sendmsg()` and `z_vrfy_zsock_recvmsg()` in `subsys/net/lib/sockets/sockets.c` snapshot the caller-supplied `struct net_msghdr` into a kernel-side copy with `k_usermode_from_copy()`, but then re-read the still-live user struct for subsequent decisions. The kernel `iovec` shadow buffer is sized from one read of `msg->msg_iovlen`, while the population loop is bounded by a second, live read of the same field.

Because `msg` points into ordinary user memory, a cooperating second thread in the same memory domain can inflate `msg->msg_iovlen` in the window between the sizing read and the loop test (a classic double-fetch / TOCTOU). The population loop then iterates past the number of `net_iovec` slots actually allocated, writing attacker-influenced `iov_base`/`iov_len` values beyond the end of the kernel-heap shadow buffer. The `recvmsg` verifier has the same defect on both its inbound and result write-back loops.

The code is reachable from an unprivileged user thread whenever `CONFIG_USERSPACE` is enabled and the `zsock_sendmsg`/`zsock_recvmsg` syscalls are available. A successful race corrupts kernel-managed heap memory across the user-to-kernel privilege boundary, yielding a local privilege-escalation primitive or, at minimum, a kernel-fault denial of service. The fix copies the header

once and derives every size, bound, and gate from the snapshot, copying each `iovec` entry atomically so its base and length can no longer be raced apart.

CVE 2026-12235

Out-of-bounds write in Xtensa llext PLT relocation from malformed ELF (CWE-787)

The Linkable Loadable Extensions (llext) subsystem mis-handles PLT/RELA relocation entries when linking a relocatable (partially-linked) ELF extension. In `llext_link_plt()` (subsys/llext/llext_link.c), the relocatable branch (`tgt != NULL`, the path used for Xtensa relocatable objects) computed the patch address as `ext->mem[LLEXT_MEM_TEXT] - text.sh_offset + rela.r_offset + tgt->sh_offset` and then performed the relocation write there without validating `rela.r_offset`. Its sibling shared/dynamic branch already rejected out-of-range offsets via `llext_file_offset()`.

`rela.r_offset` is read directly from the ELF's RELA table, so a crafted entry with an offset larger than the target section makes the write land arbitrarily far outside the extension's text buffer. The result is an attacker-influenced out-of-bounds write (the location via `r_offset`, the written value being the resolved symbol address) performed in supervisor context at link time, before any extension code runs.

The path is reached from `llext_load()` whenever an application loads an attacker-influenced ELF extension on Xtensa with writable storage; llext is documented to accept extensions of untrusted origin. Impact is supervisor-context memory corruption (integrity and availability loss, and a sandbox-boundary escape for user-mode extensions). Exploitation is gated by the Xtensa relocatable PLT path and writable storage, and turning the out-of-range write into a useful primitive is non-trivial.

The fix adds a bound check rejecting any RELA entry whose `r_offset >= tgt->sh_size`, mirroring the existing validation in the shared branch.

CVE 2026-12236

Infinite loop (DoS) in Bluetooth GATT client parsing of Read-By-Type responses with zero data length

The Bluetooth host GATT client function `parse_read_std_char_desc()` in `subsys/bluetooth/host/gatt.c` parses an ATT Read By Type Response received from a remote GATT server during `BT_GATT_DISCOVER_STD_CHAR_DESC` discovery. The per-entry stride `rsp->len` is taken directly from the peer's PDU, and the parse loop both tests its exit condition (`length >= rsp->len`) and advances (`length -= rsp->len`, `pdu += rsp->len`) using that value. The minimum value of `rsp->len` was never validated before the loop.

A malicious or malfunctioning peer can reply with `rsp->len = 0`. Because `length` is unsigned and never decreases, the loop condition stays true forever and the read pointer never advances; as long as the body is at least a few bytes with a non-zero handle and a matching descriptor UUID, the host repeatedly re-parses the same bytes and invokes the discovery callback, never terminating. This hangs the Bluetooth host processing thread (CWE-835, loop with unreachable exit condition).

The condition is reachable by any connected peer once the local device initiates standard-descriptor-value discovery; GATT discovery does not require bonding or encryption, so an unauthenticated adjacent attacker that the device connects to can trigger it. The impact is denial of service of the Bluetooth subsystem (and likely a watchdog reset on constrained targets); there is no memory disclosure or corruption.

The fix adds a `rsp->len < sizeof(struct bt_att_data)` check before the loop, rejecting under-length responses so the stride is always non-zero and the loop terminates. The sibling parsers `parse_include()` and `parse_characteristic()` already validated `rsp->len` and are unaffected.

CVE 2026-7007

Division by zero in Zephyr ext2 superblock parsing allows DoS via crafted filesystem image

The Zephyr ext2 file system validates the on-disk superblock in `ext2_verify_disk_superblock()` (`subsys/fs/ext2/ext2_impl.c`) before completing a mount. The validator checked the magic number, block size, revision and feature flags, but did not verify that the on-disk fields `s_blocks_per_group` and `s_inodes_per_group` are non-zero. Both fields are read directly from the image and are later used as divisors during mount-time initialization.

During mount, `get_ngroups()` divides and modulos `s_blocks_count` by `s_blocks_per_group` (reached via `ext2_fetch_block_group()` from `ext2_init_fs()`), and `get_itable_entry()` divides `(ino - 1)` by `s_inodes_per_group` when fetching the root inode (both in `subsys/fs/ext2/ext2_diskops.c`). A superblock with either field set to zero therefore causes an integer division by zero during the mount sequence.

An attacker who can present a crafted ext2 image to a device that mounts ext2 — removable media such as an SD card or a USB mass-storage device — can trigger this. On ARMv7-M / ARMv8-M-mainline Cortex-M targets, divide-by-zero trapping is enabled (`SCB_CCR_DIV_0_TRP`), so the division raises a UsageFault that Zephyr treats as a fatal error, producing a denial of service. The impact is limited to availability; the malformed value is consumed only as a divisor.

The fix rejects a zero `s_blocks_per_group` or `s_inodes_per_group` in the superblock validator, returning `-EINVAL` so the mount fails before any block-group or inode I/O occurs.

CVE 2026-8023

Path traversal in Zephyr HTTP server static-filesystem resource handler allows unauthenticated remote arbitrary file read

Zephyr's HTTP server (`subsys/net/lib/http`) provides a static-filesystem resource type (`HTTP_RESOURCE_TYPE_STATIC_FS`, available when `CONFIG_FILE_SYSTEM` is enabled) that serves files from a configured root directory. Before this fix, both the HTTP/1 and HTTP/2 front-ends placed the raw, attacker-controlled request path into `client->url_buffer` (assembled in `on_url()` for HTTP/1 and copied verbatim from the `:path` pseudo-header for HTTP/2) without resolving `./..` segments. The static-FS handler then built the on-disk filename by directly concatenating the configured root with that raw URL (`snprintk(fname, ..., "%s%s", static_fs_detail->fs_path, client->url_buffer)` at `http_server_http1.c:603` and `http_server_http2.c:490`) and opened it with `fs_open(fname, FS_O_READ)`. Because the handler is reached via wildcard/leading-dir (`fnmatch FNM_LEADING_DIR`) or fallback resource matching, a request such as `GET /<prefix>/../../<file>` is dispatched to the handler and, after the underlying filesystem (e.g. LittleFS/FAT) resolves the `..` segments, escapes the configured web root, letting an unauthenticated remote client read arbitrary readable files on the mounted volume (information disclosure). The HTTP server requires no TLS or authentication to reach this path. The fix adds `http_server_remove_dot_segments()`, which canonicalizes the path portion of the URL before resource lookup in both protocol handlers, neutralizing the traversal. Affects releases v4.0.0 through v4.4.0 for deployments that register a static-filesystem resource.

CVE 2026-9728

TOCTOU race in mbox_send syscall verifier allows userspace to leak kernel memory

The userspace syscall verifier `z_vrfy_mbox_send()` in `drivers/mbox/mbox_handlers.c` validated the nested `msg->data`/`msg->size` fields by reading them directly out of live userspace memory, and then forwarded the original, still-mutable userspace `struct mbox_msg *` pointer to `z_impl_mbox_send()` and the underlying driver. Between the access check and the driver's use of `msg->data`, the validated pointer could be replaced, leaving a time-of-check/time-of-use window.

On a system built with `CONFIG_USERSPACE`, any unprivileged userspace thread may invoke the `mbox_send()` system call. A second thread sharing the caller's address space can race to overwrite `msg->data` with a supervisor (kernel) address after the verifier's bounds check has passed but before the driver dereferences it. The driver then reads from the attacker-chosen address in supervisor context (for example `memcpy(&data32, msg->data, msg->size)` in the NXP mailbox driver, whose bytes are subsequently emitted to the peer mailbox endpoint).

The impact is a userspace-to-supervisor access-control bypass: disclosure of kernel memory contents (high confidentiality impact), or, for an invalid/unmapped target address, a faulting kernel read causing denial of service. The fix snapshots the entire `struct mbox_msg` into a kernel-stack copy with `k_usermode_from_copy()` and validates and forwards that immutable copy, closing the race.

CVE 2026-9771

Missing device-pointer validation in flash_copy() syscall allows userspace privilege escalation

The `flash_copy()` system call is verified by `z_vrfy_flash_copy()` in `drivers/flash/flash_util.c`. On builds with `CONFIG_USERSPACE` enabled, this handler is the kernel-side trust boundary for a user-mode caller. Prior to the fix it validated only the output buffer (`K_SYSCALL_MEMORY_WRITE`) and passed the two `struct device *` arguments, `src_dev` and `dst_dev`, directly into the implementation without any object validation — unlike every sibling flash syscall, which guards its device pointer with `K_SYSCALL_DRIVER_FLASH`.

A user-mode thread fully controls the values of `src_dev`/`dst_dev` and the contents of its own address space. The implementation `z_impl_flash_copy()` dereferences these pointers and calls through their driver-API function tables (e.g. `api->get_parameters(dst_dev)`, `flash_read(src_dev, ...)`, `flash_write(dst_dev, ...)`). By supplying a pointer to a forged `struct device` whose `api` table contains attacker-chosen function pointers, an unprivileged thread can cause the kernel to call arbitrary code in supervisor mode; passing any arbitrary or invalid address otherwise yields a kernel crash or out-of-bounds read.

The result is a local privilege escalation out of the userspace sandbox (with kernel denial-of-service and information disclosure as lesser outcomes). The fix adds `K_SYSCALL_DRIVER_FLASH(src_dev, read)` and `K_SYSCALL_DRIVER_FLASH(dst_dev, write)` to `z_vrfy_flash_copy()`, which verify each device is a registered flash-driver kernel object the calling thread is permitted to use before any dereference, closing the path completely.

CVE 2026-12363

Out-of-bounds write in LoRaWAN fragmented transport from a fragment index of 0

The LoRaWAN Fragmented Data Block Transport service (`subsys/lorawan/services/frag_transport.c`) does not validate the fragment counter in a received `DATA_FRAGMENT` command before forwarding it to the configured decoder. In `frag_transport_package_callback()` the value `frag_counter = hdr->frag_index_n & 0x3FFF` is taken directly from the downlink payload and passed to the decoder, which derives an array index and flash offset as `frag_counter - 1`. DataFragment fragments are 1-indexed, so a `frag_counter` of `0` underflows that arithmetic.

With the default Semtech/LoRaMAC-node decoder, this reaches `FragDecoder.FragNbMissingIndex[fragCounter - 1] = 0;` in `FragDecoderProcess()`, where `fragCounter - 1` evaluates to `-1` and writes a `uint16_t` zero out of bounds, just before the array and into the adjacent `MatrixM2B` recovery-matrix state of the static decoder object (`CWE-787`). A companion write derives a wild flash offset, but that path is rejected by the `flash_area_write()` bounds check. The in-tree low-memory decoder (`frag_dec()`) is not corrupted: its out-of-range bit-array and flash accesses are caught by `sys_bitarray_*` and `flash_area_*` bounds checks.

The handler is the registered downlink callback for the fragmentation transport port, reachable whenever an active fragmentation session exists, so the triggering byte is attacker-influenceable LoRaWAN/FUOTA network input. Triggering it requires authenticated downlinks (LoRaWAN MAC session keys or a malicious/compromised network or FUOTA server) and an active fragmentation session. The impact is contained: corruption of decoder state and denial of the firmware-update (FUOTA) session rather than controllable memory corruption or code execution. The fix

adds a transport-layer check that rejects `frag_counter == 0`, closing the defect for both decoder backends.

CVE 2026-12364

Missing user-space pointer validation in logging syscall z_log_msg_static_create allows kernel memory disclosure and denial of service

The user-space system-call verifier `z_vrfy_z_log_msg_static_create()` in `subsys/logging/log_msg.c` was a pure pass-through: it forwarded the caller-supplied `source`, `desc`, `package`, and `data` arguments directly to the kernel-mode implementation `z_impl_z_log_msg_static_create()` without performing any of the mandatory `K_SYSCALL_*` checks. Because `z_log_msg_static_create()` is declared `__syscall`, under `CONFIG_USERSPACE` any unprivileged user-mode thread can invoke it directly with fully attacker-controlled arguments.

The kernel-mode handler dereferences each of these untrusted values: `frontend_runtime_filtering()` reads through the `source` pointer as a `struct log_source_dynamic_data`, `cbprintf_package_copy()` reads `desc.package_len` bytes from the `package` pointer, and `z_log_msg_finalize()` performs a `memcpy()` of `desc.data_len` bytes from the `data` pointer. With no verification, a user thread can supply arbitrary kernel addresses and arbitrary lengths, and the kernel will read from them.

The impact is a kernel-mode denial of service (the kernel faults dereferencing an attacker-chosen pointer) and, where a log backend output is observable to the attacker, disclosure of arbitrary kernel memory copied into the emitted log message — a confidentiality breach across the user/kernel boundary that the userspace sandbox is meant to enforce. The reads do not corrupt kernel memory, so there is no out-of-bounds write primitive.

The fix adds the required validation to the verifier: it bounds `desc.package_len` against `Z_LOG_MSG_MAX_PACKAGE`, rejects non-NULL/length mismatches, and applies `K_SYSCALL_MEMORY_READ()` to `package`, `data`, and (when runtime filtering with a frontend is enabled) `source`, so any out-of-bounds or kernel pointer now raises `K_OOPS` instead of being honored.

CVE 2026-12365

Use-after-free in Zephyr delayable work-queue cancellation under SMP timing race

A use-after-free exists in the Zephyr second-generation work queue (`kernel/work.c`) in the handling of delayable work timeouts. When a delayable work item's timeout has been dequeued and its handler `work_timeout()` is in flight (blocked acquiring the work-queue spinlock), a concurrent cancellation does not wait for that handler to finish. In `unschedule_locked()` the pre-fix code called `z_abort_timeout()`, which for an already-announcing record returns `-EINVAL` without removing it; `cancel_async_locked()` then observes the work as idle, so even

`k_work_cancel_delayable_sync()` and `k_work_flush_delayable()` return without blocking on the in-flight handler.

Because those are the APIs the kernel header documents as the safe way to cancel before freeing a `k_work_delayable`, a caller that frees the object immediately after a successful sync cancel can race the still-pending handler. `work_timeout()` subsequently dereferences the freed record: it reads `to->dticks` via `z_is_timeout_handler_canceled()` and, if the freed slot has been reused so the bail check fails, performs a read-modify-write of `wp->flags` (`K_WORK_DELAYED_BIT`) and submits work against a stale `dw->queue` pointer — a use-after-free read and write.

The `k_work` API is kernel-mode only (no `__syscall` entry point), so this is a kernel-internal concurrency defect rather than a userspace privilege escalation. Triggering it requires an SMP build and a subsystem that schedules and then frees (or reschedules) a delayable work item in the narrow window while its timeout is announcing; an attacker able to influence the timing of such teardown (for example via connection churn driving subsystem timers) has a plausible but probabilistic path. The impact is kernel memory corruption or crash (denial of service).

The fix makes `unschedule_locked()` wait, by spinning on `z_try_abort_timeout()` returning `-EAGAIN` while releasing and re-acquiring the work spinlock, until any in-flight handler completes before returning, and switches `work_timeout()` to atomic `K_WORK_DELAYED_BIT` ownership. This closes both the free-then-handler use-after-free and the related reschedule early-fire race.

CVE 2026-12366

Use-after-free freeing an armed dynamically-allocated k_timer in Zephyr userspace object disposal

Zephyr's dynamic kernel-object disposal path `unref_check()` in `kernel/userspace/userspace.c` frees an object's storage (`k_free(dyn->data)`) once its reference count reaches zero, after running a per-object-type cleanup. The cleanup `switch` handled only `K_OBJ_MSGQ` and `K_OBJ_STACK`; there was no `K_OBJ_TIMER` case. A dynamically-allocated, initialized, and armed `k_timer` keeps its embedded `struct _timeout` dnode linked in the global timeout queue (`_timeout_q`), so freeing the timer storage without cancelling the timeout leaves a dangling node in that queue.

When the timer next expires, the timeout machinery walks `_timeout_q` and invokes `z_timer_expiration_handler()` on the freed node, dereferencing and writing freed (and reusable) kernel heap in kernel/ISR context. This is a deterministic use-after-free that does not depend on SMP: the queued node is simply never unlinked at free time.

The disposal is reachable from an unprivileged user thread under `CONFIG_USERSPACE + CONFIG_DYNAMIC_OBJECTS`: a thread that holds the last permission on such a timer drops it via the `k_object_release()` syscall (or by exiting, through `k_thread_perms_all_clear()`), and can arm the timer itself via the `k_timer_start()` syscall. The free and the expiration handler run at kernel privilege while the actor is a user thread, so the bug is a sandbox-escape memory-corruption primitive usable for privilege escalation. The fix adds `k_timer_cleanup()` (cancel the timeout and wait for any in-flight handler) and calls it for `K_OBJ_TIMER` before freeing.

CVE 2026-12519

Out-of-bounds stack read and write in Zephyr WNC-M14A2A modem socket-notify parsing

The WNC-M14A2A LTE-M modem driver mishandles unsolicited `%NOTIFYEV:` events in `on_cmd_socknotifyev()` (`drivers/modem/vendor_standalone/wncm14a2a.c`). The response line is linearized into a fixed 40-byte stack buffer via `net_buf_linearize()`, which caps the copy at 39 bytes and returns `out_len <= 39`. The two quote-delimiter scanning loops, however, were bounded by `len` — the full CR/LF-delimited frame length returned by `net_buf_findcrlf()` — rather than by `out_len`.

When a `%NOTIFYEV:` line longer than 39 bytes contains no " within the linearized region, the loop indices `p1`/`p2` walk past `value[39]` and read adjacent stack memory until a stray quote byte is found or the index reaches `len`. The over-read string is then passed to `strncmp()`/`atoi()`/`LOG_*`, and if a quote byte is found out of bounds the subsequent `value[p2] = '\0'` performs a single-NUL out-of-bounds stack write at an attacker-influenced offset.

The `%NOTIFYEV:` payload carries network-derived content (`LTIME` network time, `SIB1` base-station system information, `CSPS`/`RRCSTATE`), so a rogue cellular base station, a malicious or compromised modem module, or RF manipulation that induces an over-long notify line reaches the defect without any application interaction; the handler runs automatically on the unsolicited event in the modem RX thread.

The impact is out-of-bounds stack disclosure (into logs and parsing) and stack corruption that can crash the modem RX thread (denial of service). The write offset is only weakly controlled, so memory-safe code execution is not demonstrated. The fix bounds both scanning loops by `out_len`, keeping all accesses within the linearized buffer.

CVE 2026-12520

Stack buffer overflow and off-by-one writes in Zephyr HL7800 modem AT response handlers

The Sierra Wireless HL7800 cellular modem driver (`drivers/modem/vendor_standalone/hl7800.c`, located at `drivers/modem/hl7800.c` in v4.4.0 and earlier) parses AT responses with roughly twenty handlers that call `net_buf_linearize(value, sizeof(value), *buf, 0, len)` into a 128-byte stack buffer and then write `value[out_len] = 0`. Because `net_buf_linearize()` (`lib/net_buf/buf.c`) can return a count equal to its destination-length argument, a field that exactly fills the buffer makes the terminating NUL land one byte past the end, a single-byte out-of-bounds write into adjacent stack memory.

The `+KCELLMEAS` cell-measurement handler `on_cmd_atcmdinfo_rssi()` is worse: it passed the wire length `len` as the destination size (`net_buf_linearize(value, len, *buf, 0, len)`), so a response line longer than 128 bytes overflows the `value` stack buffer with attacker-influenceable content. The line length comes from `net_buf_findcrlf()`, which accumulates bytes across the whole `net_buf` fragment chain and is not bounded to 128, so an over-long line reaches the defect.

The data originates from the cellular modem over UART, driven by the network: operator-scan results, `+CGCONTRDP` IP/DNS info, socket indications, and `+KCELLMEAS` neighbour-cell reports. An attacker able to shape what the modem emits — a rogue base station, a compromised modem baseband, or a remote peer feeding oversized response framing — can drive a line past 128 bytes. The handlers run in the driver's RX thread in kernel context, so the corruption is kernel-side.

The +KCELLMEAS path is a full stack buffer overflow whose worst case is code execution in kernel context and whose floor is a reliable crash; the remaining sites are single-byte NUL out-of-bounds writes. Exploitation requires the modem to emit an over-long AT response line, giving high attack complexity over an adjacent (cellular radio) vector. The fix passes `sizeof(dst) - 1` (and correct explicit bounds for the IMSI and +KCELLMEAS sites) so the terminator always stays in bounds.

CVE 2026-12521

Zephyr HTTP server kernel timeout-list corruption on spurious zsock_poll() return

The HTTP server core loop `http_server_run()` in `subsys/net/lib/http/http_server_core.c` polls the listening, stop, and client sockets with an infinite timeout and treats a `zsock_poll()` return of `0` as impossible, executing `break` and returning `0` without reaching its `closing:` cleanup. However, `zsock_poll()` (`zvfs_poll_internal()` in `lib/os/zvfs/zvfs_poll.c`) can legitimately return `0` even with an infinite timeout: after `k_poll()` wakes, the `ZFD_IOCTL_POLL_UPDATE` pass may find every fd reporting no `revents` (a spurious wakeup), yielding `ret == 0`.

On that path `close_all_sockets()` is skipped, so the per-client `inactivity_timer` (`struct k_work_delayable`) cancellations in `close_client_connection()` never run. Control returns to `http_server_thread()` with `server_running` still true, which re-enters `http_server_init()`. `http_server_init()` then `memset()`s the `ctx->clients` array — including the `k_work_delayable` timeout nodes — while one or more of those timers are still armed and linked in the kernel sys-timeout list.

When the kernel later services such a timeout it operates on a reinitialized object and follows the now-zeroed list links, corrupting the kernel timeout list and producing a delayed fault. The HTTP server loop is driven by unauthenticated remote network peers (`CONFIG_HTTP_SERVER`, all of HTTP/1/2/3), and connection churn raises the probability of the spurious-wakeup race, so a remote peer can influence the trigger. The realistic impact is a denial of service (kernel crash/hang) from the corrupted timeout list.

The fix replaces `break` with `continue`, re-polling on a spurious `0` return, which leaves the sockets and their armed timers intact and never re-initializes the context over live timers.

CVE 2026-12522

Stack buffer overflow in Zephyr hl7800 modem driver parsing network-supplied +CGCONTRDP address fields

The HL7800 cellular modem driver's `+CGCONTRDP:` response handler `on_cmd_atcmdinfo_ipaddr()` in `drivers/modem/vendor_standalone/hl7800.c` parses the PDP-context dynamic parameters (local address, subnet mask, gateway, and DNS servers) that

the cellular network assigns to the device. The response is linearized into a 256-byte stack buffer, after which each address field length is computed from comma/. delimiter positions in the network-supplied data and used directly as the length argument to `strncpy()` into the fixed 64-byte stack buffer `temp_addr_str` (and the 16-byte `iface_ctx.dns_v4_string`).

Because the field length is derived from attacker-controlled delimiter positions and was not bounded against the destination buffer, a single field can be far larger than 64 bytes. A malicious or impersonated cellular network (for example a rogue base station) can return a crafted `+CGCONTRDP` response with an overlong address field, causing `strncpy()` to write past `temp_addr_str` on the modem worker thread's stack, plus an out-of-bounds NUL write at `temp_addr_str[addr_len]`.

No device-side privileges or user interaction are required: the device itself issues the `AT+CGCONTRDP=1` query during normal network attach and parses whatever the network returns. The overflow corrupts adjacent stack memory in supervisor context, yielding at minimum a remotely triggerable crash and potentially control-flow hijacking on targets without stack protection.

The fix bounds every field length against its destination buffer (`temp_addr_str` and `dns_v4_string`) before each copy, rejecting overlong fields.

CVE 2026-7656

Broken IPv6 Neighbor Discovery input validation allows spoofed RA/NS/NA acceptance in Zephyr net stack

The IPv6 Neighbor Discovery handlers in `subsys/net/ip/ipv6_nbr.c` (`handle_ra_input`, `handle_ns_input`, `handle_na_input`) used an incorrect boolean expression that combined the RFC 4861 validity checks with the ICMPv6 code check using the wrong operator precedence: the form was `((length/hop/source/target checks) && (icmp_hdr->code != 0))`. Because every legitimate ND message carries ICMPv6 code 0, an attacker setting `code == 0` (the normal value) caused the entire predicate to evaluate false, so the packet was never dropped and all of the other checks were silently skipped. The bypassed checks include the mandatory Hop Limit == 255 verification (which proves an ND packet originated on-link and was not forwarded) and, for Router Advertisements, the requirement that the source be a link-local address, as well as multicast-target sanity checks. As a result, an adjacent on-link attacker — and, because the Hop-Limit-255 guard is bypassed, potentially a remote/off-link attacker whose packets would otherwise be rejected — can have forged Router Advertisement, Neighbor Solicitation, and Neighbor Advertisement messages accepted. A forged RA lets the attacker reconfigure the victim's default router, on-link prefixes (SLAAC), MTU, reachable/retransmit timers, and (with `CONFIG_NET_IPV6_RA_RDNSS`) DNS servers, while forged NS/NA enable neighbor-cache poisoning, enabling man-in-the-middle, traffic redirection, and denial of service. The flaw is an input-validation/authentication weakness rather than a memory-safety issue: the underlying packet-parsing primitives (`net_pkt_get_data`, `net_pkt_read`, `net_pkt_skip`) are independently bounds-safe and the validated `length` is the true buffer length, so skipping the length check causes no out-of-bounds access. The defect has existed since the logic was introduced in 2018 and shipped in all releases through v4.4.0; it is fixed by splitting the condition so any failing check drops the packet.

CVE 2026-10666

Stack buffer overflow in `net_ipaddr_parse()` IPv4 address-with-port parsing in `subsys/net/ip/utils.c`

`parse_ipv4()` in `subsys/net/ip/utils.c` (reached via `net_ipaddr_parse()` for strings of the form "a.b.c.d:port") copies the port substring into a fixed 17-byte stack buffer (`char ipaddr[NET_IPV4_ADDR_LEN + 1]`) using a length of `str_len - end - 1`, where `str_len` is the full, unbounded input length and end is only the (<=15-byte) offset of the ':' delimiter. Because the destination size is never consulted, a crafted address string with a long suffix after the colon (e.g. "1.2.3.4:" followed by hundreds of bytes) causes an out-of-bounds stack write whose length and contents are fully attacker-controlled (`memcpy` of the suffix plus a trailing NUL), enabling memory corruption and at minimum a denial of service, and potentially control-flow hijack. The parser is reached from the standard socket API (`zsock_getaddrinfo` / literal-address resolution), DNS server-string configuration, and the eswifi Wi-Fi co-processor DNS-response path, so an application that resolves a network-influenced address string is exposed. The bug was introduced when the parser was added (Zephyr v1.9.0) and shipped in all releases through v4.4.0. The fix removes the unbounded copy and validates the port length before copying into a small dedicated buffer. Note: the equivalent IPv6 "[addr]:port" path in `parse_ipv6()` retains the same unbounded copy at this commit and remains a separate, still-reachable instance of the defect.

