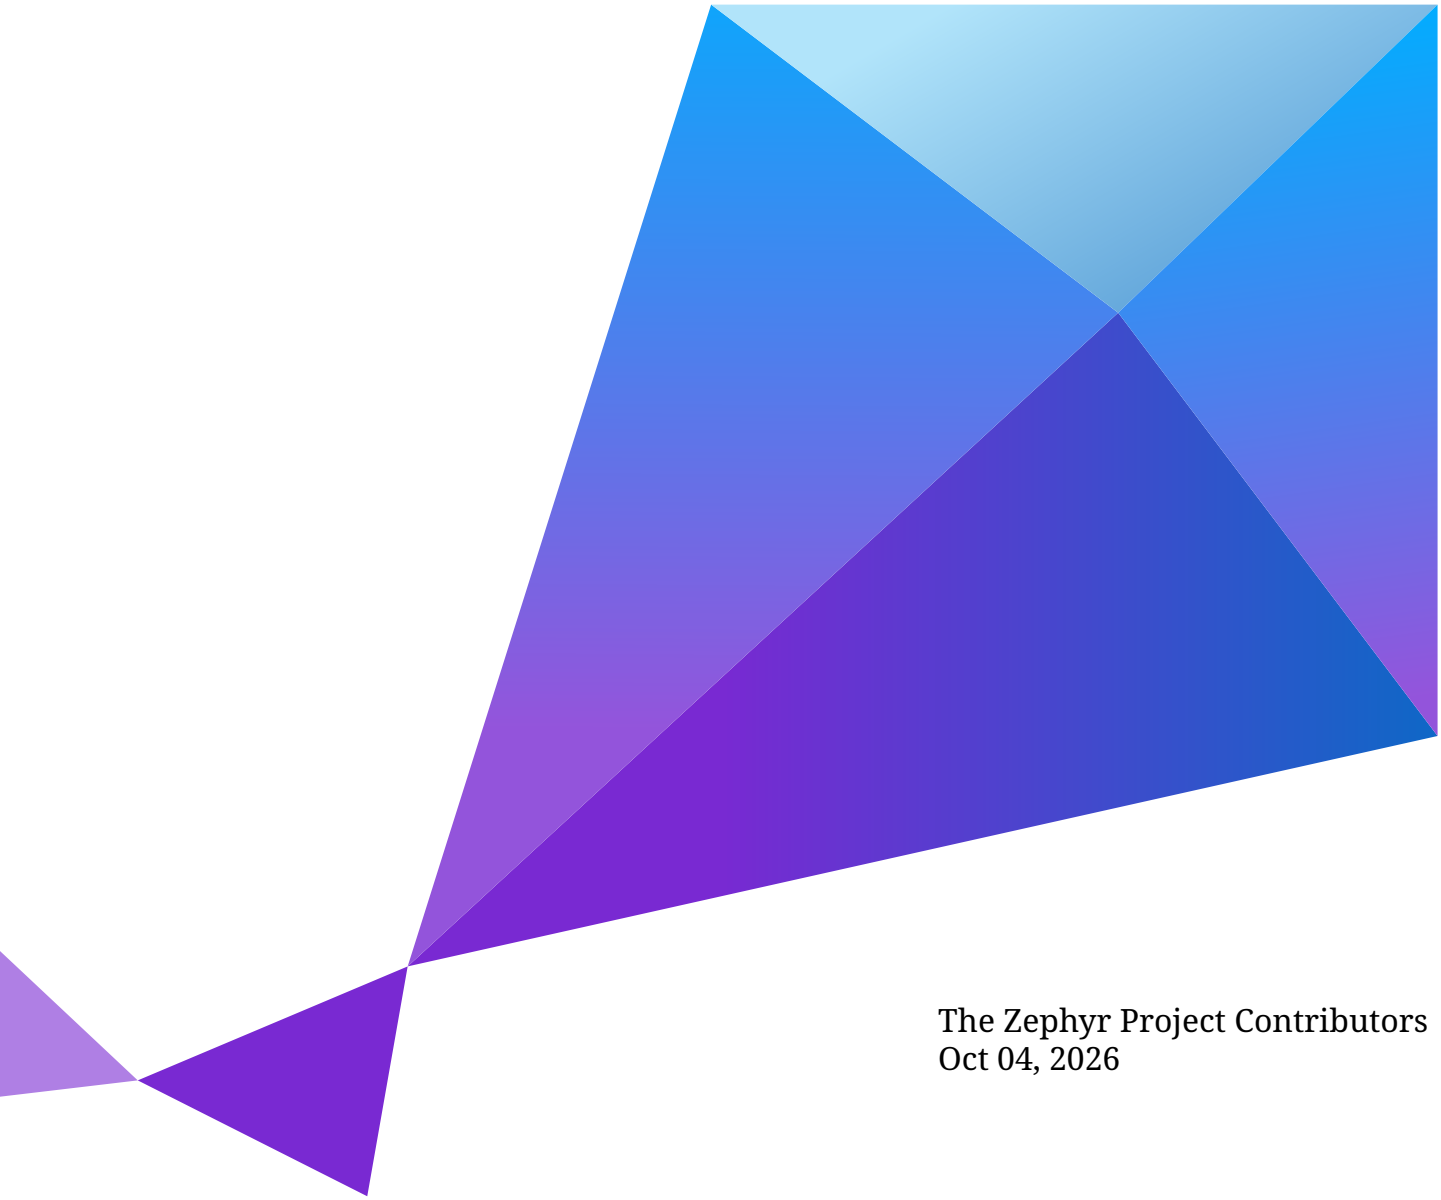
Zephyr Project Documentation

Release 4.5.0-rc1



The Zephyr Project Contributors

Oct 04, 2026

Table of contents

1 Introduction **1**
- 1.1 Licensing . . . 1
- 1.2 Distinguishing Features . . . 2
- 1.3 Community Support . . . 4
- 1.4 Resources . . . 4
  - 1.4.1 Getting Started . . . 4
  - 1.4.2 Code and Development . . . 4
  - 1.4.3 Community and Support . . . 4
  - 1.4.4 Issue Tracking and Security . . . 4
  - 1.4.5 Additional Resources . . . 4
- 1.5 Fundamental Terms and Concepts . . . 4

2 Developing with Zephyr **5**
- 2.1 Getting Started Guide . . . 5
  - 2.1.1 Select and Update OS . . . 5
  - 2.1.2 Install dependencies . . . 5
  - 2.1.3 Get Zephyr and install Python dependencies . . . 7
  - 2.1.4 Install the Zephyr SDK . . . 10
  - 2.1.5 Build the Blinky Sample . . . 10
  - 2.1.6 Flash the Sample . . . 11
  - 2.1.7 Next Steps . . . 12
  - 2.1.8 Asking for Help . . . 12
- 2.2 Beyond the Getting Started Guide . . . 13
  - 2.2.1 Python and pip . . . 13
  - 2.2.2 Advanced Platform Setup . . . 13
  - 2.2.3 Install a Toolchain . . . 17
  - 2.2.4 Updating the Zephyr SDK toolchain . . . 17
  - 2.2.5 Cloning the Zephyr Repositories . . . 17
  - 2.2.6 Export Zephyr CMake package . . . 18
  - 2.2.7 Board Aliases . . . 18
  - 2.2.8 Build and Run an Application . . . 19
- 2.3 Environment Variables . . . 21
  - 2.3.1 Setting Variables . . . 21
  - 2.3.2 Zephyr Environment Scripts . . . 23
  - 2.3.3 Important Environment Variables . . . 23
- 2.4 Application Development . . . 24
  - 2.4.1 Overview . . . 24
  - 2.4.2 Application types . . . 25
  - 2.4.3 Creating an Application . . . 26
  - 2.4.4 Important Build System Variables . . . 29
  - 2.4.5 Application CMakeLists.txt . . . 30
  - 2.4.6 CMakeCache.txt . . . 32
  - 2.4.7 Application Configuration . . . 32
  - 2.4.8 Application-Specific Code . . . 33
  - 2.4.9 Building an Application . . . 34
  - 2.4.10 Run an Application . . . 37

2.4.11 Custom Board, Devicetree and SOC Definitions . . . 38
2.5 Debugging . . . 42
2.5.1 Application Debugging . . . 42
2.5.2 Debug with Eclipse . . . 44
2.5.3 Debugging I2C communication . . . 46
2.6 API Status and Guidelines . . . 47
2.6.1 API Overview . . . 47
2.6.2 API Lifecycle . . . 92
2.6.3 Vendor-Specific API Placement Policy . . . 96
2.6.4 API Design Guidelines . . . 97
2.6.5 API Terminology . . . 99
2.7 Language Support . . . 101
2.7.1 C Language Support . . . 101
2.7.2 C++ Language Support . . . 107
2.7.3 Rust Language Support . . . 110
2.8 Optimizations . . . 112
2.8.1 Optimizing for Footprint . . . 112
2.8.2 Optimization Tools . . . 113
2.9 Flashing and Hardware Debugging . . . 122
2.9.1 Flash & Debug Host Tools . . . 122
2.9.2 Debug Probes . . . 133
2.10 Modules (External projects) . . . 140
2.10.1 Modules vs west projects . . . 141
2.10.2 Module Repositories . . . 141
2.10.3 Contributing to Zephyr modules . . . 142
2.10.4 Licensing requirements and policies . . . 144
2.10.5 Documentation requirements . . . 145
2.10.6 Testing requirements . . . 145
2.10.7 Deprecating and removing modules . . . 145
2.10.8 Integrate modules in Zephyr build system . . . 146
2.10.9 Module yaml file description . . . 146
2.10.10 Submitting changes to modules . . . 155
2.11 West (Zephyr's meta-tool) . . . 157
2.11.1 Installing west . . . 157
2.11.2 West Release Notes . . . 158
2.11.3 Troubleshooting West . . . 171
2.11.4 Basics . . . 174
2.11.5 Built-in commands . . . 176
2.11.6 Workspaces . . . 180
2.11.7 West Manifests . . . 185
2.11.8 Configuration . . . 216
2.11.9 West aliases . . . 220
2.11.10 Extensions . . . 220
2.11.11 Building, Flashing and Debugging . . . 224
2.11.12 Signing Binaries . . . 242
2.11.13 Additional Zephyr extension commands . . . 243
2.11.14 History and Motivation . . . 252
2.11.15 Using Zephyr without west . . . 254
2.12 Test Runner (Twister) . . . 255
2.12.1 Command Line Options . . . 256
2.12.2 Integration with pytest test framework . . . 266
2.12.3 Twister Status . . . 274
2.12.4 Twister blackbox tests . . . 276
2.12.5 Board Configuration . . . 280
2.12.6 Toolchain Selection . . . 282
2.12.7 Tests . . . 283
2.12.8 Harnesses . . . 296
2.12.9 Sidecars . . . 307

2.12.10 Selecting platform scope . . . 308
2.12.11 Running in Integration Mode . . . 308
2.12.12 Running tests on custom emulator . . . 308
2.12.13 Running Tests in Random Order . . . 309
2.12.14 Running Tests on Hardware . . . 309
2.12.15 Test Output and Reports . . . 317
2.12.16 Live Run Monitoring . . . 318
2.12.17 Twister Configuration File . . . 318
2.13 Testing . . . 320
2.13.1 Test Framework . . . 321
2.13.2 Benchmarking Framework . . . 335
2.13.3 Generating coverage reports . . . 339
2.13.4 BabbleSim . . . 342
2.13.5 CI Test Plan Selector (test_plan_v2) . . . 345
2.14 Static Code Analysis (SCA) . . . 350
2.14.1 SCA Tool infrastructure . . . 351
2.14.2 Native SCA Tool support . . . 351
2.15 Toolchains . . . 361
2.15.1 Zephyr SDK . . . 361
2.15.2 Arm Compiler 6 . . . 365
2.15.3 Arm Toolchain for Embedded (ATfE) . . . 365
2.15.4 Cadence Tensilica Xtensa C/C++ Compiler (XCC) . . . 367
2.15.5 DesignWare ARC MetaWare Development Toolkit (MWDT) . . . 368
2.15.6 GNU Arm Embedded . . . 369
2.15.7 Qualcomm Hexagon LLVM Toolchain . . . 369
2.15.8 IAR Arm Toolchain . . . 370
2.15.9 Intel oneAPI Toolkit . . . 371
2.15.10 MPLAB XC32 . . . 371
2.15.11 Host Toolchains . . . 372
2.15.12 Other Cross Compilers . . . 372
2.15.13 Custom CMake Toolchains . . . 373
2.15.14 Embedded Linker (ELD) . . . 373
2.16 Tools and IDEs . . . 374
2.16.1 CLion . . . 374
2.16.2 Coccinelle . . . 379
2.16.3 IDE for Zephyr (VS Code extension) . . . 387
2.16.4 Kapa.ai Documentation Assistant . . . 390
2.16.5 STM32CubeIDE . . . 392
2.16.6 Visual Studio Code . . . 397
2.16.7 Workbench for Zephyr . . . 399

3 Kernel **405**
3.1 Kernel Services . . . 405
3.1.1 Scheduling, Interrupts, and Synchronization . . . 405
3.1.2 Data Passing . . . 471
3.1.3 Memory Management . . . 493
3.1.4 Timing . . . 493
3.1.5 Other . . . 505
3.2 Device Driver Model . . . 518
3.2.1 Introduction . . . 518
3.2.2 Standard Drivers . . . 519
3.2.3 Synchronous Calls . . . 519
3.2.4 Driver APIs . . . 519
3.2.5 Driver Data Structures . . . 519
3.2.6 Subsystems and API Structures . . . 520
3.2.7 API Class Inheritance . . . 521
3.2.8 Device-Specific API Extensions . . . 522
3.2.9 Single Driver, Multiple Instances . . . 523

3.2.10 Initialization Levels . . . 524
3.2.11 Deferred initialization . . . 524
3.2.12 System Drivers . . . 525
3.2.13 Inspecting the initialization sequence . . . 525
3.2.14 Error handling . . . 525
3.2.15 Memory Mapping . . . 525
3.2.16 API Reference . . . 528
3.3 User Mode . . . 528
3.3.1 Overview . . . 528
3.3.2 Memory Protection Design . . . 531
3.3.3 Kernel Objects . . . 537
3.3.4 System Calls . . . 541
3.3.5 MPU Stack Objects . . . 550
3.3.6 MPU Backed Userspace . . . 551
3.4 Memory Management . . . 551
3.4.1 Memory Heaps . . . 551
3.4.2 Shared Multi Heap . . . 555
3.4.3 Memory Slabs . . . 556
3.4.4 Memory Blocks Allocator . . . 558
3.4.5 Demand Paging . . . 561
3.4.6 Virtual Memory . . . 565
3.5 Data Structures . . . 567
3.5.1 Single-linked List . . . 567
3.5.2 Double-linked List . . . 569
3.5.3 Multi Producer Single Consumer Packet Buffer . . . 571
3.5.4 Single Producer Single Consumer Packet Buffer . . . 573
3.5.5 Balanced Red/Black Tree . . . 573
3.5.6 Ring Buffers . . . 576
3.5.7 Multi Producer Single Consumer Lock Free Queue . . . 579
3.5.8 Single Producer Single Consumer Lock Free Queue . . . 579
3.5.9 Min-Heap Data Structure . . . 580
3.5.10 sys_ringq Data Structure . . . 581
3.6 Executing Time Functions . . . 583
3.6.1 Configuration . . . 583
3.6.2 Usage . . . 583
3.6.3 API documentation . . . 584
3.7 Object Cores . . . 584
3.7.1 Object Core Concepts . . . 584
3.7.2 Object Core Statistics Concepts . . . 585
3.7.3 Implementation . . . 586
3.7.4 Configuration Options . . . 588
3.7.5 API Reference . . . 589
3.8 Time Utilities . . . 589
3.8.1 Overview . . . 589
3.8.2 Time Utility APIs . . . 589
3.8.3 Concepts Underlying Time Support in Zephyr . . . 592
3.9 Precision Timing . . . 594
3.9.1 Precision time . . . 594
3.9.2 Precision clock . . . 594
3.9.3 PI controller . . . 594
3.9.4 Protocol integration . . . 595
3.9.5 Sample . . . 595
3.9.6 API reference . . . 595
3.10 Utilities . . . 595
3.11 Iterable Sections . . . 596
3.11.1 Overview . . . 596
3.11.2 Step 1: Define the data in C . . . 596
3.11.3 Step 2: Declare the section in CMake . . . 597

3.11.4 Step 3: Provide a linker-script . . . 597
3.11.5 Iterating over the entries . . . 597
3.11.6 API Reference . . . 598
3.12 Code And Data Relocation . . . 598
3.12.1 Overview . . . 598
3.12.2 Details . . . 598
3.13 Scope-based Cleanup Helpers . . . 600
3.13.1 Overview . . . 601
3.13.2 Core Concepts . . . 601
3.13.3 Defining Scoped Types . . . 602
3.13.4 Usage Notes . . . 604
3.13.5 API Reference . . . 605

4 Services **607**
4.1 Connectivity . . . 607
4.1.1 Networking . . . 607
4.1.2 Bluetooth . . . 821
4.1.3 USB . . . 1115
4.1.4 Controller Area Network (CAN) Bus Protocols . . . 1147
4.1.5 LoRa and LoRaWAN . . . 1147
4.1.6 Modbus . . . 1149
4.1.7 Modem modules . . . 1150
4.2 Input / Output . . . 1158
4.2.1 Console . . . 1158
4.2.2 Input . . . 1158
4.2.3 Real Time I/O (RTIO) . . . 1165
4.2.4 Formatted Output . . . 1169
4.3 Inter-Process Communication . . . 1171
4.3.1 Interprocessor Communication (IPC) . . . 1171
4.3.2 Zephyr bus (zbus) . . . 1182
4.3.3 Asynchronous Notifications . . . 1204
4.3.4 Virtualization . . . 1205
4.4 Logging, Tracing & Debugging . . . 1206
4.4.1 Logging . . . 1206
4.4.2 Tracing . . . 1227
4.4.3 Debugging . . . 1239
4.4.4 Profiling . . . 1255
4.4.5 Instrumentation . . . 1255
4.4.6 CPU load . . . 1260
4.4.7 Shell . . . 1260
4.4.8 Task Watchdog . . . 1279
4.5 Storage & Configuration . . . 1280
4.5.1 Disk Access . . . 1280
4.5.2 Flash Circular Buffer (FCB) . . . 1285
4.5.3 File Systems . . . 1286
4.5.4 Flash map . . . 1287
4.5.5 Non-Volatile Memory (NVMEM) . . . 1289
4.5.6 Non-Volatile Storage (NVS) . . . 1291
4.5.7 Retention System . . . 1293
4.5.8 Secure Storage . . . 1298
4.5.9 Settings . . . 1301
4.5.10 Stream Flash . . . 1307
4.5.11 Zephyr Memory Storage (ZMS) . . . 1307
4.6 Memory Management . . . 1317
4.6.1 Memory Attributes . . . 1317
4.6.2 Network Buffers . . . 1320
4.7 Power Management . . . 1323
4.7.1 Power Management . . . 1323

4.7.2 CPU Frequency Scaling . . . 1347
4.7.3 Power off . . . 1351
4.7.4 Resource Management . . . 1351
4.8 Security . . . 1352
4.8.1 Cryptography . . . 1353
4.8.2 Authentication . . . 1358
4.8.3 JSON Web Token (JWT) . . . 1360
4.8.4 Trusted Firmware-M (TF-M) . . . 1361
4.8.5 UUID . . . 1371
4.9 Device Management . . . 1372
4.9.1 MCUmgr . . . 1373
4.9.2 MCUmgr handlers . . . 1376
4.9.3 MCUmgr Callbacks . . . 1385
4.9.4 SMP Protocol Specification . . . 1390
4.9.5 SMP Transport Specification . . . 1442
4.9.6 Device Firmware Upgrade . . . 1445
4.9.7 Over-the-Air Update . . . 1446
4.9.8 Firmware Over-the-Air over HTTP . . . 1447
4.9.9 EC Host Command . . . 1449
4.9.10 Binary Descriptors . . . 1453
4.10 Algorithms & Data . . . 1455
4.10.1 CRC . . . 1455
4.10.2 Digital Signal Processing (DSP) . . . 1457
4.10.3 Serialization . . . 1457
4.11 Frameworks . . . 1460
4.11.1 Linkable Loadable Extensions (LLEXT) . . . 1460
4.11.2 Multimedia Pipeline (mpipe) . . . 1477
4.11.3 Sensing Subsystem . . . 1483
4.11.4 State Machine Framework . . . 1489
4.12 OS Abstraction . . . 1501
4.12.1 POSIX . . . 1501
4.12.2 CMSIS RTOS v1 . . . 1529
4.12.3 CMSIS RTOS v2 . . . 1529

5 Build and Configuration Systems 1531
5.1 Build System (CMake) . . . 1531
5.1.1 Build and Configuration Phases . . . 1531
5.1.2 Supporting Scripts and Tools . . . 1537
5.2 CMake Reference . . . 1541
5.2.1 Core Build System & Hardware Modules . . . 1541
5.2.2 Sysbuild Modules . . . 1578
5.2.3 Utility & Tooling Modules . . . 1583
5.2.4 Target properties . . . 1588
5.2.5 Variables . . . 1588
5.3 Devicetree . . . 1593
5.3.1 Devicetree Guide . . . 1593
5.3.2 Devicetree Reference . . . 1663
5.4 Configuration System (Kconfig) . . . 1903
5.4.1 Interactive Kconfig interfaces . . . 1903
5.4.2 Tracing values to their source . . . 1908
5.4.3 Setting Kconfig configuration values . . . 1909
5.4.4 Kconfig - Tips and Best Practices . . . 1914
5.4.5 Custom Kconfig Preprocessor Functions . . . 1929
5.4.6 Kconfig extensions . . . 1932
5.5 Snippets . . . 1934
5.5.1 Using Snippets . . . 1934
5.5.2 Built-in snippets . . . 1935
5.5.3 Writing Snippets . . . 1947

5.5.4 Snippets Design . . . 1951
5.6 Zephyr CMake Package . . . 1952
5.6.1 Zephyr CMake package export (west) . . . 1952
5.6.2 Zephyr CMake package export (without west) . . . 1953
5.6.3 Zephyr Base Environment Setting . . . 1953
5.6.4 Zephyr CMake Package Search Order . . . 1953
5.6.5 Zephyr CMake Package Version . . . 1954
5.6.6 Multiple Zephyr Installations (Zephyr workspace) . . . 1955
5.6.7 Zephyr Build Configuration CMake packages . . . 1956
5.6.8 Zephyr CMake package source code . . . 1958
5.7 Sysbuild (System build) . . . 1958
5.7.1 Definitions . . . 1958
5.7.2 Architectural Overview . . . 1959
5.7.3 Building with sysbuild . . . 1960
5.7.4 Configuration namespacing . . . 1960
5.7.5 Sysbuild flashing using `west flash` . . . 1962
5.7.6 Sysbuild debugging using `west debug` . . . 1962
5.7.7 Building a sample with MCUboot . . . 1962
5.7.8 Sysbuild Kconfig file . . . 1963
5.7.9 Sysbuild targets . . . 1963
5.7.10 Dedicated image build targets . . . 1964
5.7.11 Adding Zephyr applications to sysbuild . . . 1964
5.7.12 Merged hex files . . . 1968
5.7.13 Adding non-Zephyr applications to sysbuild . . . 1969
5.7.14 Configuring sysbuild internal state . . . 1969
5.7.15 Extending sysbuild . . . 1969
5.7.16 Sysbuild and CMake presets . . . 1976
5.8 Application version management . . . 1976
5.8.1 VERSION file . . . 1977
5.8.2 Application build version . . . 1977
5.8.3 Use in code . . . 1978
5.8.4 Use in Kconfig . . . 1978
5.8.5 Use in CMake . . . 1979
5.8.6 Use in MCUboot-supported applications . . . 1980
5.8.7 Use in Shell . . . 1980
5.9 Flashing . . . 1980
5.9.1 Flashing configuration . . . 1981
5.10 Signing Binaries . . . 1982
5.10.1 MCUboot / imgtool . . . 1982
5.10.2 Signing key files . . . 1983
5.10.3 Extending signing externally . . . 1984

6 Hardware Support 1987
6.1 Architecture-related Guides . . . 1987
6.1.1 Zephyr support status on ARC processors . . . 1987
6.1.2 Arm Cortex-M Developer Guide . . . 1989
6.1.3 ARM64 Developer Guide . . . 2001
6.1.4 Zephyr support status on RISC-V processors . . . 2002
6.1.5 Semihosting Guide . . . 2004
6.1.6 x86 Developer Guide . . . 2005
6.1.7 Xtensa Developer Guide . . . 2006
6.2 Barriers API . . . 2008
6.3 Caching . . . 2008
6.3.1 Cache Control Configuration . . . 2008
6.3.2 Caching Basics . . . 2009
6.4 Zephyr's device emulators/simulators . . . 2011
6.4.1 Overview . . . 2011
6.4.2 Available Emulators . . . 2012

6.5 External Bus and Bus Connected Peripherals Emulators . . . 2013
6.5.1 Overview . . . 2013
6.5.2 Concept . . . 2013
6.5.3 Creating a Device Driver Emulator . . . 2014
6.5.4 Available Emulators . . . 2016
6.5.5 Samples . . . 2016
6.5.6 API Reference . . . 2017
6.6 Firmware . . . 2017
6.6.1 Overview . . . 2017
6.6.2 API Reference . . . 2017
6.6.3 Samples . . . 2017
6.6.4 Resources . . . 2017
6.7 Peripherals . . . 2018
6.7.1 Analog . . . 2018
6.7.2 Audio . . . 2021
6.7.3 Communication . . . 2024
6.7.4 Display . . . 2052
6.7.5 GPIO & Input . . . 2058
6.7.6 Memory & Storage . . . 2061
6.7.7 Power . . . 2066
6.7.8 Sensors . . . 2072
6.7.9 Motion & Actuation . . . 2089
6.7.10 System & Diagnostics . . . 2097
6.7.11 Timing . . . 2103
6.8 Pin Control . . . 2108
6.8.1 Introduction . . . 2108
6.8.2 State model . . . 2109
6.8.3 Dynamic pin control . . . 2111
6.8.4 Devicetree representation . . . 2111
6.8.5 Implementation guidelines . . . 2114
6.8.6 Pin Control API . . . 2115
6.8.7 Other reference material . . . 2116
6.9 Porting . . . 2116
6.9.1 Architecture Porting Guide . . . 2116
6.9.2 SoC Porting Guide . . . 2131
6.9.3 Board Porting Guide . . . 2135
6.9.4 Shields . . . 2149
6.10 Virtualization . . . 2161
6.10.1 Virtual I/O (VIRTIO) . . . 2161

7 Contributing to Zephyr 2165
7.1 General Guidelines . . . 2165
7.1.1 Contribution Guidelines . . . 2165

Chapter 1

Introduction

The Zephyr OS is based on a small-footprint kernel designed for use on resource-constrained and embedded systems: from simple embedded environmental sensors and LED wearables to sophisticated embedded controllers, smart watches, and IoT wireless applications.

The Zephyr kernel supports multiple architectures, including:

- ARCv2 (EM and HS) and ARCv3 (HS6X)
- ARMv6-M, ARMv7-M, and ARMv8-M (Cortex-M)
- ARMv7-A and ARMv8-A (Cortex-A, 32- and 64-bit)
- ARMv7-R, ARMv8-R (Cortex-R, 32- and 64-bit)
- Qualcomm Hexagon
- Intel x86 (32- and 64-bit)
- MIPS (MIPS32 Release 1 specification)
- OpenRISC (32-bit)
- Renesas RX
- RISC-V (32- and 64-bit)
- SPARC V8
- Tensilica Xtensa
- TriCore (TC1.6.2 and TC1.8)

The full list of supported boards based on these architectures can be found here.

In the context of the Zephyr OS, a *subsystem* refers to a logically distinct part of the operating system that handles specific functionality or provides certain services. Subsystems can include components such as networking, file systems, device driver classes, power management, and communication protocols, among others. Each subsystem is designed to be modular and can be configured, customized, and extended to meet the requirements of different embedded applications.

1.1 Licensing

Zephyr is permissively licensed using the Apache 2.0 license (as found in the `LICENSE` file in the project's GitHub repo). There are some imported or reused components of the Zephyr project that use other licensing, as described in *Licensing of Zephyr Project components*.

1.2 Distinguishing Features

Zephyr offers a large and ever growing number of features including:

Extensive suite of Kernel services
Zephyr offers a number of familiar services for development:

- *Multi-threading Services* for cooperative, priority-based, non-preemptive, and preemptive threads with optional round robin time-slicing. Includes POSIX pthreads compatible API support.
- *Interrupt Services* for compile-time registration of interrupt handlers.
- *Memory Allocation Services* for dynamic allocation and freeing of fixed-size or variable-size memory blocks.
- *Inter-thread Synchronization Services* for binary semaphores, counting semaphores, and mutex semaphores.
- *Inter-thread Data Passing Services* for basic message queues, enhanced message queues, and byte streams.
- *Power Management Services* such as overarching, application or policy-defined, System Power Management and fine-grained, driver-defined, Device Power Management.

Multiple Scheduling Algorithms
Zephyr provides a comprehensive set of thread scheduling choices:

- Cooperative and Preemptive Scheduling
- Earliest Deadline First (EDF)
- Meta IRQ scheduling implementing “interrupt bottom half” or “tasklet” behavior
- Timeslicing: Enables time slicing between preemptible threads of equal priority
- Multiple queuing strategies:
  - Simple linked-list ready queue
  - Red/black tree ready queue
  - Traditional multi-queue ready queue

Highly configurable / Modular for flexibility
Allows an application to incorporate *only* the capabilities it needs as it needs them, and to specify their quantity and size.

Cross Architecture
Supports a wide variety of supported boards with different CPU architectures and developer tools. Contributions have added support for an increasing number of SoCs, platforms, and drivers.

Memory Protection
Implements configurable architecture-specific stack-overflow protection, kernel object and device driver permission tracking, and thread isolation with thread-level memory protection on x86, ARC, and ARM architectures, userspace, and memory domains.

For platforms without MMU/MPU and memory constrained devices, supports combining application-specific code with a custom kernel to create a monolithic image that gets loaded and executed on a system’s hardware. Both the application code and kernel code execute in a single shared address space.

Compile-time resource definition
Allows system resources to be defined at compile-time, which reduces code size and increases performance for resource-limited systems.

Optimized Device Driver Model
Provides a consistent device model for configuring the drivers that are part of the platform/system and a consistent model for initializing all the drivers configured into the system and allows the reuse of drivers across platforms that have common devices/IP blocks.

Devicetree Support
Use of *devicetree* to describe hardware. Information from devicetree is used to create the application image.

Native Networking Stack supporting multiple protocols
Networking support is fully featured and optimized, including LwM2M and BSD sockets compatible support. OpenThread support (on Nordic chipsets) is also provided - a mesh network designed to securely and reliably connect hundreds of products around the home.

Bluetooth Low Energy 5.0 support
Bluetooth 5.0 compliant (ESR10) and Bluetooth Low Energy Controller support (LE Link Layer). Includes Bluetooth Mesh and a Bluetooth qualification-ready Bluetooth controller.

- Generic Access Profile (GAP) with all possible LE roles
- Generic Attribute Profile (GATT)
- Pairing support, including the Secure Connections feature from Bluetooth 4.2
- Clean HCI driver abstraction
- Raw HCI interface to run Zephyr as a Controller instead of a full Host stack
- Verified with multiple popular controllers
- Highly configurable

Mesh Support:

- Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
- Both Provisioning bearers supported (PB-ADV & PB-GATT)
- Highly configurable, fitting in devices with at least 16k RAM

Native Linux, macOS, and Windows Development
A command-line CMake build environment runs on popular developer OS systems. A native port (native_sim) lets you build and run Zephyr as a native application on Linux, aiding development and testing.

Virtual File System Interface with ext2, FatFs, and LittleFS Support
ext2, LittleFS and FatFS support; FCB (Flash Circular Buffer) for memory constrained applications.

Powerful multi-backend logging Framework
Support for log filtering, object dumping, panic mode, multiple backends (memory, networking, filesystem, console, ...) and integration with the shell subsystem.

User friendly and full-featured Shell interface
A multi-instance shell subsystem with user-friendly features such as autocompletion, wildcards, coloring, metakeys (arrows, backspace, ctrl+u, etc.) and history. Support for static commands and dynamic sub-commands.

Settings on non-volatile storage
The settings subsystem gives modules a way to store persistent per-device configuration and runtime state. Settings items are stored as key-value pair strings.

Non-volatile storage (NVS)
NVS allows storage of binary blobs, strings, integers, longs, and any combination of these.

Native port
Native sim allows running Zephyr as a Linux application with support for various subsystems and networking.

1.3 Community Support

Community support is provided via mailing lists and Discord; see the Resources below for details.

1.4 Resources

Here's a quick summary of resources to help you find your way around:

1.4.1 Getting Started

- Zephyr Documentation
- Getting Started Guide
- Tips when asking for help
- Code samples

1.4.2 Code and Development

- Source Code Repository
- Releases
- Contribution Guide

1.4.3 Community and Support

- Discord Server for real-time community discussions
- User mailing list (users@lists.zephyrproject.org)
- Developer mailing list (devel@lists.zephyrproject.org)
- Other project mailing lists
- Project Wiki

1.4.4 Issue Tracking and Security

- GitHub Issues
- Security documentation
- Security Advisories Repository
- Report security vulnerabilities at vulnerabilities@zephyrproject.org

1.4.5 Additional Resources

- Zephyr Project Website
- Zephyr Tech Talks

1.5 Fundamental Terms and Concepts

See *Glossary of Terms*

Chapter 2

Developing with Zephyr

2.1 Getting Started Guide

Follow this guide to:

- Set up a command-line Zephyr development environment on Ubuntu, macOS, or Windows (instructions for other Linux distributions are discussed in *Install Linux Host Dependencies*)
- Get the source code
- Build, flash, and run a sample application

2.1.1 Select and Update OS

Click the operating system you are using.

Ubuntu

This guide covers Ubuntu version 24.04 LTS and later. If you are using a different Linux distribution see *Install Linux Host Dependencies*.

```
sudo apt update
sudo apt upgrade
```

macOS

Select *System Settings* ‣ *General* ‣ *Software Update* and install any available updates. See this Apple support topic for more details.

Note

x86-64 macOS is not supported.

Windows

Select *Start* ‣ *Settings* ‣ *Update & Security* ‣ *Windows Update*. Click *Check for updates* and install any that are available.

2.1.2 Install dependencies

Next, install the host tools Zephyr needs to configure and build applications. The instructions below use the recommended package manager for each operating system so the tools are available from your terminal.

The current minimum required versions for the main dependencies are:

Tool	Min. Version
CMake	3.28.0
Python	3.12
Devicetree compiler	1.4.6

Note

Python 3.12 is strongly recommended. Using a newer Python release may fail on some systems, for example when installing the required packages on Windows.

Ubuntu

1. Use `apt` to install the required dependencies:

```
sudo apt install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget python3-dev python3-venv␣
↪python3-tk \
  xz-utils file make gcc gcc-multilib g++-multilib libsdl2-dev libmagic1
```

Note

Due to the unavailability of `gcc-multilib` and `g++-multilib` on AArch64 (ARM64) systems, you may need to omit them from the list of packages to install.

2. Verify the versions of the main dependencies installed on your system by entering:

```
cmake --version
python3 --version
dtc --version
```

Check those against the versions in the table in the beginning of this section. Refer to the *Install Linux Host Dependencies* page for additional information on updating the dependencies manually.

macOS

1. Install Homebrew:

```
/bin/bash -c "$(curl -fsSL␣
↪https://raw.githubusercontent.com/Homebrew/install/HEAD/install.sh)"
```

2. After the Homebrew installation script completes, follow the on-screen instructions to add the Homebrew installation to the path.

```
(echo; echo 'eval "$(/opt/homebrew/bin/brew shellenv)"') >> ~/.zprofile
source ~/.zprofile
```

3. Use `brew` to install the required dependencies:

```
brew install cmake ninja gperf python3 python-tk ccache qemu dtc libmagic␣
↪wget openocd
```

4. Add the Homebrew Python folder to the path so you can execute `python` and `pip` as well as `python3` and `pip3`.

```
(echo; echo 'export PATH="'$(brew --prefix)'/
↪opt/python/libexec/bin:$PATH"') >> ~/.zprofile
source ~/.zprofile
```

Windows

Note

These instructions cover the native Windows environment. You may also use the Windows Subsystem for Linux (WSL) by following the Ubuntu instructions in this guide instead. In that case, note that flashing and debugging hardware from within WSL requires first making the USB device visible to WSL, for example using usbipd-win.

On modern versions of Windows (10 and later), install Windows Terminal from the Microsoft Store. The instructions below work in either `cmd.exe` or PowerShell.

These instructions use Windows' official package manager, winget. If winget isn't an option, install the dependencies from their respective websites and make sure their command line tools are on your *PATH environment variable*.

1. In modern Windows versions, winget is already pre-installed by default. You can verify that this is the case by typing `winget` in a terminal window. If that fails, you can then install winget.
2. Open a Command Prompt (`cmd.exe`) or PowerShell terminal window. To do so, press the Windows key, type `cmd.exe` or PowerShell and click on the result.
3. Use `winget` to install the required dependencies:

   ```
   winget install Kitware.CMake Ninja-build.Ninja oss-winget.gperf␣
   ↪Python.Python.3.12 Git.Git oss-winget.dtc wget 7zip.7zip
   ```

4. Close the terminal window.

Note

You may need to add the 7zip installation folder to your `PATH`.

2.1.3 Get Zephyr and install Python dependencies

Next, use *west* to create a workspace and fetch Zephyr together with its *modules*.

These commands use `zephyrproject` as the workspace name; you can choose another name and location. You will also install Zephyr's Python dependencies in a Python virtual environment so they stay separate from your system Python installation.

1. Create a new virtual environment:

   Ubuntu

   ```
   python3 -m venv ~/zephyrproject/.venv
   ```

   macOS

   ```
   python3 -m venv ~/zephyrproject/.venv
   ```

   Windows

Open a `cmd.exe` or PowerShell terminal window **as a regular user**.

Batchfile

```
cd %HOMEPATH%
py -3.12 -m venv zephyrproject\.venv
```

PowerShell

```
cd $Env:HOMEPATH
py -3.12 -m venv zephyrproject\.venv
```

2. Activate the virtual environment:

   Ubuntu

   ```
   source ~/zephyrproject/.venv/bin/activate
   ```

   macOS

   ```
   source ~/zephyrproject/.venv/bin/activate
   ```

   Windows

   Note

   Python's virtual environment activation in PowerShell requires running a script itself, which needs to be allowed.

   ```
   Set-ExecutionPolicy -ExecutionPolicy RemoteSigned -Scope CurrentUser
   ```

   Batchfile

   ```
   zephyrproject\.venv\Scripts\activate.bat
   ```

   PowerShell

   ```
   zephyrproject\.venv\Scripts\Activate.ps1
   ```

   Once activated your shell will be prefixed with `(.venv)`. The virtual environment can be deactivated at any time by running `deactivate`.

   Note

   Remember to activate the virtual environment every time you start a new terminal session before working with Zephyr. If you don't, commands such as `west` will not be found, or may run against a different Python environment, leading to confusing errors.

3. Install west:

   West is Zephyr's workspace manager; the next commands use it to create and update the workspace.

   ```
   pip install west
   ```

4. Get the Zephyr source code:

   `west init` creates a *west workspace* and clones `https://github.com/zephyrproject-rtos/zephyr` as its *manifest repository*.

`west update` then fetches the various *west projects* (modules) listed in Zephyr's *west manifest* (hardware abstraction layers (HALs), libraries, etc.).

Ubuntu

```
west init -m https://github.com/zephyrproject-rtos/zephyr ~/zephyrproject
cd ~/zephyrproject
west update
```

macOS

```
west init -m https://github.com/zephyrproject-rtos/zephyr ~/zephyrproject
cd ~/zephyrproject
west update
```

Windows

```
west init -m https://github.com/zephyrproject-rtos/zephyr zephyrproject
cd zephyrproject
west update
```

Tip

To reduce disk space usage and avoid downloading unnecessary modules or vendor HALs during setup, you may configure *Project Groups* before running `west update`.

5. Install Zephyr's Python dependencies:

   `west packages` reads the Python requirements from the checked-out Zephyr workspace (including its modules), so the installed packages match the Zephyr version you fetched.

   Ubuntu

   ```
   west packages pip --install
   ```

   macOS

   ```
   west packages pip --install
   ```

   Windows

   Batchfile

   ```
   cmd /c zephyr\scripts\utils\west-packages-pip-install.cmd
   ```

   PowerShell

   ```
   python -m pip install @((west packages pip) -split ' ')
   ```

   Note

   Installing these dependencies can downgrade or upgrade west itself.

6. Export a *Zephyr CMake package*. This registers your current Zephyr checkout in CMake's user package registry so `find_package(Zephyr)` can locate it automatically when building applications.

   ```
   west zephyr-export
   ```

2.1.4 Install the Zephyr SDK

The *Zephyr Software Development Kit (SDK)* contains toolchains for each of Zephyr's supported architectures. Those toolchains include the compiler, assembler, linker, and other programs required to build Zephyr applications for your target hardware.

It also contains additional host tools, such as custom QEMU and OpenOCD builds that are used to emulate, flash and debug Zephyr applications.

Install the Zephyr SDK with `west sdk install` from the Zephyr repository:

Ubuntu

```
cd ~/zephyrproject/zephyr
west sdk install
```

macOS

```
cd ~/zephyrproject/zephyr
west sdk install
```

Windows

Batchfile

```
cd %HOMEPATH%\zephyrproject\zephyr
west sdk install
```

PowerShell

```
cd $Env:HOMEPATH\zephyrproject\zephyr
west sdk install
```

Tip

Use command options to choose the SDK installation destination or install only selected architecture toolchains. See `west sdk install --help` for details.

Note

If you want to install Zephyr SDK without using the `west sdk` command, please see *Zephyr SDK installation*.

2.1.5 Build the Blinky Sample

Note

blinky is compatible with most, but not all, boards. If your board does not meet Blinky's blinky-sample-requirements, then hello_world is a good alternative.

If you are unsure what name west uses for your board, use `west boards` to list all boards Zephyr supports. Your board's documentation page also shows the exact board target name to pass to `west build`.

Build the blinky with *west build*. Replace `<your-board-name>` with the name of your board:

Ubuntu

```
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

macOS

```
cd ~/zephyrproject/zephyr
west build -p always -b <your-board-name> samples/basic/blinky
```

Windows

Batchfile

```
cd %HOMEPATH%\zephyrproject\zephyr
west build -p always -b <your-board-name> samples\basic\blinky
```

PowerShell

```
cd $Env:HOMEPATH\zephyrproject\zephyr
west build -p always -b <your-board-name> samples\basic\blinky
```

The `-p always` option forces a pristine build, which removes build output from any previous configuration. This avoids stale files when you are getting started. Later, you can use `-p auto` to let `west build` heuristics decide when a pristine build may be needed. See `west build -h` for details.

Note

A board may contain one or multiple SoCs and each SoC may contain one or more CPU clusters. When building for such boards, specify the SoC or CPU cluster for which the sample must be built. For example to build blinky for the cpuapp core on the nrf5340dk the board must be provided as: `nrf5340dk/nrf5340/cpuapp`. See also *Board terminology* for more details.

2.1.6 Flash the Sample

Connect your board, usually via USB, and turn it on if there's a power switch. If in doubt about what to do, check your board's page in boards, as some boards require a specific setup or procedure to flash them.

Flash the sample with *west flash*. This programs the application you just built onto the connected board:

```
west flash
```

Note

You may need to install additional *host tools* required by your board. The `west flash` command will print an error if any required dependencies are missing.

Note

On Linux, you may need to configure udev rules before flashing with a debug probe for the first time. See *Setting udev rules*.

If you're using blinky, the LED will start to blink as shown in this figure:

Fig. 1: Phytec reel_board running blinky

2.1.7 Next Steps

Here are some next steps for exploring Zephyr:

- Try other samples
- Learn about *Application Development* and the *west* tool
- Find out about west's *flashing and debugging* features, or more about *Flashing and Hardware Debugging* in general
- Check out *Beyond the Getting Started Guide* for additional setup alternatives and ideas
- Discover *Resources* for getting help from the Zephyr community

2.1.8 Asking for Help

Before asking for help, search this documentation, the Zephyr project's GitHub discussions and issues, and Discord chat history. Your question may already have an answer there. You can also ask the *chatbot* available from every page of this documentation.

- **Mailing Lists**: users@lists.zephyrproject.org is usually the right list to ask for help. Search archives and sign up here.
- **GitHub**: Use GitHub discussions for questions and GitHub issues for bugs and feature requests.
- **Discord**: You can join with this Discord invite.

When asking for help, include:

1. What you want to do
2. What you tried, including the commands you ran
3. What happened, including the full text output

Copy and paste text instead of sharing screenshots. For more than 5 lines of terminal output, source code, or logs on Discord or GitHub, create a snippet using three backticks.

2.2 Beyond the Getting Started Guide

The *Getting Started Guide* gives a straight-forward path to set up your Linux, macOS, or Windows environment for Zephyr development. In this document, we delve deeper into Zephyr development setup issues and alternatives.

2.2.1 Python and pip

Python 3 and its package manager, pip[1], are used extensively by Zephyr to install and run scripts required to compile and run Zephyr applications, set up and maintain the Zephyr development environment, and build project documentation.

Depending on your operating system, you may need to provide the `--user` flag to the `pip3` command when installing new packages. This is documented throughout the instructions. See Installing Packages in the Python Packaging User Guide for more information about pip[1], including information on -\-user.

- On Linux, make sure `~/.local/bin` is at the front of your *PATH environment variable*, or programs installed with `--user` won't be found. Installing with `--user` avoids conflicts between pip and the system package manager, and is the default on Debian-based distributions.
- On macOS, Homebrew disables -\-user.
- On Windows, see the Installing Packages information on `--user` if you require using this option.

On all operating systems, pip's `-U` flag installs or updates the package if the package is already installed locally but a more recent version is available. It is good practice to use this flag if the latest version of a package is required. (Check the scripts/requirements.txt file to see if a specific Python package version is expected.)

2.2.2 Advanced Platform Setup

Here are some alternative instructions for more advanced platform setup configurations for supported development platforms:

Install Linux Host Dependencies

Documentation is available for these Linux distributions:

- Ubuntu
- Fedora
- Clear Linux
- Arch Linux

For distributions that are not based on rolling releases, some of the requirements and dependencies may not be met by your package manager. In that case please follow the additional instructions that are provided to find software from sources other than the package manager.

> **Note**
>
> If you're working behind a corporate firewall, you'll likely need to configure a proxy for accessing the internet, if you haven't done so already. While some tools use the environment

[1] pip is Python's package installer. Its `install` command first tries to reuse packages and package dependencies already installed on your computer. If that is not possible, `pip install` downloads them from the Python Package Index (PyPI) on the Internet.
The package versions requested by Zephyr's `requirements.txt` may conflict with other requirements on your system, in which case you may want to set up a virtualenv for Zephyr development.

variables `http_proxy` and `https_proxy` to get their proxy settings, some use their own configuration files, most notably `apt` and `git`.

Update Your Operating System Ensure your host system is up to date.

Ubuntu

```
sudo apt-get update
sudo apt-get upgrade
```

Fedora

```
sudo dnf upgrade
```

Clear Linux

```
sudo swupd update
```

Arch Linux

```
sudo pacman -Syu
```

Install Requirements and Dependencies Note that both Ninja and Make are installed with these instructions; you only need one.

Ubuntu

```
sudo apt-get install --no-install-recommends git cmake ninja-build gperf \
  ccache dfu-util device-tree-compiler wget \
  python3-dev python3-pip python3-setuptools python3-tk python3-wheel xz-utils␣
↪file \
  make gcc gcc-multilib g++-multilib libsdl2-dev libmagic1
```

Fedora

```
sudo dnf group install development-tools c-development
sudo dnf install cmake ninja-build gperf dfu-util dtc wget which \
  python3-pip python3-tkinter xz file python3-devel SDL2-devel \
  libusb1-devel
```

Clear Linux

```
sudo swupd bundle-add c-basic dev-utils dfu-util dtc \
  os-core-dev python-basic python3-basic python3-tcl
```

The Clear Linux focus is on *native* performance and security and not cross-compilation. For that reason it uniquely exports by default to the *environment* of all users a list of compiler and linker flags. Zephyr's CMake build system will either warn or fail because of these. To clear the C/C++ flags among these and fix the Zephyr build, run the following command as root then log out and back in:

```
echo 'unset CFLAGS CXXFLAGS' >> /etc/profile.d/unset_cflags.sh
```

Note this command unsets the C/C++ flags for *all users on the system*. Each Linux distribution has a unique, relatively complex and potentially evolving sequence of bash initialization files sourcing each other and Clear Linux is no exception. If you need a more flexible solution, start by looking at the logic in `/usr/share/defaults/etc/profile`.

Arch Linux

```
sudo pacman -S git cmake ninja gperf ccache dfu-util dtc wget \
    python-pip python-setuptools python-wheel tk xz file make which
```

CMake A *recent CMake version* is required. Check what version you have by using `cmake --version`. If you have an older version, there are several ways of obtaining a more recent one:

- On Ubuntu, you can follow the instructions for adding the kitware third-party apt repository to get an updated version of cmake using apt.
- Download and install a packaged cmake from the CMake project site. (Note this won't uninstall the previous version of cmake.)

  ```
  cd ~
  wget␣
  ↪https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-Linux-x86_64.sh
  chmod +x cmake-3.21.1-Linux-x86_64.sh
  sudo ./cmake-3.21.1-Linux-x86_64.sh --skip-license --prefix=/usr/local
  hash -r
  ```

  The `hash -r` command may be necessary if the installation script put cmake into a new location on your PATH.
- Download and install from the pre-built binaries provided by the CMake project itself in the CMake Downloads page. For example, to install version 3.21.1 in `~/bin/cmake`:

  ```
  mkdir $HOME/bin/cmake && cd $HOME/bin/cmake
  wget␣
  ↪https://github.com/Kitware/CMake/releases/download/v3.21.1/cmake-3.21.1-Linux-x86_64.sh
  yes | sh cmake-3.21.1-Linux-x86_64.sh | cat
  echo "export PATH=$PWD/cmake-3.21.1-Linux-x86_64/bin:\$PATH" >>
  ↪$HOME/.zephyrrc
  ```
- Use `pip3`:

  ```
  pip3 install --user cmake
  ```

  Note this won't uninstall the previous version of cmake and will install the new cmake into your ~/.local/bin folder so you'll need to add ~/.local/bin to your PATH. (See *Python and pip* for details.)
- Check your distribution's beta or unstable release package library for an update.
- On Ubuntu you can also use snap to get the latest version available:

  ```
  sudo snap install cmake
  ```

After updating cmake, verify that the newly installed cmake is found using `cmake --version`. You might also want to uninstall the CMake provided by your package manager to avoid conflicts. (Use `whereis cmake` to find other installed versions.)

DTC (Device Tree Compiler) A *recent DTC version* is required. Check what version you have by using `dtc --version`. If you have an older version, either install a more recent one by building from source, or use the one that is bundled in the *Zephyr SDK* by installing it.

Python A *modern Python 3 version* is required. Check what version you have by using `python3 --version`.

If you have an older version, you will need to install a more recent Python 3. You can build from source, or use a backport from your distribution's package manager channels if one is available.

Isolating this Python in a virtual environment is recommended to avoid interfering with your system Python.

Install the Zephyr Software Development Kit (SDK) The Zephyr Software Development Kit (SDK) contains toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

To install the SDK, follow the Linux steps from the Zephyr SDK installation guide.

Building on Linux without the Zephyr SDK The Zephyr SDK is provided for convenience and ease of use. It provides toolchains for all Zephyr target architectures, and does not require any extra flags when building applications or running tests. In addition to cross-compilers, the Zephyr SDK also provides prebuilt host tools. It is, however, possible to build without the SDK's toolchain by using another toolchain as described in the *Toolchains* section.

As already noted above, the SDK also includes prebuilt host tools. To use the SDK's prebuilt host tools with a toolchain from another source, you must set the *ZEPHYR_SDK_INSTALL_DIR* environment variable to the Zephyr SDK installation directory. To build without the Zephyr SDK's prebuilt host tools, the *ZEPHYR_SDK_INSTALL_DIR* environment variable must be unset.

To make sure this variable is unset, run:

```
unset ZEPHYR_SDK_INSTALL_DIR
```

macOS alternative setup instructions

Important note about Gatekeeper Starting with macOS 10.15 Catalina, applications launched from the macOS Terminal application (or any other terminal emulator) are subject to the same system security policies that are applied to applications launched from the Dock. This means that if you download executable binaries using a web browser, macOS will not let you execute those from the Terminal by default. In order to get around this issue you can take two different approaches:

- Run `xattr -r -d com.apple.quarantine /path/to/folder` where `path/to/folder` is the path to the enclosing folder where the executables you want to run are located.
- Open *System Preferences* ▸ *Security and Privacy* ▸ *Privacy* and then scroll down to "Developer Tools". Then unlock the lock to be able to make changes and check the checkbox corresponding to your terminal emulator of choice. This will apply to any executable being launched from such terminal program.

Note that this section does **not** apply to executables installed with Homebrew, since those are automatically un-quarantined by `brew` itself. This is however relevant for most *Toolchains*.

Additional notes for MacPorts users While MacPorts is not officially supported in this guide, it is possible to use MacPorts instead of Homebrew to get all the required dependencies on macOS. Note also that you may need to install `rust` and `cargo` for the Python dependencies to install correctly.

Windows alternative setup instructions

Windows 10 WSL (Windows Subsystem for Linux) If you are running a recent version of Windows 10 you can make use of the built-in functionality to natively run Ubuntu binaries directly on a standard command-prompt. This allows you to use software such as the *Zephyr SDK* without setting up a virtual machine.

Warning

Windows 10 version 1803 has an issue that will cause CMake to not work properly and is fixed in version 1809 (and later). More information can be found in Zephyr Issue 10420.

1. Install the Windows Subsystem for Linux (WSL).

   Note

   For the Zephyr SDK to function properly you will need Windows 10 build 15002 or greater. You can check which Windows 10 build you are running in the "About your PC" section of the System Settings. If you are running an older Windows 10 build you might need to install the Creator's Update.

2. Follow the Ubuntu instructions in the *Install Linux Host Dependencies* document.

2.2.3 Install a Toolchain

Zephyr binaries are compiled and linked by a *toolchain* comprised of a cross-compiler and related tools which are different from the compiler and tools used for developing software that runs natively on your host operating system.

You can install the *Zephyr SDK* to get toolchains for all supported architectures, or install an *alternate toolchain* recommended by the SoC vendor or a specific board (check your specific board-level documentation).

You can configure the Zephyr build system to use a specific toolchain by setting *environment variables* such as `ZEPHYR_TOOLCHAIN_VARIANT` to a supported value, along with additional variable(s) specific to the toolchain variant.

2.2.4 Updating the Zephyr SDK toolchain

When updating Zephyr SDK, check whether the `ZEPHYR_TOOLCHAIN_VARIANT` or `ZEPHYR_SDK_INSTALL_DIR` environment variables are already set.

- If the variables are not set, the latest compatible version of Zephyr SDK will be selected by default. Proceed to next step without making any changes.
- If `ZEPHYR_TOOLCHAIN_VARIANT` is set, the corresponding toolchain will be selected at build time. Zephyr SDK is identified by the value `zephyr`. If the `ZEPHYR_TOOLCHAIN_VARIANT` environment variable is not `zephyr`, then either unset it or change its value to `zephyr` to make sure Zephyr SDK is selected.
- If the `ZEPHYR_SDK_INSTALL_DIR` environment variable is set, it will override the default lookup location for Zephyr SDK. If you install Zephyr SDK to one of the *recommended locations*, you can unset this variable. Otherwise, set it to your chosen install location.

For more information about these environment variables in Zephyr, see *Important Environment Variables*.

2.2.5 Cloning the Zephyr Repositories

The Zephyr project source is maintained in the GitHub zephyr repo. External modules used by Zephyr are found in the parent GitHub Zephyr project. Because of these dependencies, it's convenient to use the Zephyr-created *west* tool to fetch and manage the Zephyr and external module source code. See *Basics* for more details.

Once your development tools are installed, use *West (Zephyr's meta-tool)* to create, initialize, and download sources from the zephyr and external module repos. We'll use the name `zephyrproject`, but you can choose any name that does not contain a space anywhere in the path.

```
west init zephyrproject
cd zephyrproject
west update
```

The `west update` command fetches and keeps *Modules (External projects)* in the `zephyrproject` folder in sync with the code in the local zephyr repo.

Warning

You must run `west update` any time the `zephyr/west.yml` changes, caused, for example, when you pull the `zephyr` repository, switch branches in it, or perform a `git bisect` inside of it.

Keeping Zephyr updated

To update the Zephyr project source code, you need to get the latest changes via `git`. Afterwards, run `west update` as mentioned in the previous paragraph. Additionally, check for updated or added Python dependencies.

Linux/macOS

```
# replace zephyrproject with the path you gave west init
cd zephyrproject/zephyr
git pull
west update
west packages pip --install
```

Windows

Batchfile

```
:: replace zephyrproject with the path you gave west init
cd zephyrproject\zephyr
git pull
west update
cmd /c scripts\utils\west-packages-pip-install.cmd
```

PowerShell

```
# replace zephyrproject with the path you gave west init
cd zephyrproject\zephyr
git pull
west update
python -m pip install @((west packages pip) -split ' ')
```

2.2.6 Export Zephyr CMake package

The *Zephyr CMake Package* can be exported to CMake's user package registry if it has not already been done as part of *Getting Started Guide*.

2.2.7 Board Aliases

Developers who work with multiple boards may find explicit board names cumbersome and want to use aliases for common targets. This is supported by a CMake file with content like this:

```
# Variable foo_BOARD_ALIAS=bar replaces BOARD=foo with BOARD=bar and
# sets BOARD_ALIAS=foo in the CMake cache.
set(pca10028_BOARD_ALIAS nrf51dk/nrf51822)
set(pca10056_BOARD_ALIAS nrf52840dk/nrf52840)
set(k64f_BOARD_ALIAS frdm_k64f)
set(sltb004a_BOARD_ALIAS efr32mg_sltb004a)
```

and specifying its location in *ZEPHYR_BOARD_ALIASES*. This enables use of aliases `pca10028` in contexts like `cmake -DBOARD=pca10028` and `west -b pca10028`.

2.2.8 Build and Run an Application

You can build, flash, and run Zephyr applications on real hardware using a supported host system. Depending on your operating system, you can also run it in emulation with QEMU, or as a native application with native_sim. Additional information about building applications can be found in the *Building an Application* section.

Build Blinky

Let's build the blinky sample application.

Zephyr applications are built to run on specific hardware, called a "board"[2]. We'll use the Phytec reel_board here, but you can change the `reel_board` build target to another value if you have a different board. See boards or run `west boards` from anywhere inside the `zephyrproject` directory for a list of supported boards.

1. Go to the zephyr repository:

   ```
   cd zephyrproject/zephyr
   ```

2. Build the blinky sample for the `reel_board`:

   ```
   # From the root of the zephyr repository
   west build -b reel_board samples/basic/blinky
   ```

The main build products will be in `build/zephyr`; `build/zephyr/zephyr.elf` is the blinky application binary in ELF format. Other binary formats, disassembly, and map files may be present depending on your board.

The other sample applications in the samples folder are documented in samples.

> **Note**
>
> If you want to reuse an existing build directory for another board or application, you need to add the parameter `-p=auto` to `west build` to clean out settings and artifacts from the previous build.

Run the Application by Flashing to a Board

Most hardware boards supported by Zephyr can be flashed by running `west flash`. This may require board-specific tool installation and configuration to work properly.

See *Run an Application* and your specific board's documentation in boards for additional details.

[2] This has become something of a misnomer over time. While the target can be, and often is, a microprocessor running on its own dedicated hardware board, Zephyr also supports using QEMU to run targets built for other architectures in emulation, targets which produce native host system binaries that implement Zephyr's driver interfaces with POSIX APIs, and even running different Zephyr-based binaries on CPU cores of differing architectures on the same physical chip. Each of these hardware configurations is called a "board," even though that doesn't always make perfect sense in context.

Setting udev rules

Flashing a board requires permission to directly access the board hardware, usually managed by installation of the flashing tools. On Linux systems, if the `west flash` command fails, you likely need to define udev rules to grant the needed access permission.

Udev is a device manager for the Linux kernel and the udev daemon handles all user space events raised when a hardware device is added (or removed) from the system. We can add a rules file to grant access permission by non-root users to certain USB-connected devices.

The OpenOCD (On-Chip Debugger) project conveniently provides a rules file that defined board-specific rules for most Zephyr-supported arm-based boards, so we recommend installing this rules file by downloading it from their sourceforge repo, or if you've installed the Zephyr SDK there is a copy of this rules file in the SDK folder:

- Either download the OpenOCD rules file and copy it to the right location:

```
wget -O 60-openocd.rules␣
↪https://sf.net/p/openocd/code/ci/master/tree/contrib/60-openocd.rules?format=raw
sudo cp 60-openocd.rules /etc/udev/rules.d
```

- or copy the rules file from the Zephyr SDK folder:

```
sudo cp $
↪{ZEPHYR_SDK_INSTALL_DIR}/sysroots/x86_64-pokysdk-linux/usr/share/openocd/contrib/60-openoc
↪/etc/udev/rules.d
```

Then, in either case, ask the udev daemon to reload these rules:

```
sudo udevadm control --reload
```

Unplug and plug in the USB connection to your board, and you should have permission to access the board hardware for flashing. Check your board-specific documentation (boards) for further information if needed.

Run the Application in QEMU

You can run Zephyr applications via emulation on your host system using QEMU when targeting either the x86 or ARM Cortex-M3 architectures. QEMU is included with the Zephyr SDK.

If using a manual QEMU installation, ensure it is available in the system `PATH` environment variable.

`QEMU_BIN_PATH` can be used as an optional override to specify the location of QEMU binaries used by Twister. When provided, Twister validates that the specified path exists. Otherwise, Twister relies on SDK or other QEMU discovery mechanisms.

For example, you can build and run the hello_world sample using the x86 emulation board configuration (`qemu_x86`), with:

```
# From the root of the zephyr repository
west build -b qemu_x86 samples/hello_world
west build -t run
```

To exit QEMU, type `Ctrl-a`, then `x`.

Use `qemu_cortex_m3` to target an emulated Arm Cortex-M3 sample.

Run a Sample Application natively (Linux)

You can compile some samples to run as host programs on Linux. See native_sim for more information. On 64-bit host operating systems, you need to install a 32-bit C library, or build targeting native_sim/native/64.

First, build Hello World for `native_sim`.

```
# From the root of the zephyr repository
west build -b native_sim samples/hello_world
```

Next, run the application.

```
west build -t run
# or just run zephyr.exe directly:
./build/zephyr/zephyr.exe
```

Press `Ctrl-C` to exit.

You can run `./build/zephyr/zephyr.exe --help` to get a list of available options.

This executable can be instrumented using standard tools, such as gdb or valgrind.

2.3 Environment Variables

Various pages in this documentation refer to setting Zephyr-specific environment variables. This page describes how.

2.3.1 Setting Variables

Option 1: Just Once

To set the environment variable `MY_VARIABLE` to `foo` for the lifetime of your current terminal window:

Linux/macOS

```
export MY_VARIABLE=foo
```

Windows

```
set MY_VARIABLE=foo
```

Warning

This is best for experimentation. If you close your terminal window, use another terminal window or tab, restart your computer, etc., this setting will be lost forever.

Using options 2 or 3 is recommended if you want to keep using the setting.

Option 2: In all Terminals

Linux/macOS

Add the `export MY_VARIABLE=foo` line to your shell's startup script in your home directory. For Bash, this is usually `~/.bashrc` on Linux or `~/.bash_profile` on macOS. Changes in these startup scripts don't affect shell instances already started; try opening a new terminal window to get the new settings.

Windows

You can use the `setx` program in `cmd.exe` or the third-party RapidEE program.

To use `setx`, type this command, then close the terminal window. Any new `cmd.exe` windows will have `MY_VARIABLE` set to `foo`.

```
setx MY_VARIABLE foo
```

To install RapidEE, a freeware graphical environment variable editor, using Chocolatey in an Administrator command prompt:

```
choco install rapidee
```

You can then run `rapidee` from your terminal to launch the program and set environment variables. Make sure to use the "User" environment variables area – otherwise, you have to run RapidEE as administrator. Also make sure to save your changes by clicking the Save button at top left before exiting. Settings you make in RapidEE will be available whenever you open a new terminal window.

Option 3: Using `zephyrrc` files

Choose this option if you don't want to make the variable's setting available to all of your terminals, but still want to save the value for loading into your environment when you are using Zephyr.

Linux/macOS

Zephyr supports multiple locations for your `zephyrrc` file, following the XDG Base Directory Specification when possible. Create a zephyrrc file in one of the following locations (they will be checked in order):

1. `$XDG_CONFIG_HOME/zephyr/zephyrrc`
2. `$HOME/.config/zephyr/zephyrrc`
3. `$HOME/.zephyrrc`

Add this line to the file in your preferred location:

```
export MY_VARIABLE=foo
```

To get this value back into your current terminal environment, **you must run** `source zephyr-env.sh` from the main `zephyr` repository. Among other things, this script sources your `zephyrrc` (the first one it finds from the list of locations above).

The value will be lost if you close the window, etc.; run `source zephyr-env.sh` again to get it back.

Windows

Add the line `set MY_VARIABLE=foo` to the file `%userprofile%\zephyrrc.cmd` using a text editor such as Notepad to save the value.

To get this value back into your current terminal environment, **you must run** `zephyr-env.cmd` in a `cmd.exe` window after changing directory to the main `zephyr` repository. Among other things, this script runs `%userprofile%\zephyrrc.cmd`.

The value will be lost if you close the window, etc.; run `zephyr-env.cmd` again to get it back.

These scripts:

- set *ZEPHYR_BASE* to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your *PATH* environment variable
- loads any settings from the `zephyrrc` files described above in *Option 3: Using zephyrrc files*.

You can thus use them any time you need any of these settings.

2.3.2 Zephyr Environment Scripts

You can use the zephyr repository scripts `zephyr-env.sh` (for macOS and Linux) and `zephyr-env.cmd` (for Windows) to load Zephyr-specific settings into your current terminal's environment. To do so, run this command from the zephyr repository:

Linux/macOS

```
source zephyr-env.sh
```

Windows

```
zephyr-env.cmd
```

These scripts:

- set *ZEPHYR_BASE* to the location of the zephyr repository
- adds some Zephyr-specific locations (such as zephyr's `scripts` directory) to your `PATH` environment variable
- loads any settings from the `zephyrrc` files described above in *Option 3: Using zephyrrc files*.

You can thus use them any time you need any of these settings.

2.3.3 Important Environment Variables

Some *Important Build System Variables* can also be set in the environment. Here is a description of some of these important environment variables. This is not a comprehensive list.

`BOARD`
: See *Important Build System Variables*.

`CONF_FILE`
: See *Important Build System Variables*.

`SHIELD`
: See *Shields*.

`ZEPHYR_BASE`
: See *Important Build System Variables*.

`EXTRA_ZEPHYR_MODULES`
: See *Important Build System Variables*.

`ZEPHYR_MODULES`
: See *Important Build System Variables*.

`ZEPHYR_BOARD_ALIASES`
: See *Board Aliases*

The following additional environment variables are significant when configuring the *toolchain* used to build Zephyr applications.

`ZEPHYR_SDK_INSTALL_DIR`
: Path where Zephyr SDK is installed.

`ZEPHYR_TOOLCHAIN_VARIANT`
: The name of the toolchain to use.

`{TOOLCHAIN}_TOOLCHAIN_PATH`
: Path to the toolchain specified by *ZEPHYR_TOOLCHAIN_VARIANT*. For example, if `ZEPHYR_TOOLCHAIN_VARIANT=host/llvm`, use `LLVM_TOOLCHAIN_PATH`. (Note the capitalization when forming the environment variable name.)

You might need to update some of these variables when you *update the Zephyr SDK toolchain*.

Emulators and boards may also depend on additional programs. The build system will try to locate those programs automatically, but may rely on additional CMake or environment variables to do so. Please consult your emulator's or board's documentation for more information. The following environment variables may be useful in such situations:

`PATH`
: `PATH` is an environment variable used on Unix-like or Microsoft Windows operating systems to specify a set of directories where executable programs are located.

2.4 Application Development

Note

In this document, we'll assume:

- your **application directory**, <app>, is something like <home>/zephyrproject/app
- its **build directory** is <app>/build

These terms are defined below. On Linux/macOS, <home> is equivalent to ~. On Windows, it's %userprofile%.

Keeping your application inside the workspace (<home>/zephyrproject) makes it easier to use `west build` and other commands with it. (You can put your application anywhere as long as *ZEPHYR_BASE* is set appropriately, though.)

2.4.1 Overview

Zephyr's build system is based on CMake.

The build system is application-centric, and requires Zephyr-based applications to initiate building the Zephyr source code. The application build controls the configuration and build process of both the application and Zephyr itself, compiling them into a single binary.

The main zephyr repository contains Zephyr's source code, configuration files, and build system. You also likely have installed various *Modules (External projects)* alongside the zephyr repository, which provide third party source code integration.

The files in the **application directory** link Zephyr and any modules with the application. This directory contains all application-specific files, such as application-specific configuration files and source code.

Here are the files in a simple Zephyr application:

```
<app>
├── CMakeLists.txt
├── app.overlay
├── prj.conf
├── VERSION
└── src
    └── main.c
```

These contents are:

- **CMakeLists.txt**: This file tells the build system where to find the other application files, and links the application directory with Zephyr's CMake build system. This link provides features supported by Zephyr's build system, such as board-specific configuration files, the ability to run and debug compiled binaries on real or emulated hardware, and more.

- **app.overlay**: This is a devicetree overlay file that specifies application-specific changes which should be applied to the base devicetree for any board you build for. The purpose of devicetree overlays is usually to configure something about the hardware used by the application.

  The build system looks for `app.overlay` by default, but you can add more devicetree overlays, and other default files are also searched for.

  See *Devicetree* for more information about devicetree.

- **prj.conf**: This is a Kconfig fragment that specifies application-specific values for one or more Kconfig options. These application settings are merged with other settings to produce the final configuration. The purpose of Kconfig fragments is usually to configure the software features used by the application.

  The build system looks for `prj.conf` by default, but you can add more Kconfig fragments, and other default files are also searched for.

  See *Kconfig Configuration* below for more information.

- **VERSION**: A text file that contains several version information fields. These fields let you manage the lifecycle of the application and automate providing the application version when signing application images.

  See *Application version management* for more information about this file and how to use it.

- **main.c**: A source code file. Applications typically contain source files written in C, C++, or assembly language. The Zephyr convention is to place them in a subdirectory of <app> named `src`.

Once an application has been defined, you will use CMake to generate a **build directory**, which contains the files you need to build the application and Zephyr, then link them together into a final binary you can run on your board. The easiest way to do this is with *west build*, but you can use CMake directly also. Application build artifacts are always generated in a separate build directory: Zephyr does not support "in-tree" builds.

The following sections describe how to create, build, and run Zephyr applications, followed by more detailed reference material.

2.4.2 Application types

We distinguish three basic types of Zephyr application based on where <app> is located:

Application type	<app> location
repository	zephyr repository
workspace	west workspace where Zephyr is installed
freestanding	other locations

We'll discuss these more below. To learn how the build system supports each type, see *Zephyr CMake Package*.

Zephyr repository application

An application located within the `zephyr` source code repository in a Zephyr *west workspace* is referred to as a Zephyr repository application. In the following example, the hello_world sample is a Zephyr repository application:

```
zephyrproject/
├── .west/
│   └── config
└── zephyr/
```

(continues on next page)

(continued from previous page)

```
     ├── arch/
     ├── boards/
     ├── cmake/
     ├── samples/
     │    ├── hello_world/
     │    └── ...
     ├── tests/
     └── ...
```

Zephyr workspace application

An application located within a *workspace*, but outside the zephyr repository itself, is referred to as a Zephyr workspace application. In the following example, `app` is a Zephyr workspace application:

```
zephyrproject/
├─── .west/
│    └─── config
├─── zephyr/
├─── bootloader/
├─── modules/
├─── tools/
├─── <vendor/private-repositories>/
└─── applications/
     └── app/
```

Zephyr freestanding application

A Zephyr application located outside of a Zephyr *workspace* is referred to as a Zephyr freestanding application. In the following example, `app` is a Zephyr freestanding application:

```
<home>/
├─── zephyrproject/
│     ├─── .west/

2.4.3 Creating an Application

In Zephyr, you can either use a reference workspace application or create your application by hand.

Using a Reference Workspace Application

The example-application Git repository contains a reference *workspace application*. It is recommended to use it as a reference when creating your own application as described in the following sections.

The example-application repository demonstrates how to use several commonly-used features, such as:

- Custom *board ports*
- Custom *devicetree bindings*
- Custom *device drivers*
- Continuous Integration (CI) setup, including using *twister*
- A custom west *extension command*

Basic example-application Usage The easiest way to get started with the example-application repository within an existing Zephyr workspace is to follow these steps:

```
cd <home>/zephyrproject
git clone https://github.com/zephyrproject-rtos/example-application my-app
```

The directory name `my-app` above is arbitrary: change it as needed. You can now go into this directory and adapt its contents to suit your needs. Since you are using an existing Zephyr workspace, you can use `west build` or any other west commands to build, flash, and debug.

Advanced example-application Usage You can also use the example-application repository as a starting point for building your own customized Zephyr-based software distribution. This lets you do things like:

- remove Zephyr modules you don't need
- add additional custom repositories of your own
- override repositories provided by Zephyr with your own versions
- share the results with others and collaborate further

The example-application repository contains a `west.yml` file and is therefore also a west *manifest repository*. Use this to create a new, customized workspace by following these steps:

```
cd <home>
mkdir my-workspace
cd my-workspace
git clone https://github.com/zephyrproject-rtos/example-application␣
↪my-manifest-repo
west init -l my-manifest-repo
```

This will create a new workspace with the *T2 topology*, with `my-manifest-repo` as the manifest repository. The `my-workspace` and `my-manifest-repo` names are arbitrary: change them as needed.

Next, customize the manifest repository. The initial contents of this repository will match the example-application's contents when you clone it. You can then edit `my-manifest-repo/west.yml` to your liking, changing the set of repositories in it as you wish. See *Manifest Imports* for many examples of how to add or remove different repositories from your workspace as needed. Make any other changes you need to other files.

When you are satisfied, you can run:

```
west update
```

and your workspace will be ready for use.

If you push the resulting `my-manifest-repo` repository somewhere else, you can share your work with others. For example, let's say you push the repository to `https://git.example.com/my-manifest-repo`. Other people can then set up a matching workspace by running:

```
west init -m https://git.example.com/my-manifest-repo my-workspace
cd my-workspace
west update
```

From now on, you can collaborate on the shared software by pushing changes to the repositories you are using and updating `my-manifest-repo/west.yml` as needed to add and remove repositories, or change their contents.

Creating an Application by Hand

You can follow these steps to create a basic application directory from scratch. However, using the example-application repository or one of Zephyr's samples as a starting point is likely to be easier.

1. Create an application directory.

   For example, in a Unix shell or Windows `cmd.exe` prompt:

   ```
   mkdir app
   ```

   Warning

   Building Zephyr or creating an application in a directory with spaces anywhere on the path is not supported. So the Windows path `C:\Users\YourName\app` will work, but `C:\Users\Your Name\app` will not.

2. Create your source code files.

   It's recommended to place all application source code in a subdirectory named `src`. This makes it easier to distinguish between project files and sources.

   Continuing the previous example, enter:

   ```
   cd app
   mkdir src
   ```

3. Place your application source code in the `src` sub-directory. For this example, we'll assume you created a file named `src/main.c`.

4. Create a file named `CMakeLists.txt` in the `app` directory with the following contents:

   ```
   cmake_minimum_required(VERSION 3.28.0)

   find_package(Zephyr)
   project(my_zephyr_app)

   target_sources(app PRIVATE src/main.c)
   ```

   Notes:

   - The `cmake_minimum_required()` call is required by CMake. It is also invoked by the Zephyr package on the next line. CMake will error out if its version is older than either the version in your `CMakeLists.txt` or the version number in the Zephyr package.
   - `find_package(Zephyr)` pulls in the Zephyr build system, which creates a CMake target named `app` (see *Zephyr CMake Package*). Adding sources to this target is how you include them in the build. The Zephyr package will define `Zephyr-Kernel` as a CMake project and enable support for the `C`, `CXX`, `ASM` languages.

- `project(my_zephyr_app)` defines your application's CMake project. This must be called after `find_package(Zephyr)` to avoid interference with Zephyr's `project(Zephyr-Kernel)`.
- `target_sources(app PRIVATE src/main.c)` is to add your source file to the app target. This must come after `find_package(Zephyr)` which defines the target. You can add as many files as you want with `target_sources()`.

5. Create at least one Kconfig fragment for your application (usually named `prj.conf`) and set Kconfig option values needed by your application there. See *Kconfig Configuration*. If no Kconfig options need to be set, create an empty file.
6. Configure any devicetree overlays needed by your application, usually in a file named `app.overlay`. See *Set devicetree overlays*.
7. Set up any other files you may need, such as *twister* configuration files, continuous integration files, documentation, etc.

2.4.4 Important Build System Variables

You can control the Zephyr build system using many variables. This section describes the most important ones that every Zephyr developer should know about.

Note

The variables **BOARD**, **CONF_FILE**, and **DTC_OVERLAY_FILE** can be supplied to the build system in 3 ways (in order of precedence):

- As a parameter to the `west build` or `cmake` invocation via the `-D` command-line switch. If you have multiple overlay files, you should use quotations, `"file1.overlay;file2.overlay"`
- As *Environment Variables*.
- As a `set(<VARIABLE> <VALUE>)` statement in your `CMakeLists.txt`

- **ZEPHYR_BASE**: Zephyr base variable used by the build system. `find_package(Zephyr)` will automatically set this as a cached CMake variable. But `ZEPHYR_BASE` can also be set as an environment variable in order to force CMake to use a specific Zephyr installation.
- **BOARD**: Selects the board that the application's build will use for the default configuration. See boards for built-in boards, and *Board Porting Guide* for information on adding board support.
- **CONF_FILE**: Indicates the name of one or more Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. Each file includes Kconfig configuration values that override the default configuration values.

  See *The Initial Configuration* for more information.
- **EXTRA_CONF_FILE**: Additional Kconfig configuration fragment files. Multiple filenames can be separated with either spaces or semicolons. This can be useful in order to leave **CONF_FILE** at its default value, but "mix in" some additional configuration options.
- **DTC_OVERLAY_FILE**: One or more devicetree overlay files to use. Multiple files can be separated with semicolons. See *Set devicetree overlays* for examples and *Introduction to devicetree* for information about devicetree and Zephyr.
- **EXTRA_DTC_OVERLAY_FILE**: Additional devicetree overlay files to use. Multiple files can be separated with semicolons. This can be useful to leave **DTC_OVERLAY_FILE** at its default value, but "mix in" some additional overlay files.
- **SHIELD**: see *Shields*

- **ZEPHYR_MODULES**: A CMake list containing absolute paths of additional directories with source code, Kconfig, etc. that should be used in the application build. See *Modules (External projects)* for details. If you set this variable, it must be a complete list of all modules to use, as the build system will not automatically pick up any modules from west.
- **EXTRA_ZEPHYR_MODULES**: Like **ZEPHYR_MODULES**, except these will be added to the list of modules found via west, instead of replacing it.
- **FILE_SUFFIX**: Optional suffix for filenames that will be added to Kconfig fragments and devicetree overlays (if these files exists, otherwise will fallback to the name without the prefix). See *File Suffixes* for details.
- **KCONFIG_WARNING_AS_ERROR**: Treat every Kconfig warning as an error, including the ones which are only printed by default. See *Treating Kconfig warnings as errors* for details.

Note

You can use a *Zephyr Build Configuration CMake packages* to share common settings for these variables.

2.4.5 Application CMakeLists.txt

Every application must have a `CMakeLists.txt` file. This file is the entry point, or top level, of the build system. The final `zephyr.elf` image contains both the application and the kernel libraries.

This section describes some of what you can do in your `CMakeLists.txt`. Make sure to follow these steps in order.

1. If you only want to build for one board, add the name of the board configuration for your application on a new line. For example:

   ```
   set(BOARD qemu_x86)
   ```

   Refer to boards for more information on available boards.

   The Zephyr build system determines a value for **BOARD** by checking the following, in order (when a BOARD value is found, CMake stops looking further down the list):

   - Any previously used value as determined by the CMake cache takes highest precedence. This ensures you don't try to run a build with a different **BOARD** value than you set during the build configuration step.
   - Any value given on the CMake command line (directly or indirectly via `west build`) using `-DBOARD=YOUR_BOARD` will be checked for and used next.
   - If an *environment variable* `BOARD` is set, its value will then be used.
   - Finally, if you set `BOARD` in your application `CMakeLists.txt` as described in this step, this value will be used.

2. If your application uses a configuration file or files other than the usual `prj.conf`, add lines setting the **CONF_FILE** variable to these files appropriately. If multiple filenames are given, separate them by a single space or semicolon. CMake lists can be used to build up configuration fragment files in a modular way when you want to avoid setting **CONF_FILE** in a single place. For example:

   ```
   set(CONF_FILE "fragment_file1.conf")
   list(APPEND CONF_FILE "fragment_file2.conf")
   ```

   See *The Initial Configuration* for more information.

3. If your application uses devicetree overlays, you may need to set *DTC_OVERLAY_FILE*. See *Set devicetree overlays*.

4. If your application has its own kernel configuration options, create a `Kconfig` file in the same directory as your application's `CMakeLists.txt`.

   See *the Kconfig section of the manual* for detailed Kconfig documentation.

   An (unlikely) advanced use case would be if your application has its own unique configuration **options** that are set differently depending on the build configuration.

   If you just want to set application specific **values** for existing Zephyr configuration options, refer to the `CONF_FILE` description above.

   Structure your `Kconfig` file like this:

```
# SPDX-License-Identifier: Apache-2.0

mainmenu "Your Application Name"

# Your application configuration options go here

# Sources Kconfig.zephyr in the Zephyr root directory.
#
# Note: All 'source' statements work relative to the Zephyr root directory␣
↪(due
# to the $srctree environment variable being set to $ZEPHYR_BASE). If you want
# to 'source' relative to the current Kconfig file instead, use 'rsource' (or␣
↪a
# path relative to the Zephyr root).
source "Kconfig.zephyr"
```

   Note

   Environment variables in `source` statements are expanded directly, so you do not need to define an `option env="ZEPHYR_BASE"` Kconfig "bounce" symbol. If you use such a symbol, it must have the same name as the environment variable.

   See *Kconfig extensions* for more information.

   The `Kconfig` file is automatically detected when placed in the application directory, but it is also possible for it to be found elsewhere if the CMake variable `KCONFIG_ROOT` is set with an absolute path.

5. Specify that the application requires Zephyr on a new line, **after any lines added from the steps above**:

```
find_package(Zephyr)
project(my_zephyr_app)
```

   Note

   `find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})` can be used if enforcing a specific Zephyr installation by explicitly setting the `ZEPHYR_BASE` environment variable should be supported. All samples in Zephyr supports the `ZEPHYR_BASE` environment variable.

6. Now add any application source files to the 'app' target library, each on their own line, like so:

```
target_sources(app PRIVATE src/main.c)
```

Below is a simple example CMakeList.txt:

```
set(BOARD qemu_x86)

find_package(Zephyr)
project(my_zephyr_app)

target_sources(app PRIVATE src/main.c)
```

The Cmake property HEX_FILES_TO_MERGE leverages the application configuration provided by Kconfig and CMake to let you merge externally built hex files with the hex file generated when building the Zephyr application. For example:

```
set_property(GLOBAL APPEND PROPERTY HEX_FILES_TO_MERGE
    ${app_bootloader_hex}
    ${PROJECT_BINARY_DIR}/${KERNEL_HEX_NAME}
    ${app_provision_hex})
```

2.4.6 CMakeCache.txt

CMake uses a CMakeCache.txt file as persistent key/value string storage used to cache values between runs, including compile and build options and paths to library dependencies. This cache file is created when CMake is run in an empty build folder.

For more details about the CMakeCache.txt file see the official CMake Cache documentation.

2.4.7 Application Configuration

Application Configuration Directory

Zephyr will use configuration files from the application's configuration directory except for files with an absolute path provided by the arguments described earlier, for example CONF_FILE, EXTRA_CONF_FILE, DTC_OVERLAY_FILE, and EXTRA_DTC_OVERLAY_FILE.

The application configuration directory is defined by the APPLICATION_CONFIG_DIR variable.

APPLICATION_CONFIG_DIR will be set by one of the sources below with the highest priority listed first.

1. If APPLICATION_CONFIG_DIR is specified by the user with -DAPPLICATION_CONFIG_DIR=<path> or in a CMake file before find_package(Zephyr) then this folder is used a the application's configuration directory.
2. The application's source directory.

Kconfig Configuration

Application configuration options are usually set in prj.conf in the application directory. For example, C++ support could be enabled with this assignment:

```
CONFIG_CPP=y
```

Looking at existing samples is a good way to get started.

See *Setting Kconfig configuration values* for detailed documentation on setting Kconfig configuration values. The *The Initial Configuration* section on the same page explains how the initial configuration is derived. See kconfig-search for a complete list of configuration options. See *Hardening Tool* for security information related with Kconfig options.

The other pages in the *Kconfig section of the manual* are also worth going through, especially if you planning to add new configuration options.

Experimental features Zephyr is a project under constant development and thus there are features that are still in early stages of their development cycle. Such features will be marked `[EXPERIMENTAL]` in their Kconfig title.

The `CONFIG_WARN_EXPERIMENTAL` setting can be used to enable warnings at CMake configure time if any experimental feature is enabled.

```
CONFIG_WARN_EXPERIMENTAL=y
```

For example, if option `CONFIG_FOO` is experimental, then enabling it and `CONFIG_WARN_EXPERIMENTAL` will print the following warning at CMake configure time when you build an application:

```
warning: Experimental symbol FOO is enabled.
```

Devicetree Overlays

See *Set devicetree overlays*.

File Suffixes

Zephyr applications might want to have a single code base with multiple configurations for different build/product variants which would necessitate different Kconfig options and devicetree configuration. In order to better configure this, Zephyr provides a **`FILE_SUFFIX`** option when configuring applications that can be automatically appended to filenames. This is applied to Kconfig fragments and board overlays but with a fallback so that if such files do not exist, the files without these suffixes will be used instead.

Given the following example project layout:

```
<app>
├── CMakeLists.txt
├── prj.conf
├── prj_mouse.conf
├── boards
│   ├── native_sim.overlay
│   └── qemu_cortex_m3_mouse.overlay
└── src
    └── main.c
```

- If this is built normally without `FILE_SUFFIX` being defined for `native_sim` then `prj.conf` and `boards/native_sim.overlay` will be used.
- If this is built normally without `FILE_SUFFIX` being defined for `qemu_cortex_m3` then `prj.conf` will be used, no application devicetree overlay will be used.
- If this is built with `FILE_SUFFIX` set to `mouse` for `native_sim` then `prj_mouse.conf` and `boards/native_sim.overlay` will be used (there is no `native_sim_mouse.overlay` file so it falls back to `native_sim.overlay`).
- If this is built with `FILE_SUFFIX` set to `mouse` for `qemu_cortex_m3` then `prj_mouse.conf` will be used and `boards/qemu_cortex_m3_mouse.overlay` will be used.

2.4.8 Application-Specific Code

Application-specific source code files are normally added to the application's `src` directory. If the application adds a large number of files the developer can group them into sub-directories under `src`, to whatever depth is needed.

Application-specific source code should not use symbol name prefixes that have been reserved by the kernel for its own use. For more information, see Naming Conventions.

Third-party Library Code

It is possible to build library code outside the application's `src` directory but it is important that both application and library code targets the same Application Binary Interface (ABI). On most architectures there are compiler flags that control the ABI targeted, making it important that both libraries and applications have certain compiler flags in common. It may also be useful for glue code to have access to Zephyr kernel header files.

To make it easier to integrate third-party components, the Zephyr build system has defined CMake functions that give application build scripts access to the zephyr compiler options. The functions are documented and defined in cmake/modules/extensions.cmake and follow the naming convention `zephyr_get_<type>_<format>`.

The following variables will often need to be exported to the third-party build system.

- `CMAKE_C_COMPILER`, `CMAKE_AR`.
- `ARCH` and `BOARD`, together with several variables that identify the Zephyr kernel version.

samples/application_development/external_lib is a sample project that demonstrates some of these features.

2.4.9 Building an Application

The Zephyr build system compiles and links all components of an application into a single application image that can be run on simulated hardware or real hardware.

Like any other CMake-based system, the build process takes place *in two stages*. First, build files (also known as a buildsystem) are generated using the `cmake` command-line tool while specifying a generator. This generator determines the native build tool the buildsystem will use in the second stage. The second stage runs the native build tool to actually build the source files and generate an image. To learn more about these concepts refer to the CMake introduction in the official CMake documentation.

Although the default build tool in Zephyr is *west*, Zephyr's meta-tool, which invokes `cmake` and the underlying build tool (`ninja` or `make`) behind the scenes, you can also choose to invoke `cmake` directly if you prefer. On Linux and macOS you can choose between the `make` and `ninja` generators (i.e. build tools), whereas on Windows you need to use `ninja`, since `make` is not supported on this platform. For simplicity we will use `ninja` throughout this guide, and if you choose to use `west build` to build your application know that it will default to `ninja` under the hood.

As an example, let's build the Hello World sample for the `reel_board`:

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild
```

On Linux and macOS, you can also build with `make` instead of `ninja`:

Using west:

- to use `make` just once, add `-- -G"Unix Makefiles"` to the west build command line; see the *west build* documentation for an example.
- to use `make` by default from now on, run `west config build.generator "Unix Makefiles"`.

Using CMake directly:

```
# From the root of the zephyr repository
# Use cmake to configure a Make-based buildsystem:
cmake -Bbuild -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
make -Cbuild
```

Basics

1. Navigate to the application directory <app>.
2. Enter the following commands to build the application's `zephyr.elf` image for the board specified in the command-line parameters:

   Using west:

   ```
   west build -b <board>
   ```

   Using CMake and ninja:

   ```
   mkdir build && cd build

   # Use cmake to configure a Ninja-based buildsystem:
   cmake -GNinja -DBOARD=<board> ..

   # Now run the build tool on the generated build system:
   ninja
   ```

   If desired, you can build the application using the configuration settings specified in an alternate `.conf` file using the `CONF_FILE` parameter. These settings will override the settings in the application's `.config` file or its default `.conf` file. For example:

   Using west:

   ```
   west build -b <board> -- -DCONF_FILE=prj.alternate.conf
   ```

   Using CMake and ninja:

   ```
   mkdir build && cd build
   cmake -GNinja -DBOARD=<board> -DCONF_FILE=prj.alternate.conf ..
   ninja
   ```

   As described in the previous section, you can instead choose to permanently set the board and configuration settings by either exporting **`BOARD`** and **`CONF_FILE`** environment variables or by setting their values in your `CMakeLists.txt` using `set()` statements. Additionally, `west` allows you to *set a default board*.

Build Directory Contents

When using the Ninja generator a build directory looks like this:

```
<app>/build
├── build.ninja
├── CMakeCache.txt
├── CMakeFiles
├── cmake_install.cmake
├── rules.ninja
└── zephyr
```

The most notable files in the build directory are:

- `build.ninja`, which can be invoked to build the application.
- A `zephyr` directory, which is the working directory of the generated build system, and where most generated files are created and stored.

After running `ninja`, the following build output files will be written to the `zephyr` sub-directory of the build directory. (This is **not the Zephyr base directory**, which contains the Zephyr source code etc. and is described above.)

- `.config`, which contains the configuration settings used to build the application.

> **Note**
>
> The previous version of `.config` is saved to `.config.old` whenever the configuration is updated. This is for convenience, as comparing the old and new versions can be handy.

- Various object files (`.o` files and `.a` files) containing compiled kernel and application code.
- `zephyr.elf`, which contains the final combined application and kernel binary. Other binary output formats, such as `.hex` and `.bin`, are also supported.

Rebuilding an Application

Application development is usually fastest when changes are continually tested. Frequently rebuilding your application makes debugging less painful as the application becomes more complex. It's usually a good idea to rebuild and test after any major changes to the application's source files, CMakeLists.txt files, or configuration settings.

> **Important**
>
> The Zephyr build system rebuilds only the parts of the application image potentially affected by the changes. Consequently, rebuilding an application is often significantly faster than building it the first time.

Sometimes the build system doesn't rebuild the application correctly because it fails to recompile one or more necessary files. You can force the build system to rebuild the entire application from scratch with the following procedure:

1. Open a terminal console on your host computer, and navigate to the build directory `<app>/build`.
2. Enter one of the following commands, depending on whether you want to use `west` or `cmake` directly to delete the application's generated files, except for the `.config` file that contains the application's current configuration information.

   ```
   west build -t clean
   ```

   or

   ```
   ninja clean
   ```

   Alternatively, enter one of the following commands to delete *all* generated files, including the `.config` files that contain the application's current configuration information for those board types.

   ```
   west build -t pristine
   ```

   or

```
ninja pristine
```

If you use west, you can take advantage of its capability to automatically *make the build folder pristine* whenever it is required.

3. Rebuild the application normally following the steps specified in *Building an Application* above.

Building for a board revision

The Zephyr build system has support for specifying multiple hardware revisions of a single board with small variations. Using revisions allows the board support files to make minor adjustments to a board configuration without duplicating all the files described in *Create your board directory* for each revision.

To build for a particular revision, use `<board>@<revision>` or `<board>@<revision>/<qualifiers>` instead of plain `<board>` or `<board>/<qualifiers>`. For example:

Using west:

```
west build -b nrf9160dk@0.14.0/nrf9160/ns
```

Using CMake and ninja:

```
mkdir build && cd build
cmake -GNinja -DBOARD=nrf9160dk@0.14.0/nrf9160/ns ..
ninja
```

Check your board's documentation for details on whether it has multiple revisions, and what revisions are supported.

When targeting a board revision, the active revision will be printed at CMake configure time, like this:

```
-- Board: plank, Revision: 1.5.0
```

2.4.10 Run an Application

An application image can be run on a real board or emulated hardware.

Running on a Board

Most boards supported by Zephyr let you flash a compiled binary using `west flash` to copy the binary to the board and run it. Follow these instructions to flash and run an application on real hardware:

1. Build your application, as described in *Building an Application*.
2. Make sure your board is attached to your host computer. Usually, you'll do this via USB.
3. Run this console command from the build directory, `<app>/build`, to flash the compiled Zephyr image and run it on your board:

```
west flash
```

The Zephyr build system integrates with the board support files to use hardware-specific tools to flash the Zephyr binary to your hardware, then run it.

Each time you run the flash command, your application is rebuilt and flashed again.

In cases where board support is incomplete, flashing via the Zephyr build system may not be supported. If you receive an error message about flash support being unavailable, consult your board's documentation for additional information on how to flash your board.

Note

When developing on Linux, it's common to need to install board-specific udev rules to enable USB device access to your board as a non-root user. If flashing fails, consult your board's documentation to see if this is necessary.

Running in an Emulator

Zephyr has built-in emulator support for QEMU. It allows you to run and test an application virtually, before (or in lieu of) loading and running it on actual target hardware.

Check out *Beyond the Getting Started Guide* for additional steps needed on Windows.

Follow these instructions to run an application via QEMU:

1. Build your application for one of the QEMU boards, as described in *Building an Application*.

   For example, you could set `BOARD` to:

   - `qemu_x86` to emulate running on an x86-based board
   - `qemu_cortex_m3` to emulate running on an ARM Cortex M3-based board

2. Run one of these console commands from the build directory, `<app>/build`, to run the Zephyr binary in QEMU:

   ```
   west build -t run
   ```

   or

   ```
   ninja run
   ```

3. Press `Ctrl A, X` to stop the application from running in QEMU.

   The application stops running and the terminal console prompt redisplays.

Each time you execute the run command, your application is rebuilt and run again.

Note

If the *Zephyr SDK* is installed, the `run` target will use the SDK's QEMU binary by default. To use another version of QEMU, *set the environment variable* `QEMU_BIN_PATH` to the path of the QEMU binary you want to use instead.

Note

You can choose a specific emulator by appending `_<emulator>` to your target name, for example `west build -t run_qemu` or `ninja run_qemu` for QEMU.

2.4.11 Custom Board, Devicetree and SOC Definitions

In cases where the board or platform you are developing for is not yet supported by Zephyr, you can add board, Devicetree and SOC definitions to your application without having to add them to the Zephyr tree.

The structure needed to support out-of-tree board and SOC development is similar to how boards and SOCs are maintained in the Zephyr tree. By using this structure, it will be much easier to upstream your platform related work into the Zephyr tree after your initial development is done.

Add the custom board to your application or a dedicated repository using the following structure:

```
boards/
soc/
CMakeLists.txt
prj.conf
README.rst
src/
```

where the `boards` directory hosts the board you are building for:

```
.
├── boards
│   └── vendor
│       └── my_custom_board
│           ├── doc
│           │   └── img
│           └── support
└── src
```

and the `soc` directory hosts any SOC code. You can also have boards that are supported by a SOC that is available in the Zephyr tree.

Boards

Use the vendor name as the folder name (which must match the vendor prefix in dts/bindings/vendor-prefixes.txt if submitting upstream to Zephyr, or be `others` if it is not a vendor board) under `boards` for `my_custom_board`.

Documentation (under `doc/`) and support files (under `support/`) are optional, but will be needed when submitting to Zephyr.

The contents of `my_custom_board` should follow the same guidelines for any Zephyr board, and provide the following files:

```
board.yml
my_custom_board_defconfig
my_custom_board.dts
my_custom_board.yaml
board.cmake
board.h
CMakeLists.txt
doc/
Kconfig.my_custom_board
Kconfig.defconfig
support/
```

Once the board structure is in place, you can build your application targeting this board by specifying the location of your custom board information with the `-DBOARD_ROOT` parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DBOARD_ROOT=<path to boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DBOARD_ROOT=<path to boards> .
ninja -Cbuild
```

This will use your custom board configuration and will generate the Zephyr binary into your application directory.

You can also define the `BOARD_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying `BOARD_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND BOARD_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-board-root>)`. When using `-DBOARD_ROOT=<board-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Note

When using sysbuild, then `BOARD_ROOT` must defined in a module or in the sysbuild `CMakeLists.txt` file, see *Configuring sysbuild internal state* for details.

SOC Definitions

Similar to board support, the structure is similar to how SOCs are maintained in the Zephyr tree, for example:

```
soc
└── st
    └── stm32
        ├── common
        └── stm32l0x
```

The file soc/Kconfig will create the top-level `SoC/CPU/Configuration Selection` menu in Kconfig.

Out of tree SoC definitions can be added to this menu using the `SOC_ROOT` CMake variable. This variable contains a semicolon-separated list of directories which contain SoC support files.

Following the structure above, the following files can be added to load more SoCs into the menu.

```
soc
└── st
    └── stm32
        └── stm32l0x
            ├── Kconfig
            ├── Kconfig.soc
            └── Kconfig.defconfig
```

The Kconfig files above may describe the SoC or load additional SoC Kconfig files.

An example of loading `stm32l0` specific Kconfig files in this structure:

```
soc
└── st
    └── stm32
        ├── Kconfig.soc
        └── stm32l0x
            └── Kconfig.soc
```

can be done with the following content in `st/stm32/Kconfig.soc`:

```
rsource "*/Kconfig.soc"
```

Once the SOC structure is in place, you can build your application targeting this platform by specifying the location of your custom platform information with the `-DSOC_ROOT` parameter to the CMake build system:

Using west:

```
west build -b <board name> -- -DSOC_ROOT=<path to soc> -DBOARD_ROOT=<path to␣
↪boards>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DSOC_ROOT=<path to soc> -DBOARD_ROOT=
↪<path to boards> .
ninja -Cbuild
```

This will use your custom platform configurations and will generate the Zephyr binary into your application directory.

See *Build settings* for information on setting SOC_ROOT in a module's `zephyr/module.yml` file.

Or you can define the `SOC_ROOT` variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

Note

When specifying `SOC_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND SOC_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-soc-root>`. When using `-DSOC_ROOT=<soc-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree Definitions

Devicetree directory trees are found in `APPLICATION_SOURCE_DIR`, `BOARD_DIR`, and `ZEPHYR_BASE`, but additional trees, or DTS_ROOTs, can be added by creating this directory tree:

```
include/
dts/common/
dts/arm/
dts/
dts/bindings/
```

Where 'arm' is changed to the appropriate architecture. Each directory is optional. The binding directory contains bindings and the other directories contain files that can be included from DT sources.