CVE 2026-10673

Out-of-bounds write in ADIN2111/ADIN1110 OA SPI Ethernet RX frame reassembly

The Zephyr ADIN2111/ADIN1110 10BASE-T1S/T1L Ethernet driver (`drivers/ethernet/eth_adin2111.c`) reassembles received Ethernet frames in OPEN Alliance (OA) SPI mode by copying device-supplied 64-byte data chunks into a fixed static buffer `ctx->buf` of size `CONFIG_ETH_ADIN2111_BUFFER_SIZE` (default 1524 bytes). In `eth_adin2111_oa_data_read()`, each valid chunk was `memcpy`'d into `ctx->buf[ctx->scur]` and the write cursor `scur` advanced, with no check that `scur + len` stayed within the buffer. The number of chunks (up to 255, from the BUFSTS RCA field) and the per-chunk length are taken entirely from the frame data received off the wire; the cursor is only reset on a start-of-frame chunk. An attacker on the single-pair Ethernet segment can therefore send a frame whose reassembled size exceeds the configured buffer, causing the driver's RX offload thread to write attacker-controlled frame bytes past the end of the static buffer into adjacent driver/kernel memory (up to roughly 14.8 KB in the worst case). This is a remotely/adjacently reachable out-of-bounds write (CWE-787) that can corrupt memory and cause denial of service or potentially code execution. The defect was introduced when OA SPI support was added (commit 0ca8b0756b1) and shipped in releases v3.7.0 through v4.4.0. The fix adds a bounds check that drops the oversized frame and resets the cursor before the copy.

CVE 2026-12629

PL011 UART error interrupts never cleared, enabling an external-peer interrupt-storm denial of service

The ARM PL011 UART driver in `drivers/serial/uart_pl011.c` fails to acknowledge receive error interrupts. On the PL011, the framing, parity, break, and overrun error interrupts (`PL011_IMSC_ERROR_MASK`) are cleared only by writing the interrupt-clear register `UARTICR`; reading the data register clears the RX interrupt and the per-byte RSR status but not the error interrupt status in `MIS`. The interrupt service routine `pl011_isr()` acknowledged only the CTS modem-status interrupt and never wrote `icr` for the error bits, so an asserted error interrupt remains pending after the ISR returns.

When an application enables error-interrupt reporting via the public `uart_irq_err_enable()` API, an attacker who controls the serial peer can deterministically assert these error bits by injecting line errors on the RX line — a baud/stop-bit mismatch or mid-character break (framing/break error), a flipped parity bit (parity error), or FIFO flooding (overrun error). Because the error interrupt is never cleared, the interrupt line stays asserted and the CPU re-enters `pl011_isr()` immediately and indefinitely, producing an interrupt-storm livelock from which the core makes no forward progress.

The impact is an availability-only denial of service (permanent hang), reachable from an external or removable UART peer. Exploitation is gated by configuration: the error interrupt is off by default and no in-tree subsystem enables it, so only applications that explicitly call `uart_irq_err_enable()` on a PL011-based, interrupt-driven port are affected. The fix makes `pl011_isr()` acknowledge the pending error bits via `uart->icr`, breaking the loop, and additionally clears the latched RSR status in `pl011_err_check()`.

CVE 2026-12630

6LoWPAN IPHC uncompression out-of-bounds read on reserved destination addressing mode

Zephyr's 6LoWPAN IP Header Compression (IPHC) uncompression code contains an out-of-bounds read in `get_ihpc_inlined_size()` (`subsys/net/ip/6lo.c`). The destination inline size is looked up in `da_inline_size_table`, which has 13 entries, using an index built from the `M`, `DAC` and `DAM` bits of the received IPHC dispatch word (`iphc & NET_6LO_IPHC_DA_MASK`, a 4-bit value of 0-15). The reserved combinations 13, 14 and 15 are not bounds-checked and read past the end of the table.

The `iphc` word is taken directly from the received frame, and `get_ihpc_inlined_size()` is reached on every inbound 6LoWPAN frame via `net_6lo_uncompress()` from the 802.15.4 receive path (`subsys/net/l2/ieee802154/ieee802154_6lo.c` and `ieee802154_6lo_fragment.c`). An unauthenticated attacker on the radio/adjacent link can therefore craft a frame whose destination addressing-mode nibble selects an out-of-range index, with no privileges or user interaction.

The out-of-bounds value becomes the computed `inline_size`, which then drives header reconstruction before the buffer-length check: it is used to dereference `*(pkt->buffer->data + sizeof(iphc) + inline_size)` and to compute a `size_t diff` that can underflow, leading to a further out-of-bounds read of the packet buffer and malformed uncompression. The practical impact is a radio-triggerable out-of-bounds read / denial-of-service on the receiver; the leaked byte is not returned to the attacker. The fix rejects any destination index beyond the table, aborting processing of the malformed frame.

CVE 2026-12631

Broken access-control denial in k_thread_join/k_thread_abort syscall validation in Zephyr kernel

The Zephyr kernel validates the `k_thread_join()` and `k_thread_abort()` system calls (declared `__syscall` in `include/zephyr/kernel.h`) through `thread_obj_validate()` in `kernel/thread.c`. Its `default` switch branch is the access-denied path, taken when `k_object_validate()` returns `-EPERM` (the calling user thread was never granted access to the target thread object) or `-EBADF` (the supplied pointer is not a registered kernel object of the right type). That branch invoked `K_OOPS(K_SYSCALL_VERIFY_MSG(ret, "access denied"))`, but `K_SYSCALL_VERIFY_MSG` treats a true expression as success; the non-zero error code `ret` therefore read as "verified OK", the kernel oops was never raised, and control fell through to `CODE_UNREACHABLE`.

Because `k_thread_join()` and `k_thread_abort()` are system calls, an unprivileged user-mode thread (under `CONFIG_USERSPACE`) can reach this denial path directly by calling either syscall on a thread object it does not own. Instead of the offending thread being cleanly terminated, execution reaches `__builtin_unreachable()` while running in supervisor mode inside the syscall handler.

On Clang builds `CODE_UNREACHABLE` emits an illegal-instruction trap, so a user thread can deterministically crash the kernel — a locally triggerable denial of service that escapes the userspace sandbox. On GCC builds the path is undefined behavior: the compiler may drop the return-value handling for `thread_obj_validate()`, so it can return an undefined `bool`; if that is `false`, the caller proceeds into the real `k_thread_join()`/`k_thread_abort()` implementation for a thread the user was never authorized to access, an access-control bypass.

The fix changes the verification expression to `ret == 0`, so a denied (non-zero) result now correctly raises `K_OOPS` and terminates the offending caller.

CVE 2026-12632

Out-of-bounds read in Zephyr PTP message parsing from unvalidated message type

Zephyr's Precision Time Protocol receive handler `ptp_msg_post_recv()` in `subsys/net/lib/ptp/msg.c` takes the 4-bit message type straight off the wire via `ptp_msg_type()` (`msg->header.type_major_sdo_id & 0xF`, range 0-15) and uses it to index the `msg_size[]` table. That table only

defines entries up to PTP_MSG_MANAGEMENT (0xD), giving it ARRAY_SIZE == 14. Before the fix there was no upper-bound check, so the undefined types 0xE and 0xF indexed one or two int slots past the end of the array — an out-of-bounds read of adjacent read-only data.

The out-of-bounds value is then reused as a length: it gates msg_size[type] > cnt, and when it is small or negative it makes cnt - msg_size[type] a large positive budget passed to msg_tlv_post_recv(), whose TLV loop then walks the message suffix past the received bytes, performing further out-of-bounds reads and in-place byte-swap writes on memory beyond the message slab.

The defect is reached directly from the network: ptp_port_event_gen() in subsys/net/lib/ptp/port.c reads a PTP frame with ptp_transport_recv() and calls ptp_msg_post_recv() with the attacker-chosen type. PTP uses UDP multicast or raw Ethernet (0x88F7) and is unauthenticated, so any host on the same link can trigger the indexing on a CONFIG_PTP-enabled node with no preconditions.

The reliably reproducible impact is a denial of service (fault/crash); a limited memory-corruption path exists but depends on the build-specific value adjacent to msg_size[], which the attacker cannot tune. The fix rejects type >= ARRAY_SIZE(msg_size) with -EBADMSG before any indexing.

CVE 2026-12633

Out-of-bounds write in IPv6 6LoWPAN Context Option handling via unauthenticated Router Advertisement

The IPv6 neighbor-discovery code in subsys/net/ip/ipv6_nbr.c processes the 6LoWPAN Context Option (6CO, RFC 6775) carried inside ICMPv6 Router Advertisements. In handle_ra_6co() the 8-bit context_len field is taken directly from the packet and was never bounded to the RFC maximum of 128. The function computes context->context_len / 8 and then performs memset(context->prefix + context_len, 0, sizeof(context->prefix) - context_len), where context->prefix is a fixed 16-byte array.

With context_len between 136 and 255 (and the option length field set to 3, which the pre-fix validation accepts), context_len / 8 evaluates to 17..31, so the memset length 16 - context_len/8 underflows the unsigned size_t argument to roughly SIZE_MAX. This produces an unbounded out-of-bounds memset that zeroes kernel memory well past the 6lo context structure.

The defect is reachable from unauthenticated, link-local input: any host on the same link can send a crafted Router Advertisement with a 6CO option. The RA handler validates only the option length field before calling handle_ra_6co(), so a single packet triggers the wild write. The code is compiled when CONFIG_NET_6LO_CONTEXT is enabled.

The impact is a reliable remote (adjacent) denial of service via memory corruption, with collateral integrity loss as the memset zeroes contiguous memory before the system faults. Router Advertisements are link-scoped and not forwarded, so the attacker must be on the same link (AV:A). The fix rejects any context_len greater than 128 before the length computation.

CVE 2026-12634

Out-of-bounds stack write in the settings NVS backend from over-reported nvs_read length

The NVS backend of the Zephyr settings subsystem (`subsys/settings/src/settings_nvs.c`) reads stored setting-name entries into fixed 74-byte stack buffers and NUL-terminates them with `buf[rc] = '\0'`, where `rc` is the return value of `nvs_read()`. Per its contract, `nvs_read()` returns the *full stored entry length* (`wlk_ate.len`), which can exceed the supplied buffer length — only `MIN(len, stored_len)` bytes are actually copied, but the return value may be much larger, bounded only by the NVS sector size. Three sites (`settings_nvs_cache_match()`, `settings_nvs_load()`, and `settings_nvs_save()`) used this value directly as the NUL index without clamping, so an oversized stored name entry causes a single `\0` byte to be written past the end of the stack buffer at an attacker-influenced offset (CWE-787).

The oversized entry cannot arise through the normal settings API, where names are bounded by `SETTINGS_MAX_NAME_LEN`. It requires an actor able to write the flash that backs the settings partition — a co-resident or untrusted component sharing the flash device, a malicious settings image/restore, or offline/physical flash access (a shared-flash threat model). The malformed entry is parsed when `settings_load()` runs at boot or subsystem init, or during `settings_save()`.

The out-of-bounds write is a single NUL byte at an offset equal to the crafted entry length (up to the NVS sector size), so the practical impact is a crash or denial of service and limited stack corruption rather than reliable code execution. There is no confidentiality impact, and the path is not reachable from the network through the ordinary settings interface. The fix skips any entry whose `nvs_read()` length is greater than or equal to the buffer size before performing the NUL store.

CVE 2026-12999

Infineon Airoc Wi-Fi driver leaks TX buffers on send failure, leading to permanent pool exhaustion

The Infineon Airoc Wi-Fi driver's transmit callback `airoc_mgmt_send()` in `drivers/wifi/infineon/airoc_wifi.c` allocates a `net_buf` from the fixed `airoc_pool` for every outbound packet. When `whd_network_send_ethernet_data()` returns a synchronous failure, the underlying WHD library does not take ownership of the buffer, but the pre-fix driver returned `-EIO` without releasing it. Each failed transmit therefore permanently leaks one buffer from the pool.

`airoc_pool` is small and fixed (`AIROC_WIFI_TX_PACKET_POOL_COUNT + AIROC_WIFI_RX_PACKET_POOL_COUNT`, default 20 buffers) and is shared by WHD's `whd_host_buffer_get` callback for both transmit and receive. Once enough send failures have leaked the pool dry, `airoc_wifi_host_buffer_get()` returns `WHD_BUFFER_ALLOC_FAIL` for all subsequent allocations, so both transmit and the WHD-driven receive path fail and Wi-Fi connectivity is lost until the device is rebooted.

The leak occurs only on the transmit error path. A Wi-Fi-adjacent attacker can influence the conditions that cause synchronous send failures (for example by deauthenticating/disassociating the station while the local stack continues to attempt transmits), and ordinary transient failures over

the device's lifetime accumulate toward the same state. Reliable on-demand triggering is of high complexity and the impact is availability-only, but the resulting denial of service is permanent and non-recoverable without a reboot.

The fix releases the buffer with `airoc_wifi_buffer_release()` on the failure branch, returning it to the pool. The commit also removes a redundant `k_sem_give()` in `airoc_mgmt_disconnect()`; because `data->sema_common` is a binary semaphore (limit 1) the duplicate give merely saturated at 1 and had no security impact.

CVE 2026-13212

Zephyr virtio driver calls an arbitrary function pointer from an out-of-range used-ring descriptor id

The Zephyr virtio driver does not validate the descriptor-chain head id that the virtio device writes into the used ring. In `virtio_isr()` (`drivers/virtio/virtio_common.c`), the device-written `vq->used->ring[idx].id` is used directly as an index into `vq->recv_cbs[]` and `vq->desc[]`, which are both allocated with exactly `vq->num` entries. `recv_cbs[]` holds `{cb, opaque}` callback entries, and the indexed callback pointer is then invoked as `cbe.cb(cbe.opaque, used_len)`.

Because the id is consumed as a 16-bit value with no bound check, a malicious or compromised virtio backend (an untrusted hypervisor, or an untrusted hardware/peer-processor virtio device on a PCI or MMIO transport) can supply an id far beyond `vq->num`. This causes an out-of-bounds read of a `{function pointer, argument}` pair from heap memory beyond `recv_cbs[]`, after which the driver calls that attacker-shaped pointer in the guest's interrupt context. No guest privileges or user interaction are required; the backend triggers it by writing the shared used ring and raising the queue interrupt.

The result is an arbitrary / attacker-influenced function-pointer call in the Zephyr guest, i.e. a control-flow-hijack primitive that can lead to code execution or, at minimum, a reliable crash. The fix rejects any used-ring id `>= vq->num` before indexing `recv_cbs[]`/`desc[]` or invoking the callback. This affects builds using `CONFIG_VIRTIO` with the PCI or MMIO transport.

CVE 2026-13213

Bluetooth HAS: NULL-pointer dereference DoS when a bonded peer reconnects before bt_has_register

The Hearing Access Service (HAS) GATT server in `subsys/bluetooth/audio/has.c` installs a connection-callback set unconditionally via `BT_CONN_CB_DEFINE`, so `security_changed()` runs for every connection that establishes security even before

the application has called `bt_has_register()`. The service attribute pointers `hearing_aid_features_attr`, `preset_control_point_attr`, and `active_preset_index_attr` remain `NULL` until `bt_has_register()` resolves them and sets `has.registered`.

With `CONFIG_BT_SETTINGS`, `settings_set_cb()` restores each bonded client's persisted context at boot and unconditionally sets `context->flags` to `BONDED_CLIENT_INIT_FLAGS` (non-zero). When a previously bonded peer reconnects and re-establishes security during the startup window before `bt_has_register()` has been called, `security_changed()` sees the non-zero flags and schedules `notify_work_handler`, which calls `bt_gatt_is_subscribed()` with a still-`NULL` attribute pointer. That triggers an assertion (`__ASSERT(attr, ...)` in `bt_gatt_is_subscribed()`), or a NULL dereference of `attr->uuid` when assertions are compiled out.

The result is a remotely triggerable (Bluetooth, adjacent) crash of the HAS peripheral. Exploitation requires the peer to have previously bonded with the device and to reconnect within the boot-time race window before the application registers the service; a peer that reconnects persistently can prolong the outage. Impact is denial of service only, with no memory corruption or information disclosure.

The fix adds an early `if (!has.registered) { return; }` guard in `security_changed()`, so no notification work is scheduled until the GATT service is registered and its attribute pointers are valid.

CVE 2026-13214

Stack buffer overflow in OCPP GetConfiguration key parsing

The OCPP 1.6 client in `subsys/net/lib/ocpp/ocpp_j.c` contains a stack buffer overflow in `parse_getconfig_msg()`. When handling a `GetConfiguration` request from the central system, the handler copied the attacker-controlled JSON `"key"` string into the caller's fixed 50-byte stack buffer (`skey[CISTR50]`, declared in `subsys/net/lib/ocpp/ocpp.c`) using an unbounded `strcpy()`. The parsed key value points directly into the receive buffer, so its length is bounded only by the message size (`CONFIG_OCPP_RECV_BUFFER_SIZE`, default 2048).

The `GetConfiguration` message is delivered over the WebSocket connection that the charge point opens to its configured central system. The reader thread `ocpp_wsreader()` reads the message into `ui->recv_buf` and dispatches it to `parse_getconfig_msg()` via the PDU function table. An attacker who controls the central system endpoint, or a man-in-the-middle on an unencrypted connection, can send a `GetConfiguration` request whose `"key"` field exceeds 50 bytes and overflow the reader thread's stack with attacker-chosen bytes.

The consequence is a remotely triggerable stack smash on the OCPP reader thread: at minimum a denial of service, and plausibly remote code execution depending on build-time hardening such as stack canaries and MPU configuration. The fix replaces the `strcpy()` with a bounded `strncpy(key, payload.key[0], CISTR50 - 1)` followed by explicit NUL termination, matching the bounded copies already used by the sibling handlers.

CVE 2026-13215

Zephyr ext2 mount: unvalidated superblock block size causes out-of-bounds write from a crafted filesystem image

The Zephyr ext2 filesystem driver fails to validate the `s_log_block_size` field of the on-disk superblock when mounting a filesystem. `ext2_verify_disk_superblock()` in `subsys/fs/ext2/ext2_impl.c` checks the magic number, revision, inode size and group counts, but never bounds `s_log_block_size`. On a successful verify, `subsys/fs/ext2/ext2_ops.c` computes `fs->block_size = 1024 << superblock.s_log_block_size` from this attacker-controlled `uint32_t`, so a crafted value either overflows the shift (undefined behaviour) or yields a block size far larger than `CONFIG_EXT2_MAX_BLOCK_SIZE`.

That block size is then passed to `k_mem_slab_init()` by `ext2_init_blocks_slab()` to carve `CONFIG_EXT2_MAX_BLOCK_COUNT` blocks out of the fixed static buffer `__ext2_block_memory_buffer`, whose size is `CONFIG_EXT2_MAX_BLOCK_COUNT * CONFIG_EXT2_MAX_BLOCK_SIZE`. `k_mem_slab_init()` does not verify that the requested blocks fit the buffer, and the ext2 wrapper discards its return value, so the slab is laid out past the end of the static buffer. The mount immediately reads block-group, bitmap and inode blocks of `fs->block_size` bytes each into these slab blocks, producing an out-of-bounds write into adjacent static memory on the first block read.

The entire path is gated only by data read from the mounted image, making this reachable by any attacker who can present a crafted ext2 image to a device that mounts it (for example a removable SD card or storage medium). Because the ext2 driver runs in kernel mode, supplying image bytes yields a supervisor-mode memory-corruption primitive, with impact ranging from denial of service to potential code execution.

The fix rejects `s_log_block_size` values that overflow the shift (greater than 11) or that produce a block size exceeding `CONFIG_EXT2_MAX_BLOCK_SIZE`, so the block slab can no longer be initialized larger than its backing buffer.

CVE 2026-13216

Out-of-bounds stack write in Zephyr virtio PCI driver from unvalidated device-supplied capability length

The virtio PCI driver (`drivers/virtio/virtio_pci.c`) parses a device's PCI capability list during driver initialization. In `virtio_pci_read_cap()` the device-supplied capability length byte `cap_len` (read from PCI config space via `pcie_conf_read()`) was only checked with `assert(tmp.cap_len == cap_struct_size)`. That `assert` resolves to `__ASSERT_NO_MSG()`, gated by `CONFIG_ASSERT`, which defaults off in production builds, so the value reached the copy logic completely unvalidated.

The length then drives a loop that copies extra capability dwords into a fixed-size stack buffer supplied by the caller. A `cap_len` below the 24-byte base `struct virtio_pci_cap` underflows the unsigned `extra_data_words` count to a near-`SIZE_MAX` value, producing an effectively unbounded stack write; a `cap_len` above the caller's buffer (up to 255) writes up to roughly 228 bytes of device-controlled data past the buffer. Both are out-of-bounds writes of attacker-controlled content executed in kernel mode during boot-time device probe.

The input originates from the virtio device. In the common deployment where Zephyr runs as a guest under a hypervisor, the device backend is the host, which already fully outranks the guest,

so the bug yields no privilege escalation. The exploitable case is a virtio device that is untrusted relative to the Zephyr kernel — an untrusted or physical/passthrough virtio PCIe device on a bare-metal system, or a confidential-computing posture where the guest must defend against the host — where a malicious device can corrupt the kernel stack and potentially achieve code execution or a crash.

The fix replaces the compiled-out assert with a runtime range check rejecting `cap_len` outside `[sizeof(struct virtio_pci_cap), cap_struct_size]` before any arithmetic or copy.

CVE 2026-13217

NULL-pointer dereference in Zephyr OCPP CALLRESULT parsing via unchecked strtok_r/atoi

The OCPP 1.6 client in `subsys/net/lib/ocpp/ocpp.c` reconstructs a session handle and PDU id from the `uid` field of a CALLRESULT message. In `ocpp_process_server_msg()` the code calls `atoi(strtok_r(uid, "-", &tmp))` without checking the `strtok_r` return value. When the server-supplied `uid` is empty or contains no `-` delimiter, `strtok_r()` returns `NULL` and `atoi(NULL)` dereferences a NULL pointer, which is undefined behaviour.

The `uid` originates from network data: `parse_rpc_msg()` in `subsys/net/lib/ocpp/ocpp_j.c` JSON-parses a frame received from the OCPP central system over TCP/WebSocket and copies the server-controlled string into the local buffer. A malicious or compromised central system, or a man-in-the-middle on a non-TLS `ws://` connection, can return a malformed `uid` to reach the defect. No authentication beyond the existing server connection (or MITM position) is required, and the reconstructed pointer is membership-validated by `ocpp_session_is_valid()`, so the impact is limited to the NULL dereference rather than arbitrary pointer use.

On Zephyr targets that trap access to address 0 (MMU/MPU platforms or `CONFIG_NULL_POINTER_EXCEPTION_DETECTION`), the dereference faults inside the OCPP reader thread and invokes the fatal handler, producing a remote denial of service of the charge point; on bare targets where address 0 is readable the call returns 0 and is benign, so the impact is availability-only and platform-conditional.

The applied fix guards only the first `atoi()`; the second `strtok_r(NULL, "-", &tmp)` followed by `pdu = atoi(buf)` in the same function remains unguarded and the identical NULL dereference is still reachable from the same network input when the `uid` has a first token but no second `-`-delimited token. A complete fix should validate the second token as well.

CVE 2026-13343

Uninitialised stack memory disclosure in the MIDI 2.0 UMP Stream responder

The UMP Stream responder library in `lib/midi2/ump_stream_responder.c` builds reply packets in a 16-byte `struct midi_ump` (`uint32_t data[4]`). The builders `make_endpoint_info()` and `make_function_block_info()` populate only the first two words (`res.data[0]` and `res.data[1]`)

and, before this fix, declared their result as an uninitialised local (`struct midi_ump res;`). The remaining two words (`res.data[2]`, `res.data[3]`) retain stale stack contents.

Endpoint Info and Function Block Info notifications are UMP Stream messages (`UMP_MT_UMP_STREAM`), which are 4 words long, so the full 16-byte packet — including the two uninitialised words — is transmitted verbatim by `cfg->send()`. The responder is driven by attacker-supplied UMP Stream Endpoint-Discovery / Function-Block-Discovery requests via `ump_stream_respond()`. In the in-tree Network MIDI 2.0 server (`subsys/net/lib/midi2/netmidi2.c`) these requests arrive as UDP datagrams and, with the default no-authentication endpoint, a remote peer can establish a session and trigger the responses; the same library also serves USB MIDI 2.0 hosts.

Each discovery request causes the device to disclose 8 bytes of its own uninitialised stack memory to the peer, and the request is freely repeatable. This is a confidentiality-only information leak (root cause is use of an uninitialised variable, CWE-457/CWE-908); the leaked words could include residual data or pointer values. There is no memory-corruption, integrity, or availability impact.

The fix zero-initialises both result structs (`struct midi_ump res = {0};`), so the trailing words are cleared before transmission. These are the only two responder builders that left trailing words unset (`send_string()` already zeroes its buffer), so the leak is fully closed.

CVE 2026-13351

net: Maliciously fragmented IPv6 packets can prevent receiving/processing future incoming packets

The Zephyr network stack can be prevented from receiving or processing future incoming packets by sending a few maliciously fragmented IPv6 packets. When `net_ipv6_handle_fragment_hdr()` triggers an ICMPv6 error response for a malformed fragment, it returns `NET_OK` without unreferencing the packet, leaking the RX network packet buffer. Each call to `k_mem_slab_alloc()` lacks a counterpart `k_mem_slab_free()`, so replaying such a packet a few times exhausts the RX buffer slab, after which the driver repeatedly fails to obtain RX buffers, resulting in a denial of service.

CVE 2026-13478

Out-of-bounds read in Zephyr ext2 block-bitmap validation from a crafted s_blocks_count

The Zephyr ext2 filesystem driver validates the on-disk block bitmap in `ext2_init_fs()` (`subsys/fs/ext2/ext2_impl.c`) by passing `fs_blocks = s_blocks_count - s_first_data_block` to `ext2_bitmap_count_set()`. That helper (`subsys/fs/ext2/ext2_bitmap.c`) treats its argument as a number of bits and reads one bitmap byte per eight bits, but the bitmap

buffer (BGROUP_BLOCK_BITMAP) is a single fetched block of only fs->block_size bytes (capacity fs->block_size * 8 bits). s_blocks_count and s_first_data_block are taken verbatim from the superblock and were never bounded against this single-group capacity; ext2_verify_disk_superblock() checks the magic, revision, and block-size shift but not the block count.

A crafted ext2 image with an oversized s_blocks_count (up to ~4 billion, against a maximum 4096-byte block / 32768-bit bitmap) makes ext2_bitmap_count_set() scan roughly 512 MB of memory past the bitmap block — a large out-of-bounds read of the static block slab and adjacent memory.

The defect is reached during mount: ext2_init_fs() is invoked from ext2_mount() (subsys/fs/ext2/ext2_ops.c), the registered .mount operation. Any path that mounts an attacker-supplied ext2 image (removable media, a disk/flash partition, or a downloaded image) triggers it. The kernel-privileged parser operates on attacker-controlled data, so the bug is exploitable wherever untrusted ext2 media can be mounted.

Impact is an out-of-bounds read only: the resulting bit count is compared internally and the mount is rejected, so no attacker-controlled bytes are returned (not a useful information leak). The ~512 MB over-read will almost certainly cross an unmapped or MPU-protected boundary and fault, crashing the system — a denial of service triggered by mounting a single malformed image. The fix rejects any image whose fs_blocks exceeds fs->block_size * 8 before the scan.

CVE 2026-13479

Out-of-bounds read in LoRaWAN clock-sync AppTimeAns downlink handler

The LoRaWAN application-layer clock-synchronization service parses downlinks in clock_sync_package_callback() (subsys/lorawan/services/clock_sync.c). Its command loop only guarantees that the one-byte command id is in bounds; for the CLOCK_SYNC_CMD_APP_TIME (AppTimeAns) command the handler then reads a 4-byte time correction via sys_get_le32() plus a 1-byte token without checking that 5 bytes remain in the receive buffer (len - rx_pos). A short or crafted AppTimeAns therefore reads up to 5 bytes past the end of the decrypted payload.

The payload (rx_buf/len) is the decrypted application frame delivered to the registered downlink callback (mcps_indication->Buffer/BufferSize). Reaching the handler requires a frame on the clock-sync port that passes LoRaWAN's MAC integrity check and FRMPayload decryption, so the practical attacker is a malicious or compromised network/application server (the designated sender of AppTimeAns) or a party holding the session keys, rather than an arbitrary radio listener.

The over-read is bounded: the backing store is a fixed 255-byte static buffer, so the few stray bytes do not fault, and the read values (time_correction, token) are used only internally and never transmitted, so there is no disclosure to the attacker and no crash. The sole effect is that a stale token matching ctx.req_token can apply a garbage time_correction to the device's own clock offset (ctx.time_offset), a minor integrity impact confined to the victim's time estimate. The fix adds an explicit length check that drops a too-short AppTimeAns. Note the sibling one-byte reads in the periodicity and force-resync handlers remain unguarded with the same negligible impact.