Once the directory structure is in place, you can use it by specifying its location through the `DTS_ROOT` CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_ROOT=<path to dts root>
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_ROOT=<path to dts root> .
ninja -Cbuild
```

You can also define the variable in the application `CMakeLists.txt` file. Make sure to do so **before** pulling in the Zephyr boilerplate with `find_package(Zephyr ...)`.

> **Note**
>
> When specifying `DTS_ROOT` in a CMakeLists.txt, then an absolute path must be provided, for example `list(APPEND DTS_ROOT ${CMAKE_CURRENT_SOURCE_DIR}/<extra-dts-root>`. When using `-DDTS_ROOT=<dts-root>` both absolute and relative paths can be used. Relative paths are treated relatively to the application directory.

Devicetree source are passed through the C preprocessor, so you can include files that can be located in a `DTS_ROOT` directory. By convention devicetree include files have a `.dtsi` extension.

You can also use the preprocessor to control the content of a devicetree file, by specifying directives through the `DTS_EXTRA_CPPFLAGS` CMake Cache variable:

Using west:

```
west build -b <board name> -- -DDTS_EXTRA_CPPFLAGS=-DTEST_ENABLE_FEATURE
```

Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=<board name> -DDTS_EXTRA_CPPFLAGS=-
↪DTEST_ENABLE_FEATURE .
ninja -Cbuild
```

2.5 Debugging

2.5.1 Application Debugging

This section is a quick hands-on reference to start debugging your application with QEMU. Most content in this section is already covered in QEMU and GNU_Debugger reference manuals.

In this quick reference, you'll find shortcuts, specific environmental variables, and parameters that can help you to quickly set up your debugging environment.

The simplest way to debug an application running in QEMU is using the GNU Debugger and setting a local GDB server in your development system through QEMU.

You will need an ELF (Executable and Linkable Format) binary image for debugging purposes. The build system generates the image in the build directory. By default, the kernel binary name is `zephyr.elf`. The name can be changed using `CONFIG_KERNEL_BIN_NAME`.

GDB server

We will use the standard 1234 TCP port to open a GDB (GNU Debugger) server instance. This port number can be changed for a port that best suits the development environment. There are multiple ways to do this. Each way starts a QEMU instance with the processor halted at startup and with a GDB server instance listening for a connection.

Running QEMU directly You can run QEMU to listen for a "gdb connection" before it starts executing any code to debug it.

```
qemu -s -S <image>
```

will setup Qemu to listen on port 1234 and wait for a GDB connection to it.

The options used above have the following meaning:

- `-S` Do not start CPU at startup; rather, you must type 'c' in the monitor.
- `-s` Shorthand for `-gdb tcp::1234`: open a GDB server on TCP port 1234.

Running QEMU via `ninja` Run the following inside the build directory of an application:

```
ninja debugserver
```

QEMU will write the console output to the path specified in **`${QEMU_PIPE}`** via CMake, typically `qemu-fifo` within the build directory. You may monitor this file during the run with **`tail -f qemu-fifo`**.

Running QEMU via `west` Run the following from your project root:

```
west build -t debugserver_qemu
```

QEMU will write the console output to the terminal from which you invoked **`west`**.

Configuring the gdbserver listening device The Kconfig option `CONFIG_QEMU_GDBSERVER_LISTEN_DEV` controls the listening device, which can be a TCP port number or a path to a character device. GDB releases 9.0 and newer also support Unix domain sockets.

If the option is unset, then the QEMU invocation will lack a `-s` or a `-gdb` parameter. You can then use the `QEMU_EXTRA_FLAGS` shell environment variable to pass in your own listen device configuration.

GDB client

Connect to the server by running **`gdb`** and giving these commands:

```
$ path/to/gdb path/to/zephyr.elf
(gdb) target remote localhost:1234
(gdb) dir ZEPHYR_BASE
```

> **Note**
>
> Substitute the correct *ZEPHYR_BASE* for your system.

You can use a local GDB configuration `.gdbinit` to initialize your GDB instance on every run. Your home directory is a typical location for `.gdbinit`, but you can configure GDB to load from other locations, including the directory from which you invoked **`gdb`**. This example file performs the same configuration as above:

```
target remote localhost:1234
dir ZEPHYR_BASE
```

Alternate interfaces GDB provides a curses-based interface that runs in the terminal. Pass the `--tui` option when invoking **`gdb`** or give the `tui enable` command within **`gdb`**.

> **Note**
>
> The GDB version on your development system might not support the `--tui` option. Please make sure you use the GDB binary from the SDK which corresponds to the toolchain that has been used to build the binary.

Finally, the command below connects to the GDB server using the DDD (Data Display Debugger), a graphical frontend for GDB. The following command loads the symbol table from the ELF binary file, in this instance, `zephyr.elf`.

```
ddd --gdb --debugger "gdb zephyr.elf"
```

Both commands execute **gdb**. The command name might change depending on the toolchain you are using and your cross-development tools.

ddd may not be installed in your development system by default. Follow your system instructions to install it. For example, use **sudo apt-get install ddd** on an Ubuntu system.

Debugging

As configured above, when you connect the GDB client, the application will be stopped at system startup. You may set breakpoints, step through code, etc. as when running the application directly within **gdb**.

> **Note**
>
> **gdb** will not print the system console output as the application runs, unlike when you run a native application in GDB directly. If you just **continue** after connecting the client, the application will run, but nothing will appear to happen. Check the console output as described above.

2.5.2 Debug with Eclipse

Overview

CMake supports generating a project description file that can be imported into the Eclipse Integrated Development Environment (IDE) and used for graphical debugging.

The GNU MCU Eclipse plug-ins provide a mechanism to debug ARM projects in Eclipse with pyOCD, Segger J-Link, and OpenOCD debugging tools.

The following tutorial demonstrates how to debug a Zephyr application in Eclipse with pyOCD in Windows. It assumes you have already installed the GCC ARM Embedded toolchain and pyOCD.

Set Up the Eclipse Development Environment

1. Download and install Eclipse IDE for C/C++ Developers.
2. In Eclipse, install the GNU MCU Eclipse plug-ins by opening the menu `Window->Eclipse Marketplace...`, searching for `GNU MCU Eclipse`, and clicking `Install` on the matching result.
3. Configure the path to the pyOCD GDB server by opening the menu `Window->Preferences`, navigating to `MCU`, and setting the `Global pyOCD Path`.

Generate and Import an Eclipse Project

1. Set up a GNU Arm Embedded toolchain as described in *GNU Arm Embedded*.

2. Navigate to a folder outside of the Zephyr tree to build your application.

```
# On Windows
cd %userprofile%
```

> **Note**
>
> If the build directory is a subdirectory of the source directory, as is usually done in Zephyr, CMake will warn:
>
> "The build directory is a subdirectory of the source directory.
>
> This is not supported well by Eclipse. It is strongly recommended to use a build directory which is a sibling of the source directory."

3. Configure your application with CMake and build it with ninja. Note the different CMake generator specified by the `-G"Eclipse CDT4 - Ninja"` argument. This will generate an Eclipse project description file, `.project`, in addition to the usual ninja build files.

   Using west:

```
west build -b frdm_k64f samples/synchronization -- -G"Eclipse CDT4 - Ninja"
```

   Using CMake and ninja:

```
cmake -Bbuild -GNinja -DBOARD=frdm_k64f -G"Eclipse CDT4 - Ninja"␣
↪samples/synchronization
ninja -Cbuild
```

4. In Eclipse, import your generated project by opening the menu `File->Import...` and selecting the option `Existing Projects into Workspace`. Browse to your application build directory in the choice, `Select root directory:`. Check the box for your project in the list of projects found and click the `Finish` button.

Create a Debugger Configuration

1. Open the menu `Run->Debug Configurations...`.
2. Select `GDB PyOCD Debugging`, click the `New` button, and configure the following options:
   - In the Main tab:
     - Project: `my_zephyr_app@build`
     - C/C++ Application: `zephyr/zephyr.elf`
   - In the Debugger tab:
     - pyOCD Setup
       - Executable path: `$pyocd_path\$pyocd_executable`
       - Uncheck "Allocate console for semihosting"
     - Board Setup
       - Bus speed: 8000000 Hz
       - Uncheck "Enable semihosting"
     - GDB Client Setup
       - Executable path example (use your `GNUARMEMB_TOOLCHAIN_PATH`): `C:\gcc-arm-none-eabi-6_2017-q2-update\bin\arm-none-eabi-gdb.exe`
   - In the SVD Path tab:

– File path: `<workspace top>\modules\hal\nxp\mcux\devices\MK64F12\MK64F12.xml`

> **Note**
>
> This is optional. It provides the SoC's memory-mapped register addresses and bit-fields to the debugger.

3. Click the Debug button to start debugging.

RTOS Awareness

Support for Zephyr RTOS awareness is implemented in pyOCD v0.11.0 and later. It is compatible with GDB PyOCD Debugging in Eclipse, but you must enable CONFIG_DEBUG_THREAD_INFO=y in your application.

2.5.3 Debugging I2C communication

There is a possibility to log all or some of the I2C transactions done by the application. This feature is enabled by the Kconfig option `CONFIG_I2C_DUMP_MESSAGES`, but it uses the `LOG_DBG` function to print the contents so the `CONFIG_I2C_LOG_LEVEL_DBG` option must also be enabled.

The sample output of the dump looks like this:

```
D: I2C msg: io_i2c_ctrl7_port0, addr=50
D:    W      len=01: 00
D:    R Sr P len=08:
D: contents:
D: 43 42 41 00 00 00 00 00 |CBA.....
```

The first line indicates the I2C controller and the target address of the transaction. In above example, the I2C controller is named `io_i2c_ctrl7_port0` and the target device address is `0x50`

> **Note**
>
> the address, length and contents values are in hexadecimal, but lack the `0x` prefix

Next lines contain messages, both sent and received. The contents of write messages is always shown, while the content of read messages is controlled by a parameter to the function `i2c_dump_msgs_rw`. This function is available for use by user, but is also called internally by `i2c_transfer` API function with read content dump enabled. Before the length parameter, the header of the message is printed using abbreviations:

- W - write message
- R - read message
- Sr - restart bit
- P - stop bit

The above example shows one write message with byte `0x00` representing the address of register to read from the I2C target. After that the log shows the length of received message and following that, the bytes read from the target `43 42 41 00 00 00 00 00`. The content dump consist of both the hex and ASCII representation.

Filtering the I2C communication dump

By default, all I2C communication is logged between all I2C controllers and I2C targets. It may litter the log with unrelated devices and make it difficult to effectively debug the communication with a device of interest.

Enable the Kconfig option `CONFIG_I2C_DUMP_MESSAGES_ALLOWLIST` to create an allowlist of I2C targets to log. The allowlist of devices is configured using the devicetree, for example:

```
/ {
    i2c {
        display0: some-display@a {
            ...
        };
        sensor3: some-sensor@b {
            ...
        };
    };

    i2c-dump-allowlist {
        compatible = "zephyr,i2c-dump-allowlist";
        devices = <&display0>, <&sensor3>;
    };
};
```

The filters nodes are identified by the compatible string with `zephyr,i2c-dump-allowlist` value. The devices are selected using the `devices` property with phandles to the devices on the I2C bus.

In the above example, the communication with device `display0` and `sensor3` will be displayed in the log.

2.6 API Status and Guidelines

2.6.1 API Overview

The table lists Zephyr's APIs and information about them, including their current *stability level*. More details about API changes between major releases are available in the zephyr_release_notes.

The version column uses semantic version, and has the following expectations:

- Major version zero (0.y.z) is for initial development. Anything MAY change at any time. The public API SHOULD NOT be considered stable.
  - If minor version is up to one (0.1.z), API is considered *experimental*.
  - If minor version is larger than one (0.y.z | y > 1), API is considered *unstable*.
- Version 1.0.0 defines the public API. The way in which the version number is incremented after this release is dependent on this public API and how it changes.
  - APIs with major versions equal or larger than one (x.y.z | x >= 1) are considered *stable*.
  - All existing stable APIs in Zephyr will be start with version 1.0.0.
- Patch version Z (x.y.Z | x > 0) MUST be incremented if only backwards compatible bug fixes are introduced. A bug fix is defined as an internal change that fixes incorrect behavior.
- Minor version Y (x.Y.z | x > 0) MUST be incremented if new, backwards compatible functionality is introduced to the public API. It MUST be incremented if any public API functionality is marked as deprecated. It MAY be incremented if substantial new functionality or improvements are introduced within the private code. It MAY include patch level changes. Patch version MUST be reset to 0 when minor version is incremented.

- Major version X (x.Y.z | x > 0) MUST be incremented if a compatibility breaking change was made to the API.

Note

Version for existing APIs are initially set based on the current state of the APIs:

- 0.1.0 denotes an *experimental* API
- 0.8.0 denote an *unstable* API,
- and finally 1.0.0 indicates a *stable* APIs.

Changes to APIs in the future will require adapting the version following the guidelines above.

API	Version	Available in Zephyr Since

2.6.2 API Lifecycle

Developers using Zephyr's APIs need to know how long they can trust that a given API will not change in future releases. At the same time, developers maintaining and extending Zephyr's APIs need to be able to introduce new APIs that aren't yet fully proven, and to potentially retire old APIs when they're no longer optimal or supported by the underlying platforms.

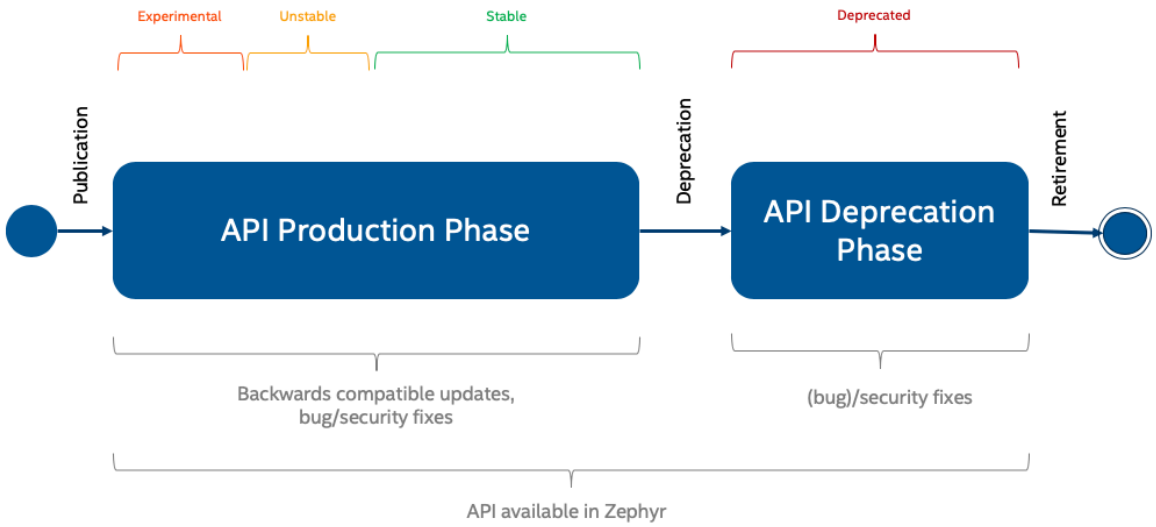

Fig. 2: API Life Cycle

An up-to-date table of all APIs and their maturity level can be found in the *API Overview* page.

Experimental

Experimental APIs denote that a feature was introduced recently, and may change or be removed in future versions. Try it out and provide feedback to the community via the Developer mailing list.

The following requirements apply to all new APIs:

- Documentation of the API (usage) explaining its design and assumptions, how it is to be used, current implementation limitations, and future potential, if appropriate.
- The API introduction should be accompanied by at least one implementation of said API (in the case of peripheral APIs, this corresponds to one driver)
- At least one sample using the new API (may only build on one single board)

When introducing a new and experimental API, mark the API version in the headers where the API is defined. An experimental API shall have a version where the minor version is up to one (0.1.z). (see *API Overview*)

Peripheral APIs (Hardware Related) When introducing an API (public header file with documentation) for a new peripheral or driver subsystem, review of the API is enforced and is driven by the Architecture working group consisting of representatives from different vendors.

The API shall be promoted to `unstable` when it has at least two implementations on different hardware platforms.

Unstable

The API is in the process of settling, but has not yet had sufficient real-world testing to be considered stable. The API is considered generic in nature and can be used on different hardware platforms.

When the API changes status to unstable API, mark the API version in the headers where the API is defined. Unstable APIs shall have a version where the minor version is larger than one (0.y.z | y > 1). (see *API Overview*)

> **Note**
>
> Changes will not be announced.

Peripheral APIs (Hardware Related) The API shall be promoted from `experimental` to `unstable` when it has at least two implementations on different hardware platforms.

Hardware Agnostic APIs For hardware agnostic APIs, multiple applications using it are required to promote an API from `experimental` to `unstable`.

Stable

The API has proven satisfactory, but cleanup in the underlying code may cause minor changes. Backwards-compatibility will be maintained if reasonable.

An API can be declared `stable` after fulfilling the following requirements:

- Test cases for the new API with 100% coverage
- Complete documentation in code. All public interfaces shall be documented and available in online documentation.
- The API has been in-use and was available in at least 2 development releases
- Stable APIs can get backward compatible updates, bug fixes and security fixes at any time.

In order to declare an API `stable`, the following steps need to be followed:

1. A Pull Request must be opened that changes the corresponding entry in the *API Overview* table
2. An email must be sent to the `devel` mailing list announcing the API upgrade request
3. The Pull Request must be submitted for discussion in the next Zephyr Architecture meeting where, barring any objections, the Pull Request will be merged

When the API changes status to stable API, mark the API version in the headers where the API is defined. Stable APIs shall have a version where the major version is one or larger (x.y.z | x >= 1). (see *API Overview*)

Introducing breaking API changes A stable API, as described above, strives to remain backwards-compatible through its life-cycle. There are however cases where fulfilling this objective prevents technical progress, or is simply unfeasible without unreasonable burden on the maintenance of the API and its implementation(s).

A breaking API change is defined as one that forces users to modify their existing code in order to maintain the current behavior of their application. The need for recompilation of applications (without changing the application itself) is not considered a breaking API change.

In order to restrict and control the introduction of a change that breaks the promise of backwards compatibility, the following steps must be followed whenever such a change is considered necessary in order to accept it in the project:

1. An *RFC issue* must be opened on GitHub with the following content:

```
Title:     RFC: Breaking API Change: <subsystem>
Contents:  - Problem Description:
             - Background information on why the change is required
           - Proposed Change (detailed):
             - Brief description of the API change
           - Detailed RFC:
             - Function call changes
             - Device Tree changes (source and bindings)
             - Kconfig option changes
           - Dependencies:
             - Impact to users of the API, including the steps required
               to adapt out-of-tree users of the API to the change
```

   Instead of a written description of the changes, the RFC issue may link to a Pull Request containing those changes in code form.

2. The RFC issue must be labeled with the GitHub `Breaking API Change` label
3. The RFC issue must be submitted for discussion in the next Zephyr Architecture meeting
4. An email must be sent to the `devel` mailing list with a subject identical to the RFC issue title and that links to the RFC issue

The RFC will then receive feedback through issue comments and will also be discussed in the Zephyr Architecture meeting, where the stakeholders and the community at large will have a chance to discuss it in detail.

Finally, and if not done as part of the first step, a Pull Request must be opened on GitHub. It is left to the person proposing the change to decide whether to introduce both the RFC and the Pull Request at the same time or to wait until the RFC has gathered consensus enough so that the implementation can proceed with confidence that it will be accepted. The Pull Request must include the following:

- A title that matches the RFC issue
- A link to the RFC issue
- The actual changes to the API
  - Changes to the API header file
  - Changes to the API implementation(s)
  - Changes to the relevant API documentation
  - Changes to Device Tree source and bindings
- The changes required to adapt in-tree users of the API to the change. Depending on the scope of this task this might require additional help from the corresponding maintainers
- An entry in the "API Changes" section of the release notes for the next upcoming release
- The labels `API`, `Breaking API Change` and `Release Notes`, as well as any others that are applicable
- The label `Architecture Review` if the RFC was not yet discussed and agreed upon in Zephyr Architecture meeting

Once the steps above have been completed, the outcome of the proposal will depend on the approval of the actual Pull Request by the maintainer of the corresponding subsystem. As with any other Pull Request, the author can request for it to be discussed and ultimately even voted on in the Zephyr TSC meeting.

If the Pull Request is merged then an email must be sent to the `devel` and `user` mailing lists informing them of the change.

The API version shall be changed to signal backward incompatible changes. This is achieved by incrementing the major version (X.y.z | X > 1). It MAY also include minor and patch level changes. Patch and minor versions MUST be reset to 0 when major version is incremented. (see *API Overview*)

Note

Breaking API changes will be listed and described in the migration guide.

Deprecated

Note

Unstable APIs can be removed without deprecation at any time. Deprecation and removal of APIs will be announced in the "API Changes" section of the release notes.

The following are the requirements for deprecating an existing API:

- Deprecation Time (stable APIs): 2 Releases The API needs to be marked as deprecated in at least two full releases. For example, if an API was first deprecated in release 4.0, it will be ready to be removed in 4.2 at the earliest. There may be special circumstances, determined by the Architecture working group, where an API is deprecated sooner.
- What is required when deprecating:
  - Mark as deprecated. This can be done by using the compiler itself (`__deprecated` for function declarations and `__DEPRECATED_MACRO` for macro definitions), or by introducing a Kconfig option (typically one that contains the `DEPRECATED` word in it) that, when enabled, reverts the APIs back to their previous form
  - Document the deprecation
  - Include the deprecation in the "API Changes" of the release notes for the next upcoming release
  - Code using the deprecated API needs to be modified to remove usage of said API
  - The change needs to be atomic and bisectable
  - Add an entry in the corresponding release GitHub issue tracking removal of deprecated APIs. In this example in the one corresponding to the 4.2 release.

During the deprecation waiting period, the API will be in the `deprecated` state. The Zephyr maintainers will track usage of deprecated APIs on `docs.zephyrproject.org` and support developers migrating their code. Zephyr will continue to provide warnings:

- API documentation will inform users that the API is deprecated.
- Attempts to use a deprecated API at build time will log a warning to the console.

Retired

In this phase, the API is removed.

The target removal date is 2 releases after deprecation is announced. The Zephyr maintainers will decide when to actually remove the API: this will depend on how many developers have successfully migrated from the deprecated API, and on how urgently the API needs to be removed.

If it's OK to remove the API, it will be removed. The maintainers will remove the corresponding documentation, and communicate the removal in the usual ways: the release notes, mailing lists, Github issues and pull-requests.

If it's not OK to remove the API, the maintainers will continue to support migration and update the roadmap with the aim to remove the API in the next release.

2.6.3 Vendor-Specific API Placement Policy

Overview

This policy defines how vendor-specific hardware functionality must be contributed, structured, and exposed within the Zephyr Project. It ensures that Zephyr's public API surface remains stable, that vendor extensions do not bypass the standard API lifecycle, and that potential cross-vendor features have a clear path to evolve into generic driver classes.

Vendor-specific APIs must not be exposed as public Zephyr interfaces unless they meet the criteria required for inclusion in Zephyr's formal API lifecycle (experimental stable deprecated). Features that are inherently tied to a single SoC or vendor must remain encapsulated within the vendor's SoC directories.

This policy provides a consistent decision model for contributors and maintainers.

Guiding Principles

- **Public Zephyr APIs must not contain vendor-specific interfaces.**

  Interfaces placed under `include/zephyr/` are expected to evolve through the standard API lifecycle. Vendor-specific interfaces that cannot satisfy this evolution must not be exposed as public Zephyr APIs.

- **Prefer generic solutions over vendor-specific ones.**

  When a hardware feature applies to multiple vendors or might in the future it should be implemented as part of an existing driver class or as a new cross-vendor driver class.

- **Vendor-specific features must be encapsulated.**

  Vendor-only mechanisms should live within the vendor's platform namespace (SoCs, boards, etc.).

- **Evolution must remain possible.**

  Placement must not prevent later promotion of a vendor-specific implementation into a portable Zephyr driver class.

Decision Process

When adding new hardware functionality or vendor-specific behavior, contributors must follow the decision tree below, in the given order:

- **Does the feature logically extend an existing driver class?**

  If yes, extend the existing class; do not create a vendor-specific API.

- **Could the feature become a cross-vendor driver class?**

  If the hardware concept is not clearly unique to a single vendor, or resembles patterns likely to appear across multiple architectures, create a new driver class.

- **Is the functionality clearly vendor-specific and unlikely to generalize?**

  In this case, place both headers and implementations under:

  ```
  soc/<vendor>/..
  ```

  This ensures true encapsulation, long-term maintainability, and clean removal when an SoC is dropped.

Vendor-specific code should be implemented in headers located under `soc/<vendor>/include` and code in `soc/<vendor>/common` or `soc/<vendor>/<series>`.

Such interfaces would be private and/or internal to the vendor to support their specific hardware and will be scrutinized in order to avoid creating feature islands specific to vendors.

Applications using these interfaces, given that they are internal and/or private to the vendor, shall expect no guarantees as to the lifecycle or backwards compatibility.

Allowed Locations Summary

1. When extending existing driver classes

- Where:

```
include/zephyr/drivers/<class>.h
drivers/<class>/
```

- Use when:

  The functionality fits or extends an existing class.

2. Vendor-specific extensions to existing driver classes

- Where:

```
include/zephyr/drivers/<class>/
drivers/<class>/
```

- Use when:

  The feature is a vendor-specific extension to an existing class, but the core concept is not unique to a single vendor and could be standardized in the future.

3. Create New Driver Class (Cross-Vendor)

- Where:

```
include/zephyr/drivers/<class>.h
drivers/<class>/
```

- Use when:

  The feature could reasonably apply to multiple vendors or evolve into a generic abstraction.

4. Vendor-Specific, SoC-Local Code (Default for Vendor-Unique Features)

- Where:

  Vendor-specific code should be implemented in headers located under `soc/<vendor>/include` and code in `soc/<vendor>/common` or `soc/<vendor>/<series>`.

- Use when:

  The feature is unique to a vendor or SoC and is not intended as a public API.

2.6.4 API Design Guidelines

Zephyr development and evolution is a group effort, and to simplify maintenance and enhancements there are some general policies that should be followed when developing a new capability or interface.

All public API must be documented using Doxygen. See *Doxygen Style Guidelines* for details.

Using Callbacks

Many APIs involve passing a callback as a parameter or as a member of a configuration structure. The following policies should be followed when specifying the signature of a callback:

- The first parameter should be a pointer to the object most closely associated with the callback. In the case of device drivers this would be `const struct device *dev`. For library functions it may be a pointer to another object that was referenced when the callback was provided.
- The next parameter(s) should be additional information specific to the callback invocation, such as a channel identifier, new status value, and/or a message pointer followed by the message length.
- The final parameter should be a `void *user_data` pointer carrying context that allows a shared callback function to locate additional material necessary to process the callback.

An exception to providing `user_data` as the last parameter may be allowed when the callback itself was provided through a structure that will be embedded in another structure. An example of such a case is `gpio_callback`, normally defined within a data structure specific to the code that also defines the callback function. In those cases further context can accessed by the callback indirectly by `CONTAINER_OF`.

Examples

- The requirements of `k_timer_expiry_t` invoked when a system timer alarm fires are satisfied by:

```
void handle_timeout(struct k_timer *timer)
{ ... }
```

  The assumption here, as with `gpio_callback`, is that the timer is embedded in a structure reachable from `CONTAINER_OF` that can provide additional context to the callback.

- The requirements of `counter_alarm_callback_t` invoked when a counter device alarm fires are satisfied by:

```
void handle_alarm(const struct device *dev,
                  uint8_t chan_id,
                  uint32_t ticks,
                  void *user_data)
{ ... }
```

  This provides more complete useful information, including which counter channel timed-out and the counter value at which the timeout occurred, as well as user context which may or may not be the `counter_alarm_cfg` used to register the callback, depending on user needs.

Conditional Data and APIs

APIs and libraries may provide features that are expensive in RAM or code size but are optional in the sense that some applications can be implemented without them. Examples of such feature include `capturing a timestamp` or `providing an alternative interface`. The developer in coordination with the community must determine whether enabling the features is to be controllable through a Kconfig option.

In the case where a feature is determined to be optional the following practices should be followed.

- Any data that is accessed only when the feature is enabled should be conditionally included via `#ifdef CONFIG_MYFEATURE` in the structure or union declaration. This reduces memory use for applications that don't need the capability.

- Function declarations that are available only when the option is enabled should be provided unconditionally. Add a note in the description that the function is available only when the specified feature is enabled, referencing the required Kconfig symbol by name. In the cases where the function is used but not enabled the definition of the function shall be excluded from compilation, so references to the unsupported API will result in a link-time error.
- Where code specific to the feature is isolated in a source file that has no other content that file should be conditionally included in `CMakeLists.txt`:

```
zephyr_sources_ifdef(CONFIG_MYFEATURE foo_funcs.c)
```

- Where code specific to the feature is part of a source file that has other content the feature-specific code should be conditionally processed using `#ifdef CONFIG_MYFEATURE`.

See *Conditional code* for details on how to ensure conditional code is visible to Doxygen and included in the public API documentation.

Return Codes

Implementations of an API, for example an API for accessing a peripheral might implement only a subset of the functions that is required for minimal operation. A distinction is needed between APIs that are not supported and those that are not implemented or optional:

- APIs that are supported but not implemented shall return `-ENOSYS`.
- Optional APIs that are not supported by the hardware should be implemented and the return code in this case shall be `-ENOTSUP`.
- When an API is implemented, but the particular combination of options requested in the call cannot be satisfied by the implementation the call shall return `-ENOTSUP`. (For example, a request for a level-triggered GPIO interrupt on hardware that supports only edge-triggered interrupts)

2.6.5 API Terminology

The following terms may be used as shorthand API tags to indicate the allowed calling context (thread, ISR, pre-kernel), the effect of a call on the current thread state, and other behavioral characteristics.

reschedule
: if executing the function reaches a reschedule point

sleep
: if executing the function can cause the invoking thread to sleep

no-wait
: if a parameter to the function can prevent the invoking thread from trying to sleep

isr-ok
: if the function can be safely called and will have its specified effect whether invoked from interrupt or thread context

pre-kernel-ok
: if the function can be safely called before the kernel has been fully initialized and will have its specified effect when invoked from that context.

async
: if the function may return before the operation it initializes is complete (i.e. function return and operation completion are asynchronous)

supervisor
: if the calling thread must have supervisor privileges to execute the function

Details on the behavioral impact of each attribute are in the following sections.

reschedule

The reschedule attribute is used on a function that can reach a *reschedule point* within its execution.

Details The significance of this attribute is that when a rescheduling function is invoked by a thread it is possible for that thread to be suspended as a consequence of a higher-priority thread being made ready. Whether the suspension actually occurs depends on the operation associated with the reschedule point and the relative priorities of the invoking thread and the head of the ready queue.

Note that in the case of timeslicing, or reschedule points executed from interrupts, any thread may be suspended in any function.

Functions that are not **reschedule** may be invoked from either thread or interrupt context.

Functions that are **reschedule** may be invoked from thread context.

Functions that are **reschedule** but not **sleep** may be invoked from interrupt context.

sleep

The sleep attribute is used on a function that can cause the invoking thread to *sleep*.

Explanation This attribute is of relevance specifically when considering applications that use only non-preemptible threads, because the kernel will not replace a running cooperative-only thread at a reschedule point unless that thread has explicitly invoked an operation that caused it to sleep.

This attribute does not imply the function will sleep unconditionally, but that the operation may require an invoking thread that would have to suspend, wait, or invoke `k_yield()` before it can complete its operation. This behavior may be mediated by **no-wait**.

Functions that are **sleep** are implicitly **reschedule**.

Functions that are **sleep** may be invoked from thread context.

Functions that are **sleep** may be invoked from interrupt and pre-kernel contexts if and only if invoked in **no-wait** mode.

no-wait

The no-wait attribute is used on a function that is also **sleep** to indicate that a parameter to the function can force an execution path that will not cause the invoking thread to sleep.

Explanation The paradigmatic case of a no-wait function is a function that takes a timeout, to which `K_NO_WAIT` can be passed. The semantics of this special timeout value are to execute the function's operation as long as it can be completed immediately, and to return an error code rather than sleep if it cannot.

It is use of the no-wait feature that allows functions like `k_sem_take()` to be invoked from ISRs, since it is not permitted to sleep in interrupt context.

A function with a no-wait path does not imply that taking that path guarantees the function is synchronous.

Functions with this attribute may be invoked from interrupt and pre-kernel contexts only when the parameter selects the no-wait path.

isr-ok

The isr-ok attribute is used on a function to indicate that it works whether it is being invoked from interrupt or thread context.

Explanation Any function that is not **sleep** is inherently **isr-ok**. Functions that are **sleep** are **isr-ok** if the implementation ensures that the documented behavior is implemented even if called from an interrupt context. This may be achieved by having the implementation detect the calling context and transfer the operation that would sleep to a thread, or by documenting that when invoked from a non-thread context the function will return a specific error (generally `-EWOULDBLOCK`).

Note that a function that is **no-wait** is safe to call from interrupt context only when the no-wait path is selected. **isr-ok** functions need not provide a no-wait path.

pre-kernel-ok

The pre-kernel-ok attribute is used on a function to indicate that it works as documented even when invoked before the kernel main thread has been started.

Explanation This attribute is similar to **isr-ok** in function, but is intended for use by any API that is expected to be called in `DEVICE_DEFINE()` or `SYS_INIT()` calls that may be invoked with `PRE_KERNEL_1` or `PRE_KERNEL_2` initialization levels.

Generally a function that is **pre-kernel-ok** checks `k_is_pre_kernel()` when determining whether it can fulfill its required behavior. In many cases it would also check `k_is_in_isr()` so it can be **isr-ok** as well.

async

A function is **async** (i.e. asynchronous) if it may return before the operation it initiates has completed. An asynchronous function will generally provide a mechanism by which operation completion is reported, e.g. a callback or event.

A function that is not asynchronous is synchronous, i.e. the operation will always be complete when the function returns. As most functions are synchronous this behavior does not have a distinct attribute to identify it.

Explanation Be aware that **async** is orthogonal to context-switching. Some APIs may provide completion information through a callback, but may suspend while waiting for the resource necessary to initiate the operation; an example is `spi_transceive_signal()`.

If a function is both **no-wait** and **async** then selecting the no-wait path only guarantees that the function will not sleep. It does not affect whether the operation will be completed before the function returns.

supervisor

The supervisor attribute is relevant only in user-mode applications, and indicates that the function cannot be invoked from user mode.

2.7 Language Support

2.7.1 C Language Support

C is a general-purpose low-level programming language that is widely used for writing code for embedded systems.

Zephyr is primarily written in C and natively supports applications written in the C language. All Zephyr API functions and macros are implemented in C and available as part of the C header files under the `include` directory, so writing Zephyr applications in C gives the developers access to the most features.

The `main()` function must have the return type of `int` as Zephyr applications run in a "hosted" environment as defined by the C standard. Applications must return zero (0) from main. All non-zero return values are reserved.

Language Standards

Zephyr does not target a specific version of the C standards; however, the Zephyr codebase makes extensive use of the features newly introduced in the 1999 release of the ISO C standard (ISO/IEC 9899:1999, hereinafter referred to as C99) such as those listed below, effectively requiring the use of a compiler toolchain that supports the C99 standard and above:

- inline functions
- standard boolean types (`bool` in `<stdbool.h>`)
- fixed-width integer types (`[u]intN_t` in `<stdint.h>`)
- designated initializers
- variadic macros
- `restrict` qualification

Additionally, some components or parts of them make use of features introduced in the C11 and C17 versions of the standard (ISO/IEC 9899:2011 and 9899:2018 respectively):

- _Generic keyword
- _Static_assert keyword

In summary, it is recommended to use a compiler toolchain that supports at least the C17 standard for developing with Zephyr. It is, however, important to note that some optional Zephyr components and external modules may make use of the C language features that have been introduced in more recent versions of the standards, in which case it will be necessary to use a more up-to-date compiler toolchain that supports such standards.

Standard Library

The C Standard Library is an integral part of any C program, and Zephyr provides the support for a number of different C libraries for the applications to choose from, depending on the compiler toolchain being used to build the application.

Common C library code Zephyr provides some C library functions that are designed to be used in conjunction with multiple C libraries. These either provide functions not available in multiple C libraries or are designed to replace functionality in the C library with code better suited for use in the Zephyr environment

Time function This provides an implementation of the standard C function, `time()`, relying on the Zephyr function, `sys_clock_gettime()`. This function can be enabled by selecting `COMMON_LIBC_TIME`.

Dynamic Memory Management The common dynamic memory management implementation can be enabled by selecting the `CONFIG_COMMON_LIBC_MALLOC` in the application configuration file.

The common C library internally uses the *kernel memory heap API* to manage the memory heap used by the standard dynamic memory management interface functions such as `malloc()` and `free()`.

The internal memory heap is normally located in the `.bss` section. When userspace is enabled, however, it is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads. The size of the internal memory heap is specified by the `CONFIG_COMMON_LIBC_MALLOC_ARENA_SIZE`.

The default heap size for applications using the common C library is zero (no heap). For other C library users, if there is an MMU present, then the default heap is 16kB. Otherwise, the heap uses all available memory.

There are also separate controls to select `calloc()` (`COMMON_LIBC_CALLOC`) and `reallocarray()` (`COMMON_LIBC_REALLOCARRAY`). Both of these are enabled by default as that doesn't impact memory usage in applications not using them.

The standard dynamic memory management interface functions implemented by the common C library are thread safe and may be simultaneously called by multiple threads. These functions are implemented in `lib/libc/common/source/stdlib/malloc.c`.

Minimal libc The most basic C library, named "minimal libc", is part of the Zephyr codebase and provides the minimal subset of the standard C library required to meet the needs of Zephyr and its subsystems, primarily in the areas of string manipulation and display.

It is very low footprint and is suitable for projects that do not rely on less frequently used portions of the ISO C standard library. It can also be used with a number of different toolchains.

The minimal libc implementation can be found in `lib/libc/minimal` in the main Zephyr tree.

Functions The minimal libc implements the minimal subset of the ISO/IEC 9899:2011 standard C library functions required to meet the needs of the Zephyr kernel, as defined by the *Coding Guidelines Rule A.4*.

Formatted Output The minimal libc does not implement its own formatted output processor; instead, it maps the C standard formatted output functions such as `printf` and `sprintf` to the `cbprintf()` function, which is Zephyr's own C99-compatible formatted output implementation.

For more details, refer to the *Formatted Output* OS service documentation.

Dynamic Memory Management The minimal libc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Error numbers Error numbers are used throughout Zephyr APIs to signal error conditions as return values from functions. They are typically returned as the negative value of the integer literals defined in this section, and are defined in the `errno.h` header file.

A subset of the error numbers defined in the POSIX errno.h specification and other de-facto standard sources have been added to the minimal libc.

A conscious effort is made in Zephyr to keep the values of the minimal libc error numbers consistent with the different implementations of the C standard libraries supported by Zephyr. The minimal libc `errno.h` is checked against that of the *Newlib* to ensure that the error numbers are kept aligned.

Below is a list of the error number definitions. For the actual numeric values please refer to errno.h.

Error numbers

Newlib Newlib is a complete C library implementation written for the embedded systems. It is a separate open source project and is not included in source code form with Zephyr. Instead, the *Zephyr SDK* includes a precompiled library for each supported architecture (`libc.a` and `libm.a`).

Note

Other 3rd-party toolchains, such as *GNU Arm Embedded*, also bundle the Newlib as a precompiled library.

Zephyr implements the "API hook" functions that are invoked by the C standard library functions in the Newlib. These hook functions are implemented in `lib/libc/newlib/libc-hooks.c` and translate the library internal system calls to the equivalent Zephyr API calls.

Types of Newlib The Newlib included in the *Zephyr SDK* comes in two versions: 'full' and 'nano' variants.

Full Newlib The Newlib full variant (`libc.a` and `libm.a`) is the most capable variant of the Newlib available in the Zephyr SDK, and supports almost all standard C library features. It is optimized for performance (prefers performance over code size) and its footprint is significantly larger than the nano variant.

This variant can be enabled by selecting the `CONFIG_NEWLIB_LIBC` and de-selecting the `CONFIG_NEWLIB_LIBC_NANO` in the application configuration file.

Nano Newlib The Newlib nano variant (`libc_nano.a` and `libm_nano.a`) is the size-optimized version of the Newlib, and supports all features that the full variant supports except the new format specifiers introduced in C99, such as the `char`, `long long` type format specifiers (i.e. `%hhX` and `%llX`).

This variant can be enabled by selecting the `CONFIG_NEWLIB_LIBC` and `CONFIG_NEWLIB_LIBC_NANO` in the application configuration file.

Note that the Newlib nano variant is not available for all architectures. The availability of the nano variant is specified by the `CONFIG_HAS_NEWLIB_LIBC_NANO`.

Formatted Output Newlib supports all standard C formatted input and output functions, including `printf`, `fprintf`, `sprintf` and `sscanf`.

The Newlib formatted input and output function implementation supports all format specifiers defined by the C standard with the following exceptions:

- Floating point format specifiers (e.g. `%f`) require `CONFIG_NEWLIB_LIBC_FLOAT_PRINTF` and `CONFIG_NEWLIB_LIBC_FLOAT_SCANF` to be enabled.
- C99 format specifiers are not supported in the Newlib nano variant (i.e. `%hhX` for `char`, `%llX` for `long long`, `%jX` for `intmax_t`, `%zX` for `size_t`, `%tX` for `ptrdiff_t`).

Dynamic Memory Management Newlib implements an internal heap allocator to manage the memory blocks used by the standard dynamic memory management interface functions (for example, `malloc()` and `free()`).

The internal heap allocator implemented by the Newlib may vary across the different types of the Newlib used. For example, the heap allocator implemented in the Full Newlib (`libc.a` and `libm.a`) of the Zephyr SDK requests larger memory chunks to the operating system and has a significantly higher minimum memory requirement compared to that of the Nano Newlib (`libc_nano.a` and `libm_nano.a`).

The only interface between the Newlib dynamic memory management functions and the Zephyr-side libc hooks is the `sbrk()` function, which is used by the Newlib to manage the size of the memory pool reserved for its internal heap allocator.

The `_sbrk()` hook function, implemented in `libc-hooks.c`, handles the memory pool size change requests from the Newlib and ensures that the Newlib internal heap allocator memory pool size

does not exceed the amount of available memory space by returning an error when the system is out of memory.

When userspace is enabled, the Newlib internal heap allocator memory pool is placed in a dedicated memory partition called `z_malloc_partition`, which can be accessed from the user mode threads.

The amount of memory space available for the Newlib heap depends on the system configurations:

- When MMU is enabled (`CONFIG_MMU` is selected), the amount of memory space reserved for the Newlib heap is set by the size of the free memory space returned by the `k_mem_free_get()` function or the `CONFIG_NEWLIB_LIBC_MAX_MAPPED_REGION_SIZE`, whichever is the smallest.
- When MPU is enabled and the MPU requires power-of-two partition size and address alignment (`CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE` is set to a non-zero value), the amount of memory space reserved for the Newlib heap is set by the `CONFIG_NEWLIB_LIBC_ALIGNED_HEAP_SIZE`.
- Otherwise, the amount of memory space reserved for the Newlib heap is equal to the amount of free (unallocated) memory in the SRAM region.

The standard dynamic memory management interface functions implemented by the Newlib are thread safe and may be simultaneously called by multiple threads.

Picolibc Picolibc is a complete C library implementation written for the embedded systems, targeting C17 (ISO/IEC 9899:2018) and POSIX 2018 (IEEE Std 1003.1-2017) standards. Picolibc is an external open source project which is provided for Zephyr as a module, and included as part of the *Zephyr SDK* in precompiled form for each supported architecture (`libc.a`).

> **Note**
>
> Picolibc is also available for other 3rd-party toolchains, such as *GNU Arm Embedded*.

Zephyr implements the "API hook" functions that are invoked by the C standard library functions in the Picolibc. These hook functions are implemented in lib/libc/picolibc/ and translate the library internal system calls to the equivalent Zephyr API calls.

Picolibc Module When built as a Zephyr module, there are several configuration knobs available to adjust the feature set in the library, balancing what the library supports versus the code size of the resulting functions. Because the standard C++ library must be compiled for the target C library, the Picolibc module cannot be used with applications which use the standard C++ library. Building the Picolibc module will increase the time it takes to compile the application.

The Picolibc module can be enabled by selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

When updating the Picolibc module to a newer version, the *toolchain-bundled Picolibc in the Zephyr SDK* must also be updated to the same version.

Toolchain Picolibc Starting with version 0.16, the Zephyr SDK includes precompiled versions of Picolibc for every target architecture, along with precompiled versions of libstdc++.

The toolchain version of Picolibc can be enabled by de-selecting `CONFIG_PICOLIBC_USE_MODULE` in the application configuration file.

For every release of Zephyr, the toolchain-bundled Picolibc and the *Picolibc module* are guaranteed to be in sync when using the *recommended version of Zephyr SDK*.

Building Without Toolchain bundled Picolibc For toolchain where there is no bundled Picolibc, it is still possible to use Picolibc by building it from source. Note that any restrictions mentioned in *Picolibc Module* still apply.

To build without toolchain bundled Picolibc, the toolchain must enable CONFIG_PICOLIBC_SUPPORTED. For example, this needs to be added to the toolchain Kconfig file:

```
config TOOLCHAIN_<name>_PICOLIBC_SUPPORTED
   def_bool y
   select PICOLIBC_SUPPORTED
```

By enabling CONFIG_PICOLIBC_SUPPORTED, the build system would automatically build Picolibc from source with its module when there is no toolchain bundled Picolibc.

Formatted Output Picolibc supports all standard C formatted input and output functions, including printf(), fprintf(), sprintf() and sscanf().

Picolibc formatted input and output function implementation supports all format specifiers defined by the C17 and POSIX 2018 standards with the following exceptions:

- Floating point format specifiers (e.g. %f) require CONFIG_PICOLIBC_IO_FLOAT.
- Long long format specifiers (e.g. %lld) require CONFIG_PICOLIBC_IO_LONG_LONG. This option is automatically enabled with CONFIG_PICOLIBC_IO_FLOAT.

Printk, cbprintf and friends When using Picolibc, Zephyr formatted output functions are implemented in terms of stdio calls. This includes:

- printk, snprintk and vsnprintk
- cbprintf and cbvprintf
- fprintfcb, vfprintfcb, printfcb, vprintfcb, snprintfcb and vsnprintfcb

When using tagged args (CONFIG_CBPRINTF_PACKAGE_SUPPORT_TAGGED_ARGUMENTS and CBPRINTF_PACKAGE_ARGS_ARE_TAGGED), calls to cbpprintf will not use Picolibc, so formatting of output using those code will differ from Picolibc results as the cbprintf functions are not completely C/POSIX compliant.

Math Functions Picolibc provides full C17/IEEE STD 754-2019 support for float, double and long double math operations, except for long double versions of the Bessel functions.

Thread Local Storage Picolibc uses Thread Local Storage (TLS) (where supported) for data which is supposed to remain local to each thread, like errno. This means that TLS support is enabled when using Picolibc. As all TLS variables are allocated out of the thread stack area, this can affect stack size requirements by a few bytes.

C Library Local Variables Picolibc uses a few internal variables for things like heap management. These are collected in a dedicated memory partition called z_libc_partition. Applications using CONFIG_USERSPACE and memory domains must ensure that this partition is included in any domain active during Picolibc calls.

Dynamic Memory Management Picolibc uses the malloc api family implementation provided by the *common C library*, which itself is built upon the *kernel memory heap API*.

Formatted Output

C defines standard formatted output functions such as `printf` and `sprintf` and these functions are implemented by the C standard libraries.

Each C standard library has its own set of requirements and configurations for selecting the formatted output modes and capabilities. Refer to each C standard library documentation for more details.

Dynamic Memory Management

C defines a standard dynamic memory management interface (for example, `malloc()` and `free()`) and these functions are implemented by the C standard libraries.

While the details of the dynamic memory management implementation varies across different C standard libraries, all supported libraries must conform to the following conventions. Every supported C standard library shall:

- manage its own memory heap either internally or by invoking the hook functions (for example, `sbrk()`) implemented in `libc-hooks.c`.
- maintain the architecture- and memory region-specific alignment requirements for the memory blocks allocated by the standard dynamic memory allocation interface (for example, `malloc()`).
- allocate memory blocks inside the `z_malloc_partition` memory partition when userspace is enabled. See *Pre-defined Memory Partitions*.

For more details regarding the C standard library-specific memory management implementation, refer to each C standard library documentation.

> **Note**
>
> Native Zephyr applications should use the *memory management API* supported by the Zephyr kernel such as `k_malloc()` in order to take advantage of the advanced features that they offer.
>
> C standard dynamic memory management interface functions such as `malloc()` should be used only by the portable applications and libraries that target multiple operating systems.

2.7.2 C++ Language Support

C++ is a general-purpose object-oriented programming language that is based on the C language.

Enabling C++ Support

Zephyr supports applications written in both C and C++. However, to use C++ in an application you must configure Zephyr to include C++ support by selecting the `CONFIG_CPP` in the application configuration file.

To enable C++ support, the compiler toolchain must also include a C++ compiler and the included compiler must be supported by the Zephyr build system. The *Zephyr SDK*, which includes the GNU C++ Compiler (part of GCC), is supported by Zephyr, and the features and their availability documented here assume the use of the Zephyr SDK.

The default C++ standard level (i.e. the language enforced by the compiler flags passed) for Zephyr apps is C++11. Other standards are available via kconfig choice, for example `CONFIG_STD_CPP98`. The oldest standard supported and tested in Zephyr is C++98.

When compiling a source file, the build system selects the C++ compiler based on the suffix (extension) of the files. Files identified with either a **cpp** or a **cxx** suffix are compiled using the C++ compiler. For example, `myCplusplusApp.cpp` is compiled using C++.

The C++ standard requires the `main()` function to have the return type of `int`. Your `main()` must be defined as `int main(void)` or `int main(int, char **)`. To use main with arguments the `CONFIG_BOOTARGS` option has to be selected. Zephyr ignores the return value from main. However, Applications must return zero (0). All non-zero return values are reserved.

Note

Do not use C++ for kernel, driver, or system initialization code.

Language Features

Zephyr currently provides only a subset of C++ functionality. The following features are *not* supported:

- Static global object destruction
- OS-specific C++ standard library classes (e.g. `std::thread`, `std::mutex`)

While not an exhaustive list, support for the following functionality is included:

- Inheritance
- Virtual functions
- Virtual tables
- Static global object constructors
- Dynamic object management with the **new** and **delete** operators
- Exceptions
- RTTI (runtime type information)
- Standard Template Library (STL)

Static global object constructors are initialized after the drivers are initialized but before the application `main()` function. Therefore, use of C++ is restricted to application code.