CVE 2026-13480

Out-of-bounds read in LoRaWAN fragmented data block transport (FUOTA) downlink handler

The LoRaWAN TS004 Fragmented Data Block Transport handler `frag_transport_package_callback()` in `subsys/lorawan/services/frag_transport.c` parses downlink command bytes without validating that enough payload bytes remain before each access. The loop's only bound is `rx_pos < len`; after consuming the one-byte command id the handler cast `rx_buf + rx_pos` to a 10-byte `struct frag_transport_setup_req`, and for a `DATA_FRAGMENT` command passed `&rx_buf[rx_pos]` to the fragment decoder, which reads exactly `ctx.frag_size` bytes — with no remaining-length check in either case.

The fragment size is attacker-chosen in a preceding `FRAG_SESSION_SETUP` command (`ctx.frag_size = req->frag_size`, capped at `CONFIG_LORAWAN_FRAG_TRANSPORT_MAX_FRAG_SIZE`, default 232). `rx_buf` aliases the 255-byte static `MacCtx.RxPayload` buffer in the loramac-node MAC layer, while `len` is the actual decrypted payload length. By padding a downlink with mismatched-index `DATA_FRAGMENT` filler commands (each advancing `rx_pos` by three bytes without producing an answer) and appending one matching-index fragment near the end of the payload, an attacker can make the decoder read up to roughly `frag_size` bytes past the end of `RxPayload`, copying adjacent static memory into the decoder buffers and the FUOTA flash image.

The handler runs only on downlinks that have already passed the LoRaWAN frame MIC and FRMPayload decryption, so the defect is reachable only by a party holding the device's session keys (the FUOTA server or an attacker who has compromised those keys). The out-of-bounds bytes are never returned to the sender — the only uplink emitted is a status answer carrying fragment counts — so there is no direct disclosure channel, and on typical flat-memory LoRaWAN MCUs the over-read stays within mapped memory, making a crash unlikely. The impact is therefore a bounded out-of-bounds read with limited confidentiality consequence and no write or control-flow primitive. The fix adds remaining-length guards before each access.

CVE 2026-13481

Out-of-bounds read in PTP management TLV TIME parsing in Zephyr net PTP

The IEEE 1588 PTP management-message parser in `subsys/net/lib/ptp/tlv.c` mishandles the `PTP_MGMT_TIME` management id. In `tlv_mgmt_post_recv()`, the `PTP_MGMT_TIME` case casts `mgmt_tlv->data` to a 10-byte `struct ptp_timestamp` and reads it (then byte-swaps and writes it back) without first checking that the TLV data field is at least `sizeof(struct ptp_timestamp)`. Every sibling management id in the same switch validates its length first; `PTP_MGMT_TIME` was the only case lacking that check.

The length passed in is the management data size (`tlv->length - 2`), and the upstream guard in `ptp_tlv_post_recv()` only requires `tlv->length > 2`, while `msg_tlv_post_recv()` validates only that the TLV fits within the received byte count, not a per-id minimum. A peer on the local PTP segment can therefore send a `PTP_MSG_MANAGEMENT` message carrying a short `PTP_MGMT_TIME`

TLV (data as small as 2 bytes), causing the parser to read and write 8 bytes beyond the validated data. The message type and TLV contents are taken straight off the wire, so the path is reachable by any adjacent attacker when `CONFIG_PTP` is enabled.

The over-read and write-back stay within the `struct ptp_msg` allocation (`mgmt_tlv->data` lives in the leading `mtu[NET_ETH_MTU]` union member, so `data + 10` lands at most a few bytes past `mtu[]`, inside the same object), so this is an out-of-bounds read of adjacent in-object memory plus a bounded in-place corruption of the message's parsed timestamp, not past-allocation memory corruption. Impact is limited to minor information exposure of adjacent bytes and corruption of the device's parsed management TIME value; there is no crash on the access and no reachable reference-count corruption.

The fix adds `if (length < sizeof(struct ptp_timestamp)) { return -EBADMSG; }` before the cast, matching the other management-id cases and fully closing the receive-path defect.

CVE 2026-13734

Zephyr WireGuard mutates peer state before anti-replay check, enabling capture-replay endpoint hijack

Zephyr's WireGuard VPN data-plane receive handler `wg_process_data_message()` in `subsys/net/lib/wireguard/wg_crypto.c` validated the anti-replay counter too late. After AEAD decryption of a `MESSAGE_TRANSPORT_DATA` packet succeeded, the code committed several peer-state changes — `update_peer_addr()` (endpoint roaming update), the `keypair->last_rx`/`peer->last_rx` liveness timers, and `keypair_update()` (promote `next`→`current` and destroy the previous keypair) — and only afterward called `wg_check_replay()`. On a replayed packet the replay check returned `-EINVAL`, but none of the preceding mutations were rolled back.

The AEAD tag authenticates content but not freshness, so a replayed-but-authentic transport packet decrypts correctly. An attacker who captures one valid ciphertext off the wire (an on-path or shared-medium observer) can re-inject it from an arbitrary spoofed source address. Reaching the handler requires no credentials: it is driven directly from inbound UDP datagrams via the dispatch in `subsys/net/lib/wireguard/wg.c`.

Because the state mutations committed before the replay check, the replay repoints the peer endpoint to the attacker-chosen source address (roaming hijack), redirecting the victim's subsequent outbound tunnel traffic until the legitimate peer's next packet re-corrects it; it also prematurely destroys the previous keypair and refreshes the RX liveness timer. The tunnel payload stays encrypted under the session keypair, so this is an integrity/availability impact (traffic redirection and session disruption), not payload disclosure. The fix moves `wg_check_replay()` to immediately after a successful decrypt, before any peer-state mutation, matching the WireGuard specification and the Linux reference implementation.

CVE 2026-13735

WireGuard keepalive transport-data messages accepted without Poly1305 authentication

Zephyr's WireGuard implementation in `subsys/net/lib/wireguard/wg_crypto.c` mishandled keepalive packets. In `wg_process_data_message()`, any type-4 transport-data message whose payload was exactly 16 bytes (an empty plaintext plus a bare Poly1305 tag, i.e. a keepalive) was accepted and returned immediately, before `wg_decrypt_packet()` was ever called. The Poly1305 authentication tag was therefore never verified; the only preceding gates were a cleartext receiver-index lookup (`get_peer_keypair_for_index()` on the attacker-supplied `data_hdr->receiver`) and a non-cryptographic keypair validity/expiry check.

The path is reachable entirely from the network: inbound UDP on the WireGuard port is dispatched by `wg_input()` to `handle_transport_data()` and then `wg_process_data_message()`. The 32-bit receiver index is transmitted in cleartext in WireGuard handshake and data messages, so an on-path observer learns it directly and an off-path attacker can brute-force it against the UDP port. Given an active receiving-valid session for that index, an attacker could send a 16-byte garbage payload and have it accepted without possessing the session key.

On acceptance the unauthenticated message caused the management layer to observe a spoofed `NET_EVENT_VPN_CONNECTED` signal (setting `peer->first_valid` and notifying any `net_mgmt` listener) and incremented the keepalive-RX statistic. The impact is limited to integrity of this status signal: no plaintext is decrypted or injected, no key is disclosed, and the early-return path did not update the peer endpoint or liveness timers, so there is no traffic-injection, session-takeover, or availability consequence.

The fix removes the pre-decrypt early return so a 16-byte payload flows through `wg_decrypt_packet()`, which verifies the Poly1305 tag over the empty plaintext, followed by the existing anti-replay check; only an authenticated, non-replayed message is then recognised as a keepalive. Forged keepalives now fail the tag check and are counted as decrypt failures.

CVE 2026-14366

SiWx91x WiFi driver double-unref / use-after-free of caller-owned TX net_pkt

The Silicon Labs SiWx917 WiFi driver's transmit callback `siwx91x_send()` in `drivers/wifi/siwx91x/siwx91x_wifi.c` frees a network packet it does not own. In the Zephyr TX path the `net_pkt` is owned by the L2/networking stack; the driver only borrows it to copy the frame bytes into a local `net_buf`. Before the fix, after transmitting, `siwx91x_send()` additionally called `net_pkt_unref(pkt)` on the caller-owned packet, dropping its last reference and returning it to the shared packet pool prematurely. This code path is compiled in by default (`CONFIG_WIFI_SILABS_SIWX91X_NET_STACK_NATIVE`).

The caller, `ethernet_send()` in `subsys/net/l2/ethernet/ethernet.c`, keeps using the packet after the driver returns: it reads `net_pkt_get_len(pkt)`, updates TX statistics, and then performs its own `net_pkt_unref(pkt)`. Because the driver already released the packet, these are use-after-free reads followed by a second unref (a double free). When concurrent network activity recycles the freed slab slot between the two unrefs, the trailing unref decrements a different, live packet's reference count and frees it, corrupting the `net_pkt` pool shared by both the receive and transmit paths.

The defect is exercised by ordinary transmission over the native-stack SiWx917 WiFi interface, and an adjacent attacker on the same WiFi network can induce transmissions (for example ARP or ICMP echo replies, or TCP handshakes) to drive the path. The primary observable impact is loss of availability (transmit hangs and crashes from pool corruption), with race-

dependent memory corruption of the kernel networking buffer pool. The fix removes the erroneous `net_pkt_unref(pkt)` from `siwx91x_send()`; the driver's receive-path unref, which correctly frees a packet the driver itself allocated, is unaffected.

CVE 2026-14367

I3C IBI work-node free-list data race between ISR and workqueue thread

The I3C IBI subsystem in `drivers/i3c/i3c_ibi_workq.c` hands out statically-allocated work nodes through a free-list `i3c_ibi_work_nodes_free` implemented as a plain `sys_slist_t`, which provides no synchronization. The allocation helpers (`i3c_ibi_work_enqueue`, `i3c_ibi_work_enqueue_target_irq`, `i3c_ibi_work_enqueue_hotjoin`, `i3c_ibi_work_enqueue_controller_request`, `i3c_ibi_work_enqueue_cb`) called `sys_slist_get()` directly from **ISR context**, while the workqueue handler `i3c_ibi_work_handler()` returned nodes with `sys_slist_append()` from the **workqueue thread**, with no lock on either side.

Because `sys_slist_get()` and `sys_slist_append()` are neither atomic nor interrupt-safe, an IBI interrupt that fires while the workqueue thread is mid-append (or a truly parallel access under `CONFIG_SMP`) races on the shared list. This corrupts the list linkage: a node may be handed to two consumers, a node may be lost, or the head/tail pointers may be left inconsistent so `sys_slist_get()` returns a stale or garbage pointer. In the double-hand-out case the subsequent `memcpy(ibi_node, ibi_work, sizeof(*ibi_node))` overwrites a node still in flight; a garbage pointer turns the same `memcpy` into an out-of-bounds write.

The race is driven by I3C bus traffic — IBIs, hot-joins, and controller-role requests originate from target devices on the bus, and I3C supports hot-joining devices. An attacker controlling an I3C peripheral on the board's chip-to-chip bus can generate high-frequency interrupts timed to collide with the free operation. Exploitation requires physical access to the bus and winning a narrow timing window; the most realistic impact is a crash or hang (denial of service), with memory corruption possible but hard to control.

The fix wraps all free-list `sys_slist_get()`/`sys_slist_append()` operations in the new `ibi_work_alloc()`/`ibi_work_free()` helpers, each guarded by a `k_spinlock` (`ibi_work_lock`), closing the race across ISR and thread contexts.

CVE 2026-14368

Off-by-one out-of-bounds NUL write in Zephyr LwM2M JSON string parser

The LwM2M JSON content formatter's `get_string()` in `subsys/net/lib/lwm2m/lwm2m_rw_json.c` copies a parsed JSON string into a caller-supplied buffer and NUL-terminates it. The length guard used `if (string_length > buflen)`, which accepts a string whose length is exactly `buflen`.

After `memcpy()` fills the whole buffer, `buf[string_length] = '\0'` then writes one byte past the end of the buffer (CWE-787).

The string value and its length are taken directly from the incoming CoAP payload during a LwM2M WRITE: `do_write_op_json()` parses the payload obtained from `coap_packet_get_payload()`, and `get_string()` is invoked from `lwm2m_write_handler()` (`engine_get_string()` in `subsys/net/lib/lwm2m/lwm2m_message_handling.c`) for a `LWM2M_RES_TYPE_STRING` resource. The destination `buf`/`buflen` is either the resource instance's fixed data buffer (`res_inst->data_ptr`/`max_data_len`) or the engine validation buffer (`msg->ctx->validate_buf`). A LwM2M server (the client's DTLS peer) can therefore write a string resource with a value whose length equals the target buffer size and force a one-byte overflow.

The overflow is a single out-of-bounds write of the constant byte `0x00` immediately past the resource or validation buffer, corrupting the adjacent byte in memory. It is not an information leak and the written value is fixed, so it is not a direct code-execution primitive, but it can corrupt adjacent state (an adjacent resource value, a length/flag field, or a struct field) and cause data corruption or a crash. Triggering the write is deterministic; the resulting impact depends on memory layout.

The fix changes the guard to `string_length >= buflen`, rejecting the exact-length case and aligning the JSON formatter with the other content formatters (`lwm2m_rw_plain_text.c`, `lwm2m_rw_oma_tlv.c`, `lwm2m_rw_senml_json.c`, `lwm2m_rw_cbor.c`, `lwm2m_rw_senml_cbor.c`), which already used the correct boundary check.

CVE 2026-14696

Ethernet bridge RX packet leak enables denial of service via RX buffer-pool exhaustion

When Ethernet bridging is enabled (`CONFIG_NET_ETHERNET_BRIDGE`), `eth_bridge_input_process()` in `subsys/net/l2/ethernet/bridge/bridge_input.c` decides how each frame received on a bridge member interface is handled. For frames that must also be delivered to the local stack, the code called `eth_bridge_handle_locally()` and returned `NET_OK`. That helper does not consume the packet — it only calls `bridge_iface_recv()` (via `virtual_recv()`), which returns `NET_CONTINUE` without taking ownership of `pkt`.

The `NET_OK` verdict then propagates through `ethernet_recv()` up to `processing_data()` in `subsys/net/ip/net_core.c`, where `NET_OK` is interpreted as "the packet was consumed, do not free it." Because no consumer actually took ownership, the RX `net_pkt` is never returned to the pool and is leaked. The concretely reproducible leak occurs for frames whose EtherType has no registered L3 handler when `CONFIG_NET_ETHERNET_FORWARD_UNRECOGNISED_ETHERTYPE` is set (default y when `CONFIG_NET_SOCKETS_PACKET` is enabled): the fall-through L3 dispatch does not overwrite the `NET_OK` verdict, so `ethernet_recv()` returns `NET_OK` and the buffer is never released.

Any device on a bridged L2 segment can emit broadcast/multicast frames carrying an arbitrary EtherType with no authentication. Each such frame permanently consumes one buffer from the finite RX pool (`CONFIG_NET_PKT_RX_COUNT`), so a brief broadcast flood exhausts the pool and the device can no longer receive traffic until it is rebooted — a persistent denial of service. There is no confidentiality or integrity impact.

The fix makes `eth_bridge_handle_locally()` propagate the real `net_verdict` and return `NET_CONTINUE` for locally-kept frames, writing the bridge interface back through a new `dst_iface` out-parameter so the packet follows the normal receive path and is unreferenced exactly once.

CVE 2026-14697

IPv6 Neighbor Solicitation packet leak causes TX pool exhaustion denial of service

`net_ipv6_send_ns()` in `subsys/net/ip/ipv6_nbr.c` allocates a transmit `net_pkt` for a Neighbor Solicitation. When it is called with a data packet pending on an unresolved neighbor and that neighbor's `pending_queue` is already non-empty (an NS is already outstanding), the function appends the data packet and returns early without ever sending the NS via `net_send_data()` or releasing it with `net_pkt_unref()`. The freshly allocated NS `net_pkt` and its attached TX buffers are held only by a local variable and are leaked permanently, never returning to `CONFIG_NET_PKT_TX_COUNT` / `CONFIG_NET_BUF_TX_COUNT`.

The leaking branch sits on the normal IPv6 transmit path: `net_ipv6_prepare_for_send()` (called from `net_if.c`) invokes `net_ipv6_send_ns()` for any outbound or forwarded IPv6 packet whose next hop is not yet in the neighbor cache. An on-link (adjacent) attacker can drive it deterministically by sending a burst of request packets (for example ICMPv6 echo requests or UDP datagrams) that all spoof a single non-existent on-link source address: the node generates a reply to each, the first reply queues an NS, and every subsequent reply during the roughly three-second `INCOMPLETE` resolution window takes the leaking branch and loses one TX packet. Router-configured nodes forwarding attacker traffic toward a non-existent on-link host leak identically.

Because the leaked packets are never reclaimed and `CONFIG_NET_PKT_TX_COUNT` defaults to only 4 (14 for Ethernet), a brief low-rate burst exhausts the TX pool. Once exhausted the node can no longer allocate any transmit packet and cannot send TCP/UDP, ARP/ND, or any reply at all, producing a complete and persistent network denial of service that does not self-heal until reboot. The fix releases the unsent NS packet with `net_pkt_unref(pkt)` before the early return.

CVE 2026-14986

Under embargo until 2026-09-04

CVE 2026-15460

Missing channel-state validation in Zephyr Bluetooth Classic L2CAP receive path

The Bluetooth Classic (BR/EDR) L2CAP receive handler `bt_l2cap_br_recv()` in `subsys/bluetooth/host/classic/l2cap_br.c` dispatched inbound data PDUs based only on the destination channel ID, without checking that the target channel had reached the `BT_L2CAP_CONNECTED` state. A dynamic channel is assigned its RX CID and added to the connection's channel list while still in `BT_L2CAP_CONNECTING` (and later `BT_L2CAP_CONFIG`) — before configuration completes and, for PSMs that require security, before the peer is authenticated (`l2cap_br_conn_req()`).

Because the channel is already findable by `bt_l2cap_br_lookup_rx_cid()` during this window, a remote peer within radio range can send a data PDU addressed to that CID and have it processed on a not-yet-established channel. The dispatch keys off channel fields (`BR_CHAN(chan)->rx.mode`, `rx.mps`) that are only initialized during configuration by `l2cap_br_conf()`; since channel objects are pooled and `bt_l2cap_br_chan_del()` does not reset `rx.mode` or the reassembly buffer `_sdu`, a reused channel can carry stale state into the `CONNECTING` window and route the frame into the retransmission/flow-control path (`bt_l2cap_br_ret_fc_recv()`) with stale parameters and a possibly stale `_sdu` pointer.

The impact is delivery of attacker data to upper-layer protocol handlers on a half-open (and possibly unauthenticated) channel, plus operation on stale or partially initialized channel state on reused channel objects — leading to channel/link teardown (denial of service) and, in the stale-`_sdu` case, a dangling-pointer condition. The fix adds an explicit `BR_CHAN(chan)->state < BT_L2CAP_CONNECTED` guard that drops any data received before the channel is fully connected.

CVE 2026-15461

Type confusion in Zephyr HL78xx GNSS NMEA driver causes wild-pointer write from GNSS input

The Sierra Wireless HL78xx modem GNSS driver (`drivers/modem/hl78xx/`, later `drivers/modem/vendor_standalone/hl78xx/`) embeds a generic `struct gnss_nmea0183_match_data match_data` inside `struct hl78xx_gnss_data`. The generic NMEA0183 match helper (`drivers/gnss/gnss_nmea0183_match.c`) requires that context to be the *first* member because its callbacks cast `user_data` directly to `struct gnss_nmea0183_match_data *`. In the affected releases `match_data` was the second member (after `const struct device *dev`), so it sat at a non-zero offset while `gnss_nmea0183_match_init()` initialized it at the correct address. The registered NMEA handlers instead pass the whole device data object (`data->devices.gnss->data`, offset 0), producing an offset-shifted type confusion between where state is initialized and where the parse callbacks read and write it.

When NMEA sentences from the GNSS receiver are parsed, the GGA/RMC callbacks write parsed fix data into the wrong location within the struct, and the GSV callback (`gnss_nmea0183_match_gsv_callback`, active under `CONFIG_GNSS_SATELLITES`) reads its `satellites` pointer and bound from the wrong offsets — non-pointer bytes of `struct hl78xx_gnss_data` — and then writes parsed `struct gnss_satellite` entries through that bogus pointer. This is a write through an uninitialized/wild pointer with a garbage bound.

The NMEA handlers are registered by default (`CONFIG_HL78XX_GNSS_SOURCE_NMEA` is the default GNSS source) on devices using the HL78xx GNSS. The driver runs in kernel context and the NMEA data originates from the GNSS radio front-end, so a party able to influence the GNSS signal (for example GNSS/GPS spoofing at radio proximity) can drive the kernel-side parser into the faulty write. The most likely impact is a crash (denial of service) because the bogus pointer resolves to a fixed near-NULL value, with adjacent-memory corruption possible on MMU-less targets. Confidentiality is not affected. Exploitation requires the satellites feature to be enabled and active, so attack complexity is high.

CVE 2026-6682

Integer overflow in FatFs FAT32 volume mount (mount_volume) yields an attacker-controlled file size and out-of-bounds access in Zephyr

Zephyr bundles ChaN's FatFs (via the `zephyrproject-rtos/fatfs` west module) as the FAT/exFAT filesystem backing `subsys/fs/fat_fs.c`. In `mount_volume()` (`modules/fs/fatfs/ff.c`), the FAT area size is computed as `fasize = ld_32(BPB_FATSz32); ... fasize *= fs->n_fats;` — a 32-bit multiply with no overflow check.

A crafted FAT32 volume that sets `BPB_FATSz32 = 0x80000001` with two FATs makes the product wrap (to `0x00000002`), so the computed data region overlaps the FAT region. Because the pre-multiply value is kept in `fs->fsize`, the later plausibility check does not catch the wrap.

An attacker who can get the device to mount such a volume (a malicious SD card or USB medium) can place forged directory entries in the overlapped region, causing `f_stat()`/directory reads to return attacker-controlled file sizes; application code that reads a file using that size as a length then overflows its buffers, giving heap- or stack-based memory corruption during ordinary file operations.

This is a core FAT32 code path with no compile-time gate (FAT12/16/32 is always built), so a default Zephyr FatFs configuration is affected. Upstream FatFs is unmaintained for security purposes (the maintainer did not respond to runZero or JPCERT/CC), so Zephyr carries the fix in its vendored copy. Tracked upstream as CVE-2026-6682.

- Zephyr project bug tracker GHSA-m537-wqw2-2wrj

This has been fixed in main for v4.5.0

CVE 2026-6683

Divide-by-zero in FatFs exFAT sync (sync_fs) crashes Zephyr on a crafted exFAT volume

Zephyr's bundled FatFs (`zephyrproject-rtos/fatfs`) supports exFAT when `CONFIG_FS_FATFS_EXFAT` is enabled. In `sync_fs()` (`modules/fs/fatfs/ff.c`) the free-cluster bookkeeping divides by `(fs->n_fatent - 2)`.

The cluster count is read from the exFAT boot region as `ncl = ld_32(BPB_NumClusEx)` and is validated only against an upper bound (`> MAX_EXFAT`), never a lower bound, so a crafted exFAT volume with `BPB_NumClusEx = 0` yields `n_fatent = 2` and a divisor of zero.

Mounting such a volume and performing any write/sync triggers a divide-by-zero (SIGFPE / CPU fault), a denial of service.

The defect is present only when exFAT is compiled in, which is not the default Zephyr configuration; devices that enable exFAT and mount untrusted removable media are exposed. Upstream FatFs is unmaintained for security, so Zephyr carries the fix in its vendored copy. Tracked upstream as CVE-2026-6683.

- Zephyr project bug tracker GHSA-c5j5-mrhx-hjg4

This has been fixed in main for v4.5.0

CVE 2026-6685

Integer underflow in FatFs dirty-sector cache (f_read/f_write) causes wrong-sector I/O on crafted fragmented media in Zephyr

In FatFs's read/write path (`f_read`/`f_write` in `modules/fs/fatfs/ff.c`), the dirty-sector cache-refill decision compares `fp->sect - sect` against the run length `cc` using unsigned arithmetic. On a fragmented FAT layout where a later cluster maps to a lower absolute sector than the currently cached one, the subtraction underflows (wraps to a large unsigned value), so the guard that decides whether the cached window overlaps the requested range is evaluated incorrectly.

The result is that FatFs flushes or reuses the wrong cached sector, reading or writing file data to/from an incorrect on-disk location — cross-file data corruption and potential disclosure of unrelated file contents, and a path to out-of-bounds behaviour during ordinary file operations.

A crafted volume with a deliberately fragmented cluster chain (attacker-controlled removable media) triggers the condition. This is on the default read/write path (no exFAT or LFN gating). Upstream FatFs is unmaintained for security, so Zephyr carries the fix in its vendored copy. Tracked upstream as CVE-2026-6685.

- Zephyr project bug tracker GHSA-rg3p-32gq-hqw3

This has been fixed in main for v4.5.0

CVE 2026-6686

FatFs f_lseek past end-of-file exposes uninitialized/stale cluster contents (deleted file data) in Zephyr

In FatFs (`f_lseek` in `modules/fs/fatfs/ff.c`), seeking a file opened for write to an offset beyond its current end extends the cluster chain via `create_chain()` but does not zero the newly allocated clusters.

FatFs marks the file as larger without initializing the backing sectors, so a subsequent read of the grown region returns whatever was previously on the medium in those clusters — typically the residual contents of deleted files. On a device where a lower-privileged or later actor can read a file that was extended this way, previously deleted or unrelated file data is disclosed (CWE-908, use of uninitialized resource). No memory-safety corruption occurs; the impact is confidentiality of on-media data.

The bug is on the default write path (no exFAT/LFN gating). Upstream FatFs is unmaintained for security, so Zephyr carries the fix in its vendored copy. Tracked upstream as CVE-2026-6686.

- Zephyr project bug tracker GHSA-rjhg-f2h7-rffm

This has been fixed in main for v4.5.0

CVE 2026-6687

Stack buffer overflow in FatFs exFAT volume-label read (f_getlabel) via an unvalidated on-disk length in Zephyr

In FatFs's `f_getlabel()` (`modules/fs/fatfs/ff.c`), the exFAT volume-label copy loop is bounded by the raw on-disk byte `dj.dir[XDIR_NumLabel]` (0–255) rather than the spec maximum of 11 characters.

A crafted exFAT volume that sets `XDIR_NumLabel` to a large value (e.g. 128) makes the loop read label characters past the 32-byte directory entry and write up to that many UTF-decoded characters into the caller-supplied `label[]` buffer, overflowing a typical fixed-size label array (e.g. `char label[12]`/`label[24]`) on the stack — memory corruption with potential control-flow impact.

In Zephyr this is reachable only in downstream applications: `f_getlabel` is compiled solely with `CONFIG_FS_FATFS_EXTRA_NATIVE_API=y`, exFAT must be enabled, and no in-tree Zephyr code calls it (application code supplies the buffer). It is nonetheless a genuine defect in the vendored library, and because upstream FatFs is unmaintained for security Zephyr carries the fix (clamp the label length) in its vendored copy so opted-in applications are protected. Tracked upstream as CVE-2026-6687.

This has been fixed in main for v4.5.0

CVE 2026-15890

Under embargo until 2026-09-21

CVE 2026-15891

NULL pointer dereference in Zephyr MQTT-SN client when removing a non-responsive gateway

The MQTT-SN client keepalive handler `process_ping()` in `subsys/net/lib/mqtt_sn/mqtt_sn.c` removes the gateway record after `PINGREQ` retries are exhausted. It invoked `SYS_SLIST_PEEK_HEAD_CONTAINER(&client->gateways, gw, next)` but discarded the result. That macro is a pure expression that does not assign to `gw`, so `gw` retained its `NULL` initializer regardless of the list contents.

The code then dereferences the NULL `gw` (`gw->gw_id`) and passes it to `mqtt_sn_gw_destroy()`, reaching `k_mem_slab_free(&gateways, NULL)`. With `CONFIG_MEM_SLAB_POINTER_VALIDATE` enabled this triggers `k_panic()`; in the default configuration it performs a write through the NULL pointer (`*(char **)mem = slab->free_list;`) and corrupts the slab free list. The outcome is a crash/kernel panic or, on targets where address 0 is writable, silent memory-allocator corruption.

The vulnerable branch runs whenever the connected MQTT-SN gateway fails to answer keepalive `PINGREQ`s for the configured number of retries. This condition is controlled by the remote peer: a malicious or compromised gateway, or an on-path/adjacent attacker that advertises itself as a gateway and then stops responding (or blackholes the real gateway's `PINGRESP`s), forces the client into the defect. MQTT-SN runs over UDP and no authentication is required.

The impact is a remotely triggerable denial of service (availability) of the affected MQTT-SN client; there is no attacker-controlled data written. The sibling remover `process_advertise()` uses `SYS_SLIST_FOR_EACH_CONTAINER_SAFE` and is not affected. The fix assigns the macro's return value to `gw`.

CVE 2026-15892

Heap memory leak in mcumgr settings-management handlers on access-hook rejection leads to denial of service

The mcumgr SMP settings-management group handlers `settings_mgmt_read()`, `settings_mgmt_write()`, and `settings_mgmt_delete()` in `subsys/mgmt/mcumgr/grp/settings_mgmt/src/settings_mgmt.c` allocate a `key_name` buffer (and, for read, a `data` buffer) via `k_malloc()` when `CONFIG_MCUMGR_GRP_SETTINGS_BUFFER_TYPE_HEAP` is enabled, relying on the `end:` label to `k_free()` them. When `CONFIG_MCUMGR_GRP_SETTINGS_ACCESS_HOOK` is also enabled and the application access hook rejects a request by returning status `MGMT_CB_ERROR_RC`, the handler executed `return ret_rc;` directly, bypassing `end:` and leaking the heap allocation on every rejected request.

The settings handlers are reachable over the unauthenticated SMP transport (Bluetooth LE, UART, or UDP, depending on product configuration). The access hook is the mechanism applications use to deny unauthorized settings access, and `MGMT_CB_ERROR_RC` is a common rejection style, so an attacker who can send `settings read/write/delete` commands that the hook rejects triggers a heap leak on each attempt.

Because the leaked memory is never reclaimed until reboot, a sustained stream of rejected requests monotonically exhausts the kernel heap until `k_malloc()` fails, denying mcumgr service and impacting any other heap consumer on the device — a denial of service. The impact is availability-only; there is no memory corruption or information disclosure. Only configurations that select the heap buffer type, enable the access hook, and register a hook that returns `MGMT_CB_ERROR_RC` are affected (the default stack buffer type cannot leak).

CVE 2026-15893

Zephyr IPv6 Neighbor Discovery zero reachable time from crafted Router Advertisement causes assertion/DoS

`net_if_ipv6_calc_reachable_time()` in `subsys/net/ip/net_if.c` derives a randomized ND reachable time from `ipv6->base_reachable_time` as `min_reachable + sys_rand32_get() % (max_reachable - min_reachable)`, where `min_reachable = base/2` and `max_reachable = 3*base/2` using integer division. When `base_reachable_time` is `1`, both `min_reachable` and the modulus collapse so the function returns `0`, and `net_if_ipv6_set_reachable_time()` stores that `0` into `ipv6->reachable_time`.

The `base_reachable_time` is attacker-controlled: `handle_ra_input()` in `subsys/net/ip/ipv6_nbr.c` accepts the Reachable Time field of an incoming Router Advertisement whenever it is nonzero and `<= MAX_REACHABLE_TIME`, so a single unauthenticated, link-local RA carrying a Reachable Time of `1` drives the computed reachable time to `0`. Router Advertisements are unauthenticated by default and require only adjacency to the target link.

When a neighbor is subsequently confirmed reachable, `net_ipv6_nbr_set_reachable_timer()` reads the value and executes `NET_ASSERT(time, "Zero reachable timeout!")`. On builds with `CONFIG_ASSERT` enabled this triggers a fatal kernel assertion — a remote denial of service; on builds without assertions the reachable timer is armed with `K_MSEC(0)` and fires immediately, forcing reachable neighbors into perpetual re-solicitation (`STALE`), degrading Neighbor Discovery. The impact is limited to availability; there is no memory-safety, confidentiality, or integrity consequence.

CVE 2026-15894

Under embargo until 2026-10-07

CVE 2026-15923

Infinite loop denial of service in Zephyr SDIO byte-I/O from a card-supplied zero max_blk_size

The Zephyr SDIO subsystem function `sdio_io_rw_extended_helper()` in `subsys/sd/sdio.c` finishes transfers with a byte-I/O loop that uses `size = MIN(remaining, func->cis.max_blk_size)` as the per-iteration step. The value `func->cis.max_blk_size` is decoded directly from the SDIO card's CIS FUNCE tuple in `sdio_decode_cis()` and is not validated. When a card reports a maximum block size of zero, `size` is always `0`, `remaining` never decreases, and the loop spins forever.

The loop is reached from the public SDIO client API used by drivers, including `sdio_read_fifo()`, `sdio_write_fifo()`, and the incrementing register read/write helpers, each of which enters the

loop while holding the per-card mutex `func->card->lock`. A card advertising `max_blk_size == 0` therefore hangs the calling thread permanently on its first non-block-aligned transfer and never releases the mutex, denying service to the SDIO peripheral (and any subsystem such as Wi-Fi that depends on it) until the device is reset.

The malicious value must come from the SDIO card itself, so the defect is exploitable where a removable SDIO/combo card slot lets an attacker insert a crafted or malfunctioning card (a physical attack vector); on boards with a soldered SDIO peripheral it is not attacker-influenceable. There is no memory-safety, confidentiality, or integrity impact — only a permanent availability loss. The fix returns `-EIO` when `func->cis.max_blk_size` is zero, before the loop is entered.

CVE 2026-15924

Use-after-free / double-free from unsynchronized concurrent access to the TLS client session cache in Zephyr sockets

Zephyr's TLS socket layer in `subsys/net/lib/sockets/sockets_tls.c` keeps a single process-global array, `client_cache`, of cached client sessions that is shared by every TLS socket context. The functions that mutate and read it — `tls_session_save()`, `tls_session_get()`, `tls_session_cache_reset()`, and the settings restore handler — allocate, free, and dereference each entry's heap buffer (`entry->session`). Before the fix these accesses were serialized only by the *per-socket* context mutex `ctx->lock` (assigned per socket in `ctx_set_lock()`), which provides no mutual exclusion between different sockets touching the shared cache.

Because `CONFIG_NET_SOCKETS_TLS_MAX_CLIENT_SESSION_COUNT` defaults to `1`, any two concurrent client sockets contend for the same slot. A thread in `tls_session_get()` reading `entry->session` inside `mbedtls_ssl_session_load()` can run concurrently with another thread in `tls_session_save()` that selects the same entry for reuse and executes `mbedtls_free(entry->session)` before reallocating — a use-after-free read, and a double-free when two saves evict the same entry. Both corrupt the mbedTLS heap. The cache is reached on ordinary client paths: at connect time via `tls_session_store()`/`tls_session_restore()`, and (on `main`) whenever a TLS 1.3 session ticket arrives during `recv()`/`poll()` via `tls_session_store_current()`.

Exploitation requires an application that opts into per-socket client session caching (the `TLS_SESSION_CACHE` socket option, off by default) and runs concurrent TLS client connections on multiple threads; the timing that opens the window is influenced by the remote peer(s), so a malicious or compromised server can raise session-ticket frequency to widen it. The reliably-demonstrable impact is memory corruption leading to a crash or heap corruption (denial of service). The fix adds a dedicated `session_cache_lock` mutex taken across every accessor of `client_cache`, serializing all reads and frees and closing the race.

CVE 2026-16147

it82xx2 USB device controller submits incomplete OUT transfer buffers, causing use-after-free and event-list corruption

The ITE IT82xx2 USB device-controller driver (`drivers/usb/udc/udc_it82xx2.c`) mishandles multi-packet OUT transfers on non-control endpoints. In `work_handler_out()` the active transfer buffer is obtained with `udc_buf_peek()` (which does not dequeue it); when a full max-packet-size packet arrives but the buffer still has tailroom (the transfer is not yet complete), the pre-fix code both re-arms the endpoint to keep filling that same `buf` via `work_handler_xfer_continue()` and simultaneously hands the same, still-being-filled buffer to the upper stack with `udc_submit_ep_event()`.

Because `udc_submit_ep_event()` transfers ownership of the buffer to the USB device stack (`usbd_event_carrier()` appends `&buf->node` to `uds_ctx->ep_events`, after which the class handler processes and `net_buf_unref()`s it), the driver continues to DMA subsequent host-controlled OUT packets into a buffer the upper stack may already have freed and recycled — a use-after-free write. In addition, since the buffer was never dequeued, the completing packet runs `udc_buf_get()` on the same object and submits it a second time, appending `&buf->node` to the event slist twice (singly-linked-list corruption) and causing a double `net_buf_unref()`.

The IT82xx2 is a USB peripheral controller, so the untrusted USB host controls OUT-transfer packetization and can force this path against any non-control OUT endpoint whose queued buffer exceeds one packet — an ordinary bulk/interrupt pattern. The driver and USB device stack run in kernel context above the external host, giving the host a device-side kernel heap-corruption primitive: a reliable denial of service and, because the written bytes are attacker-controlled, plausible corruption of adjacent `net_buf` pool memory. The vector is physical (USB attach). The fix defers submission until the buffer is completely filled and lets `xfer_work_handler()` drive continuation, so each OUT buffer is submitted to the upper stack exactly once.

CVE 2026-16148

Kernel panic in the it82xx2 USB device controller driver via re-initialization of a busy delayable work item

The ITE it82xx2 USB device-controller driver initialized its bus-suspend detection work with `k_work_init_delayable(&priv->suspended_work, suspended_handler)` inside `it82xx2_enable()` (the driver's `.enable` op) in `drivers/usb/udc/udc_it82xx2.c`. This work item is scheduled essentially continuously while the USB bus is active: the interrupt handler reschedules it on every SOF frame and `suspended_handler()` reschedules itself, so its timeout node is normally linked in the kernel timeout list / a workqueue pending queue.

`k_work_init_delayable()` (`kernel/work.c`) unconditionally overwrites the entire `k_work_delayable` structure, including its timeout and queue linkage, with no busy check. Because `it82xx2_disable()` does not cancel the work, a normal disable-then-enable cycle re-runs `api->enable()` (`udc_enable()` only rejects a redundant enable, not a re-enable after disable) and re-initializes the still-pending work in place, corrupting the kernel timeout/workqueue linked lists and causing a kernel panic.

An external USB host — for example a host performing USB DFU detach (`dfu-util --detach`) or forcing repeated attach/reset/re-enumeration — drives the `udc_disable()`/`udc_enable()` transitions and controls suspend/resume timing, so it can arrange for the suspend work to be pending

across a re-enable. This yields an unauthenticated denial of service (kernel panic) reachable across the USB boundary from a removable, physically-connected host, with no confidentiality or integrity impact demonstrated.

The fix moves the `k_work_init_delayable()` call into the one-time preinit function so the work is initialized exactly once, eliminating the re-initialization of an in-use item.

CVE 2026-2411

Bluetooth GATT notify/indicate enforces the wrong attribute's permissions, bypassing encryption/authentication requirements on characteristic values

Zephyr's Bluetooth host declares a GATT characteristic as two consecutive attributes: a Characteristic Declaration whose permission is hard-coded to `BT_GATT_PERM_READ`, and a Characteristic Value attribute that carries the application-specified security permissions (e.g. `BT_GATT_PERM_READ_ENCRYPT` / `READ_AUTHEN` / `READ_LESC`). The public notify and indicate APIs explicitly accept either attribute, and passing the declaration is the documented, common idiom. Before sending each notification or indication, the host re-checks link security with `bt_gatt_check_perm()` against `params->attr` in `gatt_notify()`, `gatt_indicate()`, and `gatt_notify_multiple_verify_params()` (`subsys/bluetooth/host/gatt.c`).

When the application passed the Characteristic Declaration attribute, the host correctly redirected the value handle but left `params->attr` pointing at the declaration, so the security check evaluated the declaration's permissions (no security required) instead of the value's. As a result the encryption/authentication/LESC requirement configured on the characteristic value was skipped. The Notify-Multiple path additionally used a mask that omitted the LE Secure Connections requirement.

A remote peer triggers the disclosure by connecting (optionally without pairing or encryption) and writing the Client Characteristic Configuration descriptor to enable notifications or indications, causing the server to emit the protected value over a link that has not reached the required security level. The impact is information disclosure / access-control bypass for characteristic values the application intended to expose only over a secured link; exposure depends on the application declaring encrypt/authen-required notify/indicate characteristics and on the CCC being writable at a lower security tier. There is no memory-safety or availability impact.

The fix adds `bt_gatt_attr_resolve_value()`, which maps a declaration attribute to the following value attribute before the permission check, and switches the Notify-Multiple path to the full `BT_GATT_PERM_READ_ENCRYPT_MASK` so the LESC requirement is also enforced.

9.8 Security standards and Zephyr

Historically, organizations managed cybersecurity independently, defining their own assessment and response protocols. Today, governments are increasingly regulating this area through new mandates and security standards. These standards define specific guidelines and compliance requirements for connected products.

This section evaluates the implications of these security standards for the Zephyr project itself, as well as downstream product developers. The goal is to provide developers with the information needed to build certifiable, compliant products using Zephyr.

9.8.1 EU Cyber Resilience Act (CRA)

Warning

This document is for informational purposes only and does not constitute legal advice. Consult with your legal counsel for compliance guidance specific to your situation. You can consult European Union accredited laboratories (see List of Notified Bodies for CRA) that can help you.

Overview

The Cyber Resilience Act ([?]) is an EU regulation that establishes cybersecurity requirements for products with digital elements (PDEs) placed on the EU market. It entered into force on December 10, 2024.

Key Dates

- **June 11, 2026**: Assessment bodies operational; market surveillance authorities defined
- **September 11, 2026: Manufacturers must report actively exploited vulnerabilities and severe** incidents
- **December 11, 2027**: Full regulation applies to products placed on the market from that date, or placed on the market before that date and substantially modified afterwards.

This page explains how the CRA relates both to manufacturers using Zephyr in commercial products, and to the Zephyr Project itself in its role as an open-source software steward.

For manufacturers, the CRA imposes essential cybersecurity requirements (Annex I Part I) along with vulnerability handling and reporting obligations (Annex I Part II). For the Zephyr Project as an open-source software steward, the CRA introduces a tailored set of obligations, including maintaining a cybersecurity policy, reporting actively exploited vulnerabilities and severe incidents, and cooperating with market surveillance authorities.

For Manufacturers Using Zephyr

Does the CRA apply to my product? The CRA applies if you place a product with digital elements (PDE) on the EU market for commercial purposes. This includes hardware devices with embedded software, and standalone software products.

A product with a digital element is hardware and/or software that is connected to another device or network. The scope of the product includes the remote data processing solution (RDPS): software not part of the product but required for it to function (for example, a mobile phone app or a cloud service).

The CRA applies to end products or components that are placed on the market in the European Union. According to definition in Blue Guide and EU CRA Guidelines: A product is placed on the market when it is made available for the first time on the Union market. A product is made available on the Union market when it is supplied for distribution, consumption or use on the Union market in the course of a commercial activity, whether in return for payment or free of charge. Placing on the market is applicable to every individual unit of a product series; development or design dates are not relevant. More information about "Placing on the market" can be found in the EU CRA Guidelines. It details specific cases like standalone software, source code releases and complex products.

Several market exceptions are defined in the law (medical, automotive, avionics, military, spare parts). These exceptions have strict conditions; refer to the CRA text (Article 2).

Which category does my product belong to? The CRA classifies products into categories based on risk: **Important Products** (Annex III) and **Critical Products** (Annex IV). Products not listed in either category are considered **Default** products and have lower requirements.

For example, default products can typically rely on self-assessment (see *Which compliance path must I choose?*) with fewer documentation and assurance requirements.

Category	Short description	Example Zephyr Use Cases
Default	Products with digital elements that are not listed as "important" or "critical".	• Wi-Fi smart bulb or switch (e.g., running Matter over Thread/Wi-Fi). • Wearable activity tracker or smartwatch for personal wellness. • Bluetooth LE audio accessory or wireless sensor tag. • Temperature sensor connected to a CAN bus.
Important (Class I)	Higher-risk products, often consumer-facing, performing security- or access-relevant functions.	• Smart door lock or access control reader for residential use. • Router managing network traffic. • Connected alarm system or security sensor. • Micro-controllers with AVA_VAN.1 protection level.
Important (Class II)	Higher-risk products used in enterprise/industrial/infra contexts or with privileged network roles.	• Micro-controllers with AVA_VAN.2 or AVA_VAN.3 protection level.
Critical	Products whose compromise could severely impact critical infrastructure or essential services.	• Smart meter gateways. • Hardware Security Module (HSM) or smartcard firmware.

Core Functionality vs. Integration

Classification is determined by the **core functionality** of the final product, not by the individual components it integrates (Article 7).

- Integrating an important or critical component (e.g., a secure element, embedded browser) into another product does **not** automatically render that product important or critical.
- A product that *can* perform the functions of an important/critical category but whose core functionality is different is **not** considered to have that core functionality.

Examples:

- If you build a network firewall using Zephyr, the core function is security, making the product an Important Product (Class II).
- If you build a coffee machine using Zephyr, and you utilize Zephyr's networking stack features to protect the device, the core function remains making coffee. This is a "default" product.

In a nutshell, using security-critical Zephyr features (like cryptography or secure boot) in a device does **not** elevate that device to a higher risk class.

For detailed classification, see Annex III and Annex IV. The full list of product categories with technical descriptions is provided in Implementing Regulation (EU) 2025/2392.

Which compliance path must I choose? The CRA defines different conformity assessment procedures based on your product category. You must choose the path that corresponds to your classification and reliance on harmonized standards.

Table 1: CRA Product Categories & Assessment Routes

Category	Conformity Assessment Procedure	Notified Body involvement?
Default	Module A (Self-assessment by the manufacturer) or Module B + Module C, or Module H.	Not Mandatory for Module A.
Important Class I	Module A **ONLY IF** harmonized standards cited in the Official Journal of the European Union are fully applied. Otherwise: Module B + Module C, or Module H.	Not Mandatory for Module A.
Important Class II	Module B + Module C, or Module H. (Self-assessment is **NOT** allowed).	Yes (Mandatory)
Critical	**European Cybersecurity Certification** (e.g., EUCC) or Module B + Module C + Module H (pending delegate acts).	Yes (Mandatory)

The "Modules" refer to specific assessment procedures defined in Decision No 768/2008/EC ("New Legislative Framework") and adapted by the CRA in Annex VIII:

- Module A (Internal production control): You create the technical documentation, perform the risk assessment, and declare conformity yourself. No external auditor is required.
- Module B (EC-type examination) + Module C (Conformity to type): A Notified Body[1] examines the technical design (Module B) and issues a certificate. You then ensure production conforms to that type (Module C).
- Module H (Full Quality Assurance): A Notified Body[1] audits your Quality Management System (QMS) governing design, production, and testing.

[1] Notified Bodies will become operational by **June 11, 2026**.

What are my main obligations as a manufacturer? The CRA defines manufacturer obligations primarily in Article 13 (product requirements and due diligence) and Article 14 (vulnerability handling and reporting). Regardless of a product's classification, the following core obligations apply to all manufacturers of products with digital elements.

Risk assessment
: Assess and document cybersecurity risks throughout the product lifecycle.

Due diligence
: Exercise due diligence when integrating third-party components (including open-source software like Zephyr).

Vulnerability handling
: Handle vulnerabilities when placing a product on the market. Monitor vulnerabilities during the support period (lifetime or 5 years minimum). Vulnerability handling means identifying hardware and software vulnerabilities (for example, via an SBOM), performing a risk assessment for your product, and providing a software update when the risk cannot be accepted.

Incident reporting
: Report actively exploited vulnerabilities affecting your product, as well as severe incidents affecting the project's infrastructure. This obligation continues after the end of the support period.

Technical documentation
: Create documentation per Article 31 and Annex VII.

Conformity assessment
: Assess conformity per Article 32 and Annex VIII.

CE marking
: Affix CE mark and draw up EU declaration of conformity.

What are the penalties for non-compliance?

- Up to EUR 15,000,000 or 2.5% of worldwide annual turnover (Article 13 & Article 14 violations).
- Up to EUR 10,000,000 or 2% of turnover (violations of other obligations).

What are the vulnerability reporting obligations? The CRA distinguishes between "ordinary" vulnerabilities (handled through your normal vulnerability management process) and cases that trigger strict notification timelines under Article 14: **actively exploited vulnerabilities** and **severe incidents**.

The tables below summarize the minimum reporting steps.

Table 2: Actively exploited vulnerabilities (Article 14 (1) and (2))

Step	Deadline	Content (minimum)
Early warning	Within 24 hours of becoming aware	Notify via the single reporting platform to your CSIRT coordinator and ENISA that an actively exploited vulnerability affects your product. Indicate, where known, in which Member States the product is available.
Vulnerability notification	Within 72 hours of becoming aware	Provide general information on the affected product, the general nature of the exploit and the vulnerability, corrective or mitigating measures already taken, and measures users can take. Indicate, where applicable, how sensitive you consider the notified information to be.
Final report	No later than 14 days after a corrective or mitigating measure is available	Describe the vulnerability, its severity and impact, any information on malicious actors exploiting it (if available), and details on the security update or other corrective measures made available.

Table 3: Severe incidents (Article 14 (3) through (6))

Step	Deadline	Content (minimum)
Early warning	Within 24 hours of becoming aware	Notify via the single reporting platform to your CSIRT coordinator and ENISA that a severe incident impacts the security of your product. Indicate whether it is suspected to be caused by unlawful or malicious acts and, where known, in which Member States the product is available.
Incident notification	Within 72 hours of becoming aware	Provide general information on the nature of the incident, an initial assessment (including impact/severity as known at the time), corrective or mitigating measures already taken, and measures users can take. Indicate, where applicable, how sensitive you consider the notified information to be.
Final report	Within 1 month after the incident notification	Provide a detailed description of the incident, including severity and impact, the type of threat or likely root cause, and applied and ongoing mitigation measures.

How can I obtain an SBOM (Software Bill of Materials)? Zephyr can automatically generate SBOMs for your application using the `west spdx` command.

See *Software bill of materials: west spdx* for details on how to configure and use this tool.

How should I handle Zephyr vulnerabilities? As a manufacturer integrating Zephyr into a product, you remain responsible for vulnerability management and, where applicable, CRA reporting. Zephyr provides vulnerability information, but you must assess and act on it for your own product.

A practical workflow is:

1. **Stay informed**. Register to the Zephyr Vulnerability Alert Registry to receive notifications when vulnerabilities are disclosed.
2. **Assess impact**. For each advisory, use your SBOM and configuration to determine whether the affected Zephyr component is present, reachable, and security-relevant in your product.

3. **Plan remediation**. Decide on the appropriate response (e.g., apply a patch, adjust configuration, ...).
4. **Deploy fixes**. Integrate, test, and roll out the chosen fix, and update your SBOM and product documentation as needed.
5. **Meet reporting obligations**. If the vulnerability affects your product and is actively exploited, or leads to a severe incident, report it in line with the Article 14 timelines and as per the previous section, *What are the vulnerability reporting obligations?*.

What timelines does Zephyr follow for vulnerability handling? Zephyr operates its own PSIRT process with target timelines for triage, notification, and disclosure. These are *project* timelines, not legal deadlines for manufacturers.

Your CRA reporting obligations as per Article 14 are triggered by when *you* become aware that your product is affected by an actively exploited vulnerability or a severe incident. This can be **earlier than** some of the Zephyr milestones below, meaning you might have to send an early warning or incident report even before a Zephyr fix is available or before public disclosure.

Zephyr uses private GitHub security advisories and an embargo period (at most 90 days) to coordinate fixes and disclosure. While the full process is described in *Security Vulnerability Reporting*, the key milestones are:

- **Within 7 days**: PSIRT feedback to initial reporter.
- **Within 30 days**: Manufacturers notified via alert registry and fix made available from the project.
- **Up to 90 days total**: Security-sensitive vulnerabilities are made public after embargo period.

Do I need to report vulnerabilities I find in Zephyr? **Yes**, under Article 13(6), if you discover a vulnerability in a component (including Zephyr) integrated into your product, you **must** report it. What's more, if you develop a fix for that vulnerability, you must also share the relevant code or documentation. See *Security Vulnerability Reporting*.

Additionally, consider voluntary reporting to CSIRT or ENISA per Article 15.

For Zephyr as an Open Source Steward

What is Zephyr's role under the CRA? Zephyr is an **"open-source software steward"** under Article 3 (14): a legal person that systematically provides sustained support for developing PDEs intended for commercial activities.

Zephyr's obligations under Article 24:

Cybersecurity policy
: Document security policies and vulnerability handling.

Cooperation
: Work with market surveillance authorities to mitigate risks.

Incident reporting
: Report actively exploited vulnerabilities for the project and severe incidents affecting Zephyr's infrastructure (to the extent Zephyr is involved).

Does the CRA apply to Zephyr contributors? **No.** The CRA does not apply to individual contributors to Zephyr (Recital 18).

Contributors developing features or fixing bugs are not subject to CRA obligations.

How is Zephyr meeting its steward obligations?

Article 24(1): Security policy (Complete)

- Documented at *Zephyr Security Overview*
- Vulnerability reporting process: *Security Vulnerability Reporting*
- Secure coding guidelines: *Secure Coding*

Article 24(2): Cooperation with authorities (In Progress)

- Registered CVE Numbering Authority (CNA) since 2017
- Active Zephyr Project Security Incident Response Team (PSIRT)
- **In Progress**: Identifying CSIRT coordinator for EU

Article 14(1) & Article 14(3): Incident reporting (In Progress)

- **In Progress**: Determining if NVD processes work for CSIRT/ENISA reporting
- Plan to align with EU reporting requirements

Article 14(8): User notification (Complete)

- Vulnerability Alert Registry for manufacturers and integrators
- CVE publication and security advisories

Article 52(3): Corrective actions (Complete)

- Established processes in place with CVE authorities
- Timely response through PSIRT

Standards and Technical Specifications Relevant existing standards:

ETSI and CEN/CENELC are developing harmonized standards in response to the CRA Standardisation Request (M/606).

CRA horizontal standards developed by CEN/CENELEC:

- EN40000-1-1 : Vocabulary definition
- EN40000-1-2 : Quality process for the development of Secure by Design product. It includes risk assessment, sourcing due diligence, development, test, validation, manufacturing, decommissioning...
- EN40000-1-3 : Vulnerability handling process
- EN40000-1-4 : Security controls : technical solutions to reduce cybersecurity risk. This is based on the hEN18031-x standard developed for the CE RED Delegated Act.

Presentation of early draft of EN40000-1-4 is available on CEN/CENELEC website: Security Controls.

ETSI Public draft standards include product-specific requirements for:

- Operating Systems (prEN 304 626)
- Browsers (prEN 304 617)
- Password Managers (prEN 304 618)
- Firewalls (prEN 304 636)

For the complete list of draft standards and participation in public consultations, see the ETSI Cyber Resilience Act Portal.

- Once harmonized, these standards could be freely accessible to EU, EFTA, and UK citizens via Harmonized standards.

9.8.2 ETSI 303-645

ETSI EN 303 645, also known as "Cyber Security for Consumer Internet of Things: Baseline Requirements," is a standard developed by the European Telecommunications Standards Institute (ETSI).

The standard includes provisions for secure software updates, data protection, secure communication, and the minimization of exposed attack surfaces, among other things. It is part of a broader effort to address the challenges and risks associated with IoT devices.

Full version of the standard can be found here.