In order to make use of the C++ exceptions, the `CONFIG_CPP_EXCEPTIONS` must be selected in the application configuration file.

Zephyr Minimal C++ Library

Zephyr minimal C++ library (`lib/cpp/minimal`) provides a minimal subset of the C++ standard library and application binary interface (ABI) functions to enable basic C++ language support. This includes:

- `new` and `delete` operators
- virtual function stub and vtables
- static global initializers for global constructors

The scope of the minimal C++ library is strictly limited to providing the basic C++ language support, and it does not implement any Standard Template Library (STL) classes and functions. For this reason, it is only suitable for use in the applications that implement their own (non-standard) class library and do not rely on the Standard Template Library (STL) components.

Any application that makes use of the Standard Template Library (STL) components, such as `std::string` and `std::vector`, must enable the C++ standard library support.

C++ Standard Library

The C++ Standard Library is a collection of classes and functions that are part of the ISO C++ standard (`std` namespace).

Zephyr does not include any C++ standard library implementation in source code form. Instead, it allows configuring the build system to link against the pre-built C++ standard library included in the C++ compiler toolchain.

To enable C++ standard library, select an applicable toolchain-specific C++ standard library type from the `CONFIG_LIBCPP_IMPLEMENTATION` in the application configuration file.

For instance, when building with the *Zephyr SDK*, the build system can be configured to link against the GNU C++ Library (`libstdc++.a`), which is a fully featured C++ standard library that provides all features required by the ISO C++ standard including the Standard Template Library (STL), by selecting `CONFIG_GLIBCXX_LIBCPP` in the application configuration file.

The following C++ standard libraries are supported by Zephyr:

- GNU C++ Library (`CONFIG_GLIBCXX_LIBCPP`)
- ARC MetaWare C++ Library (`CONFIG_ARCMWDT_LIBCPP`)

A Zephyr subsystem that requires the features from the full C++ standard library can select, from its config, `CONFIG_REQUIRES_FULL_LIBCPP`, which automatically selects a compatible C++ standard library unless the Kconfig symbol for a specific C++ standard library is selected.

Header files and incompatibilities between C and C++

To interact with each other, C and C++ must share code through header files: data structures, macros, static functions,... While C and C++ have a large overlap, they're different languages with known incompatibilities. C is not just a C++ subset. Standard levels (e.g.: "C++11") add another level of complexity as new features are often inspired by and copied from the other language but many years later and with subtle differences. Making things more complex, compilers often offer early prototypes of features before they become standardized. Standards can have ambiguities interpreted differently by different compilers. Compilers can have bugs and these may need workarounds. To help with this, many projects restrict themselves to a limited number of toolchains. Zephyr does not.

These compatibility issues affect header files dis-proportionally. Not just because they have to be compatible between C and C++, but also because they end up being compiled in a surprisingly high number of other source files due to *indirect* inclusion and the lack of structure and headers organization that is typical in real-world projects. So, header files are exposed to a much larger variety of toolchains and project configurations. Adding more constraints, the Zephyr project has demanding policies with respect to code style, compiler warnings, static analyzers and standard compliance (e.g.: MISRA).

Put together, all these constraints can make writing header files very challenging. The purpose of this section is to document some best "header practices" and lessons learned in a Zephyr-specific context. While a lot of the information here is not Zephyr-specific, this section is not a substitute for knowledge of C/C++ standards, textbooks and other references.

Testing Fortunately, the Zephyr project has an extensive test and CI infrastructure that provides coverage baselines, catches issues early, enforces policies and maintains such combinatorial explosions under some control. The `tests/lib/cpp/cxx/` are very useful in this context because their `testcase.yaml` configuration lets `twister` iterate quickly over a range of `-std` parameters: `-std=c++98`, `-std=c++11`, etc.

Keep in mind unused macros are not compiled.

Designated initializers Initialization macros are common in header files as they help reduce boilerplate code. C99 added initialization of `struct` and `union` types by "designated" member

names instead of a list of *bare* expressions. Some GCC versions support designated initializers even in their C90 mode.

When used at a simple level, designated initializers are less error-prone, more readable and more flexible. On the other hand, C99 allowed a surprisingly large and lax set of possibilities: designated initializers can be out of order, duplicated, "nested" (`.a.x =`), various other braces can be omitted, designated initializers and not can be mixed, etc.

Twenty years later, C++20 added designated initializers to C++ but in much more restricted way; partly because a C++ `struct` is actually a `class`. As described in the C++ proposal number P0329 (which compares with C) or in any complete C++ reference, a mix is not allowed and initializers must be in order (gaps are allowed).

Interestingly, the new restrictions in C++20 can cause `gcc -std=c++20` to fail to compile code that successfully compiles with `gcc -std=c++17`. For example, `gcc -std=c++17` and older allow the C-style mix of initializers and bare expressions. This fails to compile with using `gcc -std=c++20` *with the same GCC version*.

Recommendation: to maximize compatibility across different C and C++ toolchains and standards, designated initializers in Zephyr header files should follow all C++20 rules and restrictions. Non-designated, pre-C99 initialization offers more compatibility and is also allowed but designated initialization is the more readable and preferred code style. In any case, both styles must never be mixed in the same initializer.

Warning: successful compilation is not the end of the incompatibility story. For instance, the *evaluation order* of initializer expressions is unspecified in C99! It is the (expected) left-to-right order in C++20. Other standard revisions may vary. In doubt, do not rely on evaluation order (here and elsewhere).

Anonymous unions Anonymous unions (a.k.a. "unnamed" unions) seem to have been part of C++ from its very beginning. They were not officially added to C until C11. As usual, there are differences between C and C++. For instance, C supports anonymous unions only as a member of an enclosing `struct` or `union`, empty lists `{ }` have always been allowed in C++ but they require C23, etc.

When initializing anonymous members, the expression can be enclosed in braces or not. It can be either designated or bare. For maximum portability, when initializing *anonymous unions*:

- Do *not* enclose *designated* initializers with braces. This is required by C++20 and above which perceive such braces as mixing bare expressions with (other) designated initializers and fails to compile.
- Do enclose *bare* expressions with braces. This is required by C. Maybe because C is laxer and allows many initialization possibilities and variations, so it may need such braces to disambiguate? Note C does allow omitting most braces in initializer expressions - but not in this particular case of initializing anonymous unions with bare expressions.

Some pre-C11 GCC versions support some form of anonymous unions. They unfortunately require enclosing their designated initializers with braces which conflicts with this recommendation. This can be solved with an `#ifdef __STDC_VERSION__` as demonstrated in Zephyr commit c15f029a7108 and the corresponding code review.

2.7.3 Rust Language Support

Rust is a modern systems programming language designed to provide memory safety, concurrency, and performance without sacrificing low-level control. It achieves this through a unique ownership model that eliminates common bugs like null pointer dereferencing and data races at compile time.

Rust's emphasis on safety and correctness makes it particularly well-suited for embedded systems and environments where reliability is critical. Additionally, Rust offers powerful abstrac-

tions without a runtime or garbage collector, allowing developers to write both high-level code and low-level hardware interactions with confidence and efficiency.

These attributes make Rust a strong choice for projects on Zephyr, where resource constraints and system stability are paramount.

Enabling Rust Support

In order to enable Rust support in a Zephyr application, a few things need to be done:

1. As Rust is currently an optional module, the module needs to be enabled. The easiest way to do this is with west:

   ```
   west config manifest.project-filter +zephyr-lang-rust
   west update
   ```

   This should cause the Rust language support to be placed in `modules/lang/rust` in your Zephyr workspace.

2. Enable Rust support, via `CONFIG_RUST` in the `prj.conf`. The easiest way to do this (as well as the CMake setup from the next step) is to start with one of the samples in modules/lang/rust/samples.

3. Configure the application's `CMakeLists.txt` file to support Rust. Again this is easiest to copy from a sample, but this will look something like:

   ```
   cmake_minimum_required(VERSION 3.28.0)

   find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})

   project(my_app)
   rust_cargo_application()
   ```

4. Create a `Cargo.toml` that describes how to build the Rust application. From the Hello World sample:

   ```
   [package]
   # This must be rustapp for now.
   name = "rustapp"
   version = "0.1.0"
   edition = "2021"
   description = "The description of my app"
   license = "Apache-2.0 or MIT"

   [lib]
   crate-type = ["staticlib"]

   [dependencies]
   zephyr = "0.1.0"
   log = "0.4.22"
   ```

   The only required dependency is `zephyr` which provides the zephyr crate that is used to interface with Zephyr.

5. Build as you would any other Zephyr application. Only a few targets currently support Rust (these can be seen in the modules/lang/rust/etc/platforms.txt file).

API Documentation

The API Documentation for the latest version in the module is kept on gh-pages.

This documentation is generated for a general target, with all features enabled. Once you have an application that is buildable, you can generate documentation specifically for your target:

```
west build -t rustdoc

...

Generated /
↪my/path/app/zephyr/build/doc/rust/target/riscv32i-unknown-none-elf/doc/rustapp/index.html
```

The path printed at the end can be opened in a browser. This top level docs will be for your application itself. Look for the 'zephyr' crate on the left side bar, and this will take you to the docs for Zephyr. This page will also generate local docs for any dependencies used by your application, directly or indirectly.

2.8 Optimizations

Guides on how to optimize Zephyr for performance, power and footprint.

2.8.1 Optimizing for Footprint

Stack Sizes

Stack sizes of various system threads are specified generously to allow for usage in different scenarios on as many supported platforms as possible. You should start the optimization process by reviewing all stack sizes and adjusting them for your application:

`CONFIG_ISR_STACK_SIZE`
: Set to 2048 by default

`CONFIG_MAIN_STACK_SIZE`
: Set to 1024 by default

`CONFIG_IDLE_STACK_SIZE`
: Set to 320 by default

`CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
: Set to 1024 by default

`CONFIG_PRIVILEGED_STACK_SIZE`
: Set to 1024 by default, depends on userspace feature.

Unused Peripherals

Some peripherals are enabled by default. You can disable unused peripherals in your project configuration, for example:

```
CONFIG_GPIO=n
CONFIG_SPI=n
```

Various Debug/Informational Options

The following options output more information about the running application and provide means for debugging and error handling:

`CONFIG_BOOT_BANNER`
: This option can be disabled to save a few bytes.

`CONFIG_DEBUG`
: This option can be enabled for debug builds.

Note that the boot banner is enabled by default.

MPU/MMU Support

Depending on your application and platform needs, you can disable MPU/MMU support to gain some memory and improve performance. Consider the consequences of this configuration choice though, because you'll lose advanced stack checking and support.

2.8.2 Optimization Tools

The available optimization tools let you analyse *Footprint and Memory Usage* and *Data Structures* using different build system targets. An *HTML dashboard* can also be generated for a more dynamic view of build artifacts and metrics.

Footprint and Memory Usage

The build system offers 3 targets to view and analyse RAM, ROM and stack usage in generated images. The tools run on the final image and give information about size of symbols and code being used in both RAM and ROM. Additionally, with features available through the compiler, we can also generate worst-case stack usage analysis.

Some of the tools mentioned in this section are organizing their output based on the physical organization of the symbols. As some symbols might be external to the project's tree structure, or might lack metadata needed to display them by name, the following top-level containers are used to group such symbols:

- Hidden - The RAM and ROM reports list all processing symbols with no matching mapped files in the Hidden category.

  This means that the file for the listed symbol was not added to the metadata file, was empty, or was undefined. The tool was unable to get the name of the function for the given symbol nor identify where it comes from.

- No paths - The RAM and ROM reports list all processing symbols with relative paths in the No paths category.

  This means that the listed symbols cannot be placed in the tree structure of the report at an absolute path under one specific file. The tool was able to get the name of the function, but it was unable to identify where it comes from.

  > **Note**
  >
  > You can have multiple cases of the same function, and the No paths category will list the sum of these in one entry.

Build Target: ram_report List all compiled objects and their RAM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `ram_report` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t ram_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild ram_report
```

These commands will generate something similar to the output below:

```
Path                                                                    Size    %      ␣
↪Address

    ├── drivers                                                      258   5.56%  -
    |   ├── ...                                                      ...    ...%
================================================================================
                                                                    4637
```

Build Target: rom_report List all compiled objects and their ROM usage in a tabular form with bytes per symbol and the percentage it uses. The data is grouped based on the file system location of the object in the tree and the file containing the symbol.

Use the `rom_report` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t rom_report
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild rom_report
```

These commands will generate something similar to the output below:

```
Path                                                              Size    %     ␣
↪Address

```

Build Targets: ram_plot/rom_plot Similar to the `ram_report` and `rom_report` build targets, these targets generate memory usage reports in a sunburst chart as a visual representation. A user can click on segments to navigate through the directory structures, and hover over segments to get more details.

Running the targets will first generate the CLI report and then open a browser window.

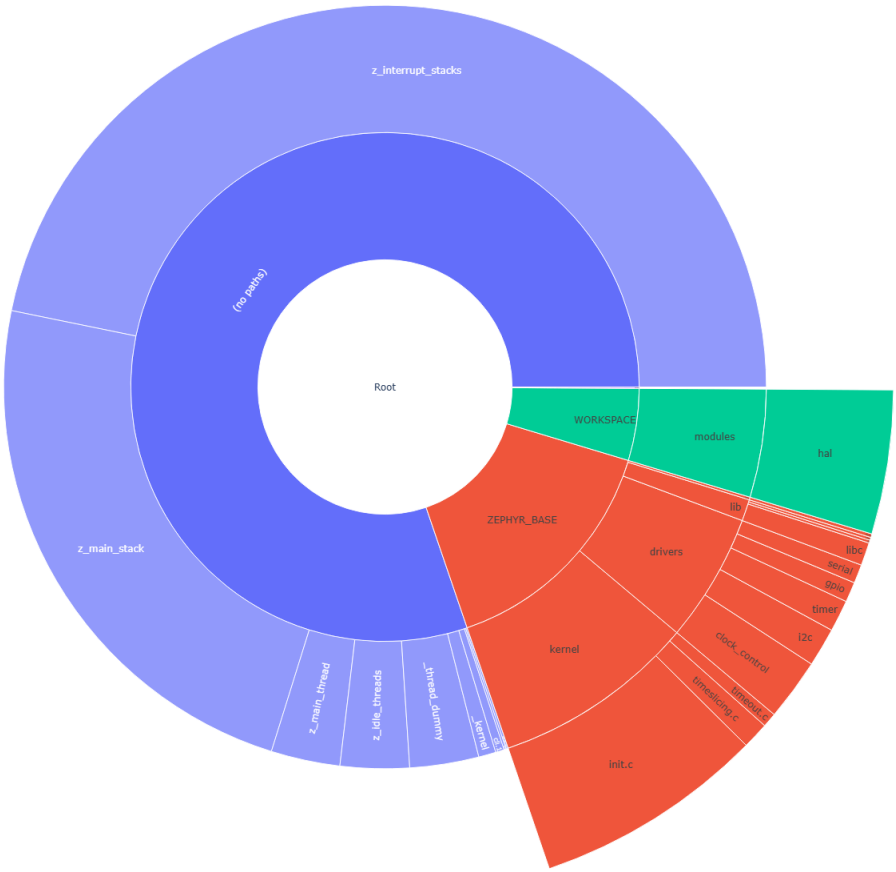
Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t ram_plot
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild ram_plot
```



And similarly for the ROM usage.

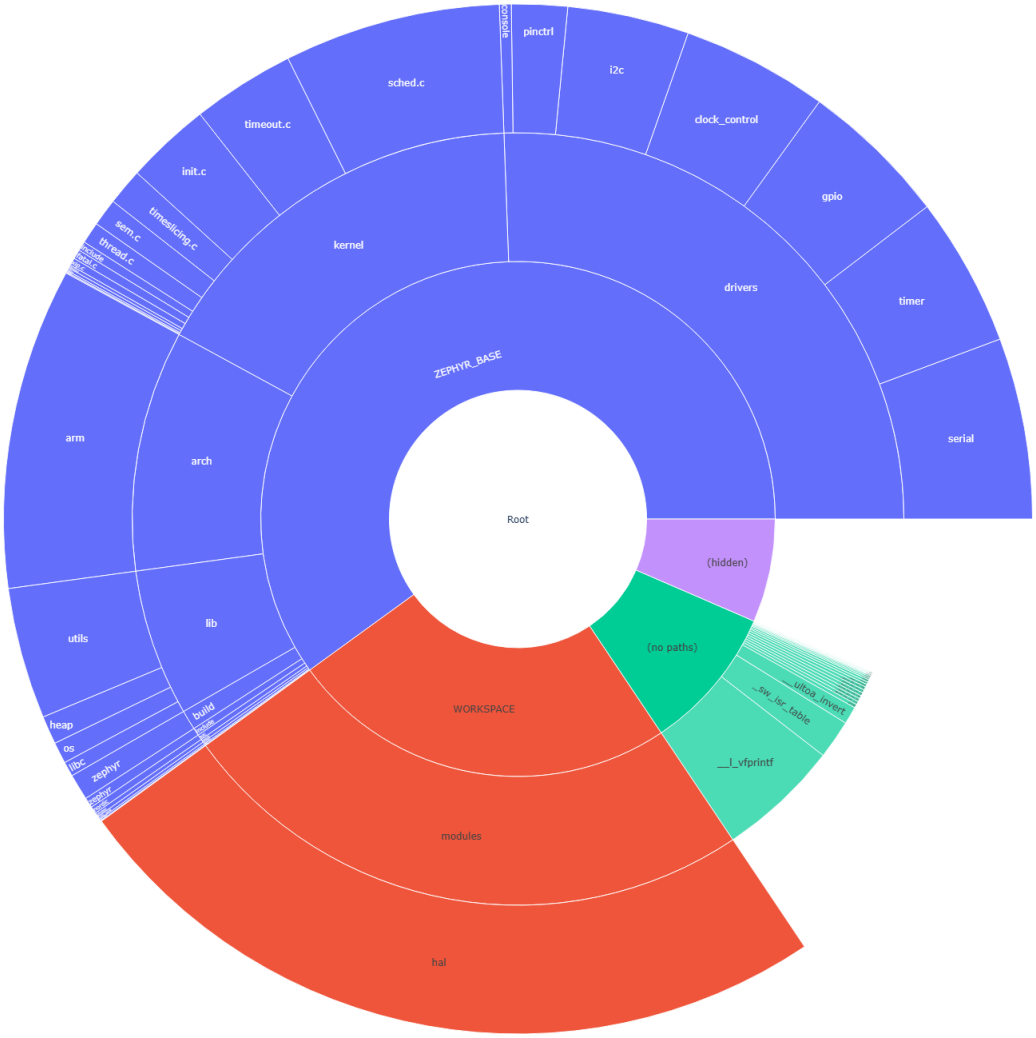
Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t rom_plot
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild rom_plot
```



Build Target: puncover This target uses a third-party tool called puncover which can be found at https://github.com/HBehrens/puncover. When this target is built, it will launch a local web server which will allow you to open a web client and browse the files and view their ROM, RAM, and stack usage.

Before you can use this target, install the puncover Python module:

```
pip3 install --user puncover
```

Warning

This is a third-party tool that might or might not be working at any given time. Please check the GitHub issues, and report new problems to the project maintainer.

After you installed the Python module, use `puncover` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t puncover
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

The puncover target will start a local web server on `localhost:5000` by default. The host IP and port the HTTP server runs on can be changed by setting the environment variables `PUNCOVER_HOST` and `PUNCOVER_PORT`. Further arguments to puncover can be provided by defining them in `EXTRA_PUNCOVER_ARGS`.

To view worst-case stack usage analysis in the interactive web app, build with the `CONFIG_STACK_USAGE` enabled.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y -
↪DCONFIG_CALLGRAPH_INFO=y
west build -t puncover
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y -
↪DCONFIG_CALLGRAPH_INFO=y samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

If you want a report in a JSON file about the worst-case stack usages found, without launching the web app you can add the option `--generate-report --non-interactive --report-type json` for non-interactive use. And add all functions you are interested in the report by adding each as an argument in the form of `--report-max-static-stack-usage FUNCTION_NAME:::MAXIMAL_STACK_SIZE` for example to export `log_process_thread_func`, `shell_thread`, `bg_thread_main` and `work_queue_main` this would look like this:

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y -
↪DCONFIG_CALLGRAPH_INFO=y -DEXTRA_PUNCOVER_ARGS="--
↪generate-report;--non-interactive;--report-type;json;--report-max-static-stack-usage;log_proces
↪$PWD/report"
west build -t puncover
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y -
↪DCONFIG_CALLGRAPH_INFO=y -DEXTRA_PUNCOVER_ARGS="--
↪generate-report;--non-interactive;--report-type;json;--report-max-static-stack-usage;log_proces
↪$PWD/report" samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

All arguments can also for better maintainability and overview be put in a yaml config:

```
elf_file: ~/zephyrproject/zephyr/samples/net/mqtt_publisher/build/zephyr/zephyr.elf
gcc-tools-base: ~/zephyr-sdk-1.0.1/gnu/arm-zephyr-eabi/bin/arm-zephyr-eabi-
src_root: ~/zephyrproject/zephyr
build_dir: ~/zephyrproject/zephyr/samples/net/mqtt_publisher/build
generate-report: true
non-interactive: true
report-type: json
report-max-static-stack-usage:
   - log_process_thread_func:::832
   - shell_thread:::4160
   - bg_thread_main:::2112
   - work_queue_main:::1088
   - mgmt_event_work_handler:::896
```

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world -- -DCONFIG_STACK_USAGE=y -
↪DCONFIG_CALLGRAPH_INFO=y -DEXTRA_PUNCOVER_ARGS="-c puncover_config.yaml"
west build -t puncover
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board -DCONFIG_STACK_USAGE=y -
↪DCONFIG_CALLGRAPH_INFO=y -DEXTRA_PUNCOVER_ARGS="-c puncover_config.yaml"␣
↪samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild puncover
```

Data Structures

Build Target: pahole Poke-a-hole (pahole) is an object-file analysis tool to find the size of the data structures, and the holes caused due to aligning the data elements to the word-size of the CPU by the compiler.

Poke-a-hole (pahole) must be installed prior to using this target. It can be obtained from https://git.kernel.org/pub/scm/devel/pahole/pahole.git and is available in the dwarves package in both fedora and ubuntu:

```
sudo apt-get install dwarves
```

Alternatively, you can get it from fedora:

```
sudo dnf install dwarves
```

After you installed the package, use `pahole` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t pahole
```

Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild pahole
```

Pahole will generate something similar to the output below in the console:

```
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <375> [...]/zephyr/include/zephyr/sys/dlist.h:37 */
union {
        struct _dnode *            head;               /*     0     4 */
        struct _dnode *            next;               /*     0     4 */
};
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <397> [...]/zephyr/include/zephyr/sys/dlist.h:36 */
struct _dnode {
        union {
                struct _dnode *    head;                 /*     0     4 */
                struct _dnode *    next;                 /*     0     4 */
        };                                               /*     0     4 */
        union {
                struct _dnode *    tail;                 /*     4     4 */
                struct _dnode *    prev;                 /*     4     4 */
        };                                               /*     4     4 */

        /* size: 8, cachelines: 1, members: 2 */
        /* last cacheline: 8 bytes */
};
/* Used at: [...]/build/zephyr/kobject_hash.c */
/* <3b7> [...]/zephyr/include/zephyr/sys/dlist.h:41 */
union {
        struct _dnode *            tail;               /*     0     4 */
        struct _dnode *            prev;               /*     0     4 */
};
...
...
```

Dashboard

An HTML dashboard can be generated that consolidates the various tool outputs and artifacts into one simple view. In addition to a basic summary of the build results, the following details are included:

- Full memory reports (ram, rom) in drill-down table form as well as *plots* (as per the `footprint`, `ram_plot`, and `rom_plot` build targets).
- Kconfig symbol values and sources (as per the `traceconfig` build target).
- Init-levels with function names, and report on any priority issues with sys-init against devicetree (as per the `initlevels` build target).
- Navigable devicetree view with property values and details from any bindings.

Use the `dashboard` target with your board, as in the following example. If you are using *Sysbuild (System build)*, see *Dedicated image build targets* instead.

Using west:

```
# From the root of the zephyr repository
west build -b reel_board samples/hello_world
west build -t dashboard
```

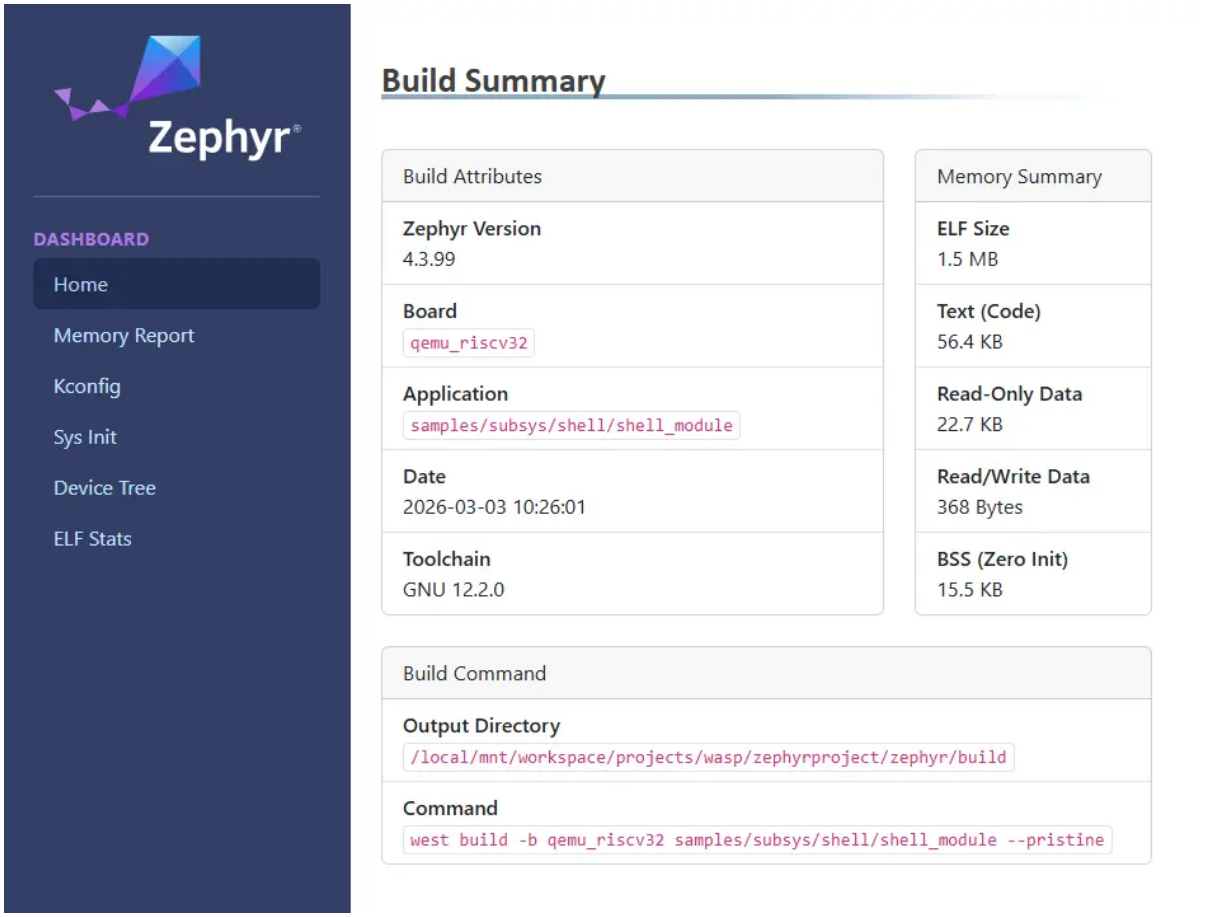
Using CMake and ninja:

```
# From the root of the zephyr repository
# Use cmake to configure a Ninja-based buildsystem:
cmake -Bbuild -GNinja -DBOARD=reel_board samples/hello_world

# Now run the build tool on the generated build system:
ninja -Cbuild dashboard
```

This will generate the following output file and open it in the default browser:

```
build/dashboard/index.html
```



2.9 Flashing and Hardware Debugging

2.9.1 Flash & Debug Host Tools

This guide describes the software tools you can run on your host workstation to flash and debug Zephyr applications.

Zephyr's west tool has built-in support for all of these in its `flash`, `debug`, `debugserver`, and `attach` commands, provided your board hardware supports them and your Zephyr board directory's `board.cmake` file declares that support properly. See *Building, Flashing and Debugging* for more information on these commands.

Black Magic Probe

Black Magic Probe (BMP) is an open-source debugging hardware incorporating GDB debug server functionality into the firmware. There is no need for a GDB server program, so there is no program equivalent to host-tool.

For more details, including usage instructions and supported targets, see *Black Magic Probe*.

SAM Boot Assistant (SAM-BA)

Atmel SAM Boot Assistant (Atmel SAM-BA) allows In-System Programming (ISP) from USB or UART host without any external programming interface. Zephyr allows users to develop and program boards with SAM-BA support using *west*. Zephyr supports devices with/without ROM bootloader and both extensions from Arduino and Adafruit. Full support was introduced in Zephyr SDK 0.12.0.

The typical command to flash the board is:

```
west flash [ -r bossac ] [ -p /dev/ttyX ] [ --erase ]
```

Note

By default, flashing with bossac will only erase the flash pages containing the flashed application, leaving other pages untouched. Should you wish to erase the entire flash of the target when flashing, pass the `--erase` parameter when flashing.

Flash configuration for devices:

With ROM bootloader

These devices don't need any special configuration. After building your application, just run `west flash` to flash the board.

Without ROM bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see *Flash map* for details.
2. Have board `.defconfig` file with the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option set to `y` to instruct the build system to use these partitions for code relocation. This option can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

With compatible SAM-BA bootloader

For these devices, the user should:

1. Define flash partitions required to accommodate the bootloader and application image; see *Flash map* for details.
2. Have board `.defconfig` file with the `CONFIG_BOOTLOADER_BOSSA` Kconfig option set to `y`. This will automatically select the `CONFIG_USE_DT_CODE_PARTITION` Kconfig option which instruct the build system to use these partitions for code relocation. The board `.defconfig` file should have `CONFIG_BOOTLOADER_BOSSA_ARDUINO` , `CONFIG_BOOTLOADER_BOSSA_ADAFRUIT_UF2` or the `CONFIG_BOOTLOADER_BOSSA_LEGACY` Kconfig option set to `y` to select the right compatible SAM-BA bootloader mode. These options can also be set in `prj.conf` or any other Kconfig fragment.
3. Build and flash the SAM-BA bootloader on the device.

Note

The CONFIG_BOOTLOADER_BOSSA_LEGACY Kconfig option should be used as last resource. Try configure first with Devices without ROM bootloader.

Typical flash layout and configuration For bootloaders that reside on flash, the devicetree partition layout is mandatory. For devices that have a ROM bootloader, they are mandatory when the application uses a storage or other non-application partition. In this special case, the boot partition should be omitted and code_partition should start from offset 0. It is necessary to define the partitions with sizes that avoid overlaps, always.

A typical flash layout for devices without a ROM bootloader is:

```
/ {
        chosen {
                zephyr,code-partition = &code_partition;
        };
};

&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                boot_partition: partition@0 {
                        label = "sam-ba";
                        reg = <0x00000000 0x2000>;
                        read-only;
                };

                code_partition: partition@2000 {
                        label = "code";
                        reg = <0x2000 0x3a000>;
                        read-only;
                };

                /*
                * The final 16 KiB is reserved for the application.
                * Storage partition will be used by FCB/LittleFS/NVS
                * if enabled.
                */
                storage_partition: partition@3c000 {
                        label = "storage";
                        reg = <0x0003c000 0x00004000>;
                };
        };
};
```

A typical flash layout for devices with a ROM bootloader and storage partition is:

```
/ {
        chosen {
                zephyr,code-partition = &code_partition;
        };
};
```

(continues on next page)

(continued from previous page)

```
&flash0 {
        partitions {
                compatible = "fixed-partitions";
                #address-cells = <1>;
                #size-cells = <1>;

                code_partition: partition@0 {
                        label = "code";
                        reg = <0x0 0xF0000>;
                        read-only;
                };

                /*
                * The final 64 KiB is reserved for the application.
                * Storage partition will be used by FCB/LittleFS/NVS
                * if enabled.
                */
                storage_partition: partition@F0000 {
                        label = "storage";
                        reg = <0x000F0000 0x00100000>;
                };
        };
};
```

Enabling SAM-BA runner In order to instruct Zephyr west tool to use the SAM-BA bootloader the `board.cmake` file must have `include(${ZEPHYR_BASE}/boards/common/bossac.board.cmake)` entry. Note that Zephyr tool accept more entries to define multiple runners. By default, the first one will be selected when using `west flash` command. The remaining options are available passing the runner option, for instance `west flash -r bossac`.

More implementation details can be found in the boards documentation. As a quick reference, see these three board documentation pages:

- sam4e_xpro (ROM bootloader)
- adafruit_feather_m0_basic_proto (Adafruit UF2 bootloader)
- arduino_nano_33_iot (Arduino bootloader)
- arduino_nano_33_ble (Arduino legacy bootloader)

Enabling BOSSAC on Windows Native [Experimental] Zephyr SDK´s bossac is currently supported on Linux and macOS only. Windows support can be achieved by using the bossac version from BOSSA official releases. After installing using default options, the `bossac.exe` must be added to Windows PATH. A specific bossac executable can be used by passing the `--bossac` option, as follows:

```
west flash -r bossac --bossac="C:\Program Files (x86)\BOSSA\bossac.exe" --
↪bossac-port="COMx"
```

Note

WSL is not currently supported.

LinkServer Debug Host Tools

Linkserver is a utility for launching and managing GDB servers for NXP debug probes, which also provides a command-line target flash programming capabilities. Linkserver can be used with the NXP MCUXpresso for Visual Studio Code implementation, with custom debug configurations based on GNU tools or as part of a headless solution for continuous integration and test. LinkServer can be used with MCU-Link, LPC-Link2, LPC11U35-based and OpenSDA based standalone or on-board debug probes from NXP.

NXP recommends installing LinkServer by using NXP's MCUXpresso Installer. This method will also install the tools supporting the debug probes below, including NXP's MCU-Link and LPC-Scrypt tools.

LinkServer is compatible with the following debug probes:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *MCU-Link CMSIS-DAP Onboard Debug Probe*
- *OpenSDA DAPLink Onboard Debug Probe*

To use LinkServer with West commands, the install folder should be added to the *PATH environment variable*. The default installation path to add is:

Linux

```
/usr/local/LinkServer
```

macOS

```
/Applications/LinkServer_<version>
```

Windows

```
c:\nxp\LinkServer_<version>
```

Supported west commands:

1. flash
2. debug
3. debugserver
4. attach

Notes:

1. Probes can be listed with LinkServer:

```
LinkServer probes
```

2. With multiple debug probes attached to the host, use the LinkServer west runner `--probe` option to pass the probe index.

```
west flash --runner=linkserver --probe=3
```

3. Device-specific settings can be overridden with the west runner for LinkServer with the option '–override'. May be used multiple times. The format is dictated by LinkServer, e.g.:

```
west flash --runner=linkserver --override /
↪device/memory/5/flash-driver=MIMXRT500_SFDP_MXIC_OSPI_S.cfx
```

4. LinkServer does not install an implicit breakpoint at the reset handler. If you would like to single step from the start of their application, you will need to add a breakpoint at `main` or the reset handler manually.
5. That breakpoint, and any other GDB command, can be installed automatically with `--gdb-init`, which this runner appends to the GDB client for `west debug` and `west attach`, e.g.:

   ```
   west debug --runner=linkserver --gdb-init 'b main'
   ```

   See *Passing Extra GDB Commands*.

J-Link Debug Host Tools

Segger provides a suite of debug host tools for Linux, macOS, and Windows operating systems:

- J-Link GDB Server: GDB remote debugging
- J-Link Commander: Command-line control and flash programming
- RTT Viewer: RTT terminal input and output
- SystemView: Real-time event visualization and recording

These debug host tools are compatible with the following debug probes:

- *LPC-Link2 J-Link Onboard Debug Probe*
- *OpenSDA J-Link Onboard Debug Probe*
- *MCU-Link JLink Onboard Debug Probe*
- *J-Link External Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in J-Link Supported Devices.

Download and install the J-Link Software and Documentation Pack to get the J-Link GDB Server and Commander, and to install the associated USB device drivers. RTT Viewer and SystemView can be downloaded separately, but are not required.

Note that the J-Link GDB server does not yet support Zephyr RTOS-awareness.

Passing Extra GDB Commands The `jlink` runner accepts `--gdb-init`, which appends a command to the GDB client started by `west debug` and `west attach`. The option can be given multiple times and the commands run in the order given, last of everything the runner sends to GDB and before the target is resumed. Since they are only appended, they cannot change the runner's own connect, load and reset sequence. `west flash`, `west reset`, `west rtt` and `west debugserver` are unaffected.

For example, to enable J-Link semihosting for the duration of a debug session:

```
west debug -r jlink --gdb-init 'monitor semihosting enable' \
  --gdb-init 'monitor semihosting basedir .'
```

The same commands can be made the default for a board by adding them to its `board.cmake`:

```
board_runner_args(jlink "--gdb-init=monitor semihosting enable")
```

Note that `--gdb-init` only reaches the GDB client. Options for the J-Link GDB server itself are passed with `--tool-opt`, and J-Link Commander commands run while flashing are passed with `--pre-script-cmd`.

The `linkserver`, `openocd` and `intel_cyclonev` runners accept the same option. Which commands it applies to, and where the commands are inserted, is up to each runner.

OpenOCD Debug Host Tools

OpenOCD is a community open source project that provides GDB remote debugging and flash programming support for a wide range of SoCs. A fork that adds Zephyr RTOS-awareness is included in the Zephyr SDK; otherwise see Getting OpenOCD for options to download OpenOCD from official repositories.

These debug host tools are compatible with the following debug probes:

- *OpenSDA DAPLink Onboard Debug Probe*
- *J-Link External Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in OpenOCD Supported Devices.

Note

On Linux, openocd is available though the Zephyr SDK. Windows users should use the following steps to install openocd:

- Download openocd for Windows from here: OpenOCD Windows
- Copy bin and share dirs to `C:\Program Files\OpenOCD\`
- Add `C:\Program Files\OpenOCD\bin` to 'PATH' environment variable

pyOCD Debug Host Tools

pyOCD is an open source project from Arm that provides GDB remote debugging and flash programming support for Arm Cortex-M SoCs. It is distributed on PyPi and installed when you complete the *Get Zephyr and install Python dependencies* step in the Getting Started Guide. pyOCD includes support for Zephyr RTOS-awareness.

These debug host tools are compatible with the following debug probes:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *MCU-Link CMSIS-DAP Onboard Debug Probe*
- *OpenSDA DAPLink Onboard Debug Probe*
- *ST-LINK/V2-1 Onboard Debug Probe*

Check if your SoC is listed in pyOCD Supported Devices.

Lauterbach TRACE32 Debug Host Tools

Lauterbach TRACE32 is a product line of microprocessor development tools, debuggers and real-time tracer with support for JTAG, SWD, NEXUS or ETM over multiple core architectures, including Arm Cortex-A/-R/-M, RISC-V, Xtensa, etc. Zephyr allows users to develop and program boards with Lauterbach TRACE32 support using *west*.

The runner consists of a wrapper around TRACE32 software, and allows a Zephyr board to execute a custom start-up script (Practice Script) for the different commands supported, including the ability to pass extra arguments from CMake. Is up to the board using this runner to define the actions performed on each command.

Install Lauterbach TRACE32 Software Download Lauterbach TRACE32 software from the Lauterbach TRACE32 download website (registration required) and follow the installation steps described in Lauterbach TRACE32 Installation Guide.

Flashing and Debugging Set the *environment variable* `T32_DIR` to the TRACE32 system directory. Then execute `west flash` or `west debug` commands to flash or debug the Zephyr application as detailed in *Building, Flashing and Debugging*. The `debug` command launches TRACE32 GUI to allow debug the Zephyr application, while the `flash` command hides the GUI and perform all operations in the background.

By default, the `t32` runner will launch TRACE32 using the default configuration file named `config.t32` located in the TRACE32 system directory. To use a different configuration file, supply the argument `--config CONFIG` to the runner, for example:

```
west flash --config myconfig.t32
```

For more options, run `west flash --context -r t32` to print the usage.

Zephyr RTOS Awareness To enable Zephyr RTOS awareness follow the steps described in Lauterbach TRACE32 Zephyr OS Awareness Manual.

NXP S32 Debug Probe Host Tools

NXP S32 Debug Probe is designed to work in conjunction with NXP S32 Design Studio for S32 Platform.

Download (registration required) NXP S32 Design Studio for S32 Platform and follow the S32 Design Studio for S32 Platform Installation User Guide to get the necessary debug host tools and associated USB device drivers.

Note that Zephyr RTOS-awareness support for the NXP S32 GDB server depends on the target device. Consult the product release notes for more information.

Supported west commands:

1. debug
2. debugserver
3. attach

Basic usage Before starting, add NXP S32 Design Studio installation directory to the system *PATH environment variable*. Alternatively, it can be passed to the runner on each invocation via `--s32ds-path` as shown below:

Linux

```
west debug --s32ds-path=/opt/NXP/S32DS.3.6
```

Windows

```
west debug --s32ds-path=C:\NXP\S32DS.3.6
```

If multiple S32 debug probes are connected to the host via USB, the runner will ask the user to select one via command line prompt before continuing. The connection string for the probe can be also specified when invoking the runner via `--dev-id=<connection-string>`. Consult NXP S32 debug probe user manual for details on how to construct the connection string. For example, if using a probe with serial ID `00:04:9f:00:ca:fe`:

```
west debug --dev-id='s32dbg:00:04:9f:00:ca:fe'
```

It is possible to pass extra options to the debug host tools via `--tool-opt`. When executing `debug` or `attach` commands, the tool options will be passed to the GDB client only. When executing `debugserver`, the tool options will be passed to the GDB server. For example, to load a Zephyr application to SRAM and afterwards detach the debug session:

```
west debug --tool-opt='--batch'
```

Requirements

- **S32 Design Studio version**: 3.6.0 or newer.
- **S32DebugProbe OS (firmware)**: 1.1.0 or newer.

S32 Debug Probe OS Upgrade Procedure Refer to the "Reprogramming S32 Debug Probe Firmware Images" chapter in the S32 Debug Probe User Guide to upgrade the OS of the S32DebugProbe.

probe-rs Debug Host Tools

probe-rs is an open-source embedded toolkit written in Rust. It provides out-of-the-box support for a variety of debug probes, including CMSIS-DAP, ST-Link, SEGGER J-Link, FTDI and built-in USB-JTAG interface on ESP32 devices.

Check probe-rs Installation for more setup details.

Check if your SoC is listed in probe-rs Supported Devices.

Renesas Flash Programmer (RFP) Host Tools

Renesas provides Renesas Flash Programmer as an official programming tool for Renesas boards using the Renesas standard boot firmware. It is available as a GUI and CLI.

For boards configured with the `rfp` west runner, the RFP CLI can be easily used to flash Zephyr.

Supported west commands:

1. flash

Once downloaded, if `rfp-cli` is not placed somewhere in your system PATH, you can pass the location to `rfp-cli` when flashing:

```
west flash --rfp-cli ~/Downloads/RFP_CLI_Linux_V31800_x64/linux-x64/rfp-cli
```

STM32CubeCLT Flash & Debug Host Tools

STMicroelectronics provides STM32CubeCLT as an official all-in-one toolset compatible with Linux®, macOS® and Windows®, allowing the use of STMicroelectronics proprietary tools within third-party development environments.

It notably provides a GDB debugging server (the *ST-LINK GDB Server*) that can be used to debug applications on STM32 boards thanks to on-board or external ST-LINK debug probes.

It is compatible with the following debug probes:

- *ST-LINK/V2-1 Onboard Debug Probe*
- Standalone ST-LINK-V2, ST-LINK-V3, and STLINK-V3PWR probes

Install STM32CubeCLT The easiest way to get the ST-LINK GDB Server is to install STM32CubeCLT from STMicroelectronics' website. A valid email address is needed to receive the downloading link.

Basic usage The ST-Link GDB Server can be used through the `west attach`, `west debug` or `west debugserver` commands to debug Zephyr applications.

```
west debug --runner stlink_gdbserver
```

Note

The STM32CubeProgrammer version contained in the STM32CubeCLT installation can also be used to flash applications. To do so, the dedicated *STM32CubeProgrammer runner* should be used instead of `stlink_gdbserver`, as done in the following example:

```
west flash --runner stm32cubeprogrammer
```

STM32CubeProgrammer Flash Host Tools

STMicroelectronics provides STM32CubeProgrammer (STM32CubeProg) as an official programming tool for STM32 boards on Linux®, macOS®, and Windows® operating systems.

It provides an easy-to-use and efficient environment for reading, writing, and verifying device memory through both the debug interface (JTAG and SWD) and the bootloader interface (UART and USB DFU, I2C, SPI, and CAN).

It offers a wide range of features to program STM32 internal memories (such as flash, RAM, and OTP) as well as external memories.

It also allows option programming and upload, programming content verification, and programming automation through scripting.

It is delivered in GUI (graphical user interface) and CLI (command-line interface) versions.

It is compatible with the following debug probes:

- *ST-LINK/V2-1 Onboard Debug Probe*
- *J-Link External Debug Probe*
- Standalone ST-LINK-V2, ST-LINK-V3, and STLINK-V3PWR probes

Install STM32CubeProgrammer The easiest way to get STM32CubeProgrammer is to download it from STMicroelectronics website. A valid email address is needed to receive the downloading link.

Alternatively, it can be installed as part of STM32CubeCLT all-in-one multi-OS command-line toolset which also includes GDB debugger client and server.

If you have STM32CubeIDE installed on your system, then STM32CubeProg is already present.

Basic usage STM32CubeProgrammer is setup as the default west runner for all active STM32 boards supported by Zephyr. It can be used through the `west flash` command to flash Zephyr applications.

```
west flash --runner stm32cubeprogrammer
```

For advanced usage via the GUI or CLI, check out the STM32CubeProgrammer User Manual.

XSDB Flash & Debug Host Tools

The AMD XSDB utility (Xilinx Software Command-line Tool for Debug) is the command-line tool used to program and debug many AMD adaptive SoC and FPGA platforms. It is **not** included in the Zephyr SDK: install AMD Vitis (or the equivalent AMD toolchain distribution for your platform) and ensure the `xsdb` executable is on your system *PATH*.

Boards that select the xsdb west runner normally ship a board-specific `support/xsdb.cfg` next to the board definition. See your board's documentation for required boot artifacts (PDI, bitstream, FSBL, etc.).

Supported west commands include `flash`, `debug`, and `debugserver`.

For this runner, `west debug` and `west debugserver` both start the same native XSDB interactive session. Unlike GDB-based runners (where `debugserver` starts a remote stub for an IDE), the xsdb runner always launches XSDB directly, loads the application through the board `xsdb.cfg`, and leaves you at the XSDB prompt.

```
west flash --runner xsdb

west debug --runner xsdb

west debugserver --runner xsdb
```

Note

This is the same class of dependency as other proprietary host tools in this chapter (for example *J-Link* or *STM32CubeCLT*): Zephyr integrates with the tool via the west runner; obtaining and licensing the toolchain is the user's responsibility.

UF2 Uploader

The uf2 runner supports flashing some boards using the UF2 (USB Flashing Format). UF2 is a user-friendly file format designed for drag-and-drop programming via a USB mass storage device.

It relies on the target device entering a special bootloader mode where it appears to the host as a USB mass storage device. Once in this mode, the application image can be uploaded by copying a `.uf2` file to the mounted volume.

```
west flash --runner uf2
```

If the UF2 volume is not automatically detected, you may need to manually specify the mount point using the `--device` option:

For more about the UF2 format and its tooling, see USB Flashing Format (UF2).

Realtek Alternate Flash Programmer (rtkprog)

`rtkprog` is an open source implementation of the protocol needed to flash Realtek Bee family SoCs via UART.

```
west flash --runner rtkprog
```

Realtek Bee Flash Programmer (MPCli) Host Tools

Realtek provides Realtek Flash Programmer (MPCli) as an official programming tool for the Bee series, supporting Linux, macOS, and Windows operating systems. MPCli enables In-System Programming (ISP) via a UART interface, eliminating the need for external programming hardware. On most official Bee-series evaluation boards, a built-in UART-to-USB converter is included for ready-to-use programming and logging.

After downloading the archive of MPCli, extract it and choose the version compatible with your operating system. Then, add the directory containing the `mpcli` executable to your system *PATH environment variable*.

Before starting, ensure your board is in download mode. Please refer to the board documentation at: Realtek Supported Boards

```
west flash [--runner mpcli] --port /dev/ttyX
```

IAR EW & C-Spy Host Tools

IAR provides Embedded Workbench and CSpyBat for debugging and flashing. The iar runner works with EWARM 10.10 or newer.

2.9.2 Debug Probes

A *debug probe* is special hardware which allows you to control execution of a Zephyr application running on a separate board. Debug probes usually allow reading and writing registers and memory, and support breakpoint debugging of the Zephyr application on your host workstation using tools like GDB. They may also support other debug software and more advanced features such as *tracing program execution*. For details on the related host software supported by Zephyr, see *Flash & Debug Host Tools*.

Debug probes are usually connected to your host workstation via USB; they are sometimes also accessible via an IP network or other means. They usually connect to the device running Zephyr using the JTAG or SWD protocols. Debug probes are either separate hardware devices or circuitry integrated into the same board which runs Zephyr.

Many supported boards in Zephyr include a second microcontroller that serves as an onboard debug probe, usb-to-serial adapter, and sometimes a drag-and-drop flash programmer. This eliminates the need to purchase an external debug probe and provides a variety of debug host tool options.

Several hardware vendors have their own branded onboard debug probe implementations: NXP boards may use *OpenSDA*, *LPC-Link2*, or *MCU-Link*, probes depending on the microcontroller the debug probe firmware runs on. ST boards have the *ST-LINK probe*. Each onboard debug probe microcontroller can support one or more types of firmware that communicate with their respective debug host tools. For example, an OpenSDA microcontroller can be programmed with DAPLink firmware to communicate with pyOCD or OpenOCD debug host tools, or with J-Link firmware to communicate with J-Link debug host tools.

Debug Probes & Host Tools Compatibility Chart		Host Tools					
		J-Link Debug	**OpenO**	**pyOCD**	**NXP S32DS**	**NXP LinkServe**	**ST-LINK GDB Server**
Debug Probes	**J-Link External**	✓	✓				
	LPC-Link2 CMSIS-DAP					✓	
	LPC-Link2 J-Link	✓					
	MCU-Link CMSIS-DAP					✓	
	MCU-Link J-Link	✓					
	NXP S32 Debug Probe				✓		
	OpenSDA DAPLink		✓	✓		✓	
	OpenSDA J-Link	✓					
	ST-LINK/V2-1	✓	✓	*some STM32 boards*			✓

Some supported boards in Zephyr do not include an onboard debug probe and therefore require an external debug probe. In addition, boards that do include an onboard debug probe often also have an SWD or JTAG header to enable the use of an external debug probe instead. One reason this may be useful is that the onboard debug probe may have limitations, such as lack of support for advanced debuggers or high-speed tracing. You may need to adjust jumpers to prevent the onboard debug probe from interfering with the external debug probe.

NXP Onboard Debug Probes

NXP boards may have one of several onboard debug probes. These probes include the *MCU-Link Onboard Debug Probe*, *LPC-LINK2 Onboard Debug Probe* and *OpenSDA Onboard Debug Probe*. Each of these probes is implemented as a secondary microcontroller present on the evaluation board. The specific debug probe type present on a given board can be determined based on the debug microcontroller SOC:

- LPC55S69: *MCU-Link Onboard Debug Probe*
- LPC4322: *LPC-LINK2 Onboard Debug Probe*
- MK20: *OpenSDA Onboard Debug Probe*

For example, the frdm_k64f board has an MK20 debug microcontroller, so this board uses the *OpenSDA Onboard Debug Probe*.

MCU-Link Onboard Debug Probe

The MCU-Link onboard debug probe uses an LPC55S69 SOC. This probe supports the following firmwares:

- *MCU-Link CMSIS-DAP Onboard Debug Probe* (default firmware)
- *MCU-Link JLink Onboard Debug Probe*

This probe is programmed using the MCU-Link host tools, which are installed with the *LinkServer Debug Host Tools*. NXP recommends using NXP's MCUXpresso Installer to install the Linkserver tools.

MCU-Link CMSIS-DAP Onboard Debug Probe This is the default firmware installed on MCU-Link debug probes. The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, NXP's MCUXpresso IDE and MCUXpresso extension for VS Code. In addition to debug probe functionality, the MCU-Link probes may also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. USB to UART, SPI and/or I2C interfaces (depending on MCU-Link type/implementation)
4. Energy measurements of the target MCU

This debug probe is compatible with the following debug host tools:

- *LinkServer Debug Host Tools*

Once the MCU-Link host tools are installed, the following steps are required to program the CMSIS-DAP firmware:

1. Make sure the MCU-Link utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper then connecting to the USB debug port on the board. This jumper may also be referred to as the ISP jumper, and will be connected to `PIO0_5` on the LPC55S69.
3. Run the `program_CMSIS` script, found in the installed MCU-Link `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

MCU-Link JLink Onboard Debug Probe This debug probe firmware provides a JLink compatible debug interface, as well as a USB-Serial adapter. It is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

These probes do not have JLink firmware installed by default, and must be updated. Once the MCU-Link host tools are installed, the following steps are required to program the JLink firmware:

1. Make sure the MCU-Link utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the MCU-Link microcontroller into DFU boot mode by attaching the DFU jumper then connecting to the USB debug port on the board. This jumper may also be referred to as the ISP jumper, and will be connected to `PIO0_5` on the LPC55S69.
3. Run the `program_JLINK` script, found in the installed MCU-Link `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

LPC-LINK2 Onboard Debug Probe

The LPC-LINK2 onboard debug probe uses an LPC4322 SOC. This probe supports the following firmwares:

- *LPC-LINK2 CMSIS DAP Onboard Debug Probe*
- *LPC-Link2 J-Link Onboard Debug Probe*
- *LPC-Link2 DAPLink Onboard Debug Probe* (default firmware)

This probe is programmed using the LPCScrypt host tools, which are installed with the *LinkServer Debug Host Tools*. NXP recommends using NXP's MCUXpresso Installer to install the Linkserver tools.

LPC-LINK2 CMSIS DAP Onboard Debug Probe The CMSIS-DAP debug probes allow debugging from any compatible toolchain, including IAR EWARM, Keil MDK, as well as NXP's MCUXpresso IDE and MCUXpresso extension for VS Code. As well as providing debug probe functionality, the LPC-Link2 probes also provide:

1. SWO trace end point: this virtual device is used by MCUXpresso to retrieve SWO trace data. See the MCUXpresso IDE documentation for more information.
2. Virtual COM (VCOM) port / UART bridge connected to the target processor
3. LPCSIO bridge that provides communication to I2C and SPI peripheral devices

This debug probe firmware is compatible with the following debug host tools:

- *LinkServer Debug Host Tools*

The probe may be updated to use CMSIS-DAP firmware with the following steps:

1. Make sure the LPCScrypt utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then connecting to the USB debug port on the board. This jumper is connected to `P2_6` on the LPC4322 SOC.
3. Run the `program_CMSIS` script, found in the installed LPCScrypt `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

Note

On some boards, the J-Link probe firmware will no longer power the board via the USB debug port. On these boards, an alternative method of powering the board must be used when this firmware is programmed.

LPC-Link2 J-Link Onboard Debug Probe This debug probe firmware provides a JLink compatible debug interface, as well as a USB-Serial adapter. It is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

The probe may be updated to use the J-Link firmware with the following steps:

Note

Verify the firmware supports your board by visiting Firmware for LPCXpresso

1. Make sure the LPCScrypt utility is present on your host machine. This can be done by installing *LinkServer Debug Host Tools*.
2. Put the LPC-Link2 microcontroller into DFU boot mode by attaching the DFU jumper, then connecting to the USB debug port on the board. This jumper is connected to `P2_6` on the LPC4322 SOC.
3. Run the `program_JLINK` script, found in the installed LPCScrypt `scripts` folder.
4. Remove the DFU jumper and power cycle the board.

LPC-Link2 DAPLink Onboard Debug Probe The LPC-Link2 DAPLink firmware is the default firmware shipped on LPC-Link2 based boards, but is not the recommended firmware. Users should update to the *LPC-LINK2 CMSIS DAP Onboard Debug Probe* firmware following the instructions provided above. For details on programming the DAPLink firmware, see NXP AN13206.

OpenSDA Onboard Debug Probe

The OpenSDA onboard debug probe is based on the NXP MK20 SOC. It features drag and drop programming supports, and supports the following debug firmwares:

- *OpenSDA DAPLink Onboard Debug Probe* (default firmware)
- *OpenSDA J-Link Onboard Debug Probe*

OpenSDA DAPLink Onboard Debug Probe This debug probe firmware is compatible with the following debug host tools:

- *pyOCD Debug Host Tools*
- *OpenOCD Debug Host Tools*
- *LinkServer Debug Host Tools*

This probe is realized by programming the OpenSDA microcontroller with DAPLink OpenSDA firmware. NXP provides OpenSDA DAPLink Board-Specific Firmwares.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you power on the board. Note that "bootloader mode" in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.
2. After you power on the board, release the reset button. A USB mass storage device called **BOOTLOADER** or **MAINTENANCE** will enumerate. If the enumerated device is named **BOOTLOADER**, please first update the bootloader to the latest revision by following the instructions for a DAPLink Bootloader Update.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see three USB devices enumerate: a CDC device (serial port), a HID device (debug port), and a mass storage device (drag-and-drop flash programming).

OpenSDA J-Link Onboard Debug Probe This debug probe is compatible with the following debug host tools:

- *J-Link Debug Host Tools*

This probe is realized by programming the OpenSDA microcontroller with J-Link OpenSDA firmware. Segger provides OpenSDA J-Link Generic Firmwares and OpenSDA J-Link Board-Specific Firmwares, where the latter is generally recommended when available. Board-specific firmwares are required for i.MX RT boards to support their external flash memories, whereas generic firmwares are compatible with all Kinetis boards.

Install the debug host tools before you program the firmware.

As with all OpenSDA debug probes, the steps for programming the firmware are:

1. Put the OpenSDA microcontroller into bootloader mode by holding the reset button while you plug a USB into the board's USB debug port. Note that "bootloader mode" in this context applies to the OpenSDA microcontroller itself, not the target microcontroller of your Zephyr application.

2. After you power on the board, release the reset button. A USB mass storage device called **BOOTLOADER** or **MAINTENANCE** will enumerate. If the enumerated device is named **BOOTLOADER**, please first update the bootloader to the latest revision by following the instructions for a DAPLink Bootloader Update.
3. Copy the OpenSDA firmware binary to the USB mass storage device.
4. Power cycle the board, this time without holding the reset button. You should see two USB devices enumerate: a CDC device (serial port) and a vendor-specific device (debug port).

J-Link External Debug Probe

Segger J-Link is a family of external debug probes, including J-Link EDU, J-Link PLUS, J-Link ULTRA+, and J-Link PRO, that support a large number of devices from different hardware architectures and vendors.

This debug probe is compatible with the following debug host tools:

- *J-Link Debug Host Tools*
- *OpenOCD Debug Host Tools*

Install the debug host tools before you program the firmware.

ST-LINK/V2-1 Onboard Debug Probe

ST-LINK/V2-1 is a serial and debug adapter built into all Nucleo and Discovery boards. It provides a bridge between your computer (or other USB host) and the embedded target processor, which can be used for debugging, flash programming, and serial communication, all over a simple USB cable.

It is compatible with the following host debug tools:

- *OpenOCD Debug Host Tools*
- *J-Link Debug Host Tools*
- *STM32CubeCLT Flash & Debug Host Tools*

For some STM32 based boards, it is also compatible with:

- *pyOCD Debug Host Tools*

While it works out of the box with OpenOCD, it requires some flashing to work with J-Link. To do this, SEGGER offers a firmware upgrading the ST-LINK/V2-1 on board on the Nucleo and Discovery boards. This firmware makes the ST-LINK/V2-1 compatible with J-LinkOB, allowing users to take advantage of most J-Link features like the ultra fast flash download and debugging speed or the free-to-use GDBServer.

More information about upgrading ST-LINK/V2-1 to JLink or restore ST-Link/V2-1 firmware please visit: Segger over ST-Link

Flash and debug with ST-Link Using OpenOCD

OpenOCD is available by default on ST-Link and configured as the default flash and debug tool. Flash and debug can be done as follows:

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west flash
```

```
# From the root of the zephyr repository
west build -b None samples/hello_world
west debug
```

Using Segger J-Link

Once STLink is flashed with SEGGER FW and J-Link GDB server is installed on your host computer, you can flash and debug as follows:

Use CMake with `-DBOARD_FLASH_RUNNER=jlink` to change the default OpenOCD runner to J-Link. Alternatively, you might add the following line to your application `CMakeList.txt` file.

```
set(BOARD_FLASH_RUNNER jlink)
```

If you use West (Zephyr's meta-tool) you can modify the default runner using the `--runner` (or `-r`) option.

```
west flash --runner jlink
```

To attach a debugger to your board and open up a debug console with `jlink`.

```
west debug --runner jlink
```

For more information about West and available options, see *West (Zephyr's meta-tool)*.

If you configured your Zephyr application to use Segger RTT console instead, open telnet:

```
$ telnet localhost 19021
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
SEGGER J-Link V6.30f - Real time terminal output
J-Link STLink V21 compiled Jun 26 2017 10:35:16 V1.0, SN=773895351
Process: JLinkGDBServerCLExe
Zephyr Shell, Zephyr version: 1.12.99
Type 'help' for a list of available commands
shell>
```

If you get no RTT output you might need to disable other consoles which conflict with the RTT one if they are enabled by default in the particular sample or application you are running, such as disable UART_CONSOLE in menuconfig

Updating or restoring ST-Link firmware ST-Link firmware can be updated using STM32CubeProgrammer Tool. It is usually useful when facing flashing issues, for instance when using twister's device-testing option.

Once installed, you can update attached board ST-Link firmware with the following command

```
s java -jar ~/
↪STMicroelectronics/STM32Cube/STM32CubeProgrammer/Drivers/FirmwareUpgrade/STLinkUpgrade.jar
↪-sn <board_uid>
```

Where board_uid can be obtained using twister's generate-hardware-map option. For more information about twister and available options, see *Test Runner (Twister)*.

OpenOCD Deprecates HLA ST-Link Interface OpenOCD has deprecated the legacy HLA interface used by ST-Link firmware in favor to the generic DAP interface in January 2024 (see OpenOCD deprecates ST-Link HLA Interface) in favor of the generic DAP interface. DAP interface is supported by ST-Link firmware since 2015 (from version v2j24).

Since OpenOCD deprecation, one using a recent OpenOCD tool (after release tag v0.12.0) may experience communication issues when the ST-Link adapter embeds a firmware prior version v2j24. In such case, it is recommended to update the ST-Link firmware (refer to *ST-LINK firmware*

update). If it is not possible to update the firmware, one may still use the old HLA interface by modifying its OpenOCD configuration script replacing (if applicable) the 2 below lines:

```
source [find interface/stlink-dap.cfg]
transport select dapdirect_swd
```

with the 2 following lines:

```
source [find interface/stlink-hla.cfg]
transport select hla_swd
```

NXP S32 Debug Probe

NXP S32 Debug Probe enables NXP S32 target system debugging via a standard debug port while connected to a developer's workstation via USB or remotely via Ethernet.

NXP S32 Debug Probe is designed to work in conjunction with NXP S32 Design Studio (S32DS) and NXP Automotive microcontrollers and processors. Install the debug host tools as in indicated in *NXP S32 Debug Probe Host Tools* before you program the firmware.

Black Magic Probe

The Black Magic Probe is an open-source hardware for debugging that is designed to be used with Black Magic Debug firmware. The firmware incorporates GDB Server so that you can connect directly from gdb to the target device.

Some of the STM32F103-based boards can run the Black Magic Debug firmware. See Black Magic Debug supported hardware.

2.10 Modules (External projects)

Zephyr relies on the source code of several externally maintained projects in order to avoid reinventing the wheel and to reuse as much well-established, mature code as possible when it makes sense. In the context of Zephyr's build system those are called *modules*. These modules must be integrated with the Zephyr build system, as described in more detail in other sections on this page.

To be classified as a candidate for being included in the default list of modules, an external project is required to have its own life-cycle outside the Zephyr Project, that is, reside in its own repository, and have its own contribution and maintenance workflow and release process. Zephyr modules should not contain code that is written exclusively for Zephyr. Instead, such code should be contributed to the main zephyr tree.

Modules to be included in the default manifest of the Zephyr project need to provide functionality or features endorsed and approved by the project Technical Steering Committee and should comply with the *module licensing requirements* and *contribution guidelines*. They should also have a Zephyr developer that is committed to maintain the module codebase.

Zephyr depends on several categories of modules, including but not limited to:

- Debugger integration
- Silicon vendor Hardware Abstraction Layers (HALs)
- Cryptography libraries
- File Systems
- Inter-Process Communication (IPC) libraries

Additionally, in some cases modules (particularly vendor HALs) can contain references to optional *binary blobs*.

This page summarizes a list of policies and best practices which aim at better organizing the workflow in Zephyr modules.

2.10.1 Modules vs west projects

Zephyr modules, described in this page, are not the same as *west projects*. In fact, modules *do not require west* at all. However, when using modules *with west*, then the build system uses west in order to find modules.

In summary:

Modules are repositories that contain a `zephyr/module.yml` file, so that the Zephyr build system can pull in the source code from the repository. *West projects* are entries in the `projects:` section in the `west.yml` manifest file. West projects are often also modules, but not always. There are west projects that are not included in the final firmware image (eg. tools) and thus do not need to be modules. Modules are found by the Zephyr build system either via *west itself*, or via the *ZEPHYR_MODULES CMake variable*.

The contents of this page only apply to modules, and not to west projects in general (unless they are a module themselves).

2.10.2 Module Repositories

- All modules included in the default manifest shall be hosted in repositories under the zephyrproject-rtos GitHub organization.
- The module repository codebase shall include a *module.yml* file in a `zephyr/` folder at the root of the repository.
- Module repository names should follow the convention of using lowercase letters and dashes instead of underscores. This rule will apply to all new module repositories, except for repositories that are directly tracking external projects (hosted in Git repositories); such modules may be named as their external project counterparts.

> **Note**
>
> Existing module repositories that do not conform to the above convention do not need to be renamed to comply with the above convention.

- Module repositories names should be explicitly set in the `zephyr/module.yml` file.
- Modules should use “zephyr” as the default name for the repository main branch. Branches for specific purposes, for example, a module branch for an LTS Zephyr version, shall have names starting with the ‘zephyr_’ prefix.
- If the module has an external (upstream) project repository, the module repository should preserve the upstream repository folder structure.

> **Note**
>
> It is not required in module repositories to maintain a ‘master’ branch mirroring the master branch of the external repository. It is not recommended as this may generate confusion around the module’s main branch, which should be ‘zephyr’.

- Modules should expose all provided header files with an include pathname beginning with the module-name. (E.g., mcuboot should expose its `bootutil/bootutil.h` as “mcuboot/bootutil/bootutil.h”.)

Synchronizing with upstream

It is preferred to synchronize a module repository with the latest stable release of the corresponding external project. It is permitted, however, to update a Zephyr module repository with the latest development branch tip, if this is required to get important updates in the module codebase. When synchronizing a module with upstream it is mandatory to document the rationale for performing the particular update.

Requirements for allowed practices Changes to the main branch of a module repository, including synchronization with upstream code base, may only be applied via pull requests. These pull requests shall be *verifiable* by Zephyr CI and *mergeable* (e.g. with the *Rebase and merge*, or *Create a merge commit* option using Github UI). This ensures that the incoming changes are always **reviewable**, and the *downstream* module repository history is incremental (that is, existing commits, tags, etc. are always preserved). This policy also allows to run Zephyr CI, git lint, identity, and license checks directly on the set of changes that are to be brought into the module repository.

> **Note**
>
> Force-pushing to a module's main branch is not allowed.

Allowed practices The following practices conform to the above requirements and should be followed in all modules repositories. It is up to the module code owner to select the preferred synchronization practice, however, it is required that the selected practice is consistently followed in the respective module repository.

Updating modules with a diff from upstream: Upstream changes brought as a single *snapshot* commit (manual diff) in a pull request against the module's main branch, which may be merged using the *Rebase & merge* operation. This approach is simple and should be applicable to all modules with the downside of suppressing the upstream history in the module repository.

> **Note**
>
> The above practice is the only allowed practice in modules where the external project is not hosted in an upstream Git repository.

The commit message is expected to identify the upstream project URL, the version to which the module is updated (upstream version, tag, commit SHA, if applicable, etc.), and the reason for the doing the update.

Updating modules by merging the upstream branch: Upstream changes brought in by performing a Git merge of the intended upstream branch (e.g. main branch, latest release branch, etc.) submitting the result in pull request against the module main branch, and merging the pull request using the *Create a merge commit* operation. This approach is applicable to modules with an upstream project Git repository. The main advantages of this approach is that the upstream repository history (that is, the original commit SHAs) is preserved in the module repository. The downside of this approach is that two additional merge commits are generated in the downstream main branch.

2.10.3 Contributing to Zephyr modules

Individual Roles & Responsibilities

To facilitate management of Zephyr module repositories, the following individual roles are defined.

Administrator: Each Zephyr module shall have an administrator who is responsible for managing access to the module repository, for example, for adding individuals as Collaborators in the repository at the request of the module owner. Module administrators are members of the Administrators team, that is a group of project members with admin rights to module GitHub repositories.

Module owner: Each module shall have a module code owner. Module owners will have the overall responsibility of the contents of a Zephyr module repository. In particular, a module owner will:

- coordinate code reviewing in the module repository
- be the default assignee in pull-requests against the repository's main branch
- request additional collaborators to be added to the repository, as they see fit
- regularly synchronize the module repository with its upstream counterpart following the policies described in *Synchronizing with upstream*
- be aware of security vulnerability issues in the external project and update the module repository to include security fixes, as soon as the fixes are available in the upstream code base
- list any known security vulnerability issues, present in the module codebase, in Zephyr release notes.

> **Note**
>
> Module owners are not required to be Zephyr *Maintainers*.

Merger: The Zephyr Release Engineering team has the right and the responsibility to merge approved pull requests in the main branch of a module repository.

Maintaining the module codebase

Updates in the zephyr main tree, for example, in public Zephyr APIs, may require patching a module's codebase. The responsibility for keeping the module codebase up to date is shared between the **contributor** of such updates in Zephyr and the module **owner**. In particular:

- the contributor of the original changes in Zephyr is required to submit the corresponding changes that are required in module repositories, to ensure that Zephyr CI on the pull request with the original changes, as well as the module integration testing are successful.
- the module owner has the overall responsibility for synchronizing and testing the module codebase with the zephyr main tree. This includes occasional advanced testing of the module's codebase in addition to the testing performed by Zephyr's CI. The module owner is required to fix issues in the module's codebase that have not been caught by Zephyr pull request CI runs.

Contributing changes to modules

Submitting and merging changes directly to a module's codebase, that is, before they have been merged in the corresponding external project repository, should be limited to:

- changes required due to updates in the zephyr main tree
- urgent changes that should not wait to be merged in the external project first, such as fixes to security vulnerabilities.

Non-trivial changes to a module's codebase, including changes in the module design or functionality should be discouraged, if the module has an upstream project repository. In that case, such changes shall be submitted to the upstream project, directly.

Submitting changes to modules describes in detail the process of contributing changes to module repositories.

Contribution guidelines Contributing to Zephyr modules shall follow the generic project *Contribution guidelines*.

Pull Requests: may be merged with minimum of 2 approvals, including an approval by the PR assignee. In addition to this, pull requests in module repositories may only be merged if the introduced changes are verified with Zephyr CI tools, as described in more detail in other sections on this page.

The merging of pull requests in the main branch of a module repository must be coupled with the corresponding manifest file update in the zephyr main tree.

Issue Reporting: GitHub issues are intentionally disabled in module repositories, in favor of a centralized policy for issue reporting. Tickets concerning, for example, bugs or enhancements in modules shall be opened in the main zephyr repository. Issues should be appropriately labeled using GitHub labels corresponding to each module, where applicable.

> **Note**
>
> It is allowed to file bug reports for zephyr modules to track the corresponding upstream project bugs in Zephyr. These bug reports shall not affect the *Release Quality Criteria*.

2.10.4 Licensing requirements and policies

All source files in a module's codebase shall include a license header, unless the module repository has **main license file** that covers source files that do not include license headers.

Main license files shall be added in the module's codebase by Zephyr developers, only if they exist as part of the external project, and they contain a permissive OSI-compliant license. Main license files should preferably contain the full license text instead of including an SPDX license identifier. If multiple main license files are present it shall be made clear which license applies to each source file in a module's codebase.

Individual license headers in module source files supersede the main license.

Any new content to be added in a module repository will require to have license coverage.

> **Note**
>
> Zephyr recommends conveying module licensing via individual license headers and main license files. This not a hard requirement; should an external project have its own practice of conveying how licensing applies in the module's codebase (for example, by having a single or multiple main license files), this practice may be accepted by and be referred to in the Zephyr module, as long as licensing requirements, for example OSI compliance, are satisfied.

License policies

When creating a module repository a developer shall:

- import the main license files, if they exist in the external project, and
- document (for example in the module README or .yml file) the default license that covers the module's codebase.

License checks License checks (via CI tools) shall be enabled on every pull request that adds new content in module repositories.

2.10.5 Documentation requirements

All Zephyr module repositories shall include an .rst file documenting:

- the scope and the purpose of the module
- how the module integrates with Zephyr
- the owner of the module repository
- synchronization information with the external project (commit, SHA, version etc.)
- licensing information as described in *Licensing requirements and policies*.

The file shall be required for the inclusion of the module and the contained information should be kept up to date.

2.10.6 Testing requirements

All Zephyr modules should provide some level of **integration** testing, ensuring that the integration with Zephyr works correctly. Integration tests:

- may be in the form of a minimal set of samples and tests that reside in the zephyr main tree
- should verify basic usage of the module (configuration, functional APIs, etc.) that is integrated with Zephyr.
- shall be built and executed (for example in QEMU) as part of twister runs in pull requests that introduce changes in module repositories.

> **Note**
>
> New modules, that are candidates for being included in the Zephyr default manifest, shall provide some level of integration testing.

> **Note**
>
> Vendor HALs are implicitly tested via Zephyr tests built or executed on target platforms, so they do not need to provide integration tests.

The purpose of integration testing is not to provide functional verification of the module; this should be part of the testing framework of the external project.

Certain external projects provide test suites that reside in the upstream testing infrastructure but are written explicitly for Zephyr. These tests may (but are not required to) be part of the Zephyr test framework.

2.10.7 Deprecating and removing modules

Modules may be deprecated for reasons including, but not limited to:

- Lack of maintainership in the module
- Licensing changes in the external project
- Codebase becoming obsolete

The module information shall indicate whether a module is deprecated and the build system shall issue a warning when trying to build Zephyr using a deprecated module.

Deprecated modules may be removed from the Zephyr default manifest after 2 Zephyr releases.

> **Note**
>
> Repositories of removed modules shall remain accessible via their original URL, as they are required by older Zephyr versions.

2.10.8 Integrate modules in Zephyr build system

The build system variable **ZEPHYR_MODULES** is a CMake list of absolute paths to the directories containing Zephyr modules. These modules contain `CMakeLists.txt` and `Kconfig` files describing how to build and configure them, respectively. Module `CMakeLists.txt` files are added to the build using CMake's add_subdirectory() command, and the `Kconfig` files are included in the build's Kconfig menu tree.

If you have *west* installed, you don't need to worry about how this variable is defined unless you are adding a new module. The build system knows how to use west to set **ZEPHYR_MODULES**. You can add additional modules to this list by setting the **EXTRA_ZEPHYR_MODULES** CMake variable or by adding a **EXTRA_ZEPHYR_MODULES** line to `.zephyrrc` (See the section on *Environment Variables* for more details). This can be useful if you want to keep the list of modules found with west and also add your own. If **EXTRA_ZEPHYR_MODULES** is set in multiple places, for example both as an environment variable and as a CMake variable, the final list of additional modules will be the merged result of all sources.

> **Note**
>
> If the module `FOO` is provided by *west* but also given with `-DEXTRA_ZEPHYR_MODULES=/<path>/foo` then the module given by the command line variable **EXTRA_ZEPHYR_MODULES** will take precedence. This allows you to use a custom version of `FOO` when building and still use other Zephyr modules provided by *west*. This can for example be useful for special test purposes.

If you want to permanently add modules to the zephyr workspace and you are using zephyr as your manifest repository, you can also add a west manifest file into the submanifests directory. See submanifests/README.txt for more details.

See *Basics* for more on west workspaces.

Finally, you can also specify the list of modules yourself in various ways, or not use modules at all if your application doesn't need them.

2.10.9 Module yaml file description

A module can be described using a file named `zephyr/module.yml`. The format of `zephyr/module.yml` is described in the following:

Module name

Each Zephyr module is given a name by which it can be referred to in the build system.

The name should be specified in the `zephyr/module.yml` file. This will ensure the module name is not changeable through user-defined directory names or `west` manifest files:

```
name: <name>
```

In CMake the location of the Zephyr module can then be referred to using the CMake variable ZEPHYR_<MODULE_NAME>_MODULE_DIR and the variable ZEPHYR_<MODULE_NAME>_CMAKE_DIR holds the location of the directory containing the module's CMakeLists.txt file.

Note

When used for CMake and Kconfig variables, all letters in module names are converted to uppercase and all non-alphanumeric characters are converted to underscores (_). As example, the module foo-bar must be referred to as ZEPHYR_FOO_BAR_MODULE_DIR in CMake and Kconfig.

Here is an example for the Zephyr module foo:

```
name: foo
```

Note

If the name field is not specified then the Zephyr module name will be set to the name of the module folder. As example, the Zephyr module located in <workspace>/modules/bar will use bar as its module name if nothing is specified in zephyr/module.yml.

Module integration files (in-module)

Inclusion of build files, CMakeLists.txt and Kconfig, can be described as:

```
build:
  cmake: <cmake-directory>
  kconfig: <directory>/Kconfig
```

The cmake: <cmake-directory> part specifies that <cmake-directory> contains the CMakeLists.txt to use. The kconfig: <directory>/Kconfig part specifies the Kconfig file to use. Neither is required: cmake defaults to zephyr, and kconfig defaults to zephyr/Kconfig.

Here is an example module.yml file referring to CMakeLists.txt and Kconfig files in the root directory of the module:

```
build:
  cmake: .
  kconfig: Kconfig
```

Sysbuild integration

Sysbuild is the Zephyr build system that allows for building multiple images as part of a single application, the sysbuild build process can be extended externally with modules as needed, for example to add custom build steps or add additional targets to a build. Inclusion of sysbuild-specific build files, CMakeLists.txt and Kconfig, can be described as:

```
build:
  sysbuild-cmake: <cmake-directory>
  sysbuild-kconfig: <directory>/Kconfig
```

The sysbuild-cmake: <cmake-directory> part specifies that <cmake-directory> contains the CMakeLists.txt to use. The sysbuild-kconfig: <directory>/Kconfig part specifies the Kconfig file to use.

Here is an example module.yml file referring to CMakeLists.txt and Kconfig files in the sysbuild directory of the module:

```
build:
  sysbuild-cmake: sysbuild
  sysbuild-kconfig: sysbuild/Kconfig
```

The module description file `zephyr/module.yml` can also be used to specify that the build files, `CMakeLists.txt` and `Kconfig`, are located in a *Module integration files (external)*.

Build files located in a `MODULE_EXT_ROOT` can be described as:

```
build:
  sysbuild-cmake-ext: True
  sysbuild-kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

Vulnerability monitoring

The module description file `zephyr/module.yml` can be used to improve vulnerability monitoring.

If your module needs to track vulnerabilities using an external reference (e.g your module is forked from another repository), you can use the `security` section. It contains the field `external-references` that contains a list of references that needs to be monitored for your module. The supported formats are:

- CPE (Common Platform Enumeration)
- PURL (Package URL)

```
security:
  external-references:
    - <module-related-cpe>
    - <an-other-module-related-cpe>
    - <module-related-purl>
```

A real life example for Mbed TLS module could look like this:

```
security:
  external-references:
    - cpe:2.3:a:arm:mbed_tls:3.5.2:*:*:*:*:*:*:*
    - pkg:github/Mbed-TLS/mbedtls@V3.5.2
```

Note

CPE field must follow the CPE 2.3 schema provided by NVD. PURL field must follow the PURL specification provided by Github.

Build system integration

When a module has a `module.yml` file, it will automatically be included into the Zephyr build system. The path to the module is then accessible through Kconfig and CMake variables.

Zephyr modules In both Kconfig and CMake, the variable `ZEPHYR_<MODULE_NAME>_MODULE_DIR` contains the absolute path to the module.

Additionally, `ZEPHYR_<MODULE_NAME>_MODULE` and `ZEPHYR_<MODULE_NAME>_MODULE_BLOBS` (in case the module declares blobs) symbols are automatically generated for available modules. These can be used e.g. to declare dependencies from other Kconfig symbols which depend on the module or blobs from the module. To satisfy compliance checking when building Zephyr without the

module present, it's recommended for the module to have default definitions for these symbols in its respective Kconfig file under `modules/` in the Zephyr main tree.

In CMake, `ZEPHYR_<MODULE_NAME>_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a CMakeLists.txt.

To read these variables for a Zephyr module named `foo`:

- In CMake: use `${ZEPHYR_FOO_MODULE_DIR}` for the module's top level directory, and `${ZEPHYR_FOO_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(ZEPHYR_FOO_MODULE_DIR)` for the module's top level directory

Notice how a lowercase module name `foo` is capitalized to `FOO` in both CMake and Kconfig.

These variables can also be used to test whether a given module exists. For example, to verify that `foo` is the name of a Zephyr module:

```
if(ZEPHYR_FOO_MODULE_DIR)
  # Do something if FOO exists.
endif()
```

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig` in module `foo`:

```
source "$(ZEPHYR_FOO_MODULE_DIR)/some/Kconfig"
```

During CMake processing of each Zephyr module, the following variables are also available:

- the current module's name: `${ZEPHYR_CURRENT_MODULE_NAME}`
- the current module's top level directory: `${ZEPHYR_CURRENT_MODULE_DIR}`
- the current module's `CMakeLists.txt` directory: `${ZEPHYR_CURRENT_CMAKE_DIR}`

This removes the need for a Zephyr module to know its own name during CMake processing. The module can source additional CMake files using these `CURRENT` variables. For example:

```
include(${ZEPHYR_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

An example of a Zephyr list where this is useful is when adding additional directories to the `SYSCALL_INCLUDE_DIRS` list.

Sysbuild modules In both Kconfig and CMake, the variable `SYSBUILD_CURRENT_MODULE_DIR` contains the absolute path to the sysbuild module. In CMake, `SYSBUILD_CURRENT_CMAKE_DIR` contains the absolute path to the directory containing the `CMakeLists.txt` file that is included into CMake build system. This variable's value is empty if the module.yml file does not specify a CMakeLists.txt.

To read these variables for a sysbuild module:

- In CMake: use `${SYSBUILD_CURRENT_MODULE_DIR}` for the module's top level directory, and `${SYSBUILD_CURRENT_CMAKE_DIR}` for the directory containing its `CMakeLists.txt`
- In Kconfig: use `$(SYSBUILD_CURRENT_MODULE_DIR)` for the module's top level directory

In Kconfig, the variable may be used to find additional files to include. For example, to include the file `some/Kconfig`:

```
source "$(SYSBUILD_CURRENT_MODULE_DIR)/some/Kconfig"
```

The module can source additional CMake files using these variables. For example:

```
include(${SYSBUILD_CURRENT_MODULE_DIR}/cmake/code.cmake)
```

It is possible to append values to a Zephyr CMake list variable from the module's first CMakeLists.txt file. To do so, append the value to the list and then set the list in the PARENT_SCOPE of the CMakeLists.txt file. For example, to append `bar` to the `FOO_LIST` variable in the Zephyr CMakeLists.txt scope:

```
list(APPEND FOO_LIST bar)
set(FOO_LIST ${FOO_LIST} PARENT_SCOPE)
```

Sysbuild modules hooks Sysbuild provides an infrastructure which allows a sysbuild module to define a function which will be invoked by sysbuild at a pre-defined point in the CMake flow.

Functions invoked by sysbuild:

- `<module-name>_pre_cmake(IMAGES <images>)`: This function is called for each sysbuild module before CMake configure is invoked for all images.
- `<module-name>_post_cmake(IMAGES <images>)`: This function is called for each sysbuild module after CMake configure has completed for all images.
- `<module-name>_pre_domains(IMAGES <images>)`: This function is called for each sysbuild module before domains yaml is created by sysbuild.
- `<module-name>_post_domains(IMAGES <images>)`: This function is called for each sysbuild module after domains yaml has been created by sysbuild.

arguments passed from sysbuild to the function defined by a module:

- `<images>` is the list of Zephyr images that will be created by the build system.

If a module `foo` want to provide a post CMake configure function, then the module's sysbuild `CMakeLists.txt` file must define function `foo_post_cmake()`.

To facilitate naming of functions, the module name is provided by sysbuild CMake through the `SYSBUILD_CURRENT_MODULE_NAME` CMake variable when loading the module's sysbuild `CMakeLists.txt` file.

Example of how the `foo` sysbuild module can define `foo_post_cmake()`:

```
function(${SYSBUILD_CURRENT_MODULE_NAME}_post_cmake)
  cmake_parse_arguments(POST_CMAKE "" "" "IMAGES" ${ARGN})

  message("Invoking ${CMAKE_CURRENT_FUNCTION}. Images: ${POST_CMAKE_IMAGES}")
endfunction()
```

Zephyr module dependencies

A Zephyr module may be dependent on other Zephyr modules to be present in order to function correctly. Or it might be that a given Zephyr module must be processed after another Zephyr module, due to dependencies of certain CMake targets.

Such a dependency can be described using the `depends` field.

```
build:
  depends:
    - <module>
```

Here is an example for the Zephyr module `foo` that is dependent on the Zephyr module `bar` to be present in the build system:

```
name: foo
build:
  depends:
    - bar
```

This example will ensure that `bar` is present when `foo` is included into the build system, and it will also ensure that `bar` is processed before `foo`.

Module integration files (external)

Module integration files can be located externally to the Zephyr module itself. The `MODULE_EXT_ROOT` variable holds a list of roots containing integration files located externally to Zephyr modules.

Module integration files in Zephyr The Zephyr repository contain `CMakeLists.txt` and `Kconfig` build files for certain known Zephyr modules.

Those files are located under

```
<ZEPHYR_BASE>
└── modules
    └── <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

Module integration files in a custom location You can create a similar `MODULE_EXT_ROOT` for additional modules, and make those modules known to Zephyr build system.

Create a `MODULE_EXT_ROOT` with the following structure

```
<MODULE_EXT_ROOT>
└── modules
    ├── modules.cmake
    └── <module_name>
        ├── CMakeLists.txt
        └── Kconfig
```

and then build your application by specifying `-DMODULE_EXT_ROOT` parameter to the CMake build system. The `MODULE_EXT_ROOT` accepts a CMake list of roots as argument.

A Zephyr module can automatically be added to the `MODULE_EXT_ROOT` list using the module description file `zephyr/module.yml`, see *Build settings*.

Note

`ZEPHYR_BASE` is always added as a `MODULE_EXT_ROOT` with the lowest priority. This allows you to overrule any integration files under `<ZEPHYR_BASE>/modules/<module_name>` with your own implementation your own `MODULE_EXT_ROOT`.

The `modules.cmake` file must contain the logic that specifies the integration files for Zephyr modules via specifically named CMake variables.

To include a module's CMake file, set the variable ZEPHYR_<MODULE_NAME>_CMAKE_DIR to the path containing the CMake file.

To include a module's Kconfig file, set the variable ZEPHYR_<MODULE_NAME>_KCONFIG to the path to the Kconfig file.

The following is an example on how to add support the FOO module.

Create the following structure

```
<MODULE_EXT_ROOT>
└── modules
    ├── modules.cmake
    └── foo
        ├── CMakeLists.txt
        └── Kconfig
```

and inside the modules.cmake file, add the following content

```
set(ZEPHYR_FOO_CMAKE_DIR ${CMAKE_CURRENT_LIST_DIR}/foo)
set(ZEPHYR_FOO_KCONFIG   ${CMAKE_CURRENT_LIST_DIR}/foo/Kconfig)
```

Module integration files (zephyr/module.yml) The module description file zephyr/module.yml can be used to specify that the build files, CMakeLists.txt and Kconfig, are located in a *Module integration files (external)*.

Build files located in a MODULE_EXT_ROOT can be described as:

```
build:
  cmake-ext: True
  kconfig-ext: True
```

This allows control of the build inclusion to be described externally to the Zephyr module.

The Zephyr repository itself is always added as a Zephyr module ext root.

Build settings

It is possible to specify additional build settings that must be used when including the module into the build system.

All root settings are relative to the root of the module.

Build settings supported in the module.yml file are:

- board_root: Contains additional boards that are available to the build system. Additional boards must be located in a <board_root>/boards folder.
- dts_root: Contains additional dts files related to the architecture/soc families. Additional dts files must be located in a <dts_root>/dts folder.
- snippet_root: Contains additional snippets that are available for use. These snippets must be defined in snippet.yml files underneath the <snippet_root>/snippets folder. For example, if you have snippet_root: foo, then you should place your module's snippet.yml files in <your-module>/foo/snippets or any nested subdirectory.
- soc_root: Contains additional SoCs that are available to the build system. Additional SoCs must be located in a <soc_root>/soc folder.
- arch_root: Contains additional architectures that are available to the build system. Additional architectures must be located in a <arch_root>/arch folder.
- module_ext_root: Contains CMakeLists.txt and Kconfig files for Zephyr modules, see also *Module integration files (external)*.

- `sca_root`: Contains additional *SCA* tool implementations available to the build system. Each tool must be located in `<sca_root>/sca/<tool>` folder. The folder must contain a `sca.cmake`.

Example of a `module.yaml` file containing additional roots, and the corresponding file system layout.

```
build:
  settings:
    board_root: .
    dts_root: .
    soc_root: .
    arch_root: .
    module_ext_root: .
```

requires the following folder structure:

```
<zephyr-module-root>
├── arch
├── boards
├── dts
├── modules
└── soc
```

Test Runner (Twister) integration

To execute both tests and samples available in modules, the Zephyr test runner (twister) should be pointed to the directories containing those samples and tests. This can be done by specifying the path to both samples and tests in the `zephyr/module.yml` file. Additionally, if a module defines out of tree boards, the module file can point twister to the path where those files are maintained in the module. For example:

```
build:
  cmake: .
samples:
  - samples
tests:
  - tests
boards:
  - boards
```

Tests and Samples defined in the `zephyr/module.yml` file are not detected by twister automatically. To make twister aware of the tests and samples defined in modules, the path for those tests and samples must be added to the command line when executing twister, for example:

```
./scripts/zephyr_module.py --twister-out module_tests.args
if [ -s module_tests.args ]; then
    west twister +module_tests.args --outdir module_tests ...
fi
```

Binary Blobs

Zephyr supports fetching and using *binary blobs*, and their metadata is contained entirely in `zephyr/module.yml`. This is because a binary blob must always be associated with a Zephyr module, and thus the blob metadata belongs in the module's description itself.

Binary blobs are fetched using *west blobs*. If `west` is *not used*, they must be downloaded and verified manually.

The `blobs` section in `zephyr/module.yml` consists of a sequence of maps, each of which has the following entries:

- `path`: The path to the binary blob, relative to the `zephyr/blobs/` folder in the module repository
- `sha256`: SHA-256 checksum of the binary blob file
- `type`: The *type of binary blob*. Currently limited to `img` or `lib`
- `version`: A version string
- `license-path`: Path to the license file for this blob, relative to the root of the module repository
- `url`: URL(s) that identify the location the blob will be fetched from, as well as the fetching scheme to use. If it contains a list instead of a single string, each URL will be considered as a fallback for fetching the same blob.
- `description`: Human-readable description of the binary blob
- `doc-url`: A URL pointing to the location of the official documentation for this blob

The following entries may also be present:

- `click-through`: A boolean indicating if a click-through license must be accepted to download this blob
- `size`: Size of the blob in bytes. May be required by some fetchers
- `fetcher`: The method used to download the blob. If not set, the method is inferred from the URL

Package manager dependencies

Zephyr modules can describe dependencies available from package managers, currently only `pip` is supported.

A west extension command `west packages <manager>` is available to list dependencies for Zephyr and present modules that leverage this feature in their `module.yml` file. Run `west help packages` for more details.

Python pip Calling `west packages pip` lists requirement files for Zephyr and modules. Passing `--install` installs these if there's an active virtual environment.

The following example demonstrates a `zephyr/module.yml` file with some requirement files in the `scripts` directory of the module.

```
package-managers:
  pip:
    requirement-files:
      - scripts/requirements-build.txt
      - scripts/requirements-doc.txt
```

External Runners

If a module has out of tree boards that require custom *runners*, then it can add a list to its `zephyr/module.yml` file, for example:

```
runners:
  - file: scripts/my-runner.py
```

Each file entry is imported when executing `west flash` or `west debug` and subclasses of the `ZephyrBinaryRunner` are registered for use.

Module Inclusion

Using West If west is installed and ZEPHYR_MODULES is not already set, the build system finds all the modules in your *west installation* and uses those. It does this by running *west list* to get the paths of all the projects in the installation, then filters the results to just those projects which have the necessary module metadata files.

Each project in the `west list` output is tested like this:

- If the project contains a file named `zephyr/module.yml`, then the content of that file will be used to determine which files should be added to the build, as described in the previous section.
- Otherwise (i.e. if the project has no `zephyr/module.yml`), the build system looks for `zephyr/CMakeLists.txt` and `zephyr/Kconfig` files in the project. If both are present, the project is considered a module, and those files will be added to the build.
- If neither of those checks succeed, the project is not considered a module, and is not added to ZEPHYR_MODULES.

Without West If you don't have west installed or don't want the build system to use it to find Zephyr modules, you can set ZEPHYR_MODULES yourself using one of the following options. Each of the directories in the list must contain either a `zephyr/module.yml` file or the files `zephyr/CMakeLists.txt` and `Kconfig`, as described in the previous section.

1. At the CMake command line, like this:

   ```
   cmake -DZEPHYR_MODULES=<path-to-module1>[;<path-to-module2>[...]] ...
   ```

2. At the top of your application's top level `CMakeLists.txt`, like this:

   ```
   set(ZEPHYR_MODULES <path-to-module1> <path-to-module2> [...])
   find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
   ```

   If you choose this option, make sure to set the variable **before** calling `find_package(Zephyr ...)`, as shown above.

3. In a separate CMake script which is pre-loaded to populate the CMake cache, like this:

   ```
   # Put this in a file with a name like "zephyr-modules.cmake"
   set(ZEPHYR_MODULES <path-to-module1> <path-to-module2>
     CACHE STRING "pre-cached modules")
   ```

   You can tell the build system to use this file by adding `-C zephyr-modules.cmake` to your CMake command line.

Not using modules If you don't have west installed and don't specify ZEPHYR_MODULES yourself, then no additional modules are added to the build. You will still be able to build any applications that don't require code or Kconfig options defined in an external repository.

2.10.10 Submitting changes to modules

When submitting new or making changes to existing modules the main repository Zephyr needs a reference to the changes to be able to verify the changes. In the main tree this is done using revisions. For code that is already merged and part of the tree we use the commit hash, a tag, or a branch name. For pull requests however, we require specifying the pull request number in the revision field to allow building the zephyr main tree with the changes submitted to the module.

To avoid merging changes to master with pull request information, the pull request should be marked as `DNM` (Do Not Merge) or preferably a draft pull request to make sure it is not merged by mistake and to allow for the module to be merged first and be assigned a permanent commit hash. Drafts reduce noise by not automatically notifying anyone until marked as "Ready for

review". Once the module is merged, the revision will need to be changed either by the submitter or by the maintainer to the commit hash of the module which reflects the changes.

Note that multiple and dependent changes to different modules can be submitted using exactly the same process. In this case you will change multiple entries of all modules that have a pull request against them.

Process for submitting a new module

Please follow the process in *Submission and review process* and obtain the TSC approval to integrate the external source code as a module

If the request is approved, a new repository will created by the project team and initialized with basic information that would allow submitting code to the module project following the project contribution guidelines.

If a module is maintained as a fork of another project on Github, the Zephyr module related files and changes in relation to upstream need to be maintained in a special branch named `zephyr`.

Maintainers from the Zephyr project will create the repository and initialize it. You will be added as a collaborator in the new repository. Submit the module content (code) to the new repository following the guidelines described *here*, and then add a new entry to the west.yml with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add *my_module* to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the *my_module* repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

Process for submitting changes to existing modules

1. Submit the changes using a pull request to an existing repository following the *contribution guidelines* and *expectations*.
2. Submit a pull request changing the entry referencing the module into the west.yml of the main Zephyr tree with the following information:

```
- name: <name of repository>
  path: <path to where the repository should be cloned>
  revision: <ref pointer to module pull request>
```

For example, to add *my_module* to the manifest:

```
- name: my_module
  path: modules/lib/my_module
  revision: pull/23/head
```

Where 23 in the example above indicated the pull request number submitted to the *my_module* repository. Once the module changes are reviewed and merged, the revision needs to be changed to the commit hash from the module repository.

2.11 West (Zephyr's meta-tool)

The Zephyr project includes a swiss-army knife command line tool named `west`[1]. West is developed in its own repository.

West's built-in commands provide a multiple repository management system with features inspired by Google's Repo tool and Git submodules. West is also "pluggable": you can write your own west extension commands which add additional features to west. Zephyr uses this to provide conveniences for building applications, flashing and debugging them, and more.

Like `git` and `docker`, the top-level `west` command takes some common options, a sub-command to run, and then options and arguments for that sub-command:

```
west [common-opts] <command> [opts] <args>
```

Since west v0.8, you can also run west like this:

```
python3 -m west [common-opts] <command> [opts] <args>
```

You can run `west --help` (or `west -h` for short) to get top-level help for available west commands, and `west <command> -h` for detailed help on each command.

2.11.1 Installing west

West is written in Python 3 and distributed through PyPI. Use `pip3` to install or upgrade west:

On Linux:

```
pip3 install --user -U west
```

On Windows and macOS:

```
pip3 install -U west
```

> **Note**
>
> See *Python and pip* for additional clarification on using the `--user` switch.

Afterwards, you can run `pip3 show -f west` for information on where the west binary and related files were installed.

Once west is installed, you can use it to *clone the Zephyr repositories*.

Structure

West's code is distributed via PyPI in a Python package named `west`. This distribution includes a launcher executable, which is also named `west` (or `west.exe` on Windows).

When west is installed, the launcher is placed by `pip3` somewhere in the user's filesystem (exactly where depends on the operating system, but should be on the `PATH` *environment variable*). This launcher is the command-line entry point to running both built-in commands like `west init`, `west update`, along with any extensions discovered in the workspace.

In addition to its command-line interface, you can also use west's Python APIs directly. See west-apis for details.

[1] Zephyr is an English name for the Latin Zephyrus, the ancient Greek god of the west wind.

Enabling shell completion

West currently supports shell completion in the following shells:

- bash
- zsh
- fish
- powershell (board qualifiers only)

In order to enable shell completion, you will need to obtain the corresponding completion script and have it sourced. Using the completion scripts:

bash

One-time setup:

```
source <(west completion bash)
```

Permanent setup:

```
west completion bash > ~/west-completion.bash; printf '\n%s\n' "source ~/
↪west-completion.bash" >> ~/.bashrc
```

zsh

One-time setup:

```
source <(west completion zsh)
```

Permanent setup:

```
west completion zsh > "${fpath[1]}/_west"
```

fish

One-time setup:

```
west completion fish | source
```

Permanent setup:

```
west completion fish > $HOME/.config/fish/completions/west.fish
```

powershell

One-time setup:

```
west completion powershell | Out-String | Invoke-Expression
```

Permanent setup:

```
Set-ExecutionPolicy RemoteSigned -Scope CurrentUser
New-item -type file -force $PROFILE
west completion powershell > $HOME/west-completion.ps1
(Add-Content -Path $PROFILE -Value ". '{$HOME/west-completion.ps1}'")
```

2.11.2 West Release Notes

v1.5.0

Major changes:

- Add support for auto-caching. Pass the `--auto-cache <directory>` argument to `west update`.

Other changes:

- Allow combining `--name-cache` and `--path-cache` for `west update`.
- Document default revision value in the manifest schema.

Bug fixes:

- Allow empty or missing manifest projects list.
- Make `manifest.group-filter` list order deterministic when freezing or resolving manifest files.

v1.4.0

Changes:

- Allow appending data to configuration strings. To append to a value for `<name>`, type: `west config -a <name> <value>`.
- Add `--untracked` argument option to `west manifest`. Run `west manifest --untracked` in a workspace to print all files and directories that are not tracked or managed by west.
- Add `--inactive` argument option to `west list` to support printing inactive projects.
- Support `--active-only` argument option for the `west manifest --resolve` and `west manifest --freeze` commands. This allows freezing workspaces with active project or group filters.

API changes:

- `west.manifest.Manifest` methods `as_dict()`, `as_frozen_dict()`, `as_yaml()` and `as_frozen_yaml()` now have an optional `active_only` argument (defaults to `False`) to return an object containing all projects or only the active ones.

v1.3.0

Major changes:

- Added support for *West aliases* commands.
- Adopt the pyproject TOML specification for packaging.

Other changes:

- Add cache support for submodules.
- Decode manifest files as UTF-8 by default.
- Pass unknown arguments for `west diff` and `west status` to underlying `git` commands.
- Added `--manifest` argument to `west diff` to allow comparing the current workspace to the manifest revisions.
- Environment variables can be used with west forall The following are defined:
  - `WEST_PROJECT_NAME`
  - `WEST_PROJECT_PATH`
  - `WEST_PROJECT_ABSPATH`
  - `WEST_PROJECT_REVISION`
  - `WEST_PROJECT_URL`
  - `WEST_PROJECT_REMOTE`

- Added support for early argument `-q/--quiet` to reduce verbosity.
- Added `-o/--clone-opt` argument to `west init` to pass to `git clone`.
- Support Python 3.13 and drop support for Python 3.8.
- Prevent manifests from having projects in the `.west` directory.
- Add NTFS workarounds and `--rename-delay` for `west init`.
- Print a stack trace when calling die in debug `-vvv`.

Bug fixes:

- Use `'backslashreplace'` not to crash on malformed UTF from subprocess.
- Fix handling in `west diff` for repositories with merge conflicts. Additionally improve error printing and handle `git diff` return codes.
- Fix `--freeze` and `--resolve` for the `west manifest` command when git submodules are used.

v1.2.0

Major changes:

- New `west grep` command for running a "grep tool" in your west workspace's repositories. Currently, `git grep`, ripgrep, and standard `grep` are supported grep tools.

  To run this command to get `git grep foo` results from all cloned, active repositories, run:

  ```
  west grep foo
  ```

  Here are some other examples for running different grep commands with `west grep`:

`git grep --untracked`	`west grep --untracked foo`
`ripgrep`	`west grep --tool ripgrep foo`
`grep --recursive`	`west grep --tool grep foo`

  To switch the default grep tool in your workspace, run the appropriate command in this table:

`ripgrep`	`west config grep.tool ripgrep`
`grep`	`west config grep.tool grep`

  For more details, run `west help grep`.

Other changes:

- The manifest file format now supports a `description` field in each `projects:` element. See *Projects* for examples.
- `west list --format` now accepts `{description}` in the format string, which prints the project's `description:` value.
- `west compare` now always prints information about *The manifest-rev branch*.

Bug fixes:

- `west init` aborts if the destination directory already exists.

API changes:

- `west.commands.WestCommand` methods `check_call()` and `check_output()` now take any kwargs that can be passed on to the underlying subprocess function.

- `west.commands.WestCommand.run_subprocess()`: new wrapper around `subprocess.run()`. This could not be named `run()` because `WestCommand` already had a method by this name.
- `west.commands.WestCommand` methods `dbg()`, `inf()`, `wrn()`, and `err()` now all take an `end` kwarg, which is passed on to the call to `print()`.
- `west.manifest.Project` now has a `description` attribute, which contains the parsed value of the `description:` field in the manifest data.

v1.1.0

Major changes:

- `west compare`: new command that compares the state of the workspace against the manifest.
- Support for a new `manifest.project-filter` configuration option. See *Built-in Configuration Options* for details. The `west manifest --freeze` and `west manifest --resolve` commands currently cannot be used when this option is set. This restriction can be removed in a later release.
- Project names which contain comma (`,`) or whitespace now generate warnings. These warnings are errors if the new `manifest.project-filter` configuration option is set. The warnings may be promoted to errors in a future major version of west.

Other changes:

- `west forall` now takese a `--group` argument that can be used to restrict the command to only run in one or more groups. Run `west help forall` for details.
- All west commands will now output log messages from west API modules at warning level or higher. In addition, the `--verbose` argument to west can be used once to include informational messages, or twice to include debug messages, from all commands.

Bug fixes:

- Various improvements to error messages, debug logging, and error handling.

API changes:

- `west.manifest.Manifest.is_active()` now respects the `manifest.project-filter` configuration option's value.

v1.0.1

Major changes:

- Manifest schema version "1.0" is now available for use in this release. This is identical to the "0.13" schema version in terms of features, but can be used by applications that do not wish to use a "0.x" manifest "version:" field. See *Version* for details on this feature.

Bug fixes:

- West no longer exits with a successful error code when sent an interrupt signal. Instead, it exits with a platform-specific error code and signals to the calling environment that the process was interrupted.

v1.0.0

Major changes in this release:

- The west-apis are now declared stable. Any breaking changes will be communicated by a major version bump from v1.x.y to v2.x.y.

- West v1.0 no longer works with the Zephyr v1.14 LTS releases. This LTS has long been obsoleted by Zephyr v2.7 LTS. If you need to use Zephyr v1.14, you must use west v0.14 or earlier.
- Like the rest of Zephyr, west now requires Python v3.8 or later
- West commands no longer accept abbreviated command line arguments. For example, you must now specify `west update --keep-descendants` instead of using an abbreviation like `west update --keep-d`. This is part of a change applied to all of Zephyr's Python scripts' command-line interfaces. The abbreviations were causing problems in practice when commands were updated to add new options with similar names but different behavior to existing ones.

Other changes:

- All built-in west functions have stopped using `west.log`
- `west update`: new `--submodule-init-config` option. See commit 9ba92b05 for details.

Bug fixes:

- West extension commands that failed to load properly sometimes dumped stack. This has been fixed and west now prints a sensible error message in this case.
- `west config` now fails on malformed configuration option arguments which lack a `.` in the option name

API changes:

- The west package now contains the metadata files necessary for some static analyzers (such as mypy) to auto-detect its type annotations. See commit d9f00e24 for details.
- the deprecated `west.build` module used for Zephyr v1.14 LTS compatibility was removed
- the deprecated `west.cmake` module used for Zephyr v1.14 LTS compatibility was removed
- the `west.log` module is now deprecated. This module uses global state, which can make it awkward to use it as an API which multiple different python modules may rely on.
- The west-apis-commands module got some new APIs which lay groundwork for a future change to add a global verbosity control to a command's output, and work to remove global state from the `west` package's API:
  - New `west.commands.WestCommand.__init__()` keyword argument: `verbosity`
  - New `west.commands.WestCommand` property: `color_ui`
  - New `west.commands.WestCommand` methods, which should be used to print output from extension commands instead of writing directly to sys.stdout or sys.stderr: `inf()`, `wrn()`, `err()`, `die()`, `banner()`, `small_banner()`
  - New `west.commands.VERBOSITY` enum

v0.14.0

Bug fixes:

- West commands that were run with a bad local configuration file dumped stack in a confusing way. This has been fixed and west now prints a sensible error message in this case.
- A bug in the way west looks for the zephyr repository was fixed. The bug itself usually appeared when running an extension command like `west build` in a new workspace for the first time; this used to fail (just for the first time, not on subsequent command invocations) unless you ran the command in the workspace's top level directory.
- West now prints sensible error messages when the user lacks permission to open the manifest file instead of dumping stack traces.

API changes:

- The `west.manifest.MalformedConfig` exception type has been moved to the `west.configuration` module
- The `west.manifest.MalformedConfig` exception type has been moved to the west.configuration module
- The `west.configuration.Configuration` class now raises `MalformedConfig` instead of `RuntimeError` in some cases

v0.13.1

Bug fix:

- When calling west.manifest.Manifest.from_file() when outside of a workspace, west again falls back on the ZEPHYR_BASE environment variable to locate the workspace.

v0.13.0

New features:

- You can now associate arbitrary user data with the manifest repository itself in the `manifest: self: userdata:` value, like so:

```
manifest:
  self:
    userdata: <any YAML value can go here>
```

Bug fixes:

- The path to the manifest repository reported by west could be incorrect in certain circumstances detailed in [issue #572](https://github.com/zephyrproject-rtos/west/issues/572). This has been fixed as part of a larger overhaul of path handling support in the `west.manifest` API module.
- The `west.Manifest.ManifestProject.__repr__` return value was fixed

API changes:

- `west.configuration.Configuration`: new object-oriented interface to the current configuration. This reflects the system, global, and workspace-local configuration values, and allows you to read, write, and delete configuration options from any or all of these locations.
- `west.commands.WestCommand`:
  - `config`: new attribute, returns a `Configuration` object or aborts the program if none is set. This is always usable from within extension command `do_run()` implementations.
  - `has_config`: new boolean attribute, which is `True` if and only if reading `self.config` will abort the program.
- The path handling in the `west.manifest` package has been overhauled in a backwards-incompatible way. For more details, see commit [56cfe8d1d1](https://github.com/zephyrproject-rtos/west/commit/56cfe8d1d1f3c9b45de3e793c738acd62db52aca).
- `west.manifest.Manifest.validate()`: this now returns the validated data as a Python dict. This can be useful if the value passed to this function was a str, and the dict is desired.
- `west.manifest.Manifest`: new:
  - path attributes `abspath`, `posixpath`, `relative_path`, `yaml_path`, `repo_path`, `repo_posixpath`
  - `userdata` attribute, which contains the parsed value from `manifest: self: userdata:`, or is None
  - `from_topdir()` factory method

- `west.manifest.ManifestProject`: new `userdata` attribute, which also contains the parsed value from `manifest: self: userdata:`, or is None
- `west.manifest.ManifestImportFailed`: the constructor can now take any value; this can be used to reflect failed imports from a *map* or other compound value.
- Deprecated configuration APIs:

  The following APIs are now deprecated in favor of using a `Configuration` object. Usually this will be done via `self.config` from a `WestCommand` instance, but this can be done directly by instantiating a `Configuration` object for other usages.

  - `west.configuration.config`
  - `west.configuration.read_config`
  - `west.configuration.update_config`
  - `west.configuration.delete_config`

v0.12.0

New features:

- West now works on the MSYS2 platform.
- West manifest files can now contain arbitrary user data associated with each project. See *Repository user data* for details.

Bug fixes:

- The `west list` command's `{sha}` format key has been fixed for the manifest repository; it now prints `N/A` ("not applicable") as expected.

API changes:

- The `west.manifest.Project.userdata` attribute was added to support project user data.

v0.11.1

New features:

- `west status` now only prints output for projects which have a nonempty status.

Bug fixes:

- The manifest file parser was incorrectly allowing project names which contain the path separator characters `/` and `\`. These invalid characters are now rejected.

  Note: if you need to place a project within a subdirectory of the workspace topdir, use the `path:` key. If you need to customize a project's fetch URL relative to its remote `url-base:`, use `repo-path:`. See *Projects* for examples.
- The changes made in west v0.10.1 to the `west init --manifest-rev` option which selected the default branch name were leaving the manifest repository in a detached HEAD state. This has been fixed by using `git clone` internally instead of `git init` and `git fetch`. See issue #522 for details.
- The `WEST_CONFIG_LOCAL` environment variable now correctly overrides the default location, `<workspace topdir>/.west/config`.
- `west update --fetch=smart` (`smart` is the default) now correctly skips fetches for project revisions which are lightweight tags (it already worked correctly for annotated tags; only lightweight tags were unnecessarily fetched).

Other changes:

- The fix for issue #522 mentioned above introduces a new restriction. The `west init --manifest-rev` option value, if given, must now be either a branch or a tag. In particular, "pseudo-branches" like GitHub's `pull/1234/head` references which could previously be used to fetch a pull request can no longer be passed to `--manifest-rev`. Users must now fetch and check out such revisions manually after running `west init`.

API changes:

- `west.manifest.Manifest.get_projects()` avoids incorrect results in some edge cases described in issue #523.
- `west.manifest.Project.sha()` now works correctly for tag revisions. (This applies to both lightweight and annotated tags.)

v0.11.0

New features:

- `west update` now supports `--narrow`, `--name-cache`, and `--path-cache` options. These can be influenced by the `update.narrow`, `update.name-cache`, and `update.path-cache` *Configuration* options. These can be used to optimize the speed of the update.
- `west update` now supports a `--fetch-opt` option that will be passed to the `git fetch` command used to fetch remote revisions when updating each project.

Bug fixes:

- `west update` now synchronizes Git submodules in projects by default. This avoids issues if the URL changes in the manifest file from when the submodule was first initialized. This behavior can be disabled by setting the `update.sync-submodules` configuration option to `false`.

Other changes:

- the west-apis-manifest module has fixed docstrings for the Project class

v0.10.1

New features:

- The *west init* command's `--manifest-rev` (`--mr`) option no longer defaults to `master`. Instead, the command will query the repository for its default branch name and use that instead. This allows users to move from `master` to `main` without breaking scripts that do not provide this option.

v0.10.0

New features:

- The `name` key in a project's *submodules list* is now optional.

Bug fixes:

- West now checks that the manifest schema version is one of the explicitly allowed values documented in *Version*. The old behavior was just to check that the schema version was newer than the west version where the `manifest: version:` key was introduced. This incorrectly allowed invalid schema versions, like `0.8.2`.

Other changes:

- A manifest file's `group-filter` is now propagated through an `import`. This is a change from how west v0.9.x handled this. In west v0.9.x, only the top level manifest file's `group-filter` had any effect; the group filter lists from any imported manifests were ignored.

  Starting with west v0.10.0, the group filter lists from imported manifests are also imported. For details, see *Group Filters and Imports*.

The new behavior will take effect if `manifest: version:` is not given or is at least `0.10`. The old behavior is still available in the top level manifest file only with an explicit `manifest: version: 0.9`. See *Version* for more information on schema versions.

See west pull request #482 for the motivation for this change and additional context.

v0.9.1

Bug fixes:

- Commands like `west manifest --resolve` now correctly include group and group filter information.

Other changes:

- West now warns if you combine `import` with `group-filter`. Semantics for this combination have changed starting with v0.10.x. See the v0.10.0 release notes above for more information.

v0.9.0

Warning

The `west config` fix described below comes at a cost: any comments or other manual edits in configuration files will be removed when setting a configuration option via that command or the `west.configuration` API.

Warning

Combining the `group-filter` feature introduced in this release with manifest imports is discouraged. The resulting behavior has changed in west v0.10.

New features:

- West manifests now support *Git Submodules in Projects*. This allows you to clone Git submodules into a west project repository in addition to the project repository itself.
- West manifests now support *Project Groups*. Project groups can be enabled and disabled to determine what projects are "active", and therefore will be acted upon by the following commands: `west update`, `west list`, `west diff`, `west status`, `west forall`.
- `west update` no longer updates inactive projects by default. It now supports a `--group-filter` option which allows for one-time modifications to the set of enabled and disabled project groups.
- Running `west list`, `west diff`, `west status`, or `west forall` with no arguments does not print information for inactive projects by default. If the user specifies a list of projects explicitly at the command line, output for them is included regardless of whether they are active.

  These commands also now support `--all` arguments to include all projects, even inactive ones.
- `west list` now supports a `{groups}` format string key in its `--format` argument.

Bug fixes:

- The `west config` command and `west.configuration` API did not correctly store some configuration values, such as strings which contain commas. This has been fixed; see commit 36f3f91e for details.

- A manifest file with an empty `manifest: self: path:` value is invalid, but west used to let it pass silently. West now rejects such manifests.
- A bug affecting the behavior of the `west init -l .` command was fixed; see issue #435.

API changes:

- added `west.manifest.Manifest.is_active()`
- added `west.manifest.Manifest.group_filter`
- added `submodules` attribute to `west.manifest.Project`, which has newly added type `west.manifest.Submodule`

Other changes:

- The *Manifest Imports* feature now supports the terms `allowlist` and `blocklist` instead of `whitelist` and `blacklist`, respectively.

  The old terms are still supported for compatibility, but the documentation has been updated to use the new ones exclusively.

v0.8.0

This is a feature release which changes the manifest schema by adding support for a `path-prefix:` key in an `import:` mapping, along with some other features and fixes.

- Manifest import mappings now support a `path-prefix:` key, which places the project and its imported repositories in a subdirectory of the workspace. See *Example 3.4: Import into a subdirectory* for an example.
- The west command line application can now also be run using `python3 -m west`. This makes it easier to run west under a particular Python interpreter without modifying the *PATH* environment variable.
- *west manifest –path* prints the absolute path to west.yml
- `west init` now supports an `--mf foo.yml` option, which initializes the workspace using `foo.yml` instead of `west.yml`.
- `west list` now prints the manifest repository's path using the `manifest.path` *configuration option*, which may differ from the `self: path:` value in the manifest data. The old behavior is still available, but requires passing a new `--manifest-path-from-yaml` option.
- Various Python API changes; see west-apis for details.

v0.7.3

This is a bugfix release.

- Fix an error where a failed import could leave the workspace in an unusable state (see [PR #415](https://github.com/zephyrproject-rtos/west/pull/415) for details)

v0.7.2

This is a bugfix and minor feature release.

- Filter out duplicate extension commands brought in by manifest imports
- Fix `west.Manifest.get_projects()` when finding the manifest repository by path

v0.7.1

This is a bugfix and minor feature release.

- `west update --stats` now prints timing for operations which invoke a subprocess, time spent in west's Python process for each project, and total time updating each project.

- `west topdir` always prints a POSIX style path
- minor console output changes

v0.7.0

The main user-visible feature in west 0.7 is the *Manifest Imports* feature. This allows users to load west manifest data from multiple different files, resolving the results into a single logical manifest.

Additional user-visible changes:

- The idea of a "west installation" has been renamed to "west workspace" in this documentation and in the west API documentation. The new term seems to be easier for most people to work with than the old one.
- West manifests now support a *schema version*.
- The "west config" command can now be run outside of a workspace, e.g. to run `west config --global section.key value` to set a configuration option's value globally.
- There is a new *west topdir* command, which prints the root directory of the current west workspace.
- The `west -vv init` command now prints the git operations being performed, and their results.
- The restriction that no project can be named "manifest" is now enforced; the name "manifest" is reserved for the manifest repository, and is usable as such in commands like `west list manifest`, instead of `west list path-to-manifest-repository` being the only way to say that
- It's no longer an error if there is no project named "zephyr". This is part of an effort to make west generally usable for non-Zephyr use cases.
- Various bug fixes.

The developer-visible changes to the west-apis are:

- west.build and west.cmake: deprecated; this is Zephyr-specific functionality and should never have been part of west. Since Zephyr v1.14 LTS relies on it, it will continue to be included in the distribution, but will be removed when that version of Zephyr is obsoleted.
- west.commands:
  - WestCommand.requires_installation: deprecated; use requires_workspace instead
  - WestCommand.requires_workspace: new
  - WestCommand.has_manifest: new
  - WestCommand.manifest: this is now settable
- west.configuration: callers can now identify the workspace directory when reading and writing configuration files
- west.log:
  - msg(): new
- west.manifest:
  - The module now uses the standard logging module instead of west.log
  - QUAL_REFS_WEST: new
  - SCHEMA_VERSION: new
  - Defaults: removed
  - Manifest.as_dict(): new

  - Manifest.as_frozen_yaml(): new
  - Manifest.as_yaml(): new
  - Manifest.from_file() and from_data(): these factory methods are more flexible to use and less reliant on global state
  - Manifest.validate(): new
  - ManifestImportFailed: new
  - ManifestProject: semi-deprecated and will likely be removed later.
  - Project: the constructor now takes a topdir argument
  - Project.format() and its callers are removed. Use f-strings instead.
  - Project.name_and_path: new
  - Project.remote_name: new
  - Project.sha() now captures stderr
  - Remote: removed

West now requires Python 3.6 or later. Additionally, some features may rely on Python dictionaries being insertion-ordered; this is only an implementation detail in CPython 3.6, but it is part of the language specification as of Python 3.7.

v0.6.3

This point release fixes an error in the behavior of the deprecated `west.cmake` module.

v0.6.2

This point release fixes an error in the behavior of `west update --fetch=smart`, introduced in v0.6.1.

All v0.6.1 users must upgrade.

v0.6.1

Warning

Do not use this point release. Make sure to use v0.6.2 instead.

The user-visible features in this point release are:

- The *west update* command has a new `--fetch` command line flag and `update.fetch` *configuration option*. The default value, "smart", skips fetching SHAs and tags which are available locally.
- Better and more consistent error-handling in the `west diff`, `west status`, `west forall`, and `west update` commands. Each of these commands can operate on multiple projects; if a subprocess related to one project fails, these commands now continue to operate on the rest of the projects. All of them also now report a nonzero error code from the west process if any of these subprocesses fails (this was previously not true of `west forall` in particular).
- The *west manifest* command also handles errors better.
- The *west list* command now works even when the projects are not cloned, as long as its format string only requires information which can be read from the manifest file. It still fails if the format string requires data stored in the project repository, e.g. if it includes the `{sha}` format string key.

- Commands and options which operate on git revisions now accept abbreviated SHAs. For example, `west init --mr SHA_PREFIX` now works. Previously, the `--mr` argument needed to be the entire 40 character SHA if it wasn't a branch or a tag.

The developer-visible changes to the west-apis are:

- west.log.banner(): new
- west.log.small_banner(): new
- west.manifest.Manifest.get_projects(): new
- west.manifest.Project.is_cloned(): new
- west.commands.WestCommand instances can now access the parsed Manifest object via a new self.manifest property during the do_run() call. If read, it returns the Manifest object or aborts the command if it could not be parsed.
- west.manifest.Project.git() now has a capture_stderr kwarg

v0.6.0

- No separate bootstrapper

  In west v0.5.x, the program was split into two components, a bootstrapper and a per-installation clone. See Multiple Repository Management in the v1.14 documentation for more details.

  This is similar to how Google's Repo tool works, and lets west iterate quickly at first. It caused confusion, however, and west is now stable enough to be distributed entirely as one piece via PyPI.

  From v0.6.x onwards, all of the core west commands and helper classes are part of the west package distributed via PyPI. This eliminates complexity and makes it possible to import west modules from anywhere in the system, not just extension commands.

- The `selfupdate` command still exists for backwards compatibility, but now simply exits after printing an error message.
- Manifest syntax changes
  - A west manifest file's `projects` elements can now specify their fetch URLs directly, like so:

    ```
    manifest:
      projects:
        - name: example-project-name
          url: https://github.com/example/example-project
    ```

    Project elements with `url` attributes set in this way may not also have `remote` attributes.
  - Project names must be unique: this restriction is needed to support future work, but was not possible in west v0.5.x because distinct projects may have URLs with the same final pathname component, like so:

    ```
    manifest:
      remotes:
        - name: remote-1
          url-base: https://github.com/remote-1
        - name: remote-2
          url-base: https://github.com/remote-2
      projects:
        - name: project
          remote: remote-1
          path: remote-1-project
    ```

(continues on next page)

(continued from previous page)

```
    - name: project
      remote: remote-2
      path: remote-2-project
```

These manifests can now be written with projects that use `url` instead of `remote`, like so:

```
manifest:
  projects:
    - name: remote-1-project
      url: https://github.com/remote-1/project
    - name: remote-2-project
      url: https://github.com/remote-2/project
```

- The `west list` command now supports a `{sha}` format string key
- The default format string for `west list` was changed to `"{name:12} {path:28} {revision:40} {url}"`.
- The command `west manifest --validate` can now be run to load and validate the current manifest file, among other error-handling fixes related to manifest parsing.
- Incompatible API changes were made to west's APIs. Further changes are expected until API stability is declared in west v1.0.
  - The `west.manifest.Project` constructor's `remote` and `defaults` positional arguments are now kwargs. A new `url` kwarg was also added; if given, the `Project` URL is set to that value, and the `remote` kwarg is ignored.
  - `west.manifest.MANIFEST_SECTIONS` was removed. There is only one section now, namely `manifest`. The *sections* kwargs in the `west.manifest.Manifest` factory methods and constructor were also removed.
  - The `west.manifest.SpecialProject` class was removed. Use `west.manifest.ManifestProject` instead.

v0.5.x

West v0.5.x is the first version used widely by the Zephyr Project as part of its v1.14 Long-Term Support (LTS) release. The west v0.5.x documentation is available as part of the Zephyr's v1.14 documentation.

West's main features in v0.5.x are:

- Multiple repository management using Git repositories, including self-update of west itself
- Hierarchical configuration files
- Extension commands

Versions Before v0.5.x

Tags in the west repository before v0.5.x are prototypes which are of historical interest only.

2.11.3 Troubleshooting West

This page covers common issues with west and how to solve them.

`west update` fetching failures

One good way to troubleshoot fetching issues is to run `west update` in verbose mode, like this:

```
west -v update
```

The output includes Git commands run by west and their outputs. Look for something like this:

```
=== updating your_project (path/to/your/project):
west.manifest: your_project: checking if cloned
[...other west.manifest logs...]
--- your_project: fetching, need revision SOME_SHA
west.manifest: running 'git fetch ...␣
↪https://github.com/your-username/your_project ...' in /some/directory
```

The `git fetch` command example in the last line above is what needs to succeed.

One strategy is to go to `/path/to/your/project`, copy/paste and run the entire `git fetch` command, then debug from there using the documentation for your credential storage helper.

If you're behind a corporate firewall and may have proxy or other issues, `curl -v FETCH_URL` (for HTTPS URLs) or `ssh -v FETCH_URL` (for SSH URLs) may be helpful.

If you can get the `git fetch` command to run successfully without prompting for a password when you run it directly, you will be able to run `west update` without entering your password in that same shell.

"'west' is not recognized as an internal or external command, operable program or batch file.'

On Windows, this means that either west is not installed, or your *PATH* environment variable does not contain the directory where pip installed `west.exe`.

First, make sure you've installed west; see *Installing west*. Then try running `west` from a new `cmd.exe` window. If that still doesn't work, keep reading.

You need to find the directory containing `west.exe`, then add it to your *PATH*. (This *PATH* change should have been done for you when you installed Python and pip, so ordinarily you should not need to follow these steps.)

Run this command in `cmd.exe`:

```
pip3 show west
```

Then:

1. Look for a line in the output that looks like `Location: C:\foo\python\python38\lib\site-packages`. The exact location will be different on your computer.
2. Look for a file named `west.exe` in the `scripts` directory `C:\foo\python\python38\scripts`.

   Important

   Notice how `lib\site-packages` in the `pip3 show` output was changed to `scripts`!

3. If you see `west.exe` in the `scripts` directory, add the full path to `scripts` to your *PATH* using a command like this:

   ```
   setx PATH "%PATH%;C:\foo\python\python38\scripts"
   ```

   Do not just copy/paste this command. The `scripts` directory location will be different on your system.

4. Close your `cmd.exe` window and open a new one. You should be able to run `west`.

"invalid choice: 'build'" (or 'flash', etc.)

If you see an unexpected error like this when trying to run a Zephyr extension command (like *west flash*, *west build*, etc.):

```
$ west build [...]
west: error: argument <command>: invalid choice: 'build' (choose from 'init',␣
↪[...])

$ west flash [...]
west: error: argument <command>: invalid choice: 'flash' (choose from 'init',␣
↪[...])
```

The most likely cause is that you're running the command outside of a *west workspace*. West needs to know where your workspace is to find *Extensions*.

To fix this, you have two choices:

1. Run the command from inside a workspace (e.g. the `zephyrproject` directory you created when you *got started*).

   For example, create your build directory inside the workspace, or run `west flash --build-dir YOUR_BUILD_DIR` from inside the workspace.

2. Set the *ZEPHYR_BASE environment variable* and re-run the west extension command. If set, west will use *ZEPHYR_BASE* to find your workspace.

If you're unsure whether a command is built-in or an extension, run `west help` from inside your workspace. The output prints extension commands separately, and looks like this for mainline Zephyr:

```
$ west help

built-in commands for managing git repositories:
  init:                 create a west workspace
  [...]

other built-in commands:
  help:                 get help for west or a command
  [...]

extension commands from project manifest (path: zephyr):
  build:                compile a Zephyr application
  flash:                flash and run a binary on a board
  [...]
```

"invalid choice: 'post-init'"

If you see this error when running `west init`:

```
west: error: argument <command>: invalid choice: 'post-init'
(choose from 'init', 'update', 'list', 'manifest', 'diff',
'status', 'forall', 'config', 'selfupdate', 'help')
```

Then you have an old version of west installed, and are trying to use it in a workspace that requires a more recent version.

The easiest way to resolve this issue is to upgrade west and retry as follows:

1. Install the latest west with the `-U` option for `pip3 install` as shown in *Installing west*.

2. Back up any contents of `zephyrproject/.west/config` that you want to save. (If you don't have any configuration options set, it's safe to skip this step.)
3. Completely remove the `zephyrproject/.west` directory (if you don't, you will get the "already in a workspace" error message discussed next).
4. Run `west init` again.

2.11.4 Basics

This page introduces west's basic concepts and provides references to further reading.

West's built-in commands allow you to work with *projects* (Git repositories) under a common *workspace* directory.

West works in the following manner: the `west init` command creates the *west workspace*, and clones the *manifest repo*, while the `west update` command initially clones, and later updates, the *projects* listed in the manifest in the workspace.

Example workspace

If you've followed the *Getting Started Guide*, your local *west workspace*, which in this case is the folder named `zephyrproject` as well as all its subfolders, looks like this:

```
zephyrproject/                # west topdir
├── .west/                    # marks the location of the topdir
│   └── config                # per-workspace local configuration file
│
│   # The manifest repository, never modified by west after creation:
├── zephyr/                   # .git/ repo
│   ├── west.yml              # manifest file
│   └── [... other files ...]
│
│   # Projects managed by west:
├── modules/
│   └── lib/
│       └── zcbor/            # .git/ project
├── tools/
│   └── net-tools/            # .git/ project
└── [ ... other projects ...]
```

Workspace concepts

Here are the basic concepts you should understand about this structure. Additional details are in *Workspaces*.

topdir
: Above, `zephyrproject` is the name of the workspace's top level directory, or *topdir*. (The name `zephyrproject` is just an example – it could be anything, like `z`, `my-zephyr-workspace`, etc.)

  You'll typically create the topdir and a few other files and directories using *west init*.

.west directory
: The topdir contains the `.west` directory. When west needs to find the topdir, it searches for `.west`, and uses its parent directory. The search starts from the current working directory (and starts again from the location in the *ZEPHYR_BASE* environment variable as a fallback if that fails).

configuration file
: The file `.west/config` is the workspace's *local configuration file*.

manifest repository
: Every west workspace contains exactly one *manifest repository*, which is a Git repository containing a *manifest file*. The location of the manifest repository is given by the *manifest.path configuration option* in the local configuration file.

  For upstream Zephyr, `zephyr` is the manifest repository, but you can configure west to use any Git repository in the workspace as the manifest repository. The only requirement is that it contains a valid manifest file. See *Topologies supported* for information on other options, and *West Manifests* for details on the manifest file format.

manifest file
: The manifest file is a YAML file that defines *projects*, which are the additional Git repositories in the workspace managed by west. The manifest file is named `west.yml` by default; this can be overridden using the `manifest.file` local configuration option.

  You use the *west update* command to update the workspace's projects based on the contents of the manifest file.

projects
: Projects are Git repositories managed by west. Projects are defined in the manifest file and can be located anywhere inside the workspace. In the above example workspace, `zcbor` and `net-tools` are projects.

  By default, the Zephyr *build system* uses west to get the locations of all the projects in the workspace, so any code they contain can be used as *Modules (External projects)*. Note however that modules and projects *are conceptually different*.

extensions
: Any repository known to west (either the manifest repository or any project repository) can define *Extensions*. Extensions are extra west commands you can run when using that workspace.

  The zephyr repository uses this feature to provide Zephyr-specific commands like *west build*. Defining these as extensions keeps west's core agnostic to the specifics of any workspace's Zephyr version, etc.

ignored files
: A workspace can contain additional Git repositories or other files and directories not managed by west. West basically ignores anything in the workspace except `.west`, the manifest repository, and the projects specified in the manifest file.

west init and west update

The two most important workspace-related commands are `west init` and `west update`.

`west init` basics This command creates a west workspace.

> **Important**
>
> West doesn't change your manifest repository contents after `west init` is run. Use ordinary Git commands to pull new versions, etc.

You will typically run it once, like this:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v2.5.0 zephyrproject
```

This will:

1. Create the topdir, `zephyrproject`, along with `.west` and `.west/config` inside it
2. Clone the manifest repository from https://github.com/zephyrproject-rtos/zephyr, placing it into `zephyrproject/zephyr`

3. Check out the `v2.5.0` git tag in your local zephyr clone
4. Set `manifest.path` to `zephyr` in `.west/config`
5. Set `manifest.file` to `west.yml`

Your workspace is now almost ready to use; you just need to run `west update` to clone the rest of the projects into the workspace to finish.

For more details, see *west init*.

`west update` basics This command makes sure your workspace contains Git repositories matching the projects in the manifest file.

Important

Whenever you check out a different revision in your manifest repository, you should run `west update` to make sure your workspace contains the project repositories the new revision expects.

The `west update` command reads the manifest file's contents by:

1. Finding the topdir. In the `west init` example above, that means finding `zephyrproject`.
2. Loading `.west/config` in the topdir to read the `manifest.path` (e.g. `zephyr`) and `manifest.file` (e.g. `west.yml`) options.
3. Loading the manifest file given by these options (e.g. `zephyrproject/zephyr/west.yml`).

It then uses the manifest file to decide where missing projects should be placed within the workspace, what URLs to clone them from, and what Git revisions should be checked out locally. Project repositories which already exist are updated in place by fetching and checking out their respective Git revisions in the manifest file.

For more details, see *west update*.

Other built-in commands

See *Built-in commands*.

Zephyr Extensions

See the following pages for information on Zephyr's extension commands:

- *Building, Flashing and Debugging*
- *Signing Binaries*
- *Additional Zephyr extension commands*
- *Enabling shell completion*

Troubleshooting

See *Troubleshooting West*.

2.11.5 Built-in commands

This page describes west's built-in commands, some of which were introduced in *Basics*, in more detail.

Some commands are related to Git commands with the same name, but operate on the entire workspace. For example, `west diff` shows local changes in multiple Git repositories in the workspace.

Some commands take projects as arguments. These arguments can be project names as specified in the manifest file, or (as a fallback) paths to them on the local file system. Omitting project arguments to commands which accept them (such as `west list`, `west forall`, etc.) usually defaults to using all projects in the manifest file plus the manifest repository itself.

For additional help, run `west <command> -h` (e.g. `west init -h`).

west init

This command creates a west workspace. It can be used in two ways:

1. Cloning a new manifest repository from a remote URL
2. Creating a workspace around an existing local manifest repository

Option 1: to clone a new manifest repository from a remote URL, use:

```
west init [-m URL] [--mr REVISION] [--mf FILE] [directory]
```

The new workspace is created in the given `directory`, creating a new `.west` inside this directory. You can give the manifest URL using the `-m` switch, the initial revision to check out using `--mr`, and the location of the manifest file within the repository using `--mf`.

For example, running:

```
west init -m https://github.com/zephyrproject-rtos/zephyr --mr v1.14.0 zp
```

would clone the upstream official zephyr repository into `zp/zephyr`, and check out the `v1.14.0` release. This command creates `zp/.west`, and set the `manifest.path` *configuration option* to `zephyr` to record the location of the manifest repository in the workspace. The default manifest file location is used.

The `-m` option defaults to `https://github.com/zephyrproject-rtos/zephyr`. The `--mf` option defaults to `west.yml`. Since west v0.10.1, west will use the default branch in the manifest repository unless the `--mr` option is used to override it. (In prior versions, `--mr` defaulted to `master`.)

If no `directory` is given, the current working directory is used.

Option 2: to create a workspace around an existing local manifest repository, use:

```
west init -l [--mf FILE] directory
```

This creates `.west` **next to** `directory` in the file system, and sets `manifest.path` to `directory`.

As above, `--mf` defaults to `west.yml`.

Reconfiguring the workspace:

If you change your mind later, you are free to change `manifest.path` and `manifest.file` using *west config* after running `west init`. Just be sure to run `west update` afterwards to update your workspace to match the new manifest file.

west update

```
west update [-f {always,smart}] [-k] [-r]
            [--group-filter FILTER] [--stats] [PROJECT ...]
```

Which projects are updated:

By default, this command parses the manifest file, usually `west.yml`, and updates each project specified there. If your manifest uses *project groups*, then only the active projects are updated.

To operate on a subset of projects only, give PROJECT argument(s). Each PROJECT is either a project name as given in the manifest file, or a path that points to the project within the workspace. If you specify projects explicitly, they are updated regardless of whether they are active.

Project update procedure:

For each project that is updated, this command:

1. Initializes a local Git repository for the project in the workspace, if it does not already exist
2. Inspects the project's `revision` field in the manifest, and fetches it from the remote if it is not already available locally
3. Sets the project's *manifest-rev* branch to the commit specified by the revision in the previous step
4. Checks out `manifest-rev` in the local working copy as a detached HEAD (see *west update detached HEADs* for details about this choice)
5. If the manifest file specifies a *submodules* key for the project, recursively updates the project's submodules as described below.

To avoid unnecessary fetches, `west update` will not fetch project `revision` values which are Git SHAs or tags that are already available locally. This is the behavior when the `-f` (`--fetch`) option has its default value, `smart`. To force this command to fetch from project remotes even if the revisions appear to be available locally, either use `-f always` or set the `update.fetch` *configuration option* to `always`. SHAs may be given as unique prefixes as long as they are acceptable to Git[1].

If the project `revision` is a Git ref that is neither a tag nor a SHA (i.e. if the project is tracking a branch), `west update` always fetches, regardless of `-f` and `update.fetch`.

Some branch names might look like short SHAs, like `deadbeef`. West treats these like SHAs. You can disambiguate by prefixing the `revision` value with `refs/heads/`, e.g. `revision: refs/heads/deadbeef`.

For safety, `west update` uses `git checkout --detach` to check out a detached `HEAD` at the manifest revision for each updated project, leaving behind any branches which were already checked out. This is typically a safe operation that will not modify any of your local branches.

However, if you had added some local commits onto a previously detached `HEAD` checked out by west, then git will warn you that you've left behind some commits which are no longer referred to by any branch. These may be garbage-collected and lost at some point in the future. To avoid this if you have local commits in the project, make sure you have a local branch checked out before running `west update`.

If you would rather rebase any locally checked out branches instead, use the `-r` (`--rebase`) option.

If you would like `west update` to keep local branches checked out as long as they point to commits that are descendants of the new `manifest-rev`, use the `-k` (`--keep-descendants`) option.

Note

`west update --rebase` will fail in projects that have git conflicts between your branch and new commits brought in by the manifest. You should immediately resolve these conflicts as you usually do with `git`, or you can use `git -C <project_path> rebase --abort` to ignore incoming changes for the moment.

With a clean working tree, a plain `west update` never fails because it does not try to hold on to your commits and simply leaves them aside.

`west update --keep-descendants` offers an intermediate option that never fails either but does not treat all projects the same:

[1] West may fetch all refs from the Git server when given a SHA as a revision. This is because some Git servers have historically not allowed fetching SHAs directly.

- in projects where your branch diverged from the incoming commits, it does not even try to rebase and leaves your branches behind just like a plain `west update` does;
- in all other projects where no rebase or merge is needed it keeps your branches in place.

One-time project group manipulation:

The `--group-filter` option can be used to change which project groups are enabled or disabled for the duration of a single `west update` command. See *Project Groups* for details on the project group feature.

The `west update` command behaves as if the `--group-filter` option's value were appended to the `manifest.group-filter` *configuration option*.

For example, running `west update --group-filter=+foo,-bar` would behave the same way as if you had temporarily appended the string `"+foo,-bar"` to the value of `manifest.group-filter`, run `west update`, then restored `manifest.group-filter` to its original value.

Note that using the syntax `--group-filter=VALUE` instead of `--group-filter VALUE` avoids issues parsing command line options if you just want to disable a single group, e.g. `--group-filter=-bar`.

Submodule update procedure:

If a project in the manifest has a `submodules` key, the submodules are updated as follows, depending on the value of the `submodules` key.

If the project has `submodules: true`, west first synchronizes the project's submodules with:

```
git submodule sync --recursive
```

West then runs one of the following in the project repository, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive
```

Otherwise, the project has `submodules: <list-of-submodules>`. In this case, west synchronizes the project's submodules with:

```
git submodule sync --recursive -- <submodule-path>
```

Then it updates each submodule in the list as follows, depending on whether you run `west update` with the `--rebase` option or without it:

```
# without --rebase, e.g. "west update":
git submodule update --init --checkout --recursive <submodule-path>

# with --rebase, e.g. "west update --rebase":
git submodule update --init --rebase --recursive <submodule-path>
```

The `git submodule sync` commands are skipped if the `update.sync-submodules` *Configuration* option is false.

Other project commands

West has a few more commands for managing the projects in the workspace, which are summarized here. Run `west <command> -h` for detailed help.

- `west compare`: compare the state of the workspace against the manifest
- `west diff`: run `git diff` in local project repositories
- `west forall`: run an arbitrary command in local project repositories
- `west grep`: search for patterns in local project repositories
- `west list`: print a line of information about each project in the manifest, according to a format string
- `west manifest`: manage the manifest file. See *Manifest Command*.
- `west status`: run `git status` in local project repositories

Other built-in commands

Finally, here is a summary of other built-in commands.

- `west config`: get or set *configuration options*
- `west topdir`: print the top level directory of the west workspace
- `west help`: get help about a command, or print information about all commands in the workspace, including *Extensions*

2.11.6 Workspaces

This page describes the *west workspace* concept introduced in *Basics* in more detail.

The `manifest-rev` branch

West creates and controls a Git branch named `manifest-rev` in each project. This branch points to the revision that the manifest file specified for the project at the time *west update* was last run. Other workspace management commands may use `manifest-rev` as a reference point for the upstream revision as of this latest update. Among other purposes, the `manifest-rev` branch allows the manifest file to use SHAs as project revisions.

Although `manifest-rev` is a normal Git branch, west will recreate and/or reset it on the next update. For this reason, it is **dangerous** to check it out or otherwise modify it yourself. For instance, any commits you manually add to this branch may be lost the next time you run `west update`. Instead, check out a local branch with another name, and either rebase it on top of a new `manifest-rev`, or merge `manifest-rev` into it.

Note

West does not create a `manifest-rev` branch in the manifest repository, since west does not manage the manifest repository's branches or revisions.

The `refs/west/*` Git refs

West also reserves all Git refs that begin with `refs/west/` (such as `refs/west/foo`) for itself in local project repositories. Unlike `manifest-rev`, these refs are not regular branches. West's behavior here is an implementation detail; users should not rely on these refs' existence or behavior.

Developing in a git repository

`west` "projects" in a workspace are ordinary git repositories. Left to itself, west only creates and updates the `manifest-rev` branch and the refs under `refs/west/`; the branches you create are yours, and west only rebases them when you ask it to with `west update --rebase`.

That is also why a plain *west update* leaves you on a detached `HEAD`: it checks out the new `manifest-rev` and leaves your branches exactly where they are. See *west update detached HEADs* for the rationale.

> **Note**
>
> Zephyr *modules* and west projects are not the same thing, even though west projects are often also modules; see *Modules vs west projects*. The git workflow below applies to all west projects whether they are Zephyr modules or not.

A workflow which works well when you have local changes is:

1. Create a branch in the repository and commit to it as usual:

   ```
   git -C <repository-path> switch --create <your-branch>
   ```

2. Update your workspace with `west update --rebase`, then look at what changed:

   ```
   west update --rebase
   west compare
   ```

   Your branch stays checked out and is rebased onto the new `manifest-rev`. This is the only time west touches your own branch. If it conflicts, the command fails and you resolve it with git as usual.

3. If you would rather not have west rebase your branch, a plain `west update` will switch away from it instead (unless this causes git conflicts). `west update --keep-descendants` is a third option which never fails. See the `checked out branch behavior` option group in `west update --help`, and *west update* for all the details.

Committing on a detached `HEAD` Do not commit on a detached `HEAD` left behind by `west update`: git warns you that those commits are not reachable from any branch and they may be garbage-collected later. Create a branch for your work instead; or use an alternative git client purposely designed for "branchless" work, like for instance JJ.

Private repositories

You can use west to fetch from private repositories. There is nothing west-specific about this.

The `west update` command essentially runs `git fetch YOUR_PROJECT_URL` when a project's `manifest-rev` branch must be updated to a newly fetched commit. It's up to your environment to make sure the fetch succeeds.

You can either enter the password manually or use any of the credential helpers built in to Git. Since Git has credential storage built in, there is no need for a west-specific feature.

The following sections cover common cases for running `west update` without having to enter your password, as well as how to troubleshoot issues.

Fetching via HTTPS On Windows when fetching from GitHub, recent versions of Git prompt you for your GitHub password in a graphical window once, then store it for future use (in a default installation). Passwordless fetching from GitHub should therefore work "out of the box" on Windows after you have done it once.

In general, you can store your credentials on disk using the "store" git credential helper. See the git-credential-store manual page for details.

To use this helper for all the repositories in your workspace, run:

```
west forall -c "git config credential.helper store"
```

To use this helper on just the projects `foo` and `bar`, run:

```
west forall -c "git config credential.helper store" foo bar
```

To use this helper by default on your computer, run:

```
git config --global credential.helper store
```

On GitHub, you can set up a personal access token to use in place of your account password. (This may be required if your account has two-factor authentication enabled, and may be preferable to storing your account password in plain text even if two-factor authentication is disabled.)

You can use the Git credential store to authenticate with a GitHub PAT (Personal Access Token) like so:

```
echo "https://x-access-token:$GH_TOKEN@github.com" >> ~/.git-credentials
```

If you don't want to store any credentials on the file system, you can store them in memory temporarily using git-credential-cache instead.

If you setup fetching via SSH, you can use Git URL rewrite feature. The following command instructs Git to use SSH URLs for GitHub instead of HTTPS ones:

```
git config --global url."git@github.com:".insteadOf "https://github.com/"
```

Fetching via SSH If your SSH key has no password, fetching should just work. If it does have a password, you can avoid entering it manually every time using ssh-agent.

On GitHub, see Connecting to GitHub with SSH for details on configuration and key creation.

Project locations

Projects can be located anywhere inside the workspace, but they may not "escape" it.

In other words, project repositories need not be located in subdirectories of the manifest repository or as immediate subdirectories of the topdir. However, projects must have paths inside the workspace.

You may replace a project's repository directory within the workspace with a symbolic link to elsewhere on your computer, but west will not do this for you.

Topologies supported

The following are example source code topologies supported by west.

- T1: star topology, zephyr is the manifest repository
- T2: star topology, a Zephyr application is the manifest repository
- T3: forest topology, freestanding manifest repository

T1: Star topology, zephyr is the manifest repository

- The zephyr repository acts as the central repository and specifies its *Modules (External projects)* in its `west.yml`
- Analogy with existing mechanisms: Git submodules with zephyr as the super-project

This is the default. See *Workspace concepts* for how mainline Zephyr is an example of this topology.

T2: Star topology, application is the manifest repository

- Useful for those focused on a single application
- A repository containing a Zephyr application acts as the central repository and names other projects required to build it in its `west.yml`. This includes the zephyr repository and any modules.
- Analogy with existing mechanisms: Git submodules with the application as the superproject, zephyr and other projects as submodules

A workspace using this topology looks like this:

```
west-workspace/
|
├── application/         # .git/     |
|   ├── CMakeLists.txt                |
|   ├── prj.conf                      |  never modified by west
|   ├── src/                          |
|   |   └── main.c                    |
|   └── west.yml         # main manifest with optional import(s) and override(s)
|                                     |
├── modules/
|   └── lib/
|       └── zcbor/       # .git/ project from either the main manifest or some␣
↪import.
|
└── zephyr/              # .git/ project
    └── west.yml         # This can be partially imported with lower precedence or␣
↪ignored.
                         # Only the 'manifest-rev' version can be imported.
```

Here is an example `application/west.yml` which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules into the application manifest file:

```
# Example T2 west.yml, using manifest imports.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
  self:
    path: application
```

You can still selectively "override" individual Zephyr modules if you use `import:` in this way; see *Example 1.3: Downstream of a Zephyr release, with module fork* for an example.

Another way to do the same thing is to copy/paste `zephyr/west.yml` to `application/west.yml`, adding an entry for the zephyr project itself, like this:

```
# Equivalent to the above, but with manually maintained Zephyr modules.
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  defaults:
    remote: zephyrproject-rtos
```

(continues on next page)

(continued from previous page)

```
  projects:
    - name: zephyr
      revision: v2.5.0
      west-commands: scripts/west-commands.yml
    - name: net-tools
      revision: some-sha-goes-here
      path: tools/net-tools
    # ... other Zephyr modules go here ...
  self:
    path: application
```

(The `west-commands` is there for *Building, Flashing and Debugging* and other Zephyr-specific *Extensions*. It's not necessary when using `import`.)

The main advantage to using `import` is not having to track the revisions of imported projects separately. In the above example, using `import` means Zephyr's *module* versions are automatically determined from the `zephyr/west.yml` revision, instead of having to be copy/pasted (and maintained) on their own.

T3: Forest topology

- Useful for those supporting multiple independent applications or downstream distributions with no "central" repository
- A dedicated manifest repository which contains no Zephyr source code, and specifies a list of projects all at the same "level"
- Analogy with existing mechanisms: Google repo-based source distribution

A workspace using this topology looks like this:

```
west-workspace/
├── app1/               # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── app2/               # .git/ project
│   ├── CMakeLists.txt
│   ├── prj.conf
│   └── src/
│       └── main.c
├── manifest-repo/      # .git/ never modified by west
│   └── west.yml        # main manifest with optional import(s) and override(s)
├── modules/
│   └── lib/
│       └── zcbor/      # .git/ project from either the main manifest or
│                       #       from some import
│
└── zephyr/             # .git/ project
    └── west.yml        # This can be partially imported with lower precedence or␣
↪ignored.
                        # Only the 'manifest-rev' version can be imported.
```

Here is an example T3 `manifest-repo/west.yml` which uses *Manifest Imports*, available since west 0.7, to import Zephyr v2.5.0 and its modules, then add the `app1` and `app2` projects:

```
manifest:
  remotes:
```

(continues on next page)

(continued from previous page)

```
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: your-git-server
      url-base: https://git.example.com/your-company
  defaults:
    remote: your-git-server
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v2.5.0
      import: true
    - name: app1
      revision: SOME_SHA_OR_BRANCH_OR_TAG
    - name: app2
      revision: ANOTHER_SHA_OR_BRANCH_OR_TAG
  self:
    path: manifest-repo
```

You can also do this "by hand" by copy/pasting `zephyr/west.yml` as shown *above* for the T2 topology, with the same caveats.

Not supported: workspace topdir as .git repository

Some users have asked for support making the workspace *topdir* a git repository, like this example:

```
my-workspace/                  # workspace topdir
├── .git/                      # puts the entire workspace in a git repository
├── .west/                     # marks the location of the topdir
└── [ ... other projects ...]
```

This is **not** an officially supported topology. As a design decision, west assumes that the workspace topdir itself is not a git repository.

You may be able to make something like this "work" for yourself and your own goals. However, future versions of west might contain changes which can "break" your setup.

2.11.7 West Manifests

This page contains detailed information about west's multiple repository model, manifest files, and the `west manifest` command. For API documentation on the `west.manifest` module, see west-apis-manifest. For a more general introduction and command overview, see *Basics*.

Multiple Repository Model

West's view of the repositories in a *west workspace*, and their history, looks like the following figure (though some parts of this example are specific to upstream Zephyr's use of west):

The history of the manifest repository is the line of Git commits which is "floating" on top of the gray plane. Parent commits point to child commits using solid arrows. The plane below contains the Git commit history of the repositories in the workspace, with each project repository boxed in by a rectangle. Parent/child commit relationships in each repository are also shown with solid arrows.

The commits in the manifest repository (again, for upstream Zephyr this is the zephyr repository itself) each have a manifest file. The manifest file in each commit specifies the corresponding commits which it expects in each of the project repositories. This relationship is shown using

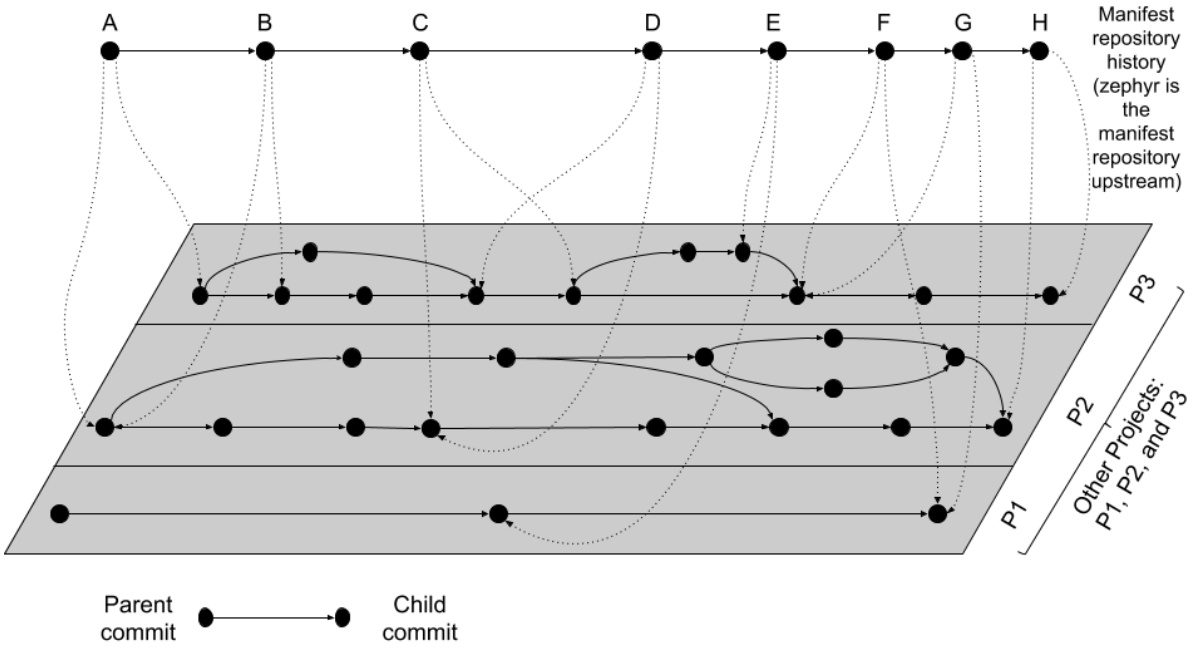


Fig. 3: West multi-repo history

dotted line arrows in the diagram. Each dotted line arrow points from a commit in the manifest repository to a corresponding commit in a project repository.

Notice the following important details:

- Projects can be added (like `P1` between manifest repository commits `D` and `E`) and removed (`P2` between the same manifest repository commits)
- Project and manifest repository histories don't have to move forwards or backwards together:
  - `P2` stays the same from `A → B`, as do `P1` and `P3` from `F → G`.
  - `P3` moves forward from `A → B`.
  - `P3` moves backward from `C → D`.

  One use for moving backward in project history is to "revert" a regression by going back to a revision before it was introduced.
- Project repository commits can be "skipped": `P3` moves forward multiple commits in its history from `B → C`.
- In the above diagram, no project repository has two revisions "at the same time": every manifest file refers to exactly one commit in the projects it cares about. This can be relaxed by using a branch name as a manifest revision, at the cost of being able to bisect manifest repository history.

Manifest Files

West manifests are YAML files. Manifests have a top-level `manifest` section with some subsections, like this:

```
manifest:
  remotes:
    # short names for project URLs
  projects:
```

(continues on next page)

(continued from previous page)

```
    # a list of projects managed by west
  defaults:
    # default project attributes
  self:
    # configuration related to the manifest repository itself,
    # i.e. the repository containing west.yml
  version: "<schema-version>"
  group-filter:
    # a list of project groups to enable or disable
```

In YAML terms, the manifest file contains a mapping, with a `manifest` key. Any other keys and their contents are ignored (west v0.5 also required a `west` key, but this is ignored starting with v0.6).

The manifest contains subsections, like `defaults`, `remotes`, `projects`, and `self`. In YAML terms, the value of the `manifest` key is also a mapping, with these "subsections" as keys. As of west v0.10, all of these "subsection" keys are optional.

The `projects` value is a list of repositories managed by west and associated metadata. We'll discuss it soon, but first we will describe the `remotes` section, which can be used to save typing in the `projects` list.

Remotes The `remotes` subsection contains a sequence which specifies the base URLs where projects can be fetched from.

Each `remotes` element has a name and a "URL base". These are used to form the complete Git fetch URL for each project. A project's fetch URL can be set by appending a project-specific path onto a remote URL base. (As we'll see below, projects can also specify their complete fetch URLs.)

For example:

```
manifest:
  # ...
  remotes:
    - name: remote1
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2
```

The `remotes` keys and their usage are in the following table.

Table 2: remotes keys

Key	Description
`name`	Mandatory; a unique name for the remote.
`url-base`	A prefix that is prepended to the fetch URL for each project with this remote.

Above, two remotes are given, with names `remote1` and `remote2`. Their URL bases are respectively `https://git.example.com/base1` and `https://git.example.com/base2`. You can use SSH URL bases as well; for example, you might use `git@example.com:base1` if `remote1` supported Git over SSH as well. Anything acceptable to Git will work.

Projects The `projects` subsection contains a sequence describing the project repositories in the west workspace. Every project has a unique name. You can specify what Git remote URLs to use when cloning and fetching the projects, what revisions to track, and where the project should be stored on the local file system. Note that west projects *are different from modules*.

Here is an example. We'll assume the `remotes` given above.