Terminology

Table 4: ETSI 303645 terminology

administrator	user who has the highest-privilege level possible for a user of the device, which can mean they are able to change any configuration related to the intended functionality.
associated services	digital services that, together with the device, are part of the overall consumer IoT product and that are typically required to provide the product's intended functionality.
authentication mechanism	method used to prove the authenticity of an entity.
authentication value	individual value of an attribute used by an authentication mechanism.
best practice cryptography	cryptography that is suitable for the corresponding use case and has no indications of a feasible attack with current readily available techniques.

continues on next page

Table 4 – continued from previous page

constrained device	device which has physical limitations in either the ability to process data, the ability to communicate data, the ability to store data or the ability to interact with the user, due to restrictions that arise from its intended use.
consumer	natural person who is acting for purposes that are outside her/his trade, business, craft or profession.
consumer IoT device	network-connected (and network-connectable) device that has relationships to associated services and are used by the consumer typically in the home or as electronic wearables.
critical security parameter	security-related secret information whose disclosure or modification can compromise the security of a security module.
debug interface	physical interface used by the manufacturer to communicate with the device during development or to perform triage of issues with the device and that is not used as part of the consumer-facing functionality
defined support period	minimum length of time, expressed as a period or by an end-date, for which a manufacturer will provide security updates.
device manufacturer	entity that creates an assembled final consumer IoT product, which is likely to contain the products and components of many other suppliers.
factory default	state of the device after factory reset or after final production/assembly.
initialization	process that activates the network connectivity of the device for operation and optionally sets authentication features for a user or for network access.
initialized state	state of the device after initialization.
IoT product	consumer IoT device and its associated services.
isolable	able to be removed from the network it is connected to, where any functionality loss caused is related only to that connectivity and not to its main function; alternatively, able to be placed in a self-contained environment with other devices if and only if the integrity of devices within that environment can be ensured
logical interface	software implementation that utilizes a network interface to communicate over the network via channels or ports.
manufacturer	relevant economic operator in the supply chain (including the device manufacturer).
network interface	physical interface that can be used to access the functionality of consumer IoT via a network.
owner	user who owns or who purchased the device.
personal data	Any information relating to an identified or identifiable natural person.
physical interface	physical port or air interface (such as radio, audio or optical) used to communicate with the device at the physical layer.
public security parameter	security related public information whose modification can compromise the security of a security module.
remotely accessible	intended to be accessible from outside the local network.
security module	set of hardware, software, and/or firmware that implements security functions.
security update	software update that addresses security vulnerabilities either discovered by or reported to the manufacturer.
sensitive security parameters	critical security parameters and public security parameters.
software service	software component of a device that is used to support functionality.
telemetry	data from a device that can provide information to help the manufacturer identify issues or information related to device usage.

continues on next page

Table 4 – continued from previous page

unique per device	unique for each individual device of a given product class or type.
user	natural person or organization.

Provisions Assessment

The following table is a self-assessment using Table B.1 from ETSI EN 303 645, specifically focusing on the Zephyr RTOS as a component within IoT products.

According with ETSI 303 645, table B.1 provides a mechanism to give information about the implementation of the provisions presented in the standard. Zephyr has adopted the following notations used in the standard:

Table 5: ETSI 303645 Table B.1 notations

M	the provision is a mandatory requirement
R	the provision is a recommendation
M C	the provision is a mandatory requirement and conditional
R C	the provision is a recommendation and conditional
Y	The provision is supported by Zephyr
N	The provision is not supported by Zephyr
N/A	The provision is not applicable to Zephyr or it is product makers responsibility

Table 6: ETSI 303645 provisions assessment using table B.1

Provision	Description	Status	Support	Detail
Provision 5.1-1	Where passwords are used and in any state other than the factory default, all consumer IoT device passwords shall be unique per device or defined by the user.	M C	N/A	
Provision 5.1-2	Where pre-installed unique per device passwords are used, these shall be generated with a mechanism that reduces the risk of automated attacks against a class or type of device.	M C	N/A	
Provision 5.1-3	Authentication mechanisms used to authenticate users against a device shall use best practice cryptography, appropriate to the properties of the technology, risk and usage.	M	N/A	
Provision 5.1-4	Where a user can authenticate against a device, the device shall provide to the user or an administrator a simple mechanism to change the authentication value used.	M C	N/A	
Provision 5.1-5	When the device is not a constrained device, it shall have a mechanism available which makes brute-force attacks on authentication mechanisms via network interfaces impracticable.	M C	N	**TODO**
Provision 5.2-1	The manufacture shall make a vulnerability disclosure policy publicly available.	M	Y	*Vulnerability Management*
Provision 5.2-2	Disclosed vulnerabilities should be acted on in a timely manner.	R	Y	*Vulnerability Timeline*
Provision 5.2-3	Manufacturers should continually monitor for, identify and rectify security vulnerabilities within products and services they sell, produce, have produced and services they operate during the defined support period.	R	Y	Modules are covered
Provision 5.3-1	All software components in consumer IoT devices should be securely updatable.	R	Y	*Device firwmware upgrade*
Provision 5.3-2	When the device is not a constrained device, it shall have an update mechanism for the secure installation of updates.	M C	Y	*Device firwmware upgrade*
Provision 5.3-3	An update shall be simple for the user to apply.	M C	N/A	

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.3-4	Automatic mechanisms should be used for software updates.	R C	N/A	
Provision 5.3-5	The device should check after initialization, and then periodically, whether security updates are available.	R C	N/A	
Provision 5.3-6	If the device supports automatic updates and/or update notifications, these should be enabled in the initialized state and configurable so that the user can enable, disable, or postpone installation of security updates and/or update notifications.	R C	N/A	
Provision 5.3-7	The device shall use best practice cryptography to facilitate secure update mechanisms.	M C	Y	*West Sign*
Provision 5.3-8	Security updates shall be timely.	M C	N/A	
Provision 5.3-9	The device should verify the authenticity and integrity of software updates.	R C	Y	Functionality provided by MCUboot. Also see *Device Firwmware Upgrade*.
Provision 5.3-10	Where updates are delivered over a network interface, the device shall verify the authenticity and integrity of each update via a trust relationship.	M	N/A	
Provision 5.3-11	The manufacturer should inform the user in a recognizable and apparent manner that a security update is required together with information on the risks mitigated by that update.	R C	N/A	
Provision 5.3-12	The device should notify the user when the application of a software update will disrupt the basic functioning of the device.	R C	N/A	Zephyr provides this information for its updates. Anyone using Zephyr in their products must check if they are affected
Provision 5.3-13	The manufacturer shall publish, in an accessible way that is clear and transparent to the user, the defined support period.	M	Y	Release Life Cycle and Maintenance
Provision 5.3-14	For constrained devices that cannot have their software updated, the rationale for the absence of software updates, the period and method of hardware replacement support and a defined support period should be published by the manufacturer in an accessible way that is clear and transparent to the user.	R C	N/A	

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.3-15	For constrained devices that cannot have their software updated, the product should be isolable and the hardware replaceable.	R C	N/A	
Provision 5.3-16	The model designation of the consumer IoT device shall be clearly recognizable, either by labelling on the device or via a physical interface.	M	N/A	
Provision 5.4-1	Sensitive security parameters in persistent storage shall be stored securely by the device.	M	N	There is not secure storage within Zephyr
Provision 5.4-2	Where a hard-coded unique per device identity is used in a device for security purposes, it shall be implemented in such a way that it resists tampering by means such as physical, electrical or software.	M C	N/A	
Provision 5.4-3	Hard-coded critical security parameters in device software source code shall not be used.	M	Y	*Hardening Tool*
Provision 5.4-4	Any critical security parameters used for integrity and authenticity checks of software updates and for protection of communication with associated services in device software shall be unique per device and shall be produced with a mechanism that reduces the risk of automated attacks against classes of devices.	M	N/A	
Provision 5.5-1	The consumer IoT device shall use best practice cryptography to communicate securely.	M	Y	
Provision 5.5-2	The consumer IoT device should use reviewed or evaluated implementations to deliver network and security functionalities, particularly in the field of cryptography.	R	Y	
Provision 5.5-3	Cryptographic algorithms and primitives should be updatable.	R	N	The whole image must be updated
Provision 5.5-4	Access to device functionality via a network interface in the initialized state should only be possible after authentication on that interface.	R	N/A	

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.5-5	Device functionality that allows security-relevant changes in configuration via a network interface shall only be accessible after authentication. The exception is for network service protocols that are relied upon by the device and where the manufacturer cannot guarantee what configuration will be required for the device to operate.	M	N/A	
Provision 5.5-6	Critical security parameters should be encrypted in transit, with such encryption appropriate to the properties of the technology, risk and usage.	R	Y	
Provision 5.5-7	The consumer IoT device shall protect the confidentiality of critical security parameters that are communicated via remotely accessible network interfaces.	M	Y	
Provision 5.5-8	The manufacturer shall follow secure management processes for critical security parameters that relate to the device.	M	N/A	
Provision 5.6-1	All unused network and logical interfaces shall be disabled.	M	Y	*Kconfig*
Provision 5.6-2	In the initialized state, the network interfaces of the device shall minimize the unauthenticated disclosure of security-relevant information.	M	Y	
Provision 5.6-3	Device hardware should not unnecessarily expose physical interfaces to attack.	R	Y	*Kconfig* and *Hardening Tool*
Provision 5.6-4	Where a debug interface is physically accessible, it shall be disabled in software.	M C	Y	*Hardening Tool*
Provision 5.6-5	The manufacturer should only enable software services that are used or required for the intended use or operation of the device.	R	Y	*Kconfig* and *Hardening Tool*
Provision 5.6-6	Code should be minimized to the functionality necessary for the service/device to operate.	R	Y	*Kconfig*
Provision 5.6-7	Software should run with least necessary privileges, taking account of both security and functionality.	R	Y	*Security Overview*
Provision 5.6-8	The device should include a hardware-level access control mechanism for memory.	R	Y	*Memory protection*

continues on next page

Table 6 – continued from previous page

Provision	Description	Status	Support	Detail
Provision 5.6-9	The manufacturer should follow secure development processes for software deployed on the device.	R	Y	*Security Overview* and *Coding guidelines*
Provision 5.7-1	The consumer IoT device should verify its software using secure boot mechanisms.	R	Y	Functionality provided by MCUboot. Also see *Security Overview*.
Provision 5.7-2	If an unauthorized change is detected to the software, the device should alert the user and/or administrator to the issue and should not connect to wider networks than those necessary to perform the alerting function.	R	N	Zephyr does not provide runtime detection / notification.
Provision 5.8-1	The confidentiality of personal data transiting between a device and a service, especially associated services, should be protected, with best practice cryptography.	R	Y	
Provision 5.8-2	The confidentiality of sensitive personal data communicated between the device and associated services shall be protected, with cryptography appropriate to the properties of the technology and usage.	M	Y	
Provision 5.8-3	All external sensing capabilities of the device shall be documented in an accessible way that is clear and transparent for the user.	M	Y	*Sensing Subsystem*
Provision 5.9-1	Resilience should be built in to consumer IoT devices and services, taking into account the possibility of outages of data networks and power.	R	Y	
Provision 5.9-2	Consumer IoT devices should remain operating and locally functional in the case of a loss of network access and should recover cleanly in the case of restoration of a loss of power.	R	Y	
Provision 5.9-3	The consumer IoT device should connect to networks in an expected, operational and stable state and in an orderly fashion, taking the capability of the infrastructure into consideration.	R	Y	
Provision 5.10-1	If telemetry data is collected from consumer IoT devices and services, such as usage and measurement data, it should be examined for security anomalies.	R C	N/A

Provision	Description	Status	Support	Detail
Provision 6.1-4	If telemetry data is collected from consumer IoT devices and services, the processing of personal data should be kept to the minimum necessary for the intended functionality.	R C	N/A	
Provision 6.1-5	If telemetry data is collected from consumer IoT devices and services, consumers shall be provided with information on what telemetry data is collected, how it is being used, by whom, and for what purposes.	M C	N/A	

Chapter 10

Safety

These documents describe the processes, developer guidelines and requirements for ensuring safety is addressed within the Zephyr project.

10.1 Zephyr Safety Overview

10.1.1 Introduction

This document is the safety documentation providing an overview over the safety-relevant activities and what the Zephyr Project and the Zephyr Safety Working Group / Committee try to achieve.

This overview is provided for people who are interested in the functional safety development part of the Zephyr RTOS and project members who want to contribute to the safety aspects of the project.

10.1.2 Overview

In this section we give the reader an overview of what the general goal of the safety certification is, what standard we aim to achieve and what quality standards and processes need to be implemented to reach such a safety certification.

10.1.3 Safety Document update

This document is a living document and may evolve over time as new requirements, guidelines, or processes are introduced.

1. Changes will be submitted from the interested party(ies) via pull requests to the Zephyr documentation repository.
2. The Zephyr Safety Committee will review these changes and provide feedback or acceptance of the changes.
3. Once accepted, these changes will become part of the document.

10.1.4 General safety scope

The general scope of the Safety Committee is to achieve a certification for the IEC 61508 standard and the Safety Integrity Level (SIL) 3 / Systematic Capability (SC) 3 for a limited source scope (see certification scope TBD). Since the code base is pre-existing, we use the route 3s/1s approach defined by the IEC 61508 standard.

Route 3s
Assessment of non-compliant development. Which is basically the route 1s with existing sources.

Route 1s
Compliant development. Compliance with the requirements of this standard for the avoidance and control of systematic faults in software.

Summarization IEC 61508 standard

The IEC 61508 standard is a widely recognized international standard for functional safety of electrical, electronic, and programmable electronic safety-related systems. Here's an overview of some of the key safety aspects of the standard:

1. **Hazard and Risk Analysis**: The IEC 61508 standard requires a thorough analysis of potential hazards and risks associated with a system in order to determine the appropriate level of safety measures needed to reduce those risks to acceptable levels.
2. **Safety Integrity Level (SIL)**: The standard introduces the concept of Safety Integrity Level (SIL) to classify the level of risk reduction required for each safety function. The higher the SIL, the greater the level of risk reduction required.
3. **System Design**: The IEC 61508 standard requires a systematic approach to system design that includes the identification of safety requirements, the development of a safety plan, and the use of appropriate safety techniques and measures to ensure that the system meets the required SIL.
4. **Verification and Validation**: The standard requires rigorous testing and evaluation of the safety-related system to ensure that it meets the specified SIL and other safety requirements. This includes verification of the system design, validation of the system's functionality, and ongoing monitoring and maintenance of the system.
5. **Documentation and Traceability**: The IEC 61508 standard requires a comprehensive documentation process to ensure that all aspects of the safety-related system are fully documented and that there is full traceability from the safety requirements to the final system design and implementation.

Overall, the IEC 61508 standard provides a framework for the design, development, and implementation of safety-related systems that aims to reduce the risk of accidents and improve overall safety. By following the standard, organizations can ensure that their safety-related systems are designed and implemented to the highest level of safety integrity.

Why IEC 61508?

The IEC 61508 standard was selected because it serves as a foundational functional safety standard applicable across various industry sectors. It provides a robust framework that can be used as base for specific standards for different industries. This makes IEC 61508 particularly relevant for Zephyr, as the operating system's versatility allows it to be effectively utilized across a wide range of industry sectors.

The following diagram illustrates the relationship between the IEC 61508 standard and other related standards:

10.1.5 Quality

Quality is a mandatory expectation for software across the industry. The code base of the project must achieve various software quality goals in order to be considered an auditable code base from a safety perspective and to be usable for certification purposes. But software quality is not an additional requirement caused by functional safety standards. Functional safety considers quality as an existing pre-condition and therefore the "quality managed" status should be pursued for any project regardless of the functional safety goals. The following list describes the quality goals which need to be reached to achieve an auditable code base:

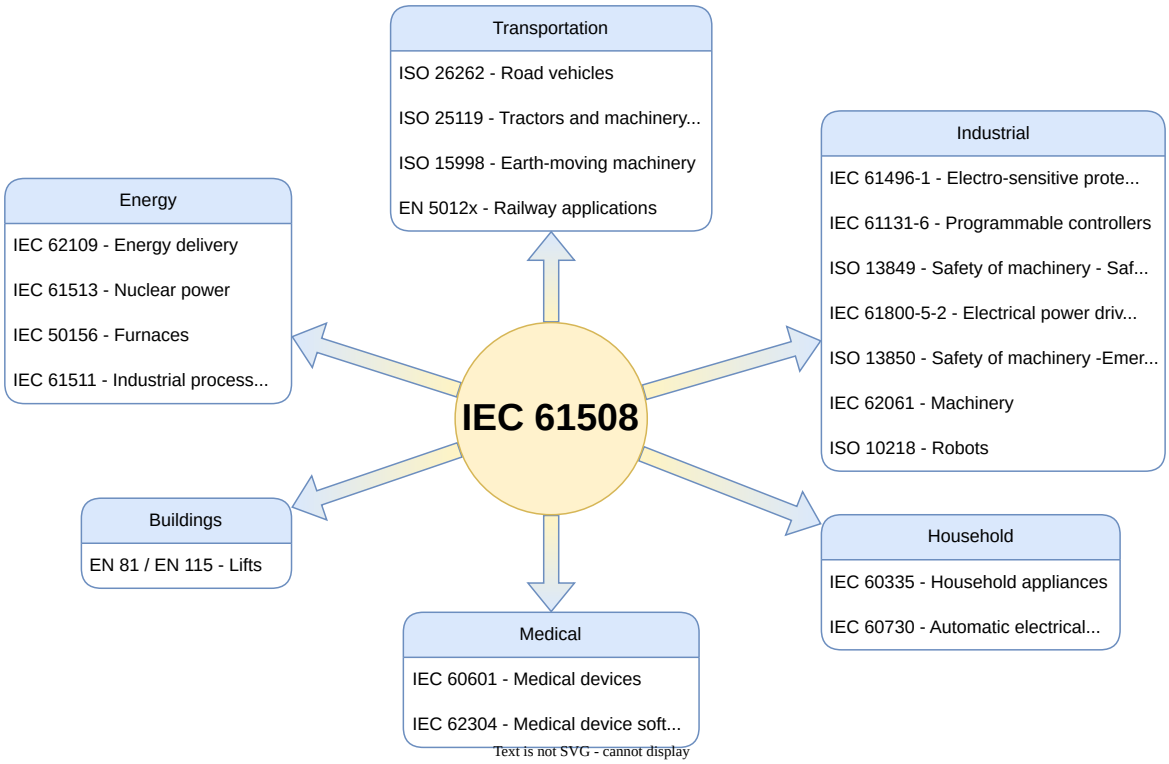

Fig. 1: IEC 61508 relation to other standards

1. Basic software quality standards
   a. *Coding Guidelines* (including: static code analysis, coding style, etc.)
   b. *Safety Requirements* and requirements tracing
   c. Test coverage
2. Software architecture design principles
   a. Layered architecture model
   b. Encapsulated components
   c. Encapsulated single functionality (if not fitable and manageable in safety)

Basic software quality standards - Safety view

In this chapter the Safety Committee describes why they need the above listed quality goals as pre-condition and what needs to be done to achieve an auditable code base from the safety perspective. Generally speaking, it can be said that all of these quality measures regarding safety are used to minimize the error rate during code development.

Coding Guidelines The coding guidelines are the basis to a common understanding and a unified ruleset and development style for industrial software products. For safety the coding guidelines are essential and have another purpose beside the fact of a unified ruleset. It is also necessary to prove that the developers follow a unified development style to prevent **systematic errors** in the process of developing software and thus to minimize the overall **error rate** of the complete software system.

Also the **IEC 61508 standard** sets a pre-condition and recommendation towards the use of coding standards / guidelines to reduce likelihood of errors.

The project TSC and the Safety Committee of the project agreed to implement a staged and incremental approach for complying with a set of coding rules (AKA Coding Guidelines) to improve quality and consistency of the code base. Below are the agreed upon stages:

Stage I (COMPLETED)
: Coding guideline rules are available to be followed and referenced, but not enforced. Rules are not yet enforced in CI and pull-requests cannot be blocked by reviewers/approvers due to violations.

Stage II
: Reviewers/approvers can block pull-requests due to violations of the coding guidelines in pull-requests across the codebase.

  Begin enforcement on a limited scope of the code base. Initially, this would be the safety certification scope. For rules easily applied across codebase, we should not limit compliance to initial scope. This step requires tooling, CI setup and an enforcement strategy.

Stage III
: Revisit the coding guideline rules and based on experience from previous stages, refine/iterate on selected rules.

Stage IV
: Expand enforcement to the wider codebase. Exceptions may be granted on some areas of the codebase with a proper justification. Exception would require TSC approval.

Note

Coding guideline rules may be removed/changed at any time by filing a GH issue/RFC.

Important

Current stage: The prerequisites to complete **Stage II** are currently being looked at: The tooling is in evaluation, CI setup and enforcement strategy is being worked on.

Requirements and requirements tracing Requirements and requirement management are not only important for software development, but also very important in terms of safety. On the one hand, this specifies and describes in detail and on a technical level what the software should do, and on the other hand, it is an important and necessary tool to verify whether the described functionality is implemented as expected. For this purpose, tracing the requirements down to the code level is used. With the requirements management and tracing in hand, it can now be verified whether the functionality has been tested and implemented correctly, thus minimizing the systematic error rate.

Also the IEC 61508 standard highly recommends (which is like a must-have for the certification) requirements and requirements tracing.

Test coverage A high test coverage, in turn, is evidence of safety that the code conforms precisely to what it was developed for and does not execute any unforeseen instructions. If the entire code is tested and has a high (ideally 100%) test coverage, it has the additional advantage of quickly detecting faulty changes and further minimizing the error rate. However, it must be noted that different requirements apply to safety for test coverage, and various metrics must be considered, which are prescribed by the IEC 61508 standard for the SIL 3 / SC3 target. The following must be fulfilled, among other things:

- Structural test coverage (entry points) 100%
- Structural test coverage (statements) 100%
- Structural test coverage (branches) 100%

If the 100% cannot be reached (e.g. statement coverage of defensive code) that part needs to be described and justified in the documentation.

Software architecture design principles

To create and maintain a structured software product it is also necessary to consider individual software architecture designs and implement them in accordance with safety standards because some designs and implementations are not reasonable in safety, so that the overall software and code base can be used as auditable code. However, most of these software architecture designs have already been implemented in the Zephyr project and need to be verified by the Safety Committee / Safety Working Group and the safety architect.

Layered architecture model The **IEC 61508 standard** strongly recommends a modular approach to software architecture. This approach has been pursued in the Zephyr project from the beginning with its layered architecture. The idea behind this architecture is to organize modules or components with similar functionality into layers. As a result, each layer can be assigned a specific role in the system. This model has the advantage in safety that interfaces between different components and layers can be shown at a very high level, and thus it can be determined which functionalities are safety-relevant and can be limited. Furthermore, various analyses and documentations can be built on top of this architecture, which are important for certification and the responsible certification body.

Encapsulated components Encapsulated components are an essential part of the architecture design for safety at this point. The most important aspect is the separation of safety-relevant components from non-safety-relevant components, including their associated interfaces. This ensures that the components have no **repercussions** on other components.

Encapsulated single functionality (if not reasonable and manageable in safety) Another requirement for the overall system and software environment is that individual functionalities can be disabled within components. This is because if a function is absolutely unacceptable for safety (e.g. complete dynamic memory management), then these individual functionalities should be able to be turned off. The Zephyr Project already offers such a possibility through the use of Kconfig and its flexible configurability.

10.1.6 Processes and workflow

The diagram describes the rough process defined by the Safety Committee to ensure safety in the development of the Zephyr project. To ensure understanding, a few points need to be highlighted and some details explained regarding the role of the safety architect and the role of the safety committee in the whole process. The diagram only describes the paths that are possible when a change is related to safety.

1. On the main branch, the safety scope of the project should be identified, which typically represents a small subset of the entire code base. This subset should then be made auditable during normal development on “main”, which means that special attention is paid to quality goals (*Quality*) and safety processes within this scope. The Safety Architect works alongside the Technical Steering Committee (TSC) in this area, monitoring the development process to ensure that the architecture meets the safety requirements.
2. At this point, the safety architect plays an increasingly important role. For PRs/issues that fall within the safety scope, the safety architect should ideally be involved in the discussions and decisions of minor changes in the safety scope to be able to react to safety-relevant changes that are not conformant. If a pull request or issue introduces a significant and influential change or improvement that requires extended discussion or decision-making, the safety architect should bring it to the attention of the Safety Committee or the Technical Steering Committee (TSC) as appropriate, so that they can make a decision on the best course of action.

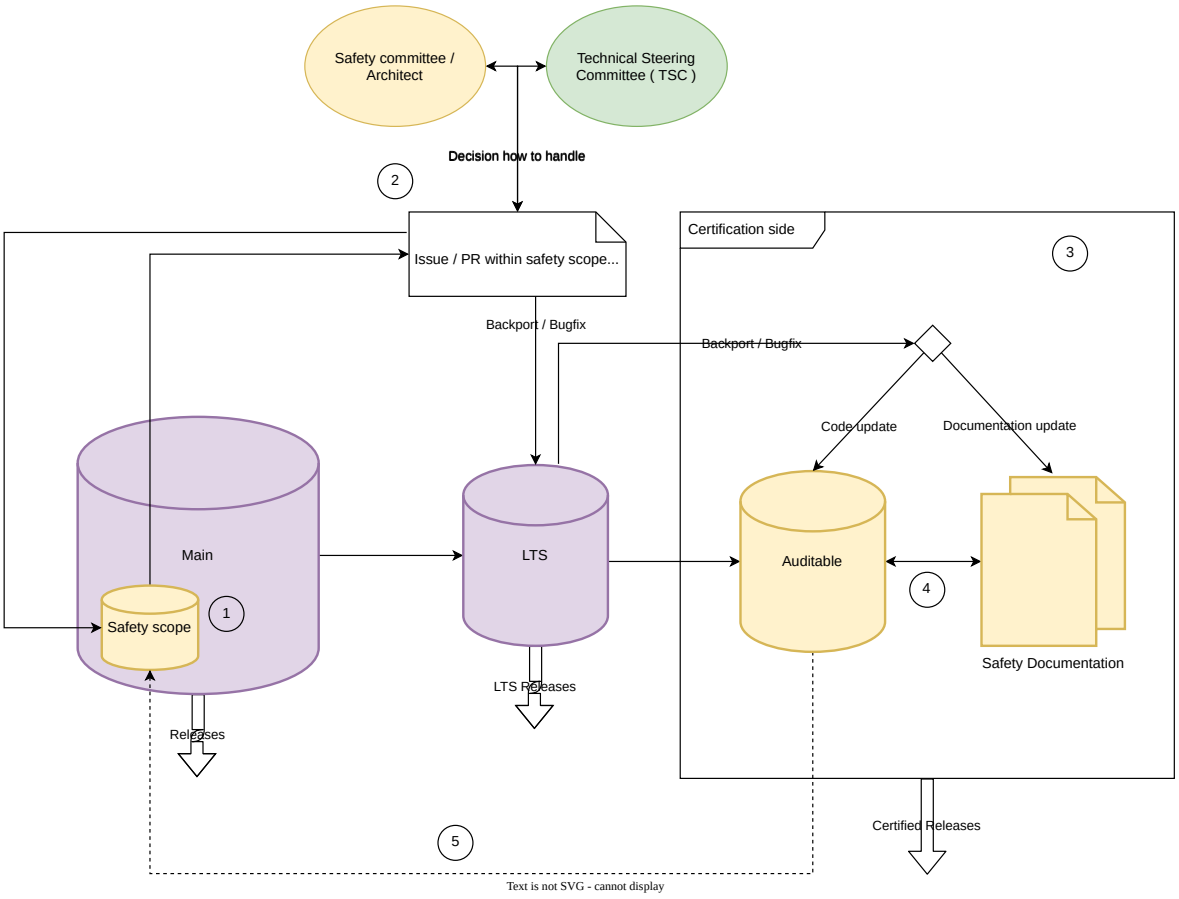

Fig. 2: Safety process and workflow overview

3. This section describes the certification side. At this point, the code base has to be in an "auditable" state, and ideally no further changes should be necessary or made to the code base. There is still a path from the main branch to this area. This is needed in case a serious bug or important change is found or implemented on the main branch in the safety scope, after the LTS and the auditable branch were created. In this case, the Safety Committee, together with the safety architect, must decide whether this bug fix or change should be integrated into the LTS so that the bug fix or change could also be integrated into the auditable branch. This integration can take three forms: First either as only a code change or second as only an update to the safety documentation or third as both.
4. This describes the necessary safety process required for certification itself. Here, the final analyses, tests, and documents are created and conducted which must be created and conducted during the certification, and which are prescribed by the certifying authority and the standard being certified. If the certification body approves everything at this stage and the safety process is completed, a safety release can be created and published.
5. This transition from the auditable branch to the main branch should only occur in exceptional circumstances, specifically when something has been identified during the certification process that needs to be quickly adapted on the "auditable" branch in order to obtain certification. In order to prevent this issue from arising again during the next certification, there needs to be a path to merge these changes back into the main branch so that they are not lost, and to have them ready for the next certification if necessary.

Important

Safety should not block the project and minimize the room to grow in any way.

Important

TODO: Find and define ways, guidelines and processes which minimally impact the daily work of the maintainers, reviewers and contributors and also the safety architect itself. But which are also suitable for safety.

10.2 Safety Requirements Management

These documents describe the processes, developer guidelines and requirements for ensuring the creation, verification and configuration management of requirements follows a suitable approach.

10.2.1 Safety Requirements

Introduction

The safety committee leads the effort to gather requirements that reflect the **actual** state of the implementation, following the *route 3s* approach of the project's safety effort. The goal is **NOT** to create new requirements to request additional features for the project.

The requirements are gathered in the separate repository: Requirement repository

The current rendered version of the Requirement Repository's content can be found at Zephyr Project Requirements.

Objectives of Requirements Management in the Zephyr Project

In the development and for documentation of implemented or expected functionality, effective Requirements Management is essential to ensure that the Zephyr RTOS meets its intended pur-

pose, performs reliably under its constraints, and can be integrated easily both with hardware platforms, within an embedded software stack and software application layers.

Requirements Management provides a structured approach to capturing, organizing, and tracing the needs and expectations of stakeholders through a system's lifecycle. The documentation provided in the project's docs already emphasizes implementation details, from kernel functionality, to API configuration options and specific module behavior. While this is essential for developers, relying solely on low-level documentation can lead to fragmented understanding, limited traceability, and difficulty scaling or certifying a final system using Zephyr RTOS.

To enhance this understanding and add value for non-coding roles like product owners, software architects, quality management, safety management and assessors, the Zephyr Project needs to have higher level requirements that describe overall functionality, structure and implementation constraints.

Guideline to Requirements Management

Below are the guidelines for the requirements repository and the expectations regarding suitable requirement structure and syntax when adding requirements to the repository.

Note: these are the guidelines to create requirements in the requirements repository, which is not written using .rst like the docs published to the Zephyr users. To learn more about the guidelines to create the docs, please refer to *Documentation Guidelines*

Scope The initial scope of the requirements covers the KERNEL functionalities. Requirements for non-kernel functionality are also welcome, but currently not the focus.

Managing Zephyr Requirements: Structure, Tools, and Grammar

Levels of requirements in the repository The safety working group has evaluated a suitable approach to enhance the existing low level descriptions with requirements. For this a two level structure of requirements has been created on top of the existing documentation structure, System Requirements at the highest level to define overarching capabilities of the Zephyr RTOS as a whole, and Software Requirements to break down the System Requirements' expectations into detailed specifications for individual components within the RTOS.

System Requirements
: System requirements describe the behavior of the Zephyr RTOS (= the system here). They describe the functionality and constraints of the Zephyr RTOS from a high-level perspective, without going into details of the functionality itself.

  The purpose of the system requirements is to get an overview of the currently implemented features of the Zephyr RTOS.

  These requirements articulate what the RTOS must achieve from a functional, performance, and interface perspective — such as deterministic task scheduling, interrupt handling latency, memory footprint limits, and compliance with industry standards. System requirements serve as the foundation for design decisions and validation criteria.

  To create these requirements it is beneficial if a person writing these requirements already has some knowledge of the Zephyr RTOS Project and/or requirements and constraints that are specific to an RTOS.

Software Requirements
: Beneath the System Requirements layer, Software requirements refine the system-level requirements to a more granular level. These component level requirements break down the system-level expectations into detailed specifications for individual components within the RTOS. These include modules such as the scheduler, memory manager and inter-process communication mechanisms.

Software requirements describe the behavior, interfaces, and constraints of each component, ensuring that they collectively fulfill the system-level goals. These requirements define the specific actions the feature shall be able to execute and the behavior of the feature so that each requirement can be verified by tests, analysis and/or inspection.

This level of requirements still has to be implementation free in its definitions. Implementation definitions should be in the docs, if not already there, they need to be added as another task of this requirements creation effort.

Requirements Management Toolchain

Requirement Repository: The Requirement repository represents Zephyr's structured approach to requirements management, currently focusing on the creation of requirements within the scope of its targeted safety certification, but not limited to this scope.

To work with this repository, follow the normal GitHub workflow of branching and pull requests. The pull requests on this repository are currently reviewed by members of the safety working group and need approval at least from one of the following roles to get merged: Zephyr Safety Manager, Zephyr Safety Chair or Zephyr Safety Architect.

Requirement Tooling: For authoring, linking and rendering a browsable .html version of the Zephyr Project's requirements we are using the tool StrictDoc

StrictDoc is a lightweight, open-source tool for writing, browsing, and exporting structured requirements. It supports hierarchical requirements, traceability, and HTML export for easy review.

Requirements are written in StrictDoc's own markdown syntax.

For those that prefer editing in a WYSIWYG fashion, the .html exports of StrictDoc can also be edited using StrictDoc's local server.

To set up your Toolchain, jump to the *Getting started with Requirements Management* section.

Verification of Requirements: New and changed requirements (what is in the PRs to the Requirements Repository) need to be verified by a review. The review comments can be captured directly in the comments during the PR review. A requirements review has to consider both technical correctness and the formal need that requirements need be created following certain criteria.

More details regarding the checklist and the formal expectations can be found in the *Safety Requirements Checklist*. In the tests of the Zephyr Project adherence of the implementation to the functionality described in the requirements must be evaluated.

Glossary of Requirements Grammar Elements All requirements must use the defined grammar:

Table 1: Structure for requirements captured in StrictDoc

Property	Description
UID	A unique ID that enables identification of the requirement. Is assigned automatically by StrictDoc.
STATUS	Describing the status of the requirement. Draft, Approved, Retired
TYPE	Functional, Non-functional
COMPONENT	the component the requirement shall be implemented in
REFERENCE	Reference to parent and/or child requirement
TITLE	A descriptive title of the requirement. Use short and concise requirement titles.
STATEMENT	Description of the requirement
USER_STORY	A user story describing the requirement (optional, only add if it adds additional value to the requirements statement)

Requirement UID (Unique identifier) Handling The tool used to manage requirements, StrictDoc, is responsible for handling the Unique Identifier (UID) associated with each requirement. To manage UIDs, follow these steps:

1. Don't add a requirement UID and UID field for new requirements
2. After completing work on the new requirements execute: `strictDoc manage auto-uid .`
3. Establish links between the requirements with the new attributed UIDs if needed

After doing this, the requirements are ready and a pull request can be created. The CI in the PR will check if the requirements UIDs are valid or if there are duplicates in it. If there are duplicates in the PR, these need to be resolved by rebasing and re-executing the steps above.

Consistency Consistency regarding language and choice of words shall be maintained across all requirements. (See: *Syntax*)

It also is recommended to take a look at the already existing requirements in the Requirement repository as well as at discussions going on in the PRs to this repository to get a feeling what makes sense in this context.

Pull Request requirement repository

- Adhere to the *Contribution Guidelines* of the Zephyr Project.
  - As long as they are applicable to the requirements repository.
- Avoid creating large commits that contain both trivial and non-trivial changes.
- Avoid moving and changing requirements in the same commit.

Characteristics of a good requirement

- Unambiguous
- Verifiable (e.g. testable for functional requirements)
- Clear (concise, brief, simple, precise)
- Correct
- Understandable
- Feasible (realistic, possible)
- Independent
- Atomic

- Necessary
- Implementation-free (abstract)

Characteristics of a set of requirements

- Complete
- Consistent
- Non redundant

Syntax

- Use of a recognized Requirements Syntax is recommended.
  - EARS is a good reference. Particularly if you are unfamiliar with requirements writing.
  - Other formats are accepted as long as the characteristics of a requirement from above are met.

10.2.2 Safety Requirements Checklist

Introduction

The requirements that are created, modified or updated need to be suitable. This means they need to be unambiguous, uniquely identifiable, feasible, testable etc. To ensure this, each requirement needs to be reviewed in its pull request, if it fulfills the basic requirements to be a requirement. This checklist shall serve as the minimum that needs to be considered when doing a review of a requirement PR.

Requirements Structure and Guidelines

You can find the approach taken by the Zephyr Project in *Safety Requirements*

Review Instructions

This checklist lists the topics and questions that shall be considered when approving requirements during a review. The review outcome must be documented in the PR review, in a way that it is clear that this checklist has been used and the actual outcome of the review regarding open questions, findings or approval. This checklist shall be applied at least once for new or changed requirements within the scope of a safety assessment before the safety scope is released.

The requirements are gathered in the separate repository: Requirement repository

The review can be done on two levels - regarding a single requirement or as a group of requirements. The checkpoints are as following:

Review checkpoints for each and every requirement

Each new or changed requirement needs to be analysed, to make sure it is suitable and to identify if it is affecting the safety of Zephyr in any kind.

Table 2: Checkpoints for requirements review

ID	Question	Explanation	Example
VerReq_	Is this requirement clearly comprehensible and unambiguous?	To make sure the requirement can be analysed it must be easy to understand and leave no room for (functional) interpretation.	Avoid vague statements such as **some, sufficient, typical, many, several, few, ...**. Statements like **The Zephyr Kernel should provide functionality xyz where possible** are not accurate enough and leave room for interpretation. Also **should** must be replaced with the unambigous **shall**. The **where possible** must be replaced with a definition where the author of the requirement wants the functionality to be provided. This can be a list of cases, system states or other conditions. As long as they are clearly defined.
VerReq_	Is this requirement atomic?	The requirement really must only describe one thing that needs to be fulfilled. Otherwise things like safety analysis, unique linking to architectural components and implementation and verifiability can be impaired.	Statements like **The signal a shall switch on and off the yellow LED and the error state shall be indicated by switching on the red LED** are not atomic. This needs to go into two requirements - **REQ1: The signal a shall switch on and off the yellow LED.** and **REQ2: The error state shall be indicated by switching on the red LED.** This also can be supplemented by a **REQ3(variant a): Yellow LED and the red Error LED must be separate** or **REQ3(variant b): Yellow LED and red Error LED can be combined in case of TBD**.
VerReq_	Is the requirement internally consistent?	The requirement itself must be fully consistent within itself.	Statements like **The system shall use a preemtpive RTOS to guarantee deterministic task scheduling. The system also need to ensure that all tasks, including low-priority background logging tasks, complete without preemption to preserve data integrity.** are contradicting. Stuff like this must be avoided. If both options shall be available, you must define the conditions for these options and how to configure the options.
VerReq_	Is the requirement feasible, achievable and verifiable?	Requirements are not a fantasy wish-list, they need to be able to reach with reasonable matter (although what is reasonable can differ between projects for sure). So generally this means something that sounds good on paper but is technically impossible, internally contradictory, or violates fundamental constraints of the sys-	A bad example is e.g. **The RTOS shall guarantee zero-latency interrupt handling for all devices under all conditions.**, which is physically impossible, as no hardware can respond in literally zero time. Better would be something more concrete like **The RTOS shall guarantee an interrupt latency of 5 µs on the target HW architecture at 80 MHz under maximum system load.**

Review checkpoints looking at a group of requirements

Table 3: Checkpoints for requirements review

ID	Question	Explanation	Example
Ver-Req_1	Are the requirements appropriately grouped and structured?	Usually a suitable requirements structure follows a hierarchical order and within the hierarchical layers the requirements are grouped e.g. regarding their functionality, criticality, parent requirement's source etc.	An unsuitably grouped requirement is e.g. in the wrong section, or in a wrong hierarchy level (e.g. in systems requirements although the requirement defines a specific property of a kernel component and therefore has to be on software component level), sections also might be overloaded and need more structuring in sub-sections.
Ver-Req_2	Is each requirement externally consistent?	The requirements must not conflict or contradict each other.	Consider having two requirements: **Requirement A: The RTOS shall support a maximum of 10 concurrent tasks. Requirement B: The RTOS shall support up to 20 concurrent tasks for high-performance applications.** - These two requirements clearly contradict each other, but might both be correct for the persons writing each one of them. Usually having requirements like this needs communication between the authors of the requirements, and a possible solution might be the following: **The RTOS shall support up to 20 concurrent tasks, with a default configuration of 10 tasks for standard applications.**
Ver-Req_3	Is each requirement suitably traceable?	Each requirement needs to have a clear source (where does it come from, why is it here...), associated verification and/or acceptance criteria and descending requirements or architectural elements.	A requirement always has to have a parent requirement linked, except for the highest level requirements, but still there needs to be an explanation in the Requirement rationale, note or comment.
Ver-Req_4	Is the requirement unique?	Requirements must not be duplicated. If you need a requirement to clarify things in multiple locations, make sure one is the "main requirement" and the others are just linked information.	This is self explanatory, two same or similar requirements must be avoided.

10.2.3 Getting Started with Requirements

These documents contain some guidance for starting to work with requirements in the Zephyr Project.

Getting started with Requirements Management

Zephyr's requirements management is powered by StrictDoc, a lightweight tool for writing, organizing, and publishing structured requirements. This section explains how to set up and use the toolchain provided in the reqmgmt repository.

Overview The `reqmgmt` repository is Zephyr's official requirements workspace. It supports:

- Authoring system and software requirements
- Linking requirements to verification artifacts
- Generating browsable HTML documentation
- Running a local web interface for editing and review

Installation StrictDoc requires Python 3.7 or newer. To install (you might need to use pip3 instead of pip):

```
pip install strictdoc
```

Clone the Zephyr requirements repository:

```
git clone https://github.com/zephyrproject-rtos/reqmgmt
cd reqmgmt
```

Usage To export the requirements to HTML:

```
strictdoc export .
```

This generates a static site in the `output/` directory.

To launch the local web interface:

```
strictdoc server .
```

You should see something like

```
Uvicorn running on http://127.0.0.1:5111 (Press CTRL+C to quit)
```

Bring up your local browser and paste in the address above to access the browser-based editor for navigating and editing requirements.

Structure The repository contains:

- `docs/` — Requirements documents organized by subsystem
- `strictdoc.toml` — Configuration file for StrictDoc
- `tasks.py` — Automation helpers for building and validating requirements

Live Documentation You can view the published requirements online at:

https://zephyrproject-rtos.github.io/reqmgmt

Next Steps

- Explore the `docs/` folder to see example requirement files
- Use the web interface to create or edit your own
- Link requirements to test cases or source modules for traceability

`StrictDoc` helps Zephyr move toward safety-critical readiness by formalizing the connection between system goals and software implementation.

Create your first Zephyr RTOS requirement

Repository Overview The Zephyr requirements are managed in the `reqmgmt` repository using StrictDoc. The repo includes:

- `docs/`: Contains requirement documents in StrictDoc format
- `tools/`: Utility scripts and configuration
- `strictdoc.toml`: Project configuration for StrictDoc
- `tasks.py`: Task automation using Invoke

Step 1: Create or Edit a Requirement File Navigate to the `docs/` folder in the repository.

Folder Overview The `docs/` folder contains all requirement documents written in StrictDoc format.

The `docs/` folder contains two subfolders. These are organized as follows:

- `system_requirements/` Contains high-level system requirements that describe the overall goals, constraints, and expected behavior of the Zephyr RTOS.
  - `system_requirements.sgra` Contains the GRAMMAR, that defines the formal structure of a requirement
  - `index.sdoc` that contains the actual requirements statements
- `software_requirements/` Contains component-level requirements. Each file in this folder corresponds to a specific subsystem or module.
  - `software_requirements.sgra` contains the GRAMMAR for all software requirements
  - a list of `.sdoc` snippet files that compile together to a big software requirements document, e.g.
    - `interrupts.sdoc`
    - `queues.sdoc`
    - `semaphore.sdoc`
    - `threads.sdoc`

These files are modular and allow contributors to work independently on specific areas of the system. You can either edit an existing `.sdoc` file or create a new one. Here's a basic example of a requirement block:

```
[REQUIREMENT]
UID: ZEP-SRS-17-1
STATUS: Draft
TYPE: Functional
COMPONENT: File System
TITLE: Create file
STATEMENT: >>>
```

(continues on next page)

(continued from previous page)

```
Zephyr shall provide file create capabilities for files on the file system.
<<<
```

Set the UID to `TBD` so StrictDoc can generate it automatically in a later step.

Step 2: Save the File Save your file in the systems or software requirements subfolder in `docs/` folder. If you create a new file give it a meaningful name, usually referring to the component its content is meant for or the functionality.

Step 3: Assign a UID Automatically From the root of the repository, run the following command:

```
strictdoc manage auto-uid .
```

This command will:

- Traverse the project directory
- Find requirements with `UID: TBD`
- Assign a unique identifier to each one

Step 4: Verify the UID Assignment Open the file again. You should now see something like:

```
UID: ZEP-SRS-17-2
STATUS: Draft
TYPE: Functional
COMPONENT: File System
TITLE: Create file
STATEMENT: >>>
Zephyr shall provide file create capabilities for files on the file system.
<<<
```

Note: The UID format can be configured in `strictdoc.toml`.

Optional: Generate HTML Documentation To build the HTML version of the requirements documentation:

```
strictdoc export .
```

This will generate browsable documentation in the `output/` folder.

Optional: Launch the Web Editor To interactively browse and edit requirements:

```
strictdoc server .
```

This launches a local web interface for editing and reviewing requirements.

Summary

- Create or edit a requirement in `docs/` with `UID: TBD`
- Run `strictdoc manage auto-uid .` to assign UIDs
- Optionally generate HTML docs or launch the web editor

StrictDoc helps Zephyr maintain structured, traceable, and editable requirements across platforms.

10.2.4 Requirements Catalog

The Zephyr requirements are maintained in the dedicated `reqmgmt` repository using StrictDoc. When that repository is present in the workspace (it is pulled in as a west project), its requirements are exported and rendered directly into this documentation below.

Requirements Catalog

The following requirements are imported from the Zephyr requirements repository (`reqmgmt`).

Zephyr Software Requirements

ZEP-SRS-19-1: Atomic Operations The Zephyr RTOS shall provide an interface to access memory while ensuring mutual exclusion.

Status
Draft

Type
Functional

Component
Hardware Architecture Interface

User Story
As a Zephyr RTOS user I want to read from or write into a memory areas without being disturbed by other threads or ISRs.

Parents
ZEP-SYRS-1

ZEP-SRS-19-2: Thread Context Switching The Zephyr RTOS shall provide a mechanism for context switching between threads.

Status
Draft

Type
Functional

Component
Hardware Architecture Interface

User Story
As a Zephyr RTOS user I want to execute code concurrently in one or more threads and when interrupted at a code location in a thread, to continue at the very same location.

Parents
ZEP-SYRS-1

ZEP-SRS-19-3: Software Exceptions The Zephyr RTOS shall provide an interface to implement software exceptions.

Status
Draft

Type
Functional

Component
Hardware Architecture Interface

User Story
As a Zephyr RTOS user I want to catch any software exception and handle it according to my application needs.

Parents
ZEP-SYRS-1

ZEP-SRS-19-4: Processor Mode Support The Zephyr RTOS shall provide an interface for managing processor modes.

Status
Draft

Type
Functional

Component
Hardware Architecture Interface

User Story
If MCU power state was meant here: As a Zephyr RTOS user I want to control the MCU's power saving mode such e.g. operation, sleep, deep sleep or similar as supported by the selected MCU.

Parents
ZEP-SYRS-1

ZEP-SRS-18-1: Formatted output The Zephyr RTOS shall support formatted output.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to printf with various output formats.

Parents
ZEP-SYRS-3

ZEP-SRS-18-2: Floating Point Math Support The Zephyr RTOS shall support floating point math libraries for processors where floating point is available.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to calculate with floating point numbers.

Parents
ZEP-SYRS-3

ZEP-SRS-18-3: Boolean Primitives Support The Zephyr RTOS shall support boolean primitives.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to work with boolean values and logic.

Parents
ZEP-SYRS-3

ZEP-SRS-18-4: Standard Unix time interface The Zephyr RTOS shall support the standard UNIX time interface.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr User, I want to be able to use system time.

Parents
ZEP-SYRS-3

ZEP-SRS-18-5: Strings support The Zephyr RTOS shall support an interface to manage strings.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to manipulate text strings.

Parents
ZEP-SYRS-3

ZEP-SRS-18-6: Moving/copying regions of memory The Zephyr RTOS shall support an interface to move contents between regions of memory.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to copy the memory contents to different addresses.

Parents
ZEP-SYRS-3

ZEP-SRS-18-7: I/O based interface The Zephyr RTOS shall support a file I/O based interface for driver communication.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to use File I/O functions.

Parents
ZEP-SYRS-3

ZEP-SRS-18-8: C99 integer types The Zephyr RTOS shall support standard C99 integer types.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to calculate with C99 Integers.

Parents
ZEP-SYRS-3

ZEP-SRS-18-9: Standard System Error Numbers (IEEE Std 1003.1-2017) The Zephyr RTOS shall support standard system error numbers as defined by IEEE Std 1003.1-2017.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user, I want to be able to use IEE Std 1003.1-2017 Error Numbers for Interoperability.

Parents
ZEP-SYRS-3

ZEP-SRS-18-10: Document set of Zephyr OS required C library functions in Safety Manual The set of C Library functions required by Zephyr shall be documented in the Zephyr Safety Manual.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr user, I want to know which C library functions are being called by the Zephyr OS safety scope code.

Parents
ZEP-SYRS-3

ZEP-SRS-18-11: Support external C libraries documentation in Zephyr Safety Manual The Zephyr Safety Manual shall specify how to configure the support of external C Libraries.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr User, I need to understand how to configure the external C libraries to align with the validation that has been performed.

Parents
ZEP-SYRS-3

ZEP-SRS-14-1: Device Driver Abstraction The Zephyr RTOS shall provide abstraction of device drivers with common functionalities as an intermediate interface between applications and device drivers, where such interface is implemented by individual device drivers. Proposal for replacement: Zephyr shall provide an interface between application and individual device drivers to provide an abstraction of device drivers with common functionalities.

Status
Draft

Type
Functional

Component
Device Driver API

Parents
ZEP-SYRS-4

ZEP-SRS-14-2: Expose kernel to hardware interrupts The Zephyr RTOS shall provide an interface for managing a defined set of hardware exceptions (including interrupts) across all systems.

Status
Draft

Type
Functional

Component
Device Driver API

User Story
As a Zephyr RTOS user I want hardware exceptions (hardware failures, programming mistakes) to be handled gracefully (no program crashes as far as possible).

Parents
ZEP-SYRS-4

ZEP-SRS-16-1: Fatal Exception Error Handler The Zephyr RTOS shall provide default handlers for exceptions.

Status
Draft

Type
Functional

Component
Exception and Error Handling

User Story
As a Zephyr RTOS user I want exceptions which I did not handle explicitly (by mistake or on purpose) to be caught by a default handler, defined either by Zephyr OS or by myself.

Parents
ZEP-SYRS-5

ZEP-SRS-16-2: Default handler for fatal errors The Zephyr RTOS shall provide default handlers for fatal errors that do not have a dedicated handler.

Status
Draft

Type
Functional

Component
Exception and Error Handling

Parents
ZEP-SYRS-5

ZEP-SRS-16-3: Assigning a specific handler The Zephyr RTOS shall provide an interface to assign a specific handler for an exception.

Status
Draft

Type
Functional

Component
Exception and Error Handling

Parents
ZEP-SYRS-5

ZEP-SRS-16-4: Assigning a specific handler for a fatal error The Zephyr RTOS shall provide an interface to assign a specific handler for a fatal error.

Status
Draft

Type
Functional

Component
Exception and Error Handling

Parents
ZEP-SYRS-5

ZEP-SRS-17-1: Create file Zephyr shall provide file create capabilities for files on the file system.

Status
Draft

Type
Functional

Component
File System

User Story
As a Zephyr OS user I want to be able to create a new file or overwrite an existing file at the same filesystem location / identifier (e.g. path + name).

Parents
ZEP-SYRS-6

ZEP-SRS-17-2: Open files Zephyr shall provide file open capabilities for files on the file system.

Status
Draft

Type
Functional

Component
File System

User Story
As a Zephyr OS user I want to be able to open a file for writing or reading. When opened for writing, I want to have exclusive access to the file.

Parents
ZEP-SYRS-6

ZEP-SRS-17-3: Read files Zephyr shall provide read access to files in the file system.

Status
Draft

Type
Functional

Component
File System

User Story
As a Zephyr OS user I want to be able to read from an existing file, also while the file is read from multiple and write accessed from one other instances.

Parents
ZEP-SYRS-6

ZEP-SRS-17-4: Write to files Zephyr shall provide write access to the files in the file system.

Status
Draft

Type
Functional

Component
File System

User Story
As a Zephyr OS user I want to be able to write to a file either from the beginning of the file or appending at the end.

Parents
ZEP-SYRS-6

ZEP-SRS-17-5: Close file Zephyr shall provide file close capabilities for files on the file system.

Status
Draft

Type
Functional

Component
File System

User Story
As a Zephyr OS user I want to be able to close a file after being finished with my file operations, unlocking any access restrictions.

Parents
ZEP-SYRS-6

ZEP-SRS-17-6: Move file Zephyr shall provide the capability to move files on the file system.

Status
Draft

Type
Functional

Component
File System

Parents
ZEP-SYRS-6

ZEP-SRS-17-7: Delete file Zephyr shall provide file delete capabilities for files on the file system.

Status
Draft

Type
Functional

Component
File System

User Story
As a Zephyr OS user I want to be able to delete an existing file.

Parents
ZEP-SYRS-6

ZEP-SRS-7-1: Installing static IRQ service routines (ISR). Zephyr RTOS shall provide a mechanism to initialize a static IRQ service routine (ISR), providing all parameters needed to configure the hardware and software.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-2: Static IRQ initial status. The static IRQ shall be initially disabled.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-3: Installing direct IRQ service routines (ISR). Zephyr RTOS shall provide a mechanism to initialize a direct IRQ handler, providing all parameters needed to configure the hardware and software.

Status
Draft

Type
Functional

Component
Interrupts

User Story
As the developer of low-power and low-latency applications, I need to implement ISRs that avoid the normal interrupt and power management overhead.

Parents
ZEP-SYRS-7

ZEP-SRS-7-4: Direct IRQ initial status. The direct IRQ shall be initially disabled.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-5: Installing dynamic IRQ service routines (ISR). Zephyr RTOS shall provide a mechanism to initialize a dynamic IRQ service routine, providing all parameters needed to configure the hardware and software.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-6: Dynamic IRQ initial status. The dynamic IRQ shall be initially disabled.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-7: Uninstalling dynamic IRQ service routines (ISR). Zephyr RTOS shall provide a mechanism to uninstall a dynamic ISR.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-8: Global IRQ disable Zephyr RTOS shall provide a mechanism to disable all IRQs on a CPU and return the state of the IRQ hardware prior to being disabled.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-9: Global IRQ enable Zephyr RTOS shall provide a mechanism to enable all IRQs on a CPU and return them to their previous state.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-10: Specific IRQ disable Zephyr RTOS shall provide a mechanism to disable a specified IRQ.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-11: Specific IRQ enable Zephyr RTOS shall provide a mechanism to enable a specified IRQ.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-12: IRQ Enabled status Zephyr RTOS shall provide a mechanism that returns the enabled status of a specified IRQ, where the status is enabled or disabled.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-13: ISR Context status Zephyr RTOS shall provide a mechanism that returns the execution context, where the context is In-ISR or Not In-ISR.

Status
Draft

Type
Functional

Component
Interrupts

User Story
As the developer of functions that may run in either ISR or THREAD context, I need to know the current context to enable conditional behavior.

Parents
ZEP-SYRS-7

ZEP-SRS-7-14: Multi-level interrupts The Zephyr RTOS shall support multi-level preemptive interrupt priorities, when supported by hardware.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-15: Interrupt service routine invocation When an enabled IRQ that has a connected interrupt service routine is asserted, the Zephyr RTOS shall invoke the associated interrupt service routine.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-7-16: Interrupt service routine parameter When the Zephyr RTOS invokes a static or dynamic interrupt service routine, it shall pass to the routine the parameter that was registered with it.

Status
Draft

Type
Functional

Component
Interrupts

Parents
ZEP-SYRS-7

ZEP-SRS-11-1: Dedicated Logging Thread Support The Zephyr RTOS shall support isolation of logging from other functionality.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want to be able to configure logging of events so the execution of logging activities does have no or only a minimal impact to the timing behaviour of my application.

Parents
ZEP-SYRS-8

ZEP-SRS-11-2: Logs available for post processing The Zephyr RTOS logging shall produce logs that are capable of being post processed.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want the logging information to be stored in a format which allows to be read possibly converted or displayed by COTS tools.

Parents
ZEP-SYRS-8

ZEP-SRS-11-3: Formatting log messages The Zephyr RTOS logging shall support formatting of log messages to enable filtering.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want to be able my application to format texts (printf alike) into the log message.

Parents
ZEP-SYRS-8

ZEP-SRS-11-4: Logging Filtering Support The Zephyr RTOS logging system shall support filtering based on severity level.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want to be able to distinguish between different severity level for my log messages (e.g. DEBUG, INFO, WARN, ERROR, PANIC).

Parents
ZEP-SYRS-8

ZEP-SRS-11-5: Multiple Backend Logging Support The Zephyr RTOS shall support logging messages to multiple system resources.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want to be able to simultaneously log to different channels which may store / redirect the information on / to different hardware (EEPROM, Flash, FRAM, UART, Ethernet, USB etc.).

Parents
ZEP-SYRS-8

ZEP-SRS-11-6: Deferred Logging Support The Zephyr RTOS shall support deferred logging.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want a minimal influence of logging activities to the timing behaviour of my application. Time consuming logging threads shall be done in the background.