```
manifest:
  # [... same remotes as above...]
  projects:
    - name: proj1
      description: the first example project
      remote: remote1
      path: extra/project-1
    - name: proj2
      description: |
        A multi-line description of the second example
        project.
      repo-path: my-path
      remote: remote2
      revision: v1.3
    - name: proj3
      url: https://github.com/user/project-three
      revision: abcde413a111
    - name: proj4
      url: https://github.com/user/project-four
      revision: pull/69/head # GitHub Pull Request
```

In this manifest:

- `proj1` has remote `remote1`, so its Git fetch URL is `https://git.example.com/base1/proj1`. The remote `url-base` is appended with a `/` and the project `name` to form the URL.

  Locally, this project will be cloned at path `extra/project-1` relative to the west workspace's root directory, since it has an explicit `path` attribute with this value.

  Since the project has no `revision` specified, `master` is used by default. The current tip of this branch will be fetched and checked out as a detached `HEAD` when west next updates this project.

- `proj2` has a `remote` and a `repo-path`, so its fetch URL is `https://git.example.com/base2/my-path`. The `repo-path` attribute, if present, overrides the default `name` when forming the fetch URL.

  Since the project has no `path` attribute, its `name` is used by default. It will be cloned into a directory named `proj2`. The commit pointed to by the `v1.3` tag will be checked out when west updates the project.

- `proj3` has an explicit `url`, so it will be fetched from `https://github.com/user/project-three`.

  Its local path defaults to its name, `proj3`. Commit `abcde413a111` will be checked out when it is next updated.

The available project keys and their usage are in the following table. Sometimes we'll refer to the `defaults` subsection; it will be described next.

Table 3: projects elements keys

Key(s)	Description
`name`	Mandatory; a unique name for the project. The name cannot be one of the reserved values "west" or "manifest". The name must be unique in the manifest file.
`description`	Optional, an informational description of the project. Added in west v1.2.0.
`remote`, `url`	Mandatory (one of the two, but not both). If the project has a `remote`, that remote's `url-base` will be combined with the project's `name` (or `repo-path`, if it has one) to form the fetch URL instead. If the project has a `url`, that's the complete fetch URL for the remote Git repository. If the project has neither, the `defaults` section must specify a `remote`, which will be used as the project's remote. Otherwise, the manifest is invalid.
`repo-path`	Optional. If given, this is concatenated on to the remote's `url-base` instead of the project's `name` to form its fetch URL. Projects may not have both `url` and `repo-path` attributes.
`revision`	Optional. The Git revision that `west update` should check out. This will be checked out as a detached HEAD by default, to avoid conflicting with local branch names. If not given, the `revision` value from the `defaults` subsection will be used if present. A project revision can be any fetchable git reference: branch, tag, SHA, pull request,... The default `revision` is `master` if not otherwise specified. Using `HEAD~0`[1] as the `revision` will cause west to keep the current state of the project.
`path`	Optional. Relative path specifying where to clone the repository locally, relative to the top directory in the west workspace. If missing, the project's `name` is used as a directory name.
`clone-depth`	Optional. If given, a positive integer which creates a shallow history in the cloned repository limited to the given number of commits. This can only be used if the `revision` is a branch or tag.
`west-commands`	Optional. If given, a relative path to a YAML file within the project which describes additional west commands provided by that project. This file is named `west-commands.yml` by convention. See *Extensions* for details.
`import`	Optional. If `true`, imports projects from manifest files in the given repository into the current manifest. See *Manifest Imports* for details.
`groups`	Optional, a list of groups the project belongs to. See *Project Groups* for details.
`submodules`	Optional. You can use this to make `west update` also update Git submodules defined by the project. See *Git Submodules in Projects* for details.
`userdata`	Optional. The value is an arbitrary YAML value. See *Repository user data*.

Defaults The `defaults` subsection can provide default values for project attributes. In particular, the default remote name and revision can be specified here. Another way to write the same manifest we have been describing so far using `defaults` is:

```
manifest:
  defaults:
    remote: remote1
    revision: v1.3

  remotes:
```

(continues on next page)

[1] In git, HEAD is a reference, whereas HEAD~<n> is a valid revision but not a reference. West fetches references, such as refs/heads/main or HEAD, and commits not available locally, but will not fetch commits if they are already available. HEAD~0 is resolved to a specific commit that is locally available, and therefore west will simply checkout the locally available commit, identified by HEAD~0.

(continued from previous page)

```
    - name: remote1
      url-base: https://git.example.com/base1
    - name: remote2
      url-base: https://git.example.com/base2

  projects:
    - name: proj1
      description: the first example project
      path: extra/project-1
      revision: master
    - name: proj2
      description: |
        A multi-line description of the second example
        project.
      repo-path: my-path
      remote: remote2
    - name: proj3
      url: https://github.com/user/project-three
      revision: abcde413a111
```

The available `defaults` keys and their usage are in the following table.

Table 4: defaults keys

Key	Description
`remote`	Optional. This will be used for a project's `remote` if it does not have a `url` or `remote` key set.
`revision`	Optional. This will be used for a project's `revision` if it does not have one set. If not given, the default is `master`.

Self The `self` subsection can be used to control the manifest repository itself.

As an example, let's consider this snippet from the zephyr repository's `west.yml`:

```
manifest:
  # ...
  self:
    path: zephyr
    west-commands: scripts/west-commands.yml
```

This ensures that the zephyr repository is cloned into path `zephyr`, though as explained above that would have happened anyway if cloning from the default manifest URL, `https://github.com/zephyrproject-rtos/zephyr`. Since the zephyr repository does contain extension commands, its `self` entry declares the location of the corresponding `west-commands.yml` relative to the repository root.

The available `self` keys and their usage are in the following table.

Table 5: self keys

Key	Description
path	Optional. The path `west init` should clone the manifest repository into, relative to the west workspace topdir. If not given, the basename of the path component in the manifest repository URL will be used by default. For example, if the URL is `https://git.example.com/project-repo`, the manifest repository would be cloned to the directory `project-repo`.
west-commands	Optional. This is analogous to the same key in a project sequence element.
import	Optional. This is also analogous to the `projects` key, but allows importing projects from other files in the manifest repository. See *Manifest Imports*.

Version The `version` subsection declares that the manifest file uses features which were introduced in some version of west. Attempts to load the manifest with older versions of west will fail with an error message that explains the minimum required version of west which is needed.

Here is an example:

```
manifest:
  # Marks that this file uses version 0.10 of the west manifest
  # file format.
  #
  # An attempt to load this manifest file with west v0.8.0 will
  # fail with an error message saying that west v0.10.0 or
  # later is required.
  version: "0.10"
```

The pykwalify schema `manifest-schema.yml` in the west source code repository is used to validate the manifest section.

Here is a table with the valid `version` values, along with information about the manifest file features that were introduced in that version.

version	New features
"0.7"	Initial support for the version feature. All manifest file features that are not otherwise mentioned in this table were introduced in west v0.7.0 or earlier.
"0.8"	Support for import: path-prefix: (*Option 3: Mapping*)
"0.9"	**Use of west v0.9.x is discouraged.** This schema version is provided to allow users to explicitly request compatibility with west *v0.9.0*. However, west *v0.10.0* and later have incompatible behavior for features that were introduced in west v0.9.0. You should ignore version "0.9" if possible.
"0.10"	Support for: • submodules: in projects: (*Git Submodules in Projects*) • manifest: group-filter:, and groups: in projects: (*Project Groups*) • The import: feature now supports allowlist: and blocklist:; these are respectively recommended as replacements for older names as part of a general Zephyr-wide inclusive language change. The older key names are still supported for backwards compatibility. (*Manifest Imports*, *Option 3: Mapping*)
"0.12"	Support for userdata: in projects: (*Repository user data*)
"0.13"	Support for self: userdata: (*Repository user data*)
"1.0"	Identical to "0.13", but available for use by users that do not wish to use a "0.x" version field.
"1.2"	Support for description: in projects: (*Projects*)

Note

Versions of west without any new features in the manifest file format do not change the list of valid version values. For example, version: "0.11" is **not** valid, because west v0.11.x did not introduce new manifest file format features.

Quoting the version value as shown above forces the YAML parser to treat it as a string. Without quotes, 0.10 in YAML is just the floating point value 0.1. You can omit the quotes if the value is the same when cast to string, but it's best to include them. Always use quotes if you're not sure.

If you do not include a version in your manifest, each new release of west assumes that it should try to load it using the features that were available in that release. This may result in error messages that are harder to understand if that version of west is too old to load the manifest.

Group-filter See *Project Groups*.

Active and Inactive Projects

Projects defined in the west manifest can be *inactive* or *active*. The difference is that an inactive project is generally ignored by west. For example, west update will not update inactive projects, and west list will not print information about them by default. As another example, any *Manifest Imports* in an inactive project will be ignored by west.

There are two ways to make a project inactive:

1. Using the manifest.project-filter configuration option. If a project is made active or inactive using this option, then the rules related to making a project inactive using its groups: are ignored. That is, if a regular expression in manifest.project-filter applies to a project, the project's groups have no effect on whether it is active or inactive.

   See the entry for this option in *Built-in Configuration Options* for details.

2. Otherwise, if a project has groups, and they are all disabled, then the project is inactive.

   See the following section for details.

Project Groups

You can use the `groups` and `group-filter` keys briefly described *above* to place projects into groups, and to enable or disable groups.

For example, this lets you run a `west forall` command only on the projects in the group by using `west forall --group`. This can also let you make projects inactive; see the previous section for more information on inactive projects.

The next section introduces project groups. The following section describes *Enabled and Disabled Project Groups*. There are some basic examples in *Project Group Examples*. Finally, *Group Filters and Imports* provides a simplified overview of how `group-filter` interacts with the *Manifest Imports* feature.

Groups Basics The `groups:` and `group-filter:` keys appear in the manifest like this:

```
manifest:
  projects:
    - name: some-project
      groups: ...
  group-filter: ...
```

The `groups` key's value is a list of group names. Group names are strings.

You can enable or disable project groups using `group-filter`. Projects whose groups are all disabled, and which are not otherwise made active by a `manifest.project-filter` configuration option, are inactive.

For example, in this manifest fragment:

```
manifest:
  projects:
    - name: project-1
      groups:
        - groupA
    - name: project-2
      groups:
        - groupB
        - groupC
    - name: project-3
```

The projects are in these groups:

- `project-1`: one group, named `groupA`
- `project-2`: two groups, named `groupB` and `groupC`
- `project-3`: no groups

Project group names must not contain commas (,), colons (:), or whitespace.

Group names must not begin with a dash (-) or the plus sign (+), but they may contain these characters elsewhere in their names. For example, `foo-bar` and `foo+bar` are valid groups, but `-foobar` and `+foobar` are not.

Group names are otherwise arbitrary strings. Group names are case sensitive.

As a restriction, no project may use both `import:` and `groups:`. (This is necessary to avoid some pathological edge cases.)

Enabled and Disabled Project Groups All project groups are enabled by default. You can enable or disable groups in both your manifest file and *Configuration*.

Within a manifest file, `manifest: group-filter:` is a YAML list of groups to enable and disable.

To enable a group, prefix its name with a plus sign (+). For example, `groupA` is enabled in this manifest fragment:

```
manifest:
  group-filter: [+groupA]
```

Although this is redundant for groups that are already enabled by default, it can be used to override settings in an imported manifest file. See *Group Filters and Imports* for more information.

To disable a group, prefix its name with a dash (-). For example, `groupA` and `groupB` are disabled in this manifest fragment:

```
manifest:
  group-filter: [-groupA,-groupB]
```

Note

Since `group-filter` is a YAML list, you could have written this fragment as follows:

```
manifest:
  group-filter:
    - -groupA
    - -groupB
```

However, this syntax is harder to read and therefore discouraged.

In addition to the manifest file, you can control which groups are enabled and disabled using the `manifest.group-filter` configuration option. This option is a comma-separated list of groups to enable and/or disable.

To enable a group, add its name to the list prefixed with `+`. To disable a group, add its name prefixed with `-`. For example, setting `manifest.group-filter` to `+groupA,-groupB` enables `groupA`, and disables `groupB`.

The value of the configuration option overrides any data in the manifest file. You can think of this as if the `manifest.group-filter` configuration option is appended to the `manifest: group-filter:` list from YAML, with "last entry wins" semantics.

Practical Example: Reducing Workspace Downloads By default, `west update` fetches all active projects defined in the manifest. Large workspaces may include optional modules, vendor HALs, experimental components, or platform-specific dependencies and vulnerabilities that are not required for every workflow.

Project groups can be used to control which grouped projects are considered active during `west` operations.

For example, consider the following manifest fragment:

```
manifest:
  projects:
    - name: hal_nordic
      groups:
        - nordic
    - name: hal_stm32
      groups:
```

(continues on next page)

(continued from previous page)

```
      - stm32
  - name: experimental_lib
    groups:
      - optional
```

A workspace targeting Nordic devices can disable the `stm32` and `optional` groups before running `west update`:

```
west config manifest.group-filter -- "-stm32,-optional"
```

After configuring the filter, running:

```
west update
```

This skips projects that belong only to disabled groups.

Note

Project groups only affect projects explicitly assigned to matching groups in the manifest. Projects without matching group definitions remain active regardless of the configured `manifest.group-filter` value.

Note

Changing `manifest.group-filter` does not automatically remove repositories already cloned into the workspace. It affects whether projects are considered active during subsequent `west` operations.

This workflow can help reduce unnecessary downloads and simplify workspace management in large multi-project environments.

Project Group Examples This section contains example situations involving project groups and active projects. The examples use both `manifest: group-filter:` YAML lists and `manifest.group-filter` configuration lists, to show how they work together.

Note that the `defaults` and `remotes` data in the following manifests isn't relevant except to make the examples complete and self-contained.

Note

In all of the examples that follow, the `manifest.project-filter` option is assumed to be unset.

Example 1: no disabled groups The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB
```

(continues on next page)

(continued from previous page)

```
    - name: baz

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

No groups are disabled, because all groups are enabled by default. Therefore, all three projects (`foo`, `bar`, and `baz`) are active. Note that there is no way to make project `baz` inactive, since it has no groups.

Example 2: Disabling one group via manifest The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Since `groupA` is disabled, project `foo` is inactive. Project `bar` is active, because `groupB` is enabled.

Example 3: Disabling multiple groups via manifest The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
```

(continues on next page)

(continued from previous page)

```
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is not set (you can ensure this by running `west config -D manifest.group-filter`).

Both `foo` and `bar` are inactive, because all of their groups are disabled.

Example 4: Disabling a group via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
      groups:
        - groupA
    - name: bar
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `-groupA` (you can ensure this by running `west config manifest.group-filter -- -groupA`; the extra `--` is required so the argument parser does not treat `-groupA` as a command line option `-g` with value `roupA`).

Project `foo` is inactive because `groupA` has been disabled by the `manifest.group-filter` configuration option. Project `bar` is active because `groupB` is enabled.

Example 5: Overriding a disabled group via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  group-filter: [-groupA]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The `manifest.group-filter` configuration option is set to `+groupA` (you can ensure this by running `west config manifest.group-filter +groupA`).

In this case, groupA is enabled: the manifest.group-filter configuration option has higher precedence than the manifest: group-filter: [-groupA] content in the manifest file.

Therefore, projects foo and bar are both active.

Example 6: Overriding multiple disabled groups via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  group-filter: [-groupA,-groupB]

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The manifest.group-filter configuration option is set to +groupA,+groupB (you can ensure this by running west config manifest.group-filter "+groupA,+groupB").

In this case, both groupA and groupB are enabled, because the configuration value overrides the manifest file for both groups.

Therefore, projects foo and bar are both active.

Example 7: Disabling multiple groups via configuration The entire manifest file is:

```
manifest:
  projects:
    - name: foo
    - name: bar
      groups:
        - groupA
    - name: baz
      groups:
        - groupA
        - groupB

  defaults:
    remote: example-remote
  remotes:
    - name: example-remote
      url-base: https://git.example.com
```

The manifest.group-filter configuration option is set to -groupA,-groupB (you can ensure this by running west config manifest.group-filter -- "-groupA,-groupB").

In this case, both groupA and groupB are disabled.

Therefore, projects foo and bar are both inactive.

Group Filters and Imports This section provides a simplified description of how the `manifest: group-filter:` value behaves when combined with *Manifest Imports*. For complete details, see *Manifest Import Details*.

Warning

The below semantics apply to west v0.10.0 and later. West v0.9.x semantics are different, and combining `group-filter` with `import` in west v0.9.x is discouraged.

In short:

- if you only import one manifest, any groups it disables in its `group-filter` are also disabled in your manifest
- you can override this in your manifest file's `manifest: group-filter:` value, your workspace's `manifest.group-filter` configuration option, or both

Here are some examples.

Example 1: no overrides You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only `child` and `project-2` are active in the resolved manifest.

The `unstable` group is disabled in `child/west.yml`, and that is not overridden in `parent/west.yml`. Therefore, the final `group-filter` for the resolved manifest is `[-unstable]`.

Since `project-1` and `project-3` are in the `unstable` group and are not in any other group, they are inactive.

Example 2: overriding an imported `group-filter` via manifest You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  group-filter: [+unstable,-optional]
```

(continues on next page)

(continued from previous page)

```
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

Only the `child`, `project-1`, and `project-3` projects are active.

The `[-unstable]` group filter in `child/west.yml` is overridden in `parent/west.yml`, so the `unstable` group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same `parent/west.yml` file disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` is `[+unstable,-optional]`.

Example 3: overriding an imported `group-filter` via configuration You are using this `parent/west.yml` manifest:

```
# parent/west.yml:
manifest:
  projects:
    - name: child
      url: https://git.example.com/child
      import: true
    - name: project-1
      url: https://git.example.com/project-1
      groups:
        - unstable
```

And `child/west.yml` contains:

```
# child/west.yml:
manifest:
  group-filter: [-unstable]
  projects:
    - name: project-2
      url: https://git.example.com/project-2
      groups:
        - optional
```

(continues on next page)

(continued from previous page)

```
    - name: project-3
      url: https://git.example.com/project-3
      groups:
        - unstable
```

If you run:

```
west config manifest.group-filter +unstable,-optional
```

Then only the `child`, `project-1`, and `project-3` projects are active.

The `-unstable` group filter in `child/west.yml` is overridden in the `manifest.group-filter` configuration option, so the `unstable` group is enabled. Since `project-1` and `project-3` are in the `unstable` group, they are active.

The same configuration option disables the `optional` group, so `project-2` is inactive.

The final group filter specified by `parent/west.yml` and the `manifest.group-filter` configuration option is `[+unstable,-optional]`.

Git Submodules in Projects

You can use the `submodules` keys briefly described *above* to force `west update` to also handle any Git submodules configured in project's git repository. The `submodules` key can appear inside `projects`, like this:

```
manifest:
  projects:
    - name: some-project
      submodules: ...
```

The `submodules` key can be a boolean or a list of mappings. We'll describe these in order.

Option 1: Boolean This is the easiest way to use `submodules`.

If `submodules` is `true` as a `projects` attribute, `west update` will recursively update the project's Git submodules whenever it updates the project itself. If it's `false` or missing, it has no effect.

For example, let's say you have a source code repository `foo`, which has some submodules, and you want `west update` to keep all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules: true
    - name: bar
```

Here, `west update` will initialize and update all submodules in `foo`. If `bar` has any submodules, they are ignored, because `bar` does not have a `submodules` value.

Option 2: List of mappings The `submodules` key may be a list of mappings, one list element for each desired submodule. Each submodule listed is updated recursively. You can still track and update unlisted submodules with `git` commands manually; present or not they will be completely ignored by `west`.

The `path` key must match exactly the path of one submodule relative to its parent west project, as shown in the output of `git submodule status`. The `name` key is optional and not used by west

for now; it's not passed to `git submodule` commands either. The `name` key was briefly mandatory in west version 0.9.0, but was made optional in 0.9.1.

For example, let's say you have a source code repository `foo`, which has many submodules, and you want `west update` to keep some but not all of them in sync, along with another project named `bar` in the same workspace.

You can do that with this manifest file:

```
manifest:
  projects:
    - name: foo
      submodules:
        - path: path/to/foo-first-sub
        - name: foo-second-sub
          path: path/to/foo-second-sub
    - name: bar
```

Here, `west update` will recursively initialize and update just the submodules in `foo` with paths `path/to/foo-first-sub` and `path/to/foo-second-sub`. Any submodules in `bar` are still ignored.

Repository user data

West versions v0.12 and later support an optional `userdata` key in projects.

West versions v0.13 and later supports this key in the `manifest: self:` section.

It is meant for consumption by programs that require user-specific project metadata. Beyond parsing it as YAML, west itself ignores the value completely.

The key's value is arbitrary YAML. West parses the value and makes it accessible to programs using west-apis as the `userdata` attribute of the corresponding `west.manifest.Project` object.

Example manifest fragment:

```
manifest:
  projects:
    - name: foo
    - name: bar
      userdata: a-string
    - name: baz
      userdata:
        key: value
  self:
    userdata: blub
```

Example Python usage:

```
manifest = west.manifest.Manifest.from_file()

foo, bar, baz = manifest.get_projects(['foo', 'bar', 'baz'])

foo.userdata # None
bar.userdata # 'a-string'
baz.userdata # {'key': 'value'}
manifest.userdata # 'blub'
```

Manifest Imports

You can use the `import` key briefly described above to include projects from other manifest files in your `west.yml`. This key can be either a `project` or `self` section attribute:

```
manifest:
  projects:
    - name: some-project
      import: ...
  self:
    import: ...
```

You can use a "self: import:" to load additional files from the repository containing your `west.yml`. You can use a "project: ... import:" to load additional files defined in that project's Git history.

West resolves the final manifest from individual manifest files in this order:

1. imported files in `self`
2. your `west.yml` file
3. imported files in `projects`

During resolution, west ignores projects which have already been defined in other files. For example, a project named `foo` in your `west.yml` makes west ignore other projects named `foo` imported from your `projects` list.

The `import` key can be a boolean, path, mapping, or sequence. We'll describe these in order, using examples:

- *Boolean*
  - *Example 1.1: Downstream of a Zephyr release*
  - *Example 1.2: "Rolling release" Zephyr downstream*
  - *Example 1.3: Downstream of a Zephyr release, with module fork*
- *Relative path*
  - *Example 2.1: Downstream of a Zephyr release with explicit path*
  - *Example 2.2: Downstream with directory of manifest files*
  - *Example 2.3: Continuous Integration overrides*
- *Mapping with additional configuration*
  - *Example 3.1: Downstream with name allowlist*
  - *Example 3.2: Downstream with path allowlist*
  - *Example 3.3: Downstream with path blocklist*
  - *Example 3.4: Import into a subdirectory*
- *Sequence of paths and mappings*
  - *Example 4.1: Downstream with sequence of manifest files*
  - *Example 4.2: Import order illustration*

A more *formal description* of how this works is last, after the examples.

Troubleshooting Note If you're using this feature and find west's behavior confusing, try *resolving your manifest* to see the final results after imports are done.

Option 1: Boolean This is the easiest way to use `import`.

If `import` is `true` as a `projects` attribute, west imports projects from the `west.yml` file in that project's root directory. If it's `false` or missing, it has no effect. For example, this manifest would import `west.yml` from the `p1` git repository at revision `v1.0`:

```
manifest:
  # ...
  projects:
    - name: p1
      revision: v1.0
      import: true    # Import west.yml from p1's v1.0 git tag
    - name: p2
      import: false   # Nothing is imported from p2.
    - name: p3        # Nothing is imported from p3 either.
```

It's an error to set `import` to either `true` or `false` inside `self`, like this:

```
manifest:
  # ...
  self:
    import: true  # Error
```

Example 1.1: Downstream of a Zephyr release You have a source code repository you want to use with Zephyr v1.14.1 LTS. You want to maintain the whole thing using west. You don't want to modify any of the mainline repositories.

In other words, the west workspace you want looks like this:

```
my-downstream/
├── .west/                    # west directory
├── zephyr/                   # mainline zephyr repository
|   └── west.yml              # the v1.14.1 version of this file is imported
├── modules/                  # modules from mainline zephyr
|   ├── hal/
|   └── [...other directories..]
├── [ ... other projects ...]  # other mainline repositories
└── my-repo/                  # your downstream repository
    ├── west.yml              # main manifest importing zephyr/west.yml v1.14.1
    └── [...other files..]
```

You can do this with the following `my-repo/west.yml`:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: true
```

You can then create the workspace on your computer like this, assuming `my-repo` is hosted at `https://git.example.com/my-repo`:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

After `west init`, `my-downstream/my-repo` will be cloned.

After `west update`, all of the projects defined in the `zephyr` repository's `west.yml` at revision `v1.14.1` will be cloned into `my-downstream` as well.

You can add and commit any code to `my-repo` you please at this point, including your own Zephyr applications, drivers, etc. See *Application Development*.

Example 1.2: "Rolling release" Zephyr downstream This is similar to *Example 1.1: Downstream of a Zephyr release*, except we'll use `revision: main` for the zephyr repository:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
```

You can create the workspace in the same way:

```
west init -m https://git.example.com/my-repo my-downstream
cd my-downstream
west update
```

This time, whenever you run `west update`, the special *manifest-rev* branch in the `zephyr` repository will be updated to point at a newly fetched `main` branch tip from the URL https://github.com/zephyrproject-rtos/zephyr.

The contents of `zephyr/west.yml` at the new `manifest-rev` will then be used to import projects from Zephyr. This lets you stay up to date with the latest changes in the Zephyr project. The cost is that running `west update` will not produce reproducible results, since the remote `main` branch can change every time you run it.

It's also important to understand that west **ignores your working tree's** `zephyr/west.yml` entirely when resolving imports. West always uses the contents of imported manifests as they were committed to the latest `manifest-rev` when importing from a project.

You can only import manifest from the file system if they are in your manifest repository's working tree. See *Example 2.2: Downstream with directory of manifest files* for an example.

Example 1.3: Downstream of a Zephyr release, with module fork This manifest is similar to the one in *Example 1.1: Downstream of a Zephyr release*, except it:

- is a downstream of Zephyr 2.0
- includes a downstream fork of the `modules/hal/nordic` *module* which was included in that release

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
    - name: my-remote
      url-base: https://git.example.com
  projects:
    - name: hal_nordic          # higher precedence
      remote: my-remote
      revision: my-sha
      path: modules/hal/nordic
    - name: zephyr
```

(continues on next page)

(continued from previous page)

```
      remote: zephyrproject-rtos
      revision: v2.0.0
      import: true             # imported projects have lower precedence

# subset of zephyr/west.yml contents at v2.0.0:
manifest:
  defaults:
    remote: zephyrproject-rtos
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
  # ...
  - name: hal_nordic           # lower precedence, values ignored
    path: modules/hal/nordic
    revision: another-sha
```

With this manifest file, the project named `hal_nordic`:

- is cloned from `https://git.example.com/hal_nordic` instead of `https://github.com/zephyrproject-rtos/hal_nordic`.
- is updated to commit `my-sha` by `west update`, instead of the mainline commit `another-sha`

In other words, when your top-level manifest defines a project, like `hal_nordic`, west will ignore any other definition it finds later on while resolving imports.

This does mean you have to copy the `path: modules/hal/nordic` value into `my-repo/west.yml` when defining `hal_nordic` there. The value from `zephyr/west.yml` is ignored entirely. See *Resolving Manifests* for troubleshooting advice if this gets confusing in practice.

When you run `west update`, west will:

- update zephyr's `manifest-rev` to point at the `v2.0.0` tag
- import `zephyr/west.yml` at that `manifest-rev`
- locally check out the `v2.0.0` revisions for all zephyr projects except `hal_nordic`
- update `hal_nordic` to `my-sha` instead of `another-sha`

Option 2: Relative path The `import` value can also be a relative path to a manifest file or a directory containing manifest files. The path is relative to the root directory of the `projects` or `self` repository the `import` key appears in.

Here is an example:

```
manifest:
  projects:
    - name: project-1
      revision: v1.0
      import: west.yml
    - name: project-2
      revision: main
      import: p2-manifests
  self:
    import: submanifests
```

This will import the following:

- the contents of `project-1/west.yml` at `manifest-rev`, which points at tag `v1.0` after running `west update`

- any YAML files in the directory tree `project-2/p2-manifests` at the latest commit in the `main` branch, as fetched by `west update`, sorted by file name
- YAML files in `submanifests` in your manifest repository, as they appear on your file system, sorted by file name

Notice how `projects` imports get data from Git using `manifest-rev`, while `self` imports get data from your file system. This is because as usual, west leaves version control for your manifest repository up to you.

Example 2.1: Downstream of a Zephyr release with explicit path This is an explicit way to write an equivalent manifest to the one in *Example 1.1: Downstream of a Zephyr release*.

```
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: v1.14.1
      import: west.yml
```

The setting `import: west.yml` means to use the file `west.yml` inside the `zephyr` project. This example is contrived, but shows the idea.

This can be useful in practice when the name of the manifest file you want to import is not `west.yml`.

Example 2.2: Downstream with directory of manifest files Your Zephyr downstream has a lot of additional repositories. So many, in fact, that you want to split them up into multiple manifest files, but keep track of them all in a single manifest repository, like this:

```
my-repo/
├── submanifests
│   ├── 01-libraries.yml
│   ├── 02-vendor-hals.yml
│   └── 03-applications.yml
└── west.yml
```

You want to add all the files in `my-repo/submanifests` to the main manifest file, `my-repo/west.yml`, in addition to projects in `zephyr/west.yml`. You want to track the latest development code in the Zephyr repository's `main` branch instead of using a fixed revision.

Here's how:

```
# my-repo/west.yml:
manifest:
  remotes:
    - name: zephyrproject-rtos
      url-base: https://github.com/zephyrproject-rtos
  projects:
    - name: zephyr
      remote: zephyrproject-rtos
      revision: main
      import: true
  self:
    import: submanifests
```

Manifest files are imported in this order during resolution:

1. `my-repo/submanifests/01-libraries.yml`
2. `my-repo/submanifests/02-vendor-hals.yml`
3. `my-repo/submanifests/03-applications.yml`
4. `my-repo/west.yml`
5. `zephyr/west.yml`

Note

The `.yml` file names are prefixed with numbers in this example to make sure they are imported in the specified order.

You can pick arbitrary names. West sorts files in a directory by name before importing.

Notice how the manifests in `submanifests` are imported *before* `my-repo/west.yml` and `zephyr/west.yml`. In general, an `import` in the `self` section is processed before the manifest files in `projects` and the main manifest file.

This means projects defined in `my-repo/submanifests` take highest precedence. For example, if `01-libraries.yml` defines `hal_nordic`, the project by the same name in `zephyr/west.yml` is simply ignored. As usual, see *Resolving Manifests* for troubleshooting advice.

This may seem strange, but it allows you to redefine projects "after the fact", as we'll see in the next example.

Example 2.3: Continuous Integration overrides Your continuous integration system needs to fetch and test multiple repositories in your west workspace from a developer's forks instead of your mainline development trees, to see if the changes all work well together.

Starting with *Example 2.2: Downstream with directory of manifest files*, the CI scripts add a file `00-ci.yml` in `my-repo/submanifests`, with these contents:

```
# my-repo/submanifests/00-ci.yml:
manifest:
  projects:
    - name: a-vendor-hal
      url: https://github.com/a-developer/hal
      revision: a-pull-request-branch
    - name: an-application
      url: https://github.com/a-developer/application
      revision: another-pull-request-branch
```

The CI scripts run `west update` after generating this file in `my-repo/submanifests`. The projects defined in `00-ci.yml` have higher precedence than other definitions in `my-repo/submanifests`, because the name `00-ci.yml` comes before the other file names.

Thus, `west update` always checks out the developer's branches in the projects named `a-vendor-hal` and `an-application`, even if those same projects are also defined elsewhere.

Option 3: Mapping The `import` key can also contain a mapping with the following keys:

- `file`: Optional. The name of the manifest file or directory to import. This defaults to `west.yml` if not present.
- `name-allowlist`: Optional. If present, a name or sequence of project names to include.
- `path-allowlist`: Optional. If present, a path or sequence of project paths to match against. This is a shell-style globbing pattern, currently implemented with pathlib. Note that this means case sensitivity is platform specific.

- `name-blocklist`: Optional. Like `name-allowlist`, but contains project names to exclude rather than include.
- `path-blocklist`: Optional. Like `path-allowlist`, but contains project paths to exclude rather than include.
- `path-prefix`: Optional (new in v0.8.0). If given, this will be prepended to the project's path in the workspace, as well as the paths of any imported projects. This can be used to place these projects in a subdirectory of the workspace.

Allowlists override blocklists if both are given. For example, if a project is blocked by path, then allowed by name, it will still be imported.

Example 3.1: Downstream with name allowlist Here is a pair of manifest files, representing a mainline and a downstream. The downstream doesn't want to use all the mainline projects, however. We'll assume the mainline `west.yml` is hosted at `https://git.example.com/mainline/manifest`.

```
# mainline west.yml:
manifest:
  projects:
    - name: mainline-app                # included
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                        # included
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        name-allowlist:
          - mainline-app
          - lib2
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: downstream-app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
    - name: mainline-app                # imported
      path: examples/app
```

(continues on next page)

(continued from previous page)

```
      url: https://git.example.com/mainline/app
    - name: lib2                          # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
```

If an allowlist had not been used, the `lib` project from the mainline manifest would have been imported.

Example 3.2: Downstream with path allowlist Here is an example showing how to allowlist mainline's libraries only, using `path-allowlist`.

```
# mainline west.yml:
manifest:
  projects:
    - name: app
      path: examples/app
      url: https://git.example.com/mainline/app
    - name: lib
      path: libraries/lib                 # included
      url: https://git.example.com/mainline/lib
    - name: lib2
      path: libraries/lib2                # included
      url: https://git.example.com/mainline/lib2

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-allowlist: libraries/*
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

An equivalent manifest in a single file would be:

```
manifest:
  projects:
    - name: lib                         # imported
      path: libraries/lib
      url: https://git.example.com/mainline/lib
    - name: lib2                        # imported
      path: libraries/lib2
      url: https://git.example.com/mainline/lib2
    - name: mainline
      url: https://git.example.com/mainline/manifest
    - name: app
      url: https://git.example.com/downstream/app
    - name: lib3
      path: libraries/lib3
      url: https://git.example.com/downstream/lib3
```

Example 3.3: Downstream with path blocklist Here's an example showing how to block all vendor HALs from mainline by common path prefix in the workspace, add your own version for the chip you're targeting, and keep everything else.

```
# mainline west.yml:
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app
    - name: lib
      path: libraries/lib
    - name: lib2
      path: libraries/lib2
    - name: hal_foo
      path: modules/hals/foo     # excluded
    - name: hal_bar
      path: modules/hals/bar     # excluded
    - name: hal_baz
      path: modules/hals/baz     # excluded

# downstream west.yml:
manifest:
  projects:
    - name: mainline
      url: https://git.example.com/mainline/manifest
      import:
        path-blocklist: modules/hals/*
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

An equivalent manifest in a single file would be:

```
manifest:
  defaults:
    remote: mainline
  remotes:
    - name: mainline
      url-base: https://git.example.com/mainline
  projects:
    - name: app                  # imported
    - name: lib                  # imported
      path: libraries/lib
    - name: lib2                 # imported
      path: libraries/lib2
    - name: mainline
      repo-path: https://git.example.com/mainline/manifest
    - name: hal_foo
      path: modules/hals/foo
      url: https://git.example.com/downstream/hal_foo
```

Example 3.4: Import into a subdirectory You want to import a manifest and its projects, placing everything into a subdirectory of your *west workspace*.

For example, suppose you want to import this manifest from project `foo`, adding this project and its projects `bar` and `baz` to your workspace:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: bar
    - name: baz
```

Instead of importing these into the top level workspace, you want to place all three project repositories in an `external-code` subdirectory, like this:

```
workspace/
└── external-code/
    ├── foo/
    ├── bar/
    └── baz/
```

You can do this using this manifest:

```
manifest:
  projects:
    - name: foo
      url: https://git.example.com/foo
      import:
        path-prefix: external-code
```

An equivalent manifest in a single file would be:

```
# foo/west.yml:
manifest:
  defaults:
    remote: example
  remotes:
    - name: example
      url-base: https://git.example.com
  projects:
    - name: foo
      path: external-code/foo
    - name: bar
      path: external-code/bar
    - name: baz
      path: external-code/baz
```

Option 4: Sequence The `import` key can also contain a sequence of files, directories, and mappings.

Example 4.1: Downstream with sequence of manifest files This example manifest is equivalent to the manifest in *Example 2.2: Downstream with directory of manifest files*, with a sequence of explicitly named files.

```
# my-repo/west.yml:
manifest:
  projects:
    - name: zephyr
      url: https://github.com/zephyrproject-rtos/zephyr
      import: west.yml
  self:
    import:
      - submanifests/01-libraries.yml
      - submanifests/02-vendor-hals.yml
      - submanifests/03-applications.yml
```

Example 4.2: Import order illustration This more complicated example shows the order that west imports manifest files:

```
# my-repo/west.yml
manifest:
  # ...
  projects:
    - name: my-library
    - name: my-app
    - name: zephyr
      import: true
    - name: another-manifest-repo
      import: submanifests
  self:
    import:
      - submanifests/libraries.yml
      - submanifests/vendor-hals.yml
      - submanifests/applications.yml
  defaults:
    remote: my-remote
```

For this example, west resolves imports in this order:

1. the listed files in `my-repo/submanifests` are first, in the order they occur (e.g. `libraries.yml` comes before `applications.yml`, since this is a sequence of files), since the `self: import:` is always imported first
2. `my-repo/west.yml` is next (with projects `my-library` etc. as long as they weren't already defined somewhere in `submanifests`)
3. `zephyr/west.yml` is after that, since that's the first `import` key in the `projects` list in `my-repo/west.yml`
4. files in `another-manifest-repo/submanifests` are last (sorted by file name), since that's the final project `import`

Manifest Import Details This section describes how west resolves a manifest file that uses `import` a bit more formally.

Overview The `import` key can appear in a west manifest's `projects` and `self` sections. The general case looks like this:

```
# Top-level manifest file.
manifest:
  projects:
```

(continues on next page)

(continued from previous page)

```
  - name: foo
    import:
      ... # import-1
  - name: bar
    import:
      ... # import-2
  # ...
  - name: baz
    import:
      ... # import-N
self:
  import:
    ... # self-import
```

Import keys are optional. If any of `import-1`, `...`, `import-N` are missing, west will not import additional manifest data from that project. If `self-import` is missing, no additional files in the manifest repository (beyond the top-level file) are imported.

The ultimate outcomes of resolving manifest imports are:

- a `projects` list, which is produced by combining the `projects` defined in the top-level file with those defined in imported files
- a set of extension commands, which are drawn from the `west-commands` keys in the top-level file and any imported files
- a `group-filter` list, which is produced by combining the top-level and any imported filters

Importing is done in this order:

1. Manifests from `self-import` are imported first.
2. The top-level manifest file's definitions are handled next.
3. Manifests from `import-1`, ..., `import-N`, are imported in that order.

When an individual `import` key refers to multiple manifest files, they are processed in this order:

- If the value is a relative path naming a directory (or a map whose `file` is a directory), the manifest files it contains are processed in lexicographic order – i.e., sorted by file name.
- If the value is a sequence, its elements are recursively imported in the order they appear.

This process recurses if necessary. E.g., if `import-1` produces a manifest file that contains an `import` key, it is resolved recursively using the same rules before its contents are processed further.

The following sections describe these outcomes.

Projects This section describes how the final `projects` list is created.

Projects are identified by name. If the same name occurs in multiple manifests, the first definition is used, and subsequent definitions are ignored. For example, if `import-1` contains a project named `bar`, that is ignored, because the top-level `west.yml` has already defined a project by that name.

The contents of files named by `import-1` through `import-N` are imported from Git at the latest `manifest-rev` revisions in their projects. These revisions can be updated to the values `rev-1` through `rev-N` by running `west update`. If any `manifest-rev` reference is missing or out of date, `west update` also fetches project data from the remote fetch URL and updates the reference.

Also note that all imported manifests, from the root manifest to the repository which defines a project `P`, must be up to date in order for west to update `P` itself. For example, this means `west update P` would update `manifest-rev` in the `baz` project if `baz/west.yml` defines `P`, as well

as updating the `manifest-rev` branch in the local git clone of `P`. Confusingly, updating `baz` may result in the removal of `P` from `baz/west.yml`, which "should" cause `west update P` to fail with an unrecognized project!

For this reason, it's not possible to run `west update P` if `P` is defined in an imported manifest; you must update this project along with all the others with a plain `west update`.

By default, west won't fetch any project data over the network if a project's revision is a SHA or tag which is already available locally, so updating the extra projects shouldn't take too much time unless it's really needed. See the documentation for the *update.fetch* configuration option for more information.

Extensions All extension commands defined using `west-commands` keys discovered while handling imports are available in the resolved manifest.

If an imported manifest file has a `west-commands:` definition in its `self:` section, the extension commands defined there are added to the set of available extensions at the time the manifest is imported. They will thus take precedence over any extension commands with the same names added later on.

Group filters The resolved manifest has a `group-filter` value which is the result of concatenating the `group-filter` values in the top-level manifest and any imported manifests.

Manifest files which appear earlier in the import order have higher precedence and are therefore concatenated later into the final `group-filter`.

In other words, let:

- the submanifest resolved from `self-import` have group filter `self-filter`
- the top-level manifest file have group filter `top-filter`
- the submanifests resolved from `import-1` through `import-N` have group filters `filter-1` through `filter-N` respectively

The final resolved `group-filter` value is then `filterN + ... + filter-2 + filter-1 + top-filter + self-filter`, where `+` here refers to list concatenation.

Important

The order that filters appear in the above list matters.

The last filter element in the final concatenated list "wins" and determines if the group is enabled or disabled.

For example, in `[-foo] + [+foo]`, group `foo` is *enabled*. However, in `[+foo] + [-foo]`, group `foo` is *disabled*.

For simplicity, west and this documentation may elide concatenated group filter elements which are redundant using these rules. For example, `[+foo] + [-foo]` could be written more simply as `[-foo]`, for the reasons given above. As another example, `[-foo] + [+foo]` could be written as the empty list `[]`, since all groups are enabled by default.

Manifest Command

The `west manifest` command can be used to manipulate manifest files. It takes an action, and action-specific arguments.

The following sections describe each action and provides a basic signature for simple uses. Run `west manifest --help` for full details on all options.

Resolving Manifests The `--resolve` action outputs a single manifest file equivalent to your current manifest and all its *imported manifests*:

```
west manifest --resolve [-o outfile]
```

The main use for this action is to see the "final" manifest contents after performing any `imports`.

To print detailed information about each imported manifest file and how projects are handled during manifest resolution, set the maximum verbosity level using `-v`:

```
west -v manifest --resolve
```

Freezing Manifests The `--freeze` action outputs a frozen manifest:

```
west manifest --freeze [-o outfile]
```

A "frozen" manifest is a manifest file where every project's revision is a SHA. You can use `--freeze` to produce a frozen manifest that's equivalent to your current manifest file. The `-o` option specifies an output file; if not given, standard output is used.

Validating Manifests The `--validate` action either succeeds if the current manifest file is valid, or fails with an error:

```
west manifest --validate
```

The error message can help diagnose errors.

Here, "invalid" means that the syntax of the manifest file doesn't follow the rules documented on this page.

If your manifest is valid but it's not working the way you want it to, turning up the verbosity with `-v` is a good way to get detailed information about what decisions west made about your manifest, and why:

```
west -v manifest --validate
```

Get the manifest path The `--path` action prints the path to the top level manifest file:

```
west manifest --path
```

The output is something like `/path/to/workspace/west.yml`. The path format depends on your operating system.