Parents
ZEP-SYRS-8

ZEP-SRS-8-1: Memory Protection The Zephyr RTOS shall support memory protection features to isolate a thread's memory region.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want memory to be allocated and protected to my application threads preventing mistakenly access to foreign memory as far as the hardware allows.

Parents
ZEP-SYRS-9

ZEP-SRS-8-2: Granting access to kernel objects The Zephyr RTOS shall provide a mechanism to grant user threads access to kernel objects.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want, from the user space, under certain conditions, access to kernel objects.

Parents
ZEP-SYRS-9

ZEP-SRS-8-3: Separation between user and kernel threads for memory access The Zephyr RTOS shall be able to differentiate between user threads and kernel threads for memory access.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want, from the kernel space, unconditioned access to kernel objects.

Parents
ZEP-SYRS-9

ZEP-SRS-8-4: Safely handle unimplemented calls or invalid system calls The Zephyr RTOS shall have a defined behaviour when an invocation of an unimplemented system call is made.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want Zephyr OS to indicate any unimplemented system call by an appropriate error message.

Parents
ZEP-SYRS-9

ZEP-SRS-8-5: Response to invalid system call IDs The Zephyr RTOS shall have a defined behaviour when an invalid system call ID is used.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want Zephyr OS to indicate invalid system call by an appropriate error message.

Parents
ZEP-SYRS-9

ZEP-SRS-8-6: Prevent user threads creating higher priority threads The Zephyr RTOS shall prevent user threads from creating new threads that are higher priority than the caller.

Status
Draft

Type
Functional

Component
Memory Protection

Parents
ZEP-SYRS-9

ZEP-SRS-8-7: Revoking threads permissions on a kernel object The Zephyr RTOS shall support revoking permission to a kernel object. User mode threads may only revoke their own access to an object.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to be protected against other user threads changing access to kernel objects of my thread.

Parents
ZEP-SYRS-9

ZEP-SRS-8-8: Prevent user threads creating supervisor threads The Zephyr RTOS shall prevent user threads from creating kernel threads.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to be protected against user threads creating higher privileged kernel/supervisor threads.

Parents
ZEP-SYRS-9

ZEP-SRS-8-9: Reduced Privilege Level Threads The Zephyr RTOS shall allow the creation of threads that run in reduced privilege level.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to be able to create lower privileged threads than my own.

Parents
ZEP-SYRS-9

ZEP-SRS-8-10: User Mode Threads Performing Privileged Operations The Zephyr RTOS shall provide system calls to allow user mode threads to perform privileged operations.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to be able to perform privileged operations in the kernel mode through a well defined interface.

Parents
ZEP-SYRS-9

ZEP-SRS-8-11: User mode handling of detected stack overflow The Zephyr RTOS shall support a defined mechanism for user mode handling a of detected stack overflow.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want, when a stack overflow is detected, to be able to implement a graceful, application defined handling of the exception.

Parents
ZEP-SYRS-9

ZEP-SRS-8-12: Stack Overflow Detection The Zephyr RTOS shall support detection of stack overflows.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to get an indication when a stack overflow occurs at least during debugging / the development phase, and for safety applications also in a release version of my application.

Parents
ZEP-SYRS-9

ZEP-SRS-8-13: Boot Time Memory Access Policy The Zephyr RTOS shall support configurable access to memory during boot time.

Status
Draft

Type
Functional

Component
Memory Protection

Parents
ZEP-SYRS-9

ZEP-SRS-8-14: System Call Handler Functions The Zephyr RTOS shall provide helper functions for system call handler functions to validate the inputs passed in from user mode before invoking the implementation function to protect the kernel.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want Zepyhr OS to validate system call parameters passed from the user mode to the kernel mode to avoid crashes and undefined behaviour.

Parents
ZEP-SYRS-9

ZEP-SRS-8-15: System Call C strings in user mode The Zephyr RTOS shall support system calls to be able to safely accept C strings passed in from user mode.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want Zepyhr OS to validate system call string type parameters passed from the user mode to the kernel mode to avoid crashes and undefined behaviour. e.g. - verify the string length is smaller or equal to the syscalls defined max. - verify that the length type does not overflow when allocating one more byte ???

Parents
ZEP-SYRS-9

ZEP-SRS-8-16: Tracking kernel objects in used by user mode threads The Zephyr RTOS shall track kernel objects that are used by user mode threads. Note: this means Zephyr shall track the resources used by the user mode thread (associate this with a user story).

Status
Draft

Type
Functional

Component
Memory Protection

Parents
ZEP-SYRS-9

ZEP-SRS-8-17: Granting threads access to specific memory The Zephyr RTOS shall have an interface to request access to specific memory after initial allocation.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to be able to request read-only or read-write access to a dedicated memory area/pool during runtime.

Parents
ZEP-SYRS-9

ZEP-SRS-8-18: Assigning memory pools to act as a thread resource pool The Zephyr RTOS shall support assigning a memory pool to act as that thread's resource pool.

Status
Draft

Type
Functional

Component
Memory Protection

User Story
As a Zephyr RTOS user I want to be able, during runtime from the kernel, to request a memory area/pool which is exclusively available to the requesting thread protected against access from other threads.

Parents
ZEP-SYRS-9

ZEP-SRS-9-1: Dynamic Memory Allocation The Zephyr RTOS shall allow threads to dynamically allocate variable-sized memory regions from a specified range of memory.

Status
Draft

Type
Functional

Component
Memory Objects

User Story
As a Zephyr RTOS user I want my application to be able to dynamically allocate memory of a application defined size.

Parents
ZEP-SYRS-9

ZEP-SRS-9-2: Memory Slab Object The Zephyr RTOS shall allow threads to dynamically allocate fixed-sized memory regions from a specified range of memory.

Status
Draft

Type
Functional

Component
Memory Objects

User Story
As a Zephyr RTOS user I want a most efficient and least fragmentation prone dynamic memory allocation mechanism.

Parents
ZEP-SYRS-9

ZEP-SRS-15-1: Traditional FIFO Queue The Zephyr RTOS shall provide a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove a limited number of 32-bit data values.

Status
Draft

Type
Functional

Component
Data Passing

User Story
As a Zephyr RTOS user I want to be able to exchange 1 to N data objects between different threads and ISR in a thread-safe manner with a first-in-first-out (queue) behaviour.

ZEP-SRS-15-2: Traditional LIFO queue The Zephyr RTOS shall provide a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of 32-bit data values.

Status
Draft

Type
Functional

Component
Data Passing

User Story
As a Zephyr RTOS user I want to be able to exchange 1 to N data objects between different threads and ISR in a thread-safe manner with a last-in-first-out (stack) behaviour.

ZEP-SRS-6-1: Mutex Kernel Object The Zephyr RTOS shall provide a mutex that allows threads to obtain mutually exclusive access to a shared resource.

Status
Draft

Type
Functional

Component
Mutex

User Story
As a Zephyr RTOS user I want to be able to synchronize threads when accessing common resources, where the thread shall have the option to: - wait indefinitely until the resource becomes available. - immediately return with an error if the resource is not available and continue. - wait for a given time for the resource to become available or return with an error.

Parents
ZEP-SYRS-13

ZEP-SRS-6-2: Mutex definition at compile time The Zephyr RTOS shall provide a mechanism to define and initialize a mutex at compile time.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-3: Mutex definition at run time The Zephyr RTOS shall provide a mechanism to initialize a mutex at run time.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-4: Locking a mutex The Zephyr RTOS shall provide a mechanism for a thread to lock a mutex and become its owner.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-5: Locking an unowned mutex While a mutex is not owned by any thread, a thread that locks it shall acquire ownership of the mutex.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-6: Locking a mutex owned by another thread While a mutex is owned by another thread, a thread that attempts to lock it shall be blocked until the mutex becomes available or the specified timeout elapses.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-7: Mutex lock timeout When locking a mutex, the Zephyr RTOS shall accept a timeout that specifies the maximum time to wait for the mutex to become available.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-8: Mutex lock timeout expiry When a mutex does not become available within the specified time, the Zephyr RTOS shall return an error indicating that the mutex was not locked.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-9: Recursive mutex locking While a thread owns a mutex, the Zephyr RTOS shall allow that thread to lock the same mutex again, and shall require the thread to unlock it the same number of times before it is released.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-10: Unlocking a mutex The Zephyr RTOS shall provide a mechanism for the owning thread to unlock a mutex.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-11: Unlocking by a non-owner If a thread that does not own a mutex attempts to unlock it, then the Zephyr RTOS shall return an error and shall not release the mutex.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-6-12: Priority inheritance While a higher-priority thread is blocked waiting on a mutex, the Zephyr RTOS shall raise the priority of the owning thread to that of the highest-priority waiting thread until the mutex is released.

Status
Draft

Type
Functional

Component
Mutex

Parents
ZEP-SYRS-13

ZEP-SRS-5-1: Counting Semaphore Definition At Compile Time The Zephyr RTOS shall provide a mechanism to define and initialize a semaphore at compile time.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-2: Counting Semaphore Definition At Run Time The Zephyr RTOS shall provide a mechanism to define and initialize a semaphore at runtime.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-3: Maximum limit of a semaphore The Zephyr RTOS shall define the maximum limit of a semaphore when the semaphore is used for counting purposes and does not have an explicit limit.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-4: Initialization with maximum count value When initializing a counting semaphore, the maximum permitted count a semaphore can have shall be set.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-5: Initial semaphore value When initializing a counting semaphore, the initial semaphore value shall be set.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-6: Semaphore acquisition mechanism The Zephyr RTOS shall provide a mechanism allowing threads to acquire a semaphore.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-7: Semaphore acquisition with count greater than zero While the semaphore's count is greater than zero, the requesting thread shall acquire the semaphore and decrement its count.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-8: Semaphore acquisition with zero count While the semaphore's count is zero, the requesting thread shall be blocked until the semaphore is released by another thread.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-9: Semaphore acquisition timeout When attempting to acquire a semaphore, the Zephyr RTOS shall accept options that specify timeout periods, allowing threads to set a maximum wait time for semaphore acquisition.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-10: Semaphore acquisition timeout error handling When attempting to acquire a semaphore, where the semaphore is not acquired within the specified time, the Zephyr RTOS shall return an error indicating a timeout.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-11: Semaphore acquisition no wait error handling When attempting to acquire a semaphore, where the current count is zero and no timeout time was provided, the Zephyr RTOS shall return an error indicating the semaphore is busy.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-12: Semaphore release The Zephyr RTOS shall provide a mechanism allowing threads to release a semaphore.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-13: Semaphore count increment on release The Zephyr RTOS shall increment the semaphore's count upon release.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-14: Highest-priority waiter unblocked on release When there are threads waiting on the semaphore, the highest-priority waiting thread shall be unblocked and acquire the semaphore.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-15: Checking semaphore count The Zephyr RTOS shall provide a mechanism for threads to check the current count of a semaphore without acquiring it.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-16: Semaphore reset The Zephyr RTOS shall provide a mechanism that resets the semaphore count to zero.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-17: Semaphore acquisitions abort after reset When a semaphore is reset, the Zephyr RTOS shall abort all pending take operations on the semaphore, returning to the affected threads the same error used to indicate a wait timeout.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-18: Semaphore Initialization Option Validation When initializing a counting semaphore, where the maximum permitted count of a semaphore is invalid, then the Zephyr RTOS shall return an error indicating invalid values.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-19: Semaphore release at maximum count When a semaphore is released while its count is already at the maximum permitted count, the Zephyr RTOS shall leave the count unchanged.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-5-20: Semaphore operations from interrupt context The Zephyr RTOS shall allow a semaphore to be released from an interrupt service routine, and to be acquired from an interrupt service routine when no waiting is requested.

Status
Draft

Type
Functional

Component
Semaphore

Parents
ZEP-SYRS-14

ZEP-SRS-13-1: Power State Control The Zephyr RTOS shall provide control over changes to system power states.

Status
Draft

Type
Functional

Component
Power Management

User Story
See ZEP104 + When the power state is changed I want to get an notification in order for specific parts of my application to react accordingly.

Parents
ZEP-SYRS-10

ZEP-SRS-13-2: Power Management TBD

Status
Draft

Type
Functional

Component
Power Management

Parents
ZEP-SYRS-10

ZEP-SRS-13-3: Notification of changes to system power states The Zephyr RTOS shall provide notification of changes to system power states.

Status
Draft

Type
Functional

Component
Power Management

Parents
ZEP-SYRS-10

ZEP-SRS-3-1: Exchanging data between threads The Zephyr RTOS shall provide a mechanism for exchanging data between threads.

Status
Draft

Type
Functional

Component
Thread Communication

User Story
(Note: copying data may be needed here - what is Zephyr doing? is it configurable?)

ZEP-SRS-3-2: Waiting for results during communication The Zephyr RTOS shall provide mechanisms to enable waiting for results during communication between threads. (NOTE: waiting for results is really bad and dangerous, want to avoid if at all possible).

Status
Draft

Type
Functional

Component
Thread Communication

User Story
=N73

ZEP-SRS-3-3: Poll Operation Support The Zephyr RTOS shall support a poll operation which enables waiting concurrently for any one of multiple conditions to be fulfilled.

Status
Draft

Type
Functional

Component
Thread Communication

User Story
As a Zephyr RTOS user I want my thread to wait for one of several defined events to occur and only continue when one of them has occurred.

ZEP-SRS-3-4: Pipe Communication Primitive The Zephyr RTOS shall provide a communication primitive that allows a thread to transfer a block of data to another thread.

Status
Draft

Type
Functional

Component
Thread Communication

User Story
As a Zephyr RTOS user I want to send a byte stream from one thread to another in a thread-safe manner.

ZEP-SRS-3-5: Message Queue The Zephyr RTOS shall provide a a communication primitive that allow threads and ISRs to asynchronously exchange fixed-size data items.

Status
Draft

Type
Functional

Component
Thread Communication

ZEP-SRS-3-6: Mailbox Kernel Primitive The Zephyr RTOS shall provide a communication primitive that allows threads to exchange messages of varying sizes asynchronously or synchronously.

Status
Draft

Type
Functional

Component
Thread Communication

User Story
As a Zephyr RTOS user I want a sending thread to deposit a message into the mailbox, and a receiving thread to be able to retrieve the message at its convenience. This allows for asynchronous communication, where threads do not need to synchronize their execution explicitly.

ZEP-SRS-2-1: Support operation on more than one CPU The Zephyr RTOS shall support operation on more than one physical CPU sharing the same kernel state.

Status
Draft

Type
Functional

Component
Multi Core

ZEP-SRS-2-2: Running threads on specific CPUs The Zephyr RTOS shall provide an interface for running threads on specific sets of CPUs (default is 1 CPU).

Status
Draft

Type
Functional

Component
Multi Core

User Story
As a Zephyr RTOS user I want Zephyr OS to be able to specify the CPU core or the set of CPU cores on which a thread shall be executed.

ZEP-SRS-2-3: Exclusion between physical CPUs The Zephyr RTOS shall provide an interface for mutual exclusion between multiple physical CPUs.

Status
Draft

Type
Functional

Component
Multi Core

User Story
As a Zephyr RTOS user I want Zephyr OS to provide synchronization mechanisms between the CPU cores and the access to common resources.

ZEP-SRS-2-4: Scheduling a thread based on an event The Zephyr RTOS shall provide an interface to schedule a thread based on an event.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want to be able to execute work which reacts on events and interrupts the current executed work.

Parents
ZEP-SYRS-15

ZEP-SRS-2-5: Deadline Scheduling Priorities The Zephyr RTOS shall organize running threads by earliest deadline first priority.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want to be able to schedule threads by earliest deadline first.

ZEP-SRS-2-6: Work Queue utility capable of running preemptible work items The Zephyr RTOS shall provide a thread-pooled work queue utility capable of running preemptible work items with specific scheduler priorities.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want to be able to add work items in a thread work queue with different priorities and these shall be scheduled according their priorities.

ZEP-SRS-2-7: Run user supplied functions in-order in a separate thread(s) The Zephyr RTOS shall provide an interface for running user-supplied functions.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want to be able to run functions in-order in a separated thread/threads.

ZEP-SRS-2-8: Organize running threads into a fixed list The Zephyr RTOS shall organize running threads into a fixed list of numeric priorities.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want that the OS organize running threads in a fixed list of numeric priorities.

ZEP-SRS-2-9: Preemption support The Zephyr RTOS shall support preemption of a running thread by a higher priority thread.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want that the OS preempt running threads by a thread with higher priority.

ZEP-SRS-2-10: Un-preemptible thread priorities The Zephyr RTOS shall support thread priorities which cannot be preempted by other user threads.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want to be able to configure thread prioritizes which cannot be preempted by other user threads.

ZEP-SRS-2-11: Time sharing of CPU resources The Zephyr RTOS shall support time sharing of CPU resources among threads of the same priority.

Status
Draft

Type
Functional

Component
Thread Scheduling

User Story
As a Zephyr RTOS user, I want to be able to configure my RTOS in the way, that the CPU resources are shared evenly among executed threads of the same priority.

ZEP-SRS-1-1: Creating threads The Zephyr RTOS shall provide an interface to create (start) a thread.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-2: Setting thread priority The Zephyr RTOS shall provide an interface to set a thread's priority.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-17

ZEP-SRS-1-3: Suspending a thread The Zephyr RTOS shall provide an interface to suspend a thread.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-4: Resuming a suspended thread The Zephyr RTOS shall provide an interface to resume a suspended thread.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-5: Resuming a suspended thread after a timeout The Zephyr RTOS shall provide an interface to resume a suspended thread after a timeout.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-6: Deleting a thread The Zephyr RTOS shall provide an interface to delete (end) a thread.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-7: Thread states Threads shall have different states to fulfill the Life-cycle of a thread

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user, I want to know in what state a specific thread is.

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-8: Thread stack objects Every Thread shall have it's own stack.

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user I want to be able to configure the stack size of a thread.
And every thread shall have it's own dedicated stack.

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-9: Thread privileges The Zephyr RTOS shall provide an interface to create threads with defined privilege.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-10: Scheduling multiple threads The Zephyr RTOS shall provide an interface to schedule multiple threads.

Status
Draft

Type
Functional

Component
Threads

Parents
ZEP-SYRS-16

ZEP-SRS-1-11: Thread Options The Zephyr RTOS shall support a set of thread options.

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user, I want to be able to pass specific option to a thread.

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-1-12: Thread Custom Data Every thread shall have a custom data area.

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user, I want to be able to set a thread specific custom area for every thread I create and which can be used only by the thread itself or the can be used by the application

Parents
ZEP-SYRS-15, *ZEP-SYRS-16*

ZEP-SRS-4-1: Timer definition at compile time The Zephyr RTOS shall provide a mechanism to define and statically (i.e. compile time) initialize timers.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-2: Timer expiry function When initializing a timer, the Zephyr RTOS shall support setting a function that gets called when the timer expires.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-3: Timer stop function When initializing a timer, the Zephyr RTOS shall support setting a function that gets called when a running timer is stopped.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-4: Timer definition at run time The Zephyr RTOS shall provide a mechanism to define and initialize timers at run time.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-5: Timer start The Zephyr RTOS shall provide a mechanism to start a timer for a specific duration and periodicity.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-6: Timer stop The Zephyr RTOS shall provide a mechanism to stop a running timer.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-7: Timer status The Zephyr RTOS shall provide a mechanism to read the number of times a timer has expired and then reset this count to zero.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-8: Timer status reinitialization When a timer is initialized, started, or read via the timer status or synchronization mechanism, the Zephyr RTOS shall reset the timer's expiration count to zero.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-9: Timer thread synchronization The Zephyr RTOS shall provide a mechanism to synchronize a thread to a timer and then block the thread's execution until any of the following conditions is satisfied: - The timer is stopped - The timer's expiration count is greater than zero

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-10: Timer next expiration time in system ticks The Zephyr RTOS shall provide a mechanism to get a timer's next expiration time in system ticks.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-11: Timer remaining time until expiration in system ticks The Zephyr RTOS shall provide a mechanism to get a timer's remaining time until its next expiry in system ticks.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-12: Timer remaining time until expiration in milliseconds The Zephyr RTOS shall provide a mechanism to get the timer's remaining time until its next expiry in milliseconds.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-13: Timer set user data The Zephyr RTOS shall support adding user defined data to a timer.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-14: Timer get user data The Zephyr RTOS shall support retrieving user defined data from a timer.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-4-15: Timer expire functions in interrupt context When a timer expiry function is called, the Zephyr RTOS shall do so in the interrupt context.

Status
Draft

Type
Functional

Component
Timers

Parents
ZEP-SYRS-18

ZEP-SRS-10-1: Initializing a trace Zephyr shall provide an interface to initialize a trace.

Status
Draft

Type
Functional

Component
Tracing

Parents
ZEP-SYRS-19

ZEP-SRS-10-2: Triggering a trace Zephyr shall provide an interface to trigger a trace.

Status
Draft

Type
Functional

Component
Tracing

Parents
ZEP-SYRS-19

ZEP-SRS-10-3: Dumping trace results Zephyr shall provide an interface to dump results from a trace.

Status
Draft

Type
Functional

Component
Tracing

Parents
ZEP-SYRS-19

ZEP-SRS-10-4: Removing trace data Zephyr shall provide an interface to remove trace data.

Status
Draft

Type
Functional

Component
Tracing

Parents
ZEP-SYRS-19

ZEP-SRS-10-5: Tracing Object Identification Zephyr shall provide an interface to identify the objects being traced.

Status
Draft

Type
Functional

Component
Tracing

User Story
As a Zephyr OS user, I want to be able to give each object which I create a name / label in order to be able to identify them in a trace log.

Parents
ZEP-SYRS-19

ZEP-SRS-10-6: Tracing Non-Interference Zephyr shall prevent the tracing functionality from interfering with normal operations.

Status
Draft

Type
Functional

Component
Tracing

User Story
As a Zephyr OS user, I want that the trace functionality do not interfere or slow down the operation system functionality.

Parents
ZEP-SYRS-19

ZEP-SRS-21-1: Dynamic initialization of condition variables The Zephyr RTOS shall provide a mechanism to define and initialize a condition variable dynamically (at runtime).

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-2: Static initialization of condition variables The Zephyr RTOS shall provide a mechanism to define and initialize a condition variable statically (at compile time).

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-3: Signal one waiting thread The Zephyr RTOS shall provide a mechanism to signal the highest priority waiting thread when a condition is met.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-4: Signal multiple waiting threads The Zephyr RTOS shall provide a mechanism to signal all waiting threads when a condition is met.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-5: Wait on a condition variable The Zephyr RTOS shall provide a mechanism for a thread to wait on a condition variable.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-6: Wait timeout on a condition variable When waiting on a condition variable, the thread shall specify a timeout value.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-7: Wait timeout occurence When a timeout occurs while waiting on a condition variable, the thread shall be unblocked and a timeout error shall be returned.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-8: Release mutex on wait When a thread waits on a condition variable, the Zephyr RTOS shall atomically release the associated mutex while the thread is blocked and re-acquire it before the thread resumes.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-21-9: Unblock a waiting thread Whenever a thread signals a condition variable, the Zephyr RTOS shall unblock the highest priority thread currently waiting on that condition variable.

Status
Draft

Type
Functional

Component
Condition Variables

Parents
ZEP-SYRS-21

ZEP-SRS-20-1: Queue definition at compile time The Zephyr RTOS shall provide a mechanism to define and initialize a queue at compile time.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-2: Queue definition at run time. The Zephyr RTOS shall provide a mechanism to define and initialize a queue at run time.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-3: Queue enqueue item to the back The Zephyr RTOS shall provide a mechanism to enqueue a data item to the back of a queue (i.e. append).

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-4: Queue enqueue item to the front The Zephyr RTOS shall provide a mechanism to enqueue a data item to the front of a queue (i.e. prepend).

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-5: Queue remove item The Zephyr RTOS shall provide a mechanism to remove a specific data item from a queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-6: Queue get and dequeue item from front The Zephyr RTOS shall provide a mechanism to get and dequeue a data item from the front of a queue, within a timeout.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-7: Queue empty check The Zephyr RTOS shall provide a mechanism to check if a queue is empty.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-8: Queue peek item at back The Zephyr RTOS shall provide a mechanism to peek at the data data item at the back of a queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-9: Queue peek item at front The Zephyr RTOS shall provide a mechanism to peek at the data data item at the front of a queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-10: Queue insert The Zephyr RTOS shall provide a mechanism to insert a data item behind another specific data item in a queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-11: Queue append item list to the back The Zephyr RTOS shall provide a mechanism to append a list of data items to the back of a queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-12: Queue append and empty item list to the back The Zephyr RTOS shall provide a mechanism to append a list of data items to the back of a queue and then empty the list.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-13: Queue append unique data item The Zephyr RTOS shall provide a mechanism to append a data item uniquely to the queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-20-14: Queue implicit memory allocation The Zephyr RTOS shall provide a dedicated mechanism to implicite allocate memory from a thread when appending data items to a queue.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-22

ZEP-SRS-23-1: LIFO definition at compile time The Zephyr RTOS shall provide a mechanism to define and initialize a LIFO at compile time.

Status
Draft

Type
Functional

Component
LIFOs

Parents
ZEP-SYRS-23

ZEP-SRS-23-2: LIFO enqueue item to the back The Zephyr RTOS shall provide a mechanism to enqueue a data item to the back of a LIFO (i.e. prepend).

Status
Draft

Type
Functional

Component
LIFOs

Parents
ZEP-SYRS-23

ZEP-SRS-23-3: LIFO implicit memory allocation The Zephyr RTOS shall provide a mechanism to allocate memory from a thread when enqueuing data items to a LIFO.

Status
Draft

Type
Functional

Component
LIFOs

Parents
ZEP-SYRS-23

ZEP-SRS-23-4: LIFO get and dequeue item from front The Zephyr RTOS shall provide a mechanism to get and dequeue a data item from the back of a LIFO, within a timeout.

Status
Draft

Type
Functional

Component
LIFOs

Parents
ZEP-SYRS-23

ZEP-SRS-23-5: Queue definition at compile time The Zephyr RTOS shall provide a mechanism to define and initialize a LIFO at compile time.

Status
Draft

Type
Functional

Component
Queues

Parents
ZEP-SYRS-23

ZEP-SRS-24-1: FIFO definition at compile time The Zephyr RTOS shall provide a mechanism to define and initialize a FIFO at compile time.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-2: FIFO cancel waiting thread The Zephyr RTOS shall provide a mechanism for the first thread waiting to get and dequeue a data item to return as if the timeout had expired.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-3: FIFO enqueue item to the back The Zephyr RTOS shall provide a mechanism to enqueue a data item to the back of a FIFO (i.e. append).

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-4: FIFO implicit memory allocation The Zephyr RTOS shall provide a mechanism to allocate memory from a thread when enqueuing data items to a FIFO.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-5: FIFO append item list to the back The Zephyr RTOS shall provide a mechanism to append a list of data items to the back of a FIFO.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-6: FIFO append and empty item list to the back The Zephyr RTOS shall provide a mechanism to append a list of data items to the back of a FIFO and then empty the list.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-7: FIFO get and dequeue item from front The Zephyr RTOS shall provide a mechanism to get and dequeue a data item from the front of a FIFO, within a timeout.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-8: FIFO empty check The Zephyr RTOS shall provide a mechanism to check if a FIFO is empty.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-9: FIFO peek item at front The Zephyr RTOS shall provide a mechanism to peek at the data data item at the front of a FIFO.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-24-10: FIFO peek item at back The Zephyr RTOS shall provide a mechanism to peek at the data item at the back of a FIFO.

Status
Draft

Type
Functional

Component
FIFOs

Parents
ZEP-SYRS-24

ZEP-SRS-25-1: Mailbox Initialization At Run Time The Zephyr RTOS shall provide a mechanism to define and initialize a mailbox at run time.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to initialize a mailbox instance so that it is ready to be used for message exchange between threads.

Parents
ZEP-SYRS-25

ZEP-SRS-25-2: Mailbox Initialization At Compile Time The Zephyr RTOS shall provide a mechanism to statically define and initialize a mailbox object at compile time.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to statically define and initialize a mailbox at compile time so that it is available immediately without runtime initialization.

Parents
ZEP-SYRS-25

ZEP-SRS-25-3: Message Size Support The Zephyr RTOS shall support messages containing zero or more bytes of data.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to send messages of different sizes using the same mailbox so that I can efficiently communicate different types of information between threads.

Parents
ZEP-SYRS-25

ZEP-SRS-25-4: Mailbox Data Transfer The Zephyr RTOS shall handle the data transfer between mailbox objects of the sending and receiving threads.

Status
Draft

Type
Functional

Component
Mailboxes

Parents
ZEP-SYRS-25

ZEP-SRS-25-5: Synchronous Message Sending The Zephyr RTOS shall provide a mechanism for a thread to send a message through a mailbox and block until the message is processed or a timeout occurs.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to send a message and wait for it to be processed so that I can be sure the message was received before continuing execution.

Parents
ZEP-SYRS-25

ZEP-SRS-25-6: Synchronous Send Timeout Handling If the synchronous message send operation times out before a receiver processes the message, the Zephyr RTOS shall return an timeout error code to the sending thread.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to limit how long my thread waits for a message to be received so that I can implement fallback behavior if communication takes too long.

Parents
ZEP-SYRS-25

ZEP-SRS-25-7: Asynchronous Message Sending The Zephyr RTOS shall provide a mechanism for a thread to send a message through a mailbox without waiting for it to be processed.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to send a message without waiting for it to be processed so that my thread can continue execution immediately.

Parents
ZEP-SYRS-25

ZEP-SRS-25-8: Asynchronous Completion Signaling When a sending thread asynchronously sends a message to a mailbox object, the Zephyr RTOS shall provide a mechanism to signal to the sending thread that the message has been both received and completely processed by the receiver.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be notified when my asynchronously sent message has been fully processed so that I can perform follow-up actions without polling.

Parents
ZEP-SYRS-25

ZEP-SRS-25-9: Message Reception The Zephyr RTOS shall provide a mechanism for a thread to receive a message via a mailbox object with a timeout parameter.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to receive messages from other threads with control over how long to wait for a message to arrive.

Parents
ZEP-SYRS-25

ZEP-SRS-25-10: Message Data Retrieval The Zephyr RTOS shall provide a mechanism for a thread to retrieve message data via a mailbox object.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to extract message data into my buffer after message reception so that I can process the information contained in the message.

Parents
ZEP-SYRS-25

ZEP-SRS-25-11: Message Reception Blocking When a receiving thread requests a message via a mailbox object and no message is available, the Zephyr RTOS shall block the receiving thread until a message is available or the timeout expires.

Status
Draft

Type
Functional

Component
Mailboxes

Parents
ZEP-SYRS-25

ZEP-SRS-25-12: Message Reception Timeout Handling If the message receive operation times out before a message becomes available, the Zephyr RTOS shall return an appropriate timeout error code to the receiving thread.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to limit how long my thread waits for a message to arrive so that I can implement fallback behavior if communication takes too long.

Parents
ZEP-SYRS-25

ZEP-SRS-25-13: Non-Anonymous Messaging The Zephyr RTOS shall handle message exchange via a mailbox object non-anonymously, allowing both the sending and receiving threads to know the identity of the other thread.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to identify the source or destination of messages so that I can implement thread-specific handling of message content.

Parents
ZEP-SYRS-25

ZEP-SRS-25-14: Priority-Based Message Delivery When multiple threads are waiting on an empty mailbox object, the Zephyr RTOS shall deliver the next message to the highest priority thread.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want message delivery to respect thread priorities so that higher priority tasks receive messages before lower priority ones.

Parents
ZEP-SYRS-25

ZEP-SRS-25-15: Priority-Based Message Delivery When multiple threads of equal priority are waiting on an empty mailbox object, the Zephyr RTOS shall deliver the next message to the thread that has waited the longest.

Status
Draft

Type
Functional

Component
Mailboxes

Parents
ZEP-SYRS-25

ZEP-SRS-25-16: Mailbox Quantity Support The Zephyr RTOS shall support an arbitrary number of mailbox objects, limited only by available RAM in the system.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want to be able to create as many mailboxes as my application needs without arbitrary limitations so that I can design my communication architecture freely.

Parents
ZEP-SYRS-25

ZEP-SRS-25-17: Invalid Parameter Handling The Zephyr RTOS shall handle invalid parameters by returning error codes rather than causing system failures.

Status
Draft

Type
Functional

Component
Mailboxes

User Story
As a Zephyr RTOS developer, I want the system to validate my inputs and return errors rather than crash when I provide invalid parameters so that I can develop more robust applications.

Parents
ZEP-SYRS-25

ZEP-SRS-30-1: Stack definition at compile time The Zephyr RTOS shall provide a mechanism to define and initialize a stack at compile time.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30

ZEP-SRS-30-2: Stack initialization at run time with an user-defined memory area The Zephyr RTOS shall provide a mechanism to initialize a stack at run time, using a data buffer provided by the user.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30

ZEP-SRS-30-3: Stack initialization at run time with automatically allocated memory area The Zephyr RTOS shall provide a mechanism to initialize a stack at run time, with automatic allocation of the stack memory.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30

ZEP-SRS-30-4: Releasing a dynamically allocated stack buffer The Zephyr RTOS shall provide a mechanism to deallocate all resources previously allocated by a run-time stack definition.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30

ZEP-SRS-30-5: Push an item to the stack The Zephyr RTOS shall provide a mechanism to add a new item on top of the stack.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30, *ZEP-SRS-30-7*

ZEP-SRS-30-6: Pop an item from the stack The Zephyr RTOS shall provide a mechanism to retrieve the current item from the top of the stack and to remove such item from the stack.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30, *ZEP-SRS-30-9*

ZEP-SRS-30-7: Pushing onto a full stack If the stack is full when an item is pushed, the Zephyr RTOS shall return an error and not add the item.

Status
Draft

Type
Functional

Component
Stacks

Parents
ZEP-SYRS-30

ZEP-SRS-30-8: Concurrent access protection The Zephyr RTOS shall provide a mechanism to push items to or pop items from the same stack object from multiple execution contexts which can run concurrently.

Status
Draft

Type
Functional

Component
Stacks

User Story
As a Zephyr RTOS user I want to access a stack from different execution contexts (like threads), including interrupt handlers.

Parents
ZEP-SYRS-30

ZEP-SRS-30-9: Stack data retrieval with timeout The Zephyr RTOS shall provide a mechanism to allow waiting for a stack item availability within a specified timeout.

Status
Draft

Type
Functional

Component
Stacks

User Story
As a Zephyr RTOS user I want to share a stack object between a producer and a consumer threads. The producer thread pushes items into the stack, while the consumer thread is waiting for an item to appear in the stack.

Parents
ZEP-SYRS-30

ZEP-SRS-26-1: Atomic variable The Zephyr RTOS shall define an atomic variable type whose size matches the native word size of the target architecture: 32 bits on 32-bit architectures and 64 bits on 64-bit architectures.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-2: Atomic value The Zephyr RTOS shall define a signed integer type, whose size is determined by the target processor architecture, used as the parameter and return type of operations on atomic variables.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-3: Tearing freedom The Zephyr RTOS shall guarantee that each operation on an atomic variable is free from torn reads or writes.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-4: Cross-CPU visibility The Zephyr RTOS shall guarantee that the result of each operation on an atomic variable is visible to all processors in the system.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-5: Indivisibility The Zephyr RTOS shall provide a mechanism for performing all operations on an atomic variable in an indivisible manner.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-6: Memory ordering When performing an operation on an atomic variable, the Zephyr RTOS shall provide full memory barrier semantics, such that memory operations issued before the atomic operation are observed before it and memory operations issued after it are observed after it.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-7: Software implementation fallback The Zephyr RTOS shall support executing atomic operations on hardware that does not provide native atomic instruction support.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-8: Native atomic instructions Where the target hardware provides native atomic instructions, the Zephyr RTOS shall support implementing atomic operations using those instructions.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-9: Compute size of atomic variables The Zephyr RTOS shall provide a compile-time mechanism for computing the minimum number of atomic variables necessary to represent a bit array of a given number of bits.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-10: Define an array of atomic variables The Zephyr RTOS shall provide a compile-time mechanism for defining an array of atomic variables with the minimum size necessary to represent a bit array of a given number of bits.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-11: Initialize atomic variable The Zephyr RTOS shall provide a compile-time mechanism for initializing an atomic variable.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-12: Set atomic variable The Zephyr RTOS shall provide a mechanism for setting an atomic variable and returning its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-13: Get atomic variable The Zephyr RTOS shall provide a mechanism for getting the value from an atomic variable.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-14: Atomic bitwise operations When performing a bitwise operation on an atomic variable, the Zephyr RTOS shall store the result in the atomic variable and return its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-15: Atomic bitwise AND operation The Zephyr RTOS shall provide a mechanism for performing a bitwise AND operation on an atomic variable with a given value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-14

ZEP-SRS-26-16: Atomic bitwise OR operation The Zephyr RTOS shall provide a mechanism for performing a bitwise OR operation on an atomic variable with a given value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-14

ZEP-SRS-26-17: Atomic bitwise NAND operation The Zephyr RTOS shall provide a mechanism for performing a bitwise NAND operation on an atomic variable with a given value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-14

ZEP-SRS-26-18: Atomic bitwise XOR operation The Zephyr RTOS shall provide a mechanism for performing a bitwise XOR operation on an atomic variable with a given value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-14

ZEP-SRS-26-19: Atomic addition The Zephyr RTOS shall provide a mechanism for adding a value to an atomic variable and returning its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-20: Atomic increment The Zephyr RTOS shall provide a mechanism for incrementing an atomic variable by 1 and returning its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-19

ZEP-SRS-26-21: Atomic subtraction The Zephyr RTOS shall provide a mechanism for subtracting a value from an atomic variable and returning its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-22: Atomic decrement The Zephyr RTOS shall provide a mechanism for decrementing an atomic variable by 1 and returning its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-21

ZEP-SRS-26-23: Atomic compare and set The Zephyr RTOS shall provide a mechanism for setting an atomic variable to a new value if and only if its current value equals an expected value, leaving the atomic variable unchanged otherwise, and returning whether the atomic variable was updated.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-24: Atomic clear The Zephyr RTOS shall provide a mechanism for setting an atomic variable to zero and returning its previous value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-25: Atomic bit operations The Zephyr RTOS shall support performing bit-level operations on individual bits within either a single atomic variable or an array of atomic variables.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-26: Atomic set bit The Zephyr RTOS shall provide a mechanism for setting a specific bit within an atomic variable or an array of atomic variables to 1.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-25

ZEP-SRS-26-27: Atomic clear bit The Zephyr RTOS shall provide a mechanism for clearing a specific bit within an atomic variable or an array of atomic variables to 0.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-25

ZEP-SRS-26-28: Atomic set bit to a given state The Zephyr RTOS shall provide a mechanism for setting a specific bit within an atomic variable or an array of atomic variables to a given boolean value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-25

ZEP-SRS-26-29: Atomic test bit The Zephyr RTOS shall provide a mechanism for getting the state of a specific bit within an atomic variable or an array of atomic variables, returning its current state as a boolean value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-25

ZEP-SRS-26-30: Atomic test and set bit The Zephyr RTOS shall provide a mechanism for setting a specific bit within an atomic variable or an array of atomic variables to 1 and returning its previous state.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-25

ZEP-SRS-26-31: Atomic test and clear bit The Zephyr RTOS shall provide a mechanism for clearing a specific bit within an atomic variable or an array of atomic variables to 0 and returning its previous state.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-25

ZEP-SRS-26-32: Atomic pointer The Zephyr RTOS shall define an atomic variable type for storing a pointer value atomically.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-33: Atomic pointer value The Zephyr RTOS shall define a pointer type used as the parameter and return type of all atomic pointer operations.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-34: Initialize atomic pointer The Zephyr RTOS shall provide a compile-time mechanism for initializing an atomic pointer to a specific pointer value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-35: Atomic pointer operations The Zephyr RTOS shall provide operations that read and write atomic pointers using the atomic pointer value type.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

ZEP-SRS-26-36: Get atomic pointer The Zephyr RTOS shall provide a mechanism for getting the pointer value from an atomic pointer.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-35

ZEP-SRS-26-37: Set atomic pointer The Zephyr RTOS shall provide a mechanism for setting an atomic pointer and returning its previous pointer value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-35

ZEP-SRS-26-38: Atomic pointer compare and set The Zephyr RTOS shall provide a mechanism for setting an atomic pointer to a new value if and only if its current value equals an expected value, leaving the atomic pointer unchanged otherwise, and returning whether the atomic pointer was updated.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-35

ZEP-SRS-26-39: Atomic pointer clear The Zephyr RTOS shall provide a mechanism for setting an atomic pointer to NULL and returning its previous pointer value.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SRS-26-35

ZEP-SRS-26-40: Usable from threads and interrupt service routines The Zephyr RTOS shall support performing atomic operations from threads and from interrupt service routines, guaranteeing correct results when multiple contexts operate concurrently on the same atomic variable.

Status
Draft

Type
Functional

Component
Atomic Service

Parents
ZEP-SYRS-26

Zephyr System Requirements

ZEP-SYRS-1: Architecture Layer Interface The Zephyr RTOS shall provide a framework to communicate with a set of hardware architectural services.

Status
Draft

Type
Functional

Component
Hardware Architecture Interface

User Story
As a Zephyr RTOS user I want to be able to easily switch my application to a different MCU architecture (x86, ARM Cortex-M/A, RISCV etc.).

ZEP-SYRS-2: Support multiprocessor management The Zephyr RTOS shall support symmetric multiprocessing on multiple cores.

Status
Draft

Type
Functional

Component
Hardware Architecture Interface

User Story
As a Zephyr RTOS user I want to use Zephyr OS on multi core (SMP-)MCUs/MPUs.

Parents
ZEP-SYRS-1

ZEP-SYRS-3: Support Subset of Standard C Library The Zephyr RTOS shall support a subset of the standard C library.

Status
Draft

Type
Functional

Component
C Library

User Story
As a Zephyr RTOS user I want to have a selection of standard C library implementations e.g. a full extend and a minimal with a smaller footprint or a particular fast executing implementation.

ZEP-SYRS-4: Device Driver Abstraction The Zephyr RTOS shall provide a framework for managing device drivers and peripherals.

Status
Draft

Type
Functional

Component
Device Drivers

User Story
As a Zephyr RTOS user I want my application to be portable between different MCU architectures (ARM Cortex-M/A, Intel x86, RISCV etc.) and MCU vendors (STM, NXP, Intel, etc.) without having to change the MCU peripherals access.

ZEP-SYRS-5: Fatal error and exception handling The Zephyr RTOS shall provide a framework for error and exception handling.

Status
Draft

Type
Functional

Component
Exception and Error Handling

User Story
As a Zephyr RTOS user I want errors and exceptions to handled and react according to my applications requirements (e.g. reach/establish the applications safety state).

ZEP-SYRS-6: Common File system operation support The Zephyr RTOS shall provide a framework for managing file system access.

Status
Draft

Type
Functional

Component
File Systems

User Story
As a Zephyr RTOS user I want a posix / c like file system access to store data.

ZEP-SYRS-7: Interrupt Management The Zephyr RTOS shall provide a framework for interrupt and interrupt service routine management.

Status
Draft

Type
Functional

Component
Interrupts

User Story
As the Zephyr RTOS user I want the Kernel to provide abstracted interfaces to the platform enabling me to implement standard interrupts interrupt service routines without detailed knowledge of the platform architecture and programming model.

ZEP-SYRS-20: Direct ISR, Platform Specific helpers. Zephyr RTOS shall support development of direct ISRs by providing platform specific code fragments and factory functions including, minimal header instructions, minimal footer instructions, low power termination, and ISR construction.

Status
Draft

Type
Functional

Component
Interrupts

User Story
As the Zephyr RTOS user I want the Kernel to provide support for implementing standard low latency and low power interrupt service routines without detailed knowledge of the platform architecture and programming model.

Parents
ZEP-SYRS-7

ZEP-SYRS-8: Logging The Zephyr RTOS shall provide a framework for logging events.

Status
Draft

Type
Functional

Component
Logging

User Story
As a Zephyr RTOS user I want to be able to log application defined events as well as framework exceptions.

ZEP-SYRS-9: Memory Management framework The Zephyr RTOS shall support a memory management framework.

Status
Draft

Type
Functional

Component
Memory Management

User Story
As a Zephyr RTOS user I want memory to be allocated and protected to my application threads preventing mistakenly access to foreign memory as far as the hardware allows.

ZEP-SYRS-10: Power Management The Zephyr RTOS shall provide an interface to control hardware power states.

Status
Draft

Type
Functional

Component
Power Management

User Story
As a Zephyr RTOS user I want to be able to control the power mode of the MCU and its peripherals to take advantage of the hardware features and to be able to implement low power or battery driven long life applications.

ZEP-SYRS-11: Multiple CPU scheduling The Zephyr RTOS shall support scheduling of threads on multiple hardware CPUs.

Status
Draft

Type
Functional

Component
SMP and Multi core

User Story
As a Zephyr RTOS user I want Zephyr OS to run on MCUs/CPUs with one or more CPU cores.

ZEP-SYRS-12: Scheduling The Zephyr RTOS shall provide an interface to assign a thread to a specific CPU.

Status
Draft

Type
Functional

Component
SMP and Multi core

User Story
As a Zephyr RTOS user, I want to be able to control which thread will run on which CPU.

ZEP-SYRS-13: Mutex The Zephyr RTOS shall provide an interface for managing communication between threads.

Status
Draft

Type
Functional

Component
Mutex

User Story
As a Zephyr RTOS user I want to able to exchange information between threads in a thread-safe manner guaranteeing data consistence.

ZEP-SYRS-14: Counting Semaphore The system shall implement a semaphore synchronization primitive for coordinating access to shared resources among multiple threads.

Status
Draft

Type
Functional

Component
Semaphore

ZEP-SYRS-15: Thread support The Zephyr RTOS shall support threads.

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user, I want to be able to have support for the kernel objects named threads for processing work.

ZEP-SYRS-16: Thread management The Zephyr RTOS shall provide a framework for managing multiple threads of execution.

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user, I want to be able to manage the execute of multiple threads with different priorities.

ZEP-SYRS-17: Thread priority Threads shall have a priority.

Status
Draft

Type
Functional

Component
Threads

User Story
As a Zephyr RTOS user, I want to be able to give my threads different priorities for execution.

ZEP-SYRS-18: Timers The Zephyr RTOS shall provide a framework for managing time-based events.

Status
Draft

Type
Functional

Component
Timers

User Story
As a Zephyr RTOS user, I want to start, suspend, resume and stop timers which shall trigger an event on a set expiration time.

ZEP-SYRS-19: Tracing Zepyhr shall provide a framework mechanism for tracing low level system operations (NOTE: system calls, interrupts, kernel calls, thread, synchronization, etc.).

Status
Draft

Type
Functional

Component
Tracing

User Story
As a Zephyr RTOS user, I want to be able to trace different OS operations.

ZEP-SYRS-21: Condition Variables The Zephyr RTOS shall provide a framework to synchronize threads based on a condition variable.

Status
Draft

Type
Non-Functional

Component
Condition Variables

ZEP-SYRS-22: Queues data passing The Zephyr RTOS shall implement a queue which can be used to pass data between threads and interrupt service routines.

Status
Draft

Type
Functional

Component
Queues

ZEP-SYRS-23: LIFOs data passing The Zephyr RTOS shall implement a LIFOs which can be used to pass data between threads and interrupt service routines.

Status
Draft

Type
Functional

Component
LIFOs

ZEP-SYRS-24: FIFOs data passing The Zephyr RTOS shall implement FIFOs which can be used to pass data between threads and interrupt service routines.

Status
Draft

Type
Functional

Component
FIFOs

ZEP-SYRS-25: Mailboxes The Zephyr RTOS shall provide a framework to pass messages of arbitrary size between threads.

Status
Draft

Type
Functional

Component
Mailboxes

ZEP-SYRS-26: Atomic Service The Zephyr RTOS shall provide an interface to perform atomic operations on variables, guaranteeing that all reads and writes are free from tearing across all processors.

Status
Draft

Type
Functional

Component
Atomic Service

ZEP-SYRS-30: Stacks The Zephyr RTOS shall implement a stack which can be used to pass data between threads and interrupt service routines.

Status
Draft

Type
Functional

Component
Stacks

Chapter 11

Glossary of Terms

API
: (Application Program Interface) A defined set of routines and protocols for building application software.

application
: The set of user-supplied files that the Zephyr build system uses to build an application image for a specified board configuration. It can contain application-specific code, kernel configuration settings, and at least one CMakeLists.txt file. The application's kernel configuration settings direct the build system to create a custom kernel that makes efficient use of the board's resources. An application can sometimes be built for more than one type of board configuration (including boards with different CPU architectures), if it does not require any board-specific capabilities.

application image
: A binary file that is loaded and executed by the board for which it was built. Each application image contains both the application's code and the Zephyr kernel code needed to support it. They are compiled as a single, fully-linked binary. Once an application image is loaded onto a board, the image takes control of the system, initializes it, and runs as the system's sole application. Both application code and kernel code execute as privileged code within a single shared address space.

architecture
: An instruction set architecture (ISA) along with a programming model.

board
: A target system with a defined set of devices and capabilities, which can load and execute an application image. It may be an actual hardware system or a simulated system running under QEMU. A board can contain one or more *SoCs*. The Zephyr kernel supports a variety of boards.

board configuration
: A set of kernel configuration options that specify how the devices present on a board are used by the kernel. The Zephyr build system defines one or more board configurations for each board it supports. The kernel configuration settings that are specified by the build system can be over-ridden by the application, if desired.

board name
: The human-readable name of a *board*. Uniquely and descriptively identifies a particular system, but does not include additional information that may be required to actually build a Zephyr image for it. See *Board terminology* for additional details.

board qualifiers
: The set of additional tokens, separated by a forward slash (/) that follow the *board name* (and optionally *board revision*) to form the *board target*. The currently accepted qualifiers are *SoC*, *CPU cluster* and *variant*. See *Board terminology* for additional details.

board revision
An optional version string that identifies a particular revision of a hardware system. This is useful to avoid duplication of board files whenever small changes are introduced to a hardware system. See *Multiple board revisions* and *Building for a board revision* for more information.

board target
The full string that can be provided to any of the Zephyr build tools to compile and link an image for a particular hardware system. This string uniquely identifies the combination of *board name*, *board revision* and *board qualifiers*. See *Board terminology* for additional details.

CPU cluster
A group of one or more *CPU cores*, all executing the same image within the same address space and in a symmetrical (SMP) configuration. Only *CPU cores* of the same *architecture* can be in a single cluster. Multiple CPU clusters (each of one or more cores) can coexist in the same *SoC*.

CPU core
A single processing unit, with its own Program Counter, executing program instructions sequentially. CPU cores are part of a *CPU cluster*, which can contain one or more cores.

device runtime power management
Device Runtime Power Management (PM) refers the capability of devices to save energy independently of the system power state. Devices will keep reference of their usage and will automatically be suspended or resumed. This feature is enabled via the `CONFIG_PM_DEVICE_RUNTIME` Kconfig option.

idle thread
A system thread that runs when there are no other threads ready to run.

IDT
(Interrupt Descriptor Table) a data structure used by the x86 architecture to implement an interrupt vector table. The IDT is used to determine the correct response to interrupts and exceptions.

internal API
Any internal function, structure or macro defined anywhere in the Zephyr source tree. Internal APIs are intended to "extend" Zephyr, and are to be used only between certain *software components*, usually in-tree but in some cases out-of-tree (e.g. adding an out-of-tree architecture or driver). Applications must not invoke internal APIs outside their own scope. The context where the API is called or implemented is well defined. For example, functions prefixed with `arch_` are intended for use by the Zephyr kernel to invoke architecture-specific code. Internal APIs are mostly kept stable, but with fewer guarantees than *public APIs*.

ISR
(Interrupt Service Routine) Also known as an interrupt handler, an ISR is a callback function whose execution is triggered by a hardware interrupt (or software interrupt instructions) and is used to handle high-priority conditions that require interrupting the current code executing on the processor.

kernel
The set of Zephyr-supplied files that implement the Zephyr kernel, including its core services, device drivers, network stack, and so on.

power domain
A power domain is a collection of devices for which power is applied and removed collectively in a single action. Power domains are represented by `device`.

power gating
Power gating reduces power consumption by shutting off areas of an integrated circuit that are not in use.

private API
: Any function, structure or macro defined anywhere in the Zephyr source tree which are only intended for consumption inside the *software component* where they are defined. Private APIs may change at any time and must not be used by code outside the corresponding software component.

public API
: Any function, structure or macro defined inside the `include/zephyr` folder that is not explicitly marked as private. Public APIs are intended for consumption by any and all in-tree or out-of-tree *software components*. Public APIs cannot be modified without following the provisions described in the *API lifecycle* section, which means they provide guarantees that they will remain stable over time.

SoC
: A System on a chip, that is, an integrated circuit that contains at least one *CPU cluster* (in turn with at least one *CPU core*), as well as peripherals and memory.

SoC family
: One or more *SoCs* or *SoC series* that share enough in common to consider them related and under a single family denomination.

SoC series
: A number of different *SoCs* that share similar characteristics and features, and that the vendor typically names and markets together.

software component
: A software component is a self-contained, modular, and replaceable part of the Zephyr source code. A driver, a subsystem or an applications are all examples of software components present in Zephyr.

subsystem
: A subsystem refers to a logically distinct part of the operating system that handles specific functionality or provides certain services.

system power state
: System power states describe the power consumption of the system as a whole. System power states are represented by `pm_state`.

variant
: In the context of *board qualifiers*, a variant designates a particular type or configuration of a build for a combination of *SoC* and *CPU cluster*. Common uses of the variant concept include introducing both secure and non-secure builds for platforms with Trusted Execution Environment support, or selecting the type of RAM used in a build.

west
: A multi-repo meta-tool developed for the Zephyr project. See *West (Zephyr's meta-tool)*.

west installation
: An obsolete term for a *west workspace* used prior to west 0.7.

west manifest
: A YAML file, usually named `west.yml`, which describes projects, or the Git repositories which make up a *west workspace*, along with additional metadata. See *Basics* for general information and *West Manifests* for details.

west manifest repository
: The Git repository in a *west workspace* which contains the *west manifest*. Its location is given by the *manifest.path configuration option*. See *Basics*.

west project
: Each of the entries in a *west manifest*, which describe a Git repository that will be cloned and managed by west when working with the corresponding *west manifest repository*. Note that a west project is different from a *zephyr module*, although many projects are also modules. See *Projects* for additional information.

west workspace
: A folder on your system with a `.west` subdirectory and a *west manifest repository* in it. You clone the Zephyr source code, as well as that of its *west projects* onto your system by creating a west workspace using the `west init` command. See *Basics*.

XIP
: (eXecute In Place) a method of executing programs directly from long term storage rather than copying it into RAM, saving writable memory for dynamic data and not the static program code.

zephyr module
: A Git repository containing a `zephyr/module.yml` file, used by the Zephyr build system to integrate the source code and configuration files of the module into a regular Zephyr build. Zephyr modules may be west projects, but they do not have to. See *Modules (External projects)* for additional details.

Bibliography

[a] Real Time Counter (RTC)

[b] Programmable Peripheral Interconnect (PPI)

[c] Distributed Programmable Peripheral Interconnect (DPPI)

[d] Software Interrupt (SWI)

[e] Random Number Generator (RNG)

[j] GPIO tasks and events (GPIOTE)

[k] Temperature sensor (TEMP)

[l] Universal Asynchronous Receiver Transmitter (UART)

[m] Interprocess Communication peripheral (IPC)

[th-imboot] Must boot with an immutable bootloader.

[th-authrepl] Application image shall only be replaced with an authorized image.

[th-timely-update] Application updates shall be done in a timely manner.

[th-atomic-update] Application updates shall be atomic.

[th-root-certs] TLS must have a list of trusted root certificates.

[th-root-check] TLS must verify root certificate from server is valid.

[th-secret-storage] There must be a mechanism to securely store client secrets. The least amount of code necessary shall have access to these secrets.

[th-time] System must have moderately accurate notion of the current date/time.

[th-conf] The system must receive, and keep configuration data.

[th-logs] The system must log security-related events, and either store them locally, or send to a service.

[th-all-tls] All communications with the cloud service shall use TLS.

[th-tls-ciphers] TLS shall be configured to allow only generally agreed cipher suites (including forward secrecy).

[th-tls-client-auth] The device shall authenticate itself with the cloud provider using one of the methods described.

[th-entropy] The TLS layer shall use a modern, accepted cryptographic random-bit generator seeded by an entropy source within the SoC.

[th-initial-provision] The device shall have a per-device secret loaded before deployment.

[th-initial-secret] The initial secret shall be securely maintained, and destroyed in any external location as soon as the device is provisioned.

[th-reprovision] Reprovisioning a device shall be done securely.

[th-destruction] Upon decommissioning, the device secret shall be rendered ineffective.