2.11.8 Configuration

This page documents west's configuration file system, the `west config` command, and configuration options used by built-in commands. For API documentation on the `west.configuration` module, see west-apis-configuration.

West Configuration Files

West's configuration file syntax is INI-like; here is an example file:

```
[manifest]
path = zephyr

[zephyr]
base = zephyr
```

Above, the `manifest` section has option `path` set to `zephyr`. Another way to say the same thing is that `manifest.path` is `zephyr` in this file.

There are three types of configuration file:

1. **System**: Settings in this file affect west's behavior for every user logged in to the computer. Its location depends on the platform:
   - Linux: `/etc/westconfig`
   - macOS: `/usr/local/etc/westconfig`
   - Windows: `%PROGRAMDATA%\west\config`
2. **Global** (per user): Settings in this file affect how west behaves when run by a particular user on the computer.
   - All platforms: the default is `.westconfig` in the user's home directory.
   - Linux note: if the environment variable `XDG_CONFIG_HOME` is set, then `$XDG_CONFIG_HOME/west/config` is used.
   - Windows note: the following environment variables are tested to find the home directory: `%HOME%`, then `%USERPROFILE%`, then a combination of `%HOMEDRIVE%` and `%HOMEPATH%`.
3. **Local**: Settings in this file affect west's behavior for the current *west workspace*. The file is `.west/config`, relative to the workspace's root directory.

A setting in a file which appears lower down on this list overrides an earlier setting. For example, if `color.ui` is `true` in the system's configuration file, but `false` in the workspace's, then the final value is `false`. Similarly, settings in the user configuration file override system settings, and so on.

west config

The built-in `config` command can be used to get and set configuration values. You can pass `west config` the options `--system`, `--global`, or `--local` to specify which configuration file to use. Only one of these can be used at a time. If none is given, then writes default to `--local`, and reads show the final value after applying overrides.

Some examples for common uses follow; run `west config -h` for detailed help, and see *Built-in Configuration Options* for more details on built-in options.

To set `manifest.path` to `some-other-manifest`:

```
west config manifest.path some-other-manifest
```

Doing the above means that commands like `west update` will look for the *west manifest* inside the `some-other-manifest` directory (relative to the workspace root directory) instead of the directory given to `west init`, so be careful!

To read `zephyr.base`, the value which will be used as `ZEPHYR_BASE` if it is unset in the calling environment (also relative to the workspace root):

```
west config zephyr.base
```

You can switch to another zephyr repository without changing `manifest.path` – and thus the behavior of commands like `west update` – using:

```
west config zephyr.base some-other-zephyr
```

This can be useful if you use commands like `git worktree` to create your own zephyr directories, and want commands like `west build` to use them instead of the zephyr repository specified in the manifest. (You can go back to using the directory in the upstream manifest by running `west config zephyr.base zephyr`.)

To set `color.ui` to `false` in the global (user-wide) configuration file, so that west will no longer print colored output for that user when run in any workspace:

```
west config --global color.ui false
```

To undo the above change:

```
west config --global color.ui true
```

Built-in Configuration Options

The following table documents configuration options supported by west's built-in commands. Configuration options supported by Zephyr's extension commands are documented in the pages for those commands.

Option	Description
`alias.ALIAS`	String. If non-empty the `<ALIAS>` can be used as a west command. See *West aliases*.
`color.ui`	Boolean. If `true` (the default), then west output is colorized when stdout is a terminal.
`commands.allow_extensions`	Boolean, default `true`, disables *Extensions* if `false`
`grep.color`	String, default empty. Set this to `never` to disable `west grep` color output. If set, `west grep` passes the value to the grep tool's `--color` option.
`grep.tool`	String, one of `"git-grep"` (default), `"ripgrep"`, or `"grep"`. The grep tool that `west grep` should use.
`grep.<TOOL>-args`	String, default empty. The `<TOOL>` part is a pattern that can be any `grep.tool` value, so `grep.ripgrep-args` is an example configuration option. If set, arguments that `west grep` should pass to the corresponding grep tool. Run `west help grep` for details.
`grep.<TOOL>-path`	String, default empty. The `<TOOL>` part is a pattern that can be any `grep.tool` value, so `grep.ripgrep-path` is an example configuration option. The path to the corresponding tool that `west grep` should use instead of searching for the command. Run `west help grep` for details.
`manifest.file`	String, default `west.yml`. Relative path from the manifest repository root directory to the manifest file used by `west init` and other commands which parse the manifest.
`manifest.group-filter`	String, default empty. A comma-separated list of project groups to enable and disable within the workspace. Prefix enabled groups with `+` and disabled groups with `-`. For example, the value `"+foo,-bar"` enables group `foo` and disables `bar`. See *Project Groups*.
`manifest.path`	String, relative path from the *west workspace* root directory to the manifest repository used by `west update` and other commands which parse the manifest. Set locally by `west init`.

`manifest.project-filter`	Comma-separated list of strings.
	The option's value is a comma-separated list of regular expressions, each prefixed with `+` or `-`, like this:
	`+re1,-re2,-re3`
	Project names are matched against each regular expression (`re1`, `re2`, `re3`, ...) in the list, in order. If the entire project name matches the regular expression, that element of the list either deactivates or activates the project. The project is deactivated if the element begins with `-`. The project is activated if the element begins with `+`. (Project names cannot contain `,` if this option is used, so the regular expressions do not need to contain a literal `,` character.)
	If a project's name matches multiple regular expressions in the list, the result from the last regular expression is used. For example, if `manifest.project-filter` is:
	`-hal_.*,+hal_foo`
	Then a project named `hal_bar` is inactive, but a project named `hal_foo` is active.
	If a project is made inactive or active by a list element, the project is active or not regardless of whether any or all of its groups are disabled. (This is currently the only way to make a project that has no groups inactive.)
	Otherwise, i.e. if a project does not match any regular expressions in the list, it is active or inactive according to the usual rules related to its groups (see *Project Group Examples* for examples in that case).
	Within an element of a `manifest.project-filter` list, leading and trailing whitespace are ignored. That means these example values are equivalent:
	`+foo,-bar`
	`+foo , -bar`
	Any empty elements are ignored. That means these example values are equivalent:

2.11.9 West aliases

West allows to add alias commands to the local, global or system configuration files. These aliases make it easy to add shortcuts for frequently used, or hard to memorize commands for ease of development.

Similar to how `git` aliases work, the alias command is replaced with the alias' full text and parsed as a new shell argument list (using the Python function shlex.split() internally to split the value). This enables adding argument parameters as they were passed to the original command. Spaces are considered argument separators; use proper escaping if arguments shouldn't be split.

To add a new alias simply call the `west config` command:

```
west config alias.mylist "list -f '{name} {revision}'"
```

To list aliases, use `west help` *some_alias*.

Recursive aliases are allowed as an alias command can contain other aliases, effectively building more complex but easy-to-remember commands.

It is possible to override an existing command, for example to pass default arguments:

```
west config alias.update "update -o=--depth=1 -n"
```

Warning

Overriding/shadowing other or built-in commands is an advanced use case, it can lead to strange side-effects and should be done with great care.

Examples

Add `west run` and `west menuconfig` shortcuts to your global configuration to call `west build` with the corresponding CMake targets:

```
west config --global alias.run "build --pristine=never --target run"
west config --global alias.menuconfig "build --pristine=never --target menuconfig"
```

Create an alias for the sample you are actively developing with additional options:

```
west config alias.sample "build -b native_sim samples/hello_world -t run -- -
↪DCONFIG_ASSERT=y"
```

Override `west update` to check a local cache:

```
west config alias.update "update --path-cache $HOME/.cache/zephyrproject"
```

Automatically exclude the 32-bit native simulator target when running *Twister* via west. This is especially useful when running on hosts systems without a 32-bit host C library (i.e. Linux/AArch64):

```
west config alias.twister "twister --exclude-platform native_sim/native"
```

2.11.10 Extensions

West is "pluggable": you can add your own commands to west without editing its source code. These are called **west extension commands**, or just "extensions" for short. Extensions show up in the `west --help` output in a special section for the project which defines them. This page provides general information on west extension commands, and has a tutorial for writing your own.

Some commands you can run when using west with Zephyr, like the ones used to *build, flash, and debug* and the *ones described here*, are extensions. That's why help for them shows up like this in `west --help`:

```
extension commands from project manifest (path: zephyr):
  completion:           display shell completion scripts
  boards:               display information about supported boards
  shields:              display list of supported shields
  build:                compile a Zephyr application
  twister:              west twister wrapper
  sign:                 sign a Zephyr binary for bootloader chain-loading
  flash:                flash and run a binary on a board
  debug:                flash and interactively debug a Zephyr application
  debugserver:          connect to board and launch a debug server
  attach:               interactively debug a board
  ...
```

See `zephyr/scripts/west-commands.yml` and the `zephyr/scripts/west_commands` directory for the implementation details.

Disabling Extension Commands

To disable support for extension commands, set the `commands.allow_extensions` *configuration* option to `false`. To set this globally for whenever you run west, use:

```
west config --global commands.allow_extensions false
```

If you want to, you can then re-enable them in a particular *west workspace* with:

```
west config --local commands.allow_extensions true
```

Note that the files containing extension commands are not imported by west unless the commands are explicitly run. See below for details.

Adding a West Extension

There are three steps to adding your own extension:

1. Write the code implementing the command.
2. Add information about it to a `west-commands.yml` file.
3. Make sure the `west-commands.yml` file is referenced in the *west manifest*.

Note that west ignores extension commands whose names are the same as a built-in command.

Step 1: Implement Your Command Create a Python file to contain your command implementation (see the west project metadata on the west PyPI page for details on the currently supported versions of Python). You can put it in anywhere in any project tracked by your *west manifest*, or the manifest repository itself. This file must contain a subclass of the `west.commands.WestCommand` class. This class will be instantiated and used when your extension is run.

Here is a basic skeleton you can use to get started. It contains a subclass of `WestCommand`, with implementations for all the abstract methods. For more details on the west APIs you can use, see west-apis.

```
'''my_west_extension.py

Basic example of a west extension.'''
```

(continues on next page)

(continued from previous page)

```
from textwrap import dedent             # just for nicer code indentation

from west.commands import WestCommand  # your extension must subclass this

class MyCommand(WestCommand):

    def __init__(self):
        super().__init__(
            'my-command-name',  # gets stored as self.name
            '', # ignored self.help, will not be required by future west versions
            # self.description:
            description=dedent('''
            A multi-line description of my-command.

            You can split this up into multiple paragraphs and they'll get
            reflowed for you. You can also pass
            formatter_class=argparse.RawDescriptionHelpFormatter when calling
            parser_adder.add_parser() below if you want to keep your line
            endings.'''))

    def do_add_parser(self, parser_adder):
        # This is a bit of boilerplate, which allows you full control over the
        # type of argparse handling you want. The "parser_adder" argument is
        # the return value of an argparse.ArgumentParser.add_subparsers() call.
        parser = parser_adder.add_parser(self.name,
                                         description=self.description)

        # Add some example options using the standard argparse module API.
        parser.add_argument('-o', '--optional', help='an optional argument')
        parser.add_argument('required', help='a required argument')

        return parser           # gets stored as self.parser

    def do_run(self, args, unknown):
        # This gets called when the user runs the command, e.g.:
        #
        #   $ west my-command-name -o FOO BAR
        #   --optional is FOO
        #   required is BAR
        self.inf('--optional is', args.optional)
        self.inf('required is', args.required)
```

You can ignore the second argument to `do_run()` (`unknown` above), as `WestCommand` will reject unknown arguments by default. If you want to be passed a list of unknown arguments instead, add `accepts_unknown_args=True` to the `super().__init__()` arguments.

Step 2: Add or Update Your `west-commands.yml` You now need to add a `west-commands.yml` file to your project which describes your extension to west.

Here is an example for the above class definition, assuming it's in `my_west_extension.py` at the project root directory:

```
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
```

(continues on next page)

(continued from previous page)

```
        class: MyCommand
        help: one-line help for what my-command-name does
```

The top level of this YAML file is a map with a `west-commands` key. The key's value is a sequence of "command descriptors". Each command descriptor gives the location of a file implementing west extensions, along with the names of those extensions, and optionally the names of the classes which define them (if not given, the `class` value defaults to the same thing as `name`).

Some information in this file is redundant with definitions in the Python code. This is because west won't import `my_west_extension.py` until the user runs `west my-command-name`, since:

- It allows users to run `west update` with a manifest from an untrusted source, then use other west commands without your code being imported along the way. Since importing a Python module is shell-equivalent, this provides some peace of mind.
- It's a small optimization, since your code will only be imported if it is needed.

So, unless your command is explicitly run, west will just load the `west-commands.yml` file to get the basic information it needs to display information about your extension to the user in `west --help` output, etc.

If you have multiple extensions, or want to split your extensions across multiple files, your `west-commands.yml` will look something like this:

```
west-commands:
  - file: my_west_extension.py
    commands:
      - name: my-command-name
        class: MyCommand
        help: one-line help for what my-command-name does
  - file: another_file.py
    commands:
      - name: command2
        help: another cool west extension
      - name: a-third-command
        class: ThirdCommand
        help: a third command in the same file as command2
```

Above:

- `my_west_extension.py` defines extension `my-command-name` with class `MyCommand`
- `another_file.py` defines two extensions:
  1. `command2` with class `command2`
  2. `a-third-command` with class `ThirdCommand`

See the file `west-commands-schema.yml` in the west repository for a schema describing the contents of a `west-commands.yml`.

Step 3: Update Your Manifest Finally, you need to specify the location of the `west-commands.yml` you just edited in your west manifest. If your extension is in a project, add it like this:

```
manifest:
   # [... other contents ...]

   projects:
     - name: your-project
       west-commands: path/to/west-commands.yml
     # [... other projects ...]
```

Where `path/to/west-commands.yml` is relative to the root of the project. Note that the name `west-commands.yml`, while encouraged, is just a convention; you can name the file something else if you need to.

Alternatively, if your extension is in the manifest repository, just do the same thing in the manifest's `self` section, like this:

```
manifest:
  # [... other contents ...]

  self:
    west-commands: path/to/west-commands.yml
```

That's it; you can now run `west my-command-name`. Your command's name, help, and the project which contains its code will now also show up in the `west --help` output. If you share the updated repositories with others, they'll be able to use it, too.

2.11.11 Building, Flashing and Debugging

Zephyr provides several *west extension commands* for building, flashing, and interacting with Zephyr programs running on a board: `build`, `flash`, `debug`, `debugserver`, `rtt`, and `attach`.

For information on adding board support for the flashing and debugging commands, see *Flash and debug support* in the board porting guide.

Building: `west build`

> **Tip**
>
> Run `west build -h` for a quick overview.

The `build` command helps you build Zephyr applications from source. You can use *west config* to configure its behavior.

Its default behavior tries to "do what you mean":

- If there is a Zephyr build directory named `build` in your current working directory, it is incrementally re-compiled. The same is true if you run `west build` from a Zephyr build directory.
- Otherwise, if you run `west build` from a Zephyr application's source directory and no build directory is found, a new one is created and the application is compiled in it.

Basics The easiest way to use `west build` is to go to an application's root directory (i.e. the folder containing the application's `CMakeLists.txt`) and then run:

```
west build -b <BOARD>
```

Where `<BOARD>` is the name of the board you want to build for. This is exactly the same name you would supply to CMake if you were to invoke it with: `cmake -DBOARD=<BOARD>`.

> **Tip**
>
> You can use the *west boards* command to list all supported boards.

A build directory named `build` will be created, and the application will be compiled there after `west build` runs CMake to create a build system in that directory. If `west build` finds an existing

build directory, the application is incrementally re-compiled there without re-running CMake. You can force CMake to run again with `--cmake`.

You don't need to use the `--board` option if you've already got an existing build directory; `west build` can figure out the board from the CMake cache. For new builds, the `--board` option, *BOARD* environment variable, or `build.board` configuration option are checked (in that order).

Sysbuild (multi-domain builds) *Sysbuild (System build)* can be used to create a multi-domain build system combining multiple images for a single or multiple boards.

Use `--sysbuild` to select the *Sysbuild (System build)* build infrastructure with `west build` to build multiple domains.

More detailed information regarding the use of sysbuild can be found in the *Sysbuild (System build)* guide.

Tip

The `build.sysbuild` configuration option can be enabled to tell `west build` to default build using sysbuild. `--no-sysbuild` can be used to disable sysbuild for a specific build.

`west build` will build all domains through the top-level build folder of the domains specified by sysbuild.

A single domain from a multi-domain project can be built by using `--domain` argument.

Examples Here are some `west build` usage examples, grouped by area.

Forcing CMake to Run Again To force a CMake re-run, use the `--cmake` (or `-c`) option:

```
west build -c
```

Setting a Default Board To configure `west build` to build for the `reel_board` by default:

```
west config build.board reel_board
```

(You can use any other board supported by Zephyr here; it doesn't have to be `reel_board`.)

Setting Source and Build Directories To set the application source directory explicitly, give its path as a positional argument:

```
west build -b <BOARD> path/to/source/directory
```

To set the build directory explicitly, use `--build-dir` (or `-d`):

```
west build -b <BOARD> --build-dir path/to/build/directory
```

To change the default build directory from `build`, use the `build.dir-fmt` configuration option. This lets you name build directories using format strings, like this:

```
west config build.dir-fmt "build/{board}/{app}"
```

With the above, running `west build -b reel_board samples/hello_world` will use build directory `build/reel_board/hello_world`. See *Configuration Options* for more details on this option.

Setting the Build System Target To specify the build system target to run, use `--target` (or `-t`).

For example, on host platforms with QEMU, you can use the `run` target to build and run the hello_world sample for the emulated qemu_x86 board in one command:

```
west build -b qemu_x86 -t run samples/hello_world
```

As another example, to use `-t` to list all build system targets:

```
west build -t help
```

As a final example, to use `-t` to run the `pristine` target, which deletes all the files in the build directory:

```
west build -t pristine
```

Pristine Builds A *pristine* build directory is essentially a new build directory. All byproducts from previous builds have been removed.

To force `west build` make the build directory pristine before re-running CMake to generate a build system, use the `--pristine=always` (or `-p=always`) option.

Giving `--pristine` or `-p` without a value has the same effect as giving it the value `always`. For example, these commands are equivalent:

```
west build -p -b reel_board samples/hello_world
west build -p=always -b reel_board samples/hello_world
```

By default, `west build` makes no attempt to detect if the build directory needs to be made pristine. This can lead to errors if you do something like try to reuse a build directory for a different `--board`.

Using `--pristine=auto` makes `west build` detect some of these situations and make the build directory pristine before trying the build.

Tip

You can run `west config build.pristine always` to always do a pristine build, or `west config build.pristine never` to disable the heuristic. See the `west build` *Configuration Options* for details.

Verbose Builds To print the CMake and compiler commands run by `west build`, use the global west verbosity option, `-v`:

```
west -v build -b reel_board samples/hello_world
```

One-Time CMake Arguments To pass additional arguments to the CMake invocation performed by `west build`, pass them after a `--` at the end of the command line.

Important

Passing additional CMake arguments like this forces `west build` to re-run the CMake build configuration step, even if a build system has already been generated. This will make incremental builds slower (but still much faster than building from scratch).

After using `--` once to generate the build directory, use `west build -d <build-dir>` on subsequent runs to do incremental builds.

> Alternatively, make your CMake arguments permanent as described in the next section; it will not slow down incremental builds.

For example, to use the Unix Makefiles CMake generator instead of Ninja (which `west build` uses by default), run:

```
west build -b reel_board -- -G'Unix Makefiles'
```

To use Unix Makefiles and set CMAKE_VERBOSE_MAKEFILE to ON:

```
west build -b reel_board -- -G'Unix Makefiles' -DCMAKE_VERBOSE_MAKEFILE=ON
```

Notice how the `--` only appears once, even though multiple CMake arguments are given. All command-line arguments to `west build` after a `--` are passed to CMake.

To set *DTC_OVERLAY_FILE* to `enable-modem.overlay`, using that file as a *devicetree overlay*:

```
west build -b reel_board -- -DDTC_OVERLAY_FILE=enable-modem.overlay
```

To merge the `file.conf` Kconfig fragment into your build's `.config`:

```
west build -- -DEXTRA_CONF_FILE=file.conf
```

Permanent CMake Arguments The previous section describes how to add CMake arguments for a single `west build` command. If you want to save CMake arguments for `west build` to use every time it generates a new build system instead, you should use the `build.cmake-args` configuration option. Whenever `west build` runs CMake to generate a build system, it splits this option's value according to shell rules and includes the results in the `cmake` command line.

Remember that, by default, `west build` **tries to avoid generating a new build system if one is present** in your build directory. Therefore, you need to either delete any existing build directories or do a *pristine build* after setting `build.cmake-args` to make sure it will take effect.

For example, to always enable **CMAKE_EXPORT_COMPILE_COMMANDS**, you can run:

```
west config build.cmake-args -- -DCMAKE_EXPORT_COMPILE_COMMANDS=ON
```

(The extra `--` is used to force the rest of the command to be treated as a positional argument. Without it, *west config* would treat the `-DVAR=VAL` syntax as a use of its `-D` option.)

To enable **CMAKE_VERBOSE_MAKEFILE**, so CMake always produces a verbose build system:

```
west config build.cmake-args -- -DCMAKE_VERBOSE_MAKEFILE=ON
```

To save more than one argument in `build.cmake-args`, use a single string whose value can be split into distinct arguments (`west build` uses the Python function shlex.split() internally to split the value).

For example, to enable both **CMAKE_EXPORT_COMPILE_COMMANDS** and **CMAKE_VERBOSE_MAKEFILE**:

```
west config build.cmake-args -- "-DCMAKE_EXPORT_COMPILE_COMMANDS=ON -
↪DCMAKE_VERBOSE_MAKEFILE=ON"
```

If you want to save your CMake arguments in a separate file instead, you can combine CMake's `-C <initial-cache>` option with `build.cmake-args`. For instance, another way to set the options used in the previous example is to create a file named `~/my-cache.cmake` with the following contents:

```
set(CMAKE_EXPORT_COMPILE_COMMANDS ON CACHE BOOL "")
set(CMAKE_VERBOSE_MAKEFILE ON CACHE BOOL "")
```

Then run:

```
west config build.cmake-args "-C ~/my-cache.cmake"
```

See the cmake(1) manual page and the set() command documentation for more details.

Build tool arguments Use `-o` to pass options to the underlying build tool.

This works with both `ninja` (*the default*) and `make` based build systems.

For example, to pass `-dexplain` to `ninja`:

```
west build -o=-dexplain
```

As another example, to pass `--keep-going` to `make`:

```
west build -o=--keep-going
```

Note that using `-o=--foo` instead of `-o --foo` is required to prevent `--foo` from being treated as a `west build` option.

Build parallelism By default, `ninja` uses all of your cores to build, while `make` uses only one. You can control this explicitly with the `-j` option supported by both tools.

For example, to build with 4 cores:

```
west build -o=-j4
```

The `-o` option is described further in the previous section.

Build a single domain In a multi-domain build with hello_world and MCUboot, you can use `--domain hello_world` to only build this domain:

```
west build --sysbuild --domain hello_world
```

The `--domain` argument can be combined with the `--target` argument to build the specific target for the target, for example:

```
west build --sysbuild --domain hello_world --target help
```

Use a snippet See *Using Snippets*.

Configuration Options You can *configure* `west build` using these options.

Option	Description
build.board	String. If given, this the board used by *west build* when --board is not given and BOARD is unset in the environment.
build.board_warn	Boolean, default true. If false, disables warnings when west build can't figure out the target board.
build.cmake-args	String. If present, the value will be split according to shell rules and passed to CMake whenever a new build system is generated. See *Permanent CMake Arguments*.
build.dir-fmt	String, default build. The build folder format string, used by west whenever it needs to create or locate a build folder. The currently available arguments are: • west_topdir: The absolute path to the west workspace, as returned by the west_topdir command • board: The board name • source_dir: Path to the CMake source directory, relative to the current working directory. If the current working directory is inside the source directory, this is an empty string, as it is on Windows for a source directory on another drive, which has no relative path to the current one. If no source directory is specified, it defaults to current working directory. E.g. if west build ../app is run from <west_topdir>/app1, source_dir resolves to ../app (which is the relative path to the current working dir). • source_dir_workspace: Path to the source directory, relative to west_topdir (if it is inside the workspace). Otherwise, it is relative to the filesystem root (/ on Unix, respectively C:/ on Windows). E.g. if west build ../app is run from <west_topdir>/app1, source_dir resolves to app (which is the relative path to the west workspace dir). • app: The name of the source directory.
build.generator	String, default Ninja. The CMake Generator to use to create a build system. (To set a generator for a single build, see the *above example*)
build.guess-dir	String, instructs west whether to try to guess what build folder to use when build.dir-fmt is in use and not enough information is available to resolve the build folder name. Can take these values: • never (default): Never try to guess, bail out instead and require the user to provide a build folder with -d. • runners: Try to guess the folder when using any of the 'runner' commands. These are typically all commands that invoke an external tool, such as flash and debug.
build.pristine	String. Controls the way in which west build may clean the build folder before building. Can take the following values: • never (default): Never automatically make the build folder pristine. • auto: west build will automatically make the build folder pristine before building, if a build system is present and the build would fail otherwise (e.g. the user has specified a different board or application from the one previously used to make the build directory). • always: Always make the build folder pristine before building, if a build system is present.
build.sysbuild	Boolean, default false. If true, build application using the sysbuild infrastructure.

Flashing: `west flash`

> **Tip**
>
> Run `west flash -h` for additional help.

Basics From a Zephyr build directory, re-build the binary and flash it to your board:

```
west flash
```

To specify the build directory, use `--build-dir` (or `-d`):

```
west flash --build-dir path/to/build/directory
```

If you don't specify the build directory, `west flash` searches for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see *Setting Source and Build Directories*), `west flash` searches there instead of `build`.

Choosing a Runner If your board's Zephyr integration supports flashing with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West flashes your board with `nrfjprog` by default, but it also supports JLink, you can override the default with:

```
west flash --runner jlink
```

You can override the default flash runner at build time by using the `BOARD_FLASH_RUNNER` CMake variable, and the debug runner with `BOARD_DEBUG_RUNNER`.

For example:

```
# Set the default runner to "jlink", overriding the board's
# usual default.
west build [...] -- -DBOARD_FLASH_RUNNER=jlink
```

See *One-Time CMake Arguments* and *Permanent CMake Arguments* for more information on setting CMake arguments.

See *Configuration Options* below for more information on the `runner` library used by West. The list of runners which support flashing can be obtained with `west flash -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses while flashing, such as where the board directory is on the file system, the path to the zephyr binaries to flash in several formats, and more. You can override any of this configuration at runtime with additional options.

For example, to override the HEX file containing the Zephyr image to flash (assuming your runner expects a HEX file), but keep other flash configuration at default values:

```
west flash --hex-file path/to/some/other.hex
```

The `west flash -h` output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to flashing. For example, some runners support an `--erase` flag, which mass-erases the flash storage on your board before flashing the Zephyr image.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west flash --context
```

Important

Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west flash -H` just prints a list of runners. You can use `west flash -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west flash -H -r jlink
```

Multi-domain flashing When a *Sysbuild (multi-domain builds)* folder is detected, then `west flash` will flash all domains in the order defined by sysbuild.

It is possible to flash the image from a single domain in a multi-domain project by using `--domain`.

For example, in a multi-domain build with hello_world and MCUboot, you can use the `--domain hello_world` domain to only flash only the image from this domain:

```
west flash --domain hello_world
```

Configuration Options You can *configure* `west flash` using these options.

Option	Description
`flash.rebuild`	Boolean, default `true`. If `false`, do not rebuild on west flash.

Debugging: `west debug`, `west debugserver`

Tip

Run `west debug -h` or `west debugserver -h` for additional help.

Basics From a Zephyr build directory, to attach a debugger to your board and open up a debug console (e.g. a GDB session):

```
west debug
```

To attach a debugger to your board and open up a local network port you can connect a debugger to (e.g. an IDE debugger):

```
west debugserver
```

To specify the build directory, use `--build-dir` (or `-d`):

```
west debug --build-dir path/to/build/directory
west debugserver --build-dir path/to/build/directory
```

If you don't specify the build directory, these commands search for one in `build`, then the current working directory. If you set the `build.dir-fmt` configuration option (see *Setting Source and Build Directories*), `west debug` searches there instead of `build`.

Choosing a Runner If your board's Zephyr integration supports debugging with multiple programs, you can specify which one to use using the `--runner` (or `-r`) option. For example, if West debugs your board with `pyocd-gdbserver` by default, but it also supports JLink, you can override the default with:

```
west debug --runner jlink
west debugserver --runner jlink
```

See *Configuration Options* below for more information on the `runner` library used by West. The list of runners which support debugging can be obtained with `west debug -H`; if run from a build directory or with `--build-dir`, this will print additional information on available runners for your board.

Configuration Overrides The CMake cache contains default values West uses for debugging, such as where the board directory is on the file system, the path to the zephyr binaries containing symbol tables, and more. You can override any of this configuration at runtime with additional options.

For example, to override the ELF file containing the Zephyr binary and symbol tables (assuming your runner expects an ELF file), but keep other debug configuration at default values:

```
west debug --elf-file path/to/some/other.elf
west debugserver --elf-file path/to/some/other.elf
```

The `west debug -h` output includes a complete list of overrides supported by all runners.

Runner-Specific Overrides Each runner may support additional options related to debugging. For example, some runners support flags which allow you to set the network ports used by debug servers.

To view all of the available options for the runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west debug --context
```

(The command `west debugserver --context` will print the same output.)

Important

Note the capital H in the short option name. This re-runs the build in order to ensure the information displayed is up to date!

When running West outside of a build directory, `west debug -H` just prints a list of runners. You can use `west debug -H -r <runner-name>` to print usage information for options supported by that runner.

For example, to print usage information about the `jlink` runner:

```
west debug -H -r jlink
```

Multi-domain debugging `west debug` can only debug a single domain at a time. When a *Sysbuild (multi-domain builds)* folder is detected, `west debug` will debug the `default` domain specified by sysbuild.

The default domain will be the application given as the source directory. See the following example:

```
west build --sysbuild path/to/source/directory
```

For example, when building `hello_world` with MCUboot using sysbuild, `hello_world` becomes the default domain:

```
west build --sysbuild samples/hello_world
```

So to debug `hello_world` you can do:

```
west debug
```

or:

```
west debug --domain hello_world
```

If you wish to debug MCUboot, you must explicitly specify MCUboot as the domain to debug:

```
west debug --domain mcuboot
```

Configuration Options You can *configure* `west debug` and *configure* `west debugserver` using these options.

Option	Description
`debug.rebuild`	Boolean, default `true`. If `false`, do not rebuild on west debug.
`debugserver.rebuild`	Boolean, default `true`. If `false`, do not rebuild on west debugserver.

Flash and debug runners

The flash and debug commands use Python wrappers around various *Flash & Debug Host Tools*. These wrappers are all defined in a Python library at scripts/west_commands/runners. Each wrapper is called a *runner*. Runners can flash and/or debug Zephyr programs.

The central abstraction within this library is `ZephyrBinaryRunner`, an abstract class which represents runners. The set of available runners is determined by the imported subclasses of `ZephyrBinaryRunner`. `ZephyrBinaryRunner` is available in the `runners.core` module; individual runner implementations are in other submodules, such as `runners.nrfjprog`, `runners.openocd`, etc.

Running Robot Framework tests: `west robot`

> **Tip**
>
> Run `west robot -h` for additional help.

Basics Currently the command supports only one runner which is using `renode-test`, (essentially a wrapper for running Robot tests in Renode), but can be easily extended by adding other runners.

From a Zephyr build directory, to run a Robot test suite:

```
west robot --runner=renode-robot --testsuite path/to/testsuite.robot
```

This will run all tests from testsuite.robot and print output provided by Robot Framework.

To pass additional parameters to Renode use `--renode-robot-args` switch. For example to show Renode logs in addition to Robot Framework's output:

west robot –runner=renode-robot –testsuite path/to/testsuite.robot –renode-robot-arg="–show-log"

Runner-Specific Overrides To view all of the available options for the Robot runners your board supports, as well as their usage information, use `--context` (or `-H`):

```
west robot --runner=renode-robot --context
```

To view all available options "renode-test" runner supports, use:

```
west robot --runner=renode-robot --renode-robot-help
```

Simulating a board with: `west simulate`

Basics Currently the command supports only one runner which is using Renode, but can be easily extended by adding other runners.

From a Zephyr build directory, to run the built binary:

```
west simulate --runner=renode
```

This will start Renode and configure simulation based on a default `.resc` script for the current platform with the zephyr.elf file loaded by default. The simulation then can be started by typing "start" or "s" in Renode's Monitor. This can also be done by passing a command to Renode, using an argument provided by the runner:

west simulate –runner=renode –renode-command start

To pass an argument to Renode itself, for example to start Renode in console mode instead of a separate window:

west simulate –runner=renode –renode-arg="–console"

From that point on Renode can be used normally in both console and window modes. For details on using Renode see Renode - documentation.

Runner-Specific Overrides To view all of the available options supported by the runners, as well as their usage information, use `--context` (or `-H`):

```
west simulate --runner=renode --context
```

To view all available options Renode supports, use:

```
west simulate --runner=renode --renode-help
```

Out of tree runners

Zephyr modules can have external runners discovered by adding python files in their *module.yml*. Create an external runner class by inheriting from `ZephyrBinaryRunner` and implement all abstract methods.

> **Note**
>
> Support for custom out-of-tree runners makes the `runners.core` module part of the public API and backwards incompatible changes need to undergo the *deprecation process*.

Hacking

This section documents the `runners.core` module used by the flash and debug commands. This is the core abstraction used to implement support for these features.

Developers can add support for new ways to flash and debug Zephyr programs by implementing additional runners. To get this support into upstream Zephyr, the runner should be added into a new or existing `runners` module, and imported from `runners/__init__.py`.

Note

The test cases in scripts/west_commands/tests add unit test coverage for the runners package and individual runner classes.

Please try to add tests when adding new runners. Note that if your changes break existing test cases, CI testing on upstream pull requests will fail.

Zephyr binary runner core interfaces

This provides the core ZephyrBinaryRunner class meant for public use, as well as some other helpers for concrete runner classes.

class runners.core.**BuildConfiguration**(*build_dir: str*)

This helper class provides access to build-time configuration.

Configuration options can be read as if the object were a dict, either object['CONFIG_FOO'] or object.get('CONFIG_FOO').

Kconfig configuration values are available (parsed from .config).

Devicetree configuration is available using the edtlib API as object.edt.

property edt

Get the EDT representing the devicetree. The EDT is lazily loaded on first access, and cached for subsequent accesses.

getboolean(*option*)

If a boolean option is explicitly set to y or n, returns its value. Otherwise, falls back to False.

class runners.core.**DeprecatedAction**(*option_strings*, *dest*, *nargs=None*, *const=None*, *default=None*, *type=None*, *choices=None*, *required=False*, *help=None*, *metavar=None*)

class runners.core.**FileType**(**values*)

exception runners.core.**MissingProgram**(*program*)

FileNotFoundError subclass for missing program dependencies.

No significant changes from the parent FileNotFoundError; this is useful for explicitly signaling that the file in question is a program that some class requires to proceed.

The filename attribute contains the missing program.

class runners.core.**NetworkPortHelper**

Helper class for dealing with local IP network ports.

get_unused_ports(*starting_from*)

Find unused network ports, starting at given values.

starting_from is an iterable of ports the caller would like to use.

The return value is an iterable of ports, in the same order, using the given values if they were unused, or the next sequentially available unused port otherwise.

Ports may be bound between this call's check and actual usage, so callers still need to handle errors involving returned ports.

class runners.core.**RunnerCaps**(*commands: set[str] = <factory>*, *dev_id: bool = False*, *mult_dev_ids: bool = False*, *flash_addr: bool = False*, *erase: bool = False*, *reset: bool = False*, *reset_types: bool = False*, *reset_types_supported: list[str] | None = None*, *extload: bool = False*, *tool_opt: bool = False*, *gdb_init: bool = False*, *file: bool = False*, *hide_load_files: bool = False*, *rtt: bool = False*, *dry_run: bool = False*, *skip_load: bool = False*, *batch_debug: bool = False*)

This class represents a runner class's capabilities.

Each capability is represented as an attribute with the same name. Flag attributes are True or False.

Available capabilities:

- commands: set of supported commands; default is {'flash', 'debug', 'debugserver', 'attach', 'simulate', 'robot', 'rtt'}.
- dev_id: whether the runner supports device identifiers, in the form of an -i, –dev-id option. This is useful when the user has multiple debuggers connected to a single computer, in order to select which one will be used with the command provided.
- mult_dev_ids: whether the runner supports multiple device identifiers for a single operation, allowing for bulk flashing of devices.
- flash_addr: whether the runner supports flashing to an arbitrary address. Default is False. If true, the runner must honor the –dt-flash option.
- erase: whether the runner supports an –erase option, which does a mass-erase of the entire addressable flash on the target before flashing. On multi-core SoCs, this may only erase portions of flash specific the actual target core. (This option can be useful for things like clearing out old settings values or other subsystem state that may affect the behavior of the zephyr image. It is also sometimes needed by SoCs which have flash-like areas that can't be sector erased by the underlying tool before flashing; UICR on nRF SoCs is one example.)
- reset: whether the runner supports a –reset option, which resets the device after a flash operation is complete.
- reset_types: whether the runner supports a –reset-type=x option, which specifies a runner specific value for selecting a specific type of reset to use when resetting the device.
- reset_types_supported: a list of values allowed to be passed with the –reset-type option. If the list of supported reset types is dynamic/device specific, this should be omitted, allowing any value to be set and passed directly to the underlying tool. In addition to these, each runner implementation must always be ready to accept *None* in a runner-specific fashion. For user-friendliness, it is recommended to place first in the list the value which has the behavior identical or most similar to *None*.
- extload: whether the runner supports a –extload option, which must be given one time and is passed on to the underlying tool that the runner wraps.
- tool_opt: whether the runner supports a –tool-opt (-O) option, which can be given multiple times and is passed on to the underlying tool that the runner wraps.
- gdb_init: whether the runner supports a –gdb-init option, which can be given multiple times and appends commands, in the order given, to the GDB client invocation, after the ones the runner issues itself.
- file: whether the runner supports a –file option, which specifies exactly the file that should be used to flash, overriding any default discovered in the build directory.

- hide_load_files: whether the elf/hex/bin file arguments should be hidden.
- rtt: whether the runner supports SEGGER RTT. This adds a –rtt-address option.
- skip_load: whether the runner supports the –load/–no-load option, which allows skipping the load of image on target before starting a debug session (this option only affects the 'debug' command)

class runners.core.**RunnerConfig**(*build_dir: str*, *board_dir: str*, *elf_file: str | None*, *exe_file: str | None*, *hex_file: str | None*, *bin_file: str | None*, *uf2_file: str | None*, *mot_file: str | None*, *file: str | None*, *file_type: FileType | None = FileType.OTHER*, *gdb: str | None = None*, *openocd: str | None = None*, *openocd_search: list[str] = []*, *rtt_address: int | None = None*)

Runner execution-time configuration.

This is a common object shared by all runners. Individual runners can register specific configuration options using their do_add_parser() hooks.

class runners.core.**SysbuildConfiguration**(*build_dir: str*)

This helper class provides access to sysbuild-time configuration.

Configuration options can be read as if the object were a dict, either object['SB_CONFIG_FOO'] or object.get('SB_CONFIG_FOO').

Kconfig configuration values are available (parsed from .config).

class runners.core.**ZephyrBinaryRunner**(*cfg:* RunnerConfig)

Abstract superclass for binary runners (flashers, debuggers).

Note: this class's API has changed relatively rarely since it as added, but it is not considered a stable Zephyr API, and may change without notice.

With some exceptions, boards supported by Zephyr must provide generic means to be flashed (have a Zephyr firmware binary permanently installed on the device for running) and debugged (have a breakpoint debugger and program loader on a host workstation attached to a running target).

This is supported by four top-level commands managed by the Zephyr build system:

- 'flash': flash a previously configured binary to the board, start execution on the target, then return.
- 'debug': connect to the board via a debugging protocol, program the flash, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits.
- 'debugserver': connect via a board-specific debugging protocol, then reset and halt the target. Ensure the user is now able to connect to a debug server with symbol tables loaded from the binary.
- 'attach': connect to the board via a debugging protocol, then drop the user into a debugger interface with symbol tables loaded from the current binary, and block until it exits. Unlike 'debug', this command does not program the flash.

This class provides an API for these commands. Every subclass is called a 'runner' for short. Each runner has a name (like 'pyocd'), and declares commands it can handle (like 'flash'). Boards (like 'nrf52dk/nrf52832') declare which runner(s) are compatible with them to the Zephyr build system, along with information on how to configure the runner to work with the board.

The build system will then place enough information in the build directory to create and use runners with this class's create() method, which provides a command line argument parsing API. You can also create runners by instantiating subclasses directly.

In order to define your own runner, you need to:

1. Define a ZephyrBinaryRunner subclass, and implement its abstract methods. You may need to override capabilities().
2. Make sure the Python module defining your runner class is imported, e.g. by editing this package's __init__.py (otherwise, get_runners() won't work).
3. Give your runner's name to the Zephyr build system in your board's board.cmake.

Additional advice:

- If you need to import any non-standard-library modules, make sure to catch ImportError and defer complaints about it to a RuntimeError if one is missing. This avoids affecting users that don't require your runner, while still making it clear what went wrong to users that do require it that don't have the necessary modules installed.
- If you need to ask the user something (e.g. using input()), do it in your create() classmethod, not do_run(). That ensures your __init__() really has everything it needs to call do_run(), and also avoids calling input() when not instantiating within a command line application.

- Use self.logger to log messages using the standard library's logging API; your logger is named "runner.<your-runner-name()>"

For command-line invocation from the Zephyr build system, runners define their own argparse-based interface through the common add_parser() (and runner-specific do_add_parser() it delegates to), and provide a way to create instances of themselves from a RunnerConfig and parsed runner-specific arguments via create().

Runners use a variety of host tools and configuration values, the user interface to which is abstracted by this class. Each runner subclass should take any values it needs to execute one of these commands in its constructor. The actual command execution is handled in the run() method.

`classmethod add_parser`(*parser*)

Adds a sub-command parser for this runner.

The given object, parser, is a sub-command parser from the argparse module. For more details, refer to the documentation for argparse.ArgumentParser.add_subparsers().

The lone common optional argument is:

- –dt-flash (if the runner capabilities includes flash_addr)

Runner-specific options are added through the do_add_parser() hook.

`classmethod args_from_previous_runner`(*previous_runner*, *args: Namespace*)

Update arguments from a previously created runner.

This is intended for propagating relevant user responses between multiple runs of the same runner, for example a JTAG serial number.

`property build_conf:` *BuildConfiguration*

Get a BuildConfiguration for the build directory.

`call`(*cmd: list[str]*, ***kwargs*) → int

Subclass subprocess.call() wrapper.

Subclasses should use this method to run command in a subprocess and get its return code, rather than using subprocess directly, to keep accurate debug logs.

`classmethod capabilities`() → *RunnerCaps*

Returns a RunnerCaps representing this runner's capabilities.

This implementation returns the default capabilities.

Subclasses should override appropriately if needed.

`cfg`

RunnerConfig for this instance.

`check_call`(*cmd: list[str]*, ***kwargs*)

Subclass subprocess.check_call() wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

`check_call_ignore_sigint`(*client*, ***kwargs*)

Run a command that ignores SIGINT.

`check_output`(*cmd: list[str]*, ***kwargs*) → bytes

Subclass subprocess.check_output() wrapper.

Subclasses should use this method to run command in a subprocess and check that it executed correctly, rather than using subprocess directly, to keep accurate debug logs.

`classmethod create`(*cfg:* RunnerConfig, *args: Namespace*) → *ZephyrBinaryRunner*

Create an instance from command-line arguments.

- `cfg`: runner configuration (pass to superclass __init__)
- `args`: arguments parsed from execution environment, as specified by `add_parser()`.

`classmethod dev_id_help`() → str

Get the ArgParse help text for the –dev-id option.

`abstractmethod classmethod do_add_parser`(*parser*)

Hook for adding runner-specific options.

`abstractmethod classmethod do_create`(*cfg:* RunnerConfig, *args: Namespace*) → *ZephyrBinaryRunner*

Hook for instance creation from command line arguments.

`abstractmethod do_run`(*command: str*, ***kwargs*)

Concrete runner; run() delegates to this. Implement in subclasses.

In case of an unsupported command, raise a ValueError.

`dry_run`

log commands instead of executing them. Can be set by subclasses

`ensure_output`(*output_type: str*) → None

Ensure self.cfg has a particular output artifact.

For example, ensure_output('bin') ensures that self.cfg.bin_file refers to an existing file. Errors out if it's missing or undefined.

Parameters
`output_type` – string naming the output type

`classmethod extload_help`() → str

Get the ArgParse help text for the –extload option.

`static flash_address_from_build_conf`(*build_conf:* BuildConfiguration)

If CONFIG_FLASH_USES_MAPPED_PARTITION is y in build_conf, return the reg address of the zephyr,code-partition devicetree node. Else, if CONFIG_HAS_FLASH_LOAD_OFFSET is n in build_conf, return the CONFIG_FLASH_BASE_ADDRESS value. Otherwise, return CONFIG_FLASH_BASE_ADDRESS + CONFIG_FLASH_LOAD_OFFSET.

`static gdb_ex_args`(*commands: list[str] | None*) → list[str]

Turn GDB commands into '-ex', <command> pairs for a GDB argv.

The commands are passed on verbatim.

`static get_flash_address`(*args: Namespace*, *build_conf:* BuildConfiguration, *default: int = 0*) → int

Helper method for extracting a flash address.

If args.dt_flash is true, returns the address obtained from ZephyrBinaryRunner.flash_address_from_build_conf(build_conf).

Otherwise (when args.dt_flash is False), the default value is returned.

`get_rtt_address`() → int | None

Helper method for extracting a the RTT control block address.

If args.rtt_address was supplied, returns that.

Otherwise, attempt to locate an rtt block in the elf file. If this is not found, None is returned

`static get_runners`() → list[type[*ZephyrBinaryRunner*]]

Get a list of all currently defined runner classes.

`logger`

logging.Logger for this instance.

`abstractmethod classmethod name`() → str

Return this runner's user-visible name.

When choosing a name, pick something short and lowercase, based on the name of the tool (like openocd, jlink, etc.) or the target architecture/board (like xtensa etc.).

`static normalize_chip`(*name: str*) → str

Normalize a chip name for case- and dash-insensitive matching.

`popen_ignore_int`(*cmd: list[str]*, ***kwargs*) → Popen

Spawn a child command, ensuring it ignores SIGINT.

The returned subprocess.Popen object must be manually terminated.

`static require`(*program: str*, *path: str | None = None*) → str

Require that a program is installed before proceeding.

Parameters

- `program` – name of the program that is required, or path to a program binary.
- `path` – PATH where to search for the program binary. By default check on the system PATH.

If `program` is an absolute path to an existing program binary, this call succeeds. Otherwise, try to find the program by name on the system PATH or in the given PATH, if provided.

If the program can be found, its path is returned. Otherwise, raises MissingProgram.

`static resolve_port_by_chip`(*detect_func*, *target*, *logger*, *priority_vids=None*)

Probe serial ports and return the first one whose connected chip matches the normalized target name.

Parameters

- `detect_func` – callable taking a port device path and returning the chip name reported by that port, or None if no chip could be identified. It is responsible for opening and closing the port.
- `target` – normalized chip name to match against.
- `logger` – logger for progress and diagnostics.
- `priority_vids` – optional list of USB VIDs whose ports are probed first, to avoid resetting unrelated serial adapters.

Returns the matching port device path, or None when no match is found.

`run`(*command: str*, ***kwargs*)

Runs command ('flash', 'debug', 'debugserver', 'attach').

This is the main entry point to this runner.

`run_server_and_client`(*server*, *client*, ***kwargs*)

Run a server that ignores SIGINT, and a client that handles it.

This routine portably:

- creates a Popen object for the `server` command which ignores SIGINT
- runs `client` in a subprocess while temporarily ignoring SIGINT

- cleans up the server after the client exits.
- the keyword arguments, if any, will be passed down to both server and client subprocess calls

It's useful to e.g. open a GDB server and client.

`run_telnet_client`(*host: str*, *port: int*, *active_sock=None*, *send_on_connect: str | None = None*) → None

Run a telnet client for user interaction.

Parameters
`send_on_connect` – Send the given string right after connecting to the given socket. If provided, it will result in avoiding using *nc* as the client.

`static sram_address_from_build_conf`(*build_conf:* BuildConfiguration)

return SRAM address.

`property sysbuild_conf: SysbuildConfiguration`

Get a SysbuildConfiguration for the sysbuild directory.

`property thread_info_enabled: bool`

Returns True if self.build_conf has CONFIG_DEBUG_THREAD_INFO enabled.

`classmethod tool_opt_help`() → str

Get the ArgParse help text for the –tool-opt option.

Doing it By Hand

If you prefer not to use West to flash or debug your board, simply inspect the build directory for the binaries output by the build system. These will be named something like `zephyr/zephyr.elf`, `zephyr/zephyr.hex`, etc., depending on your board's build system integration. These binaries may be flashed to a board using alternative tools of your choice, or used for debugging as needed, e.g. as a source of symbol tables.

By default, these West commands rebuild binaries before flashing and debugging. This can of course also be accomplished using the usual targets provided by Zephyr's build system (in fact, that's how these commands do it).

2.11.12 Signing Binaries

The `west sign` *extension* command can be used to sign a Zephyr application binary for consumption by a bootloader using an external tool. In some configurations, `west sign` is also used to invoke an external, post-processing tool that "stitches" the final components of the image together. Run `west sign -h` for command line help.

rimage

rimage configuration uses an approach that does not rely on Kconfig or CMake but on *west config*, similar to *Permanent CMake Arguments*.

Signing involves a number of "wrapper" scripts stacked on top of each other: `west flash` invokes `west build` which invokes `cmake` and `ninja` which invokes `west sign` which invokes `imgtool` or rimage. As long as the signing parameters desired are the default ones and fairly static, these indirections are not a problem. On the other hand, passing `imgtool` or `rimage` options through all these layers can causes issues typical when the layers don't abstract anything. First, this usually requires boilerplate code in each layer. Quoting whitespace or other special characters through all the wrappers can be difficult. Reproducing a lower `west sign` command to debug some build-time issue can be very time-consuming: it requires at least enabling and searching verbose build logs to find which exact options were used. Copying these options from the build logs can be unreliable: it may produce different results because of subtle environment differences. Last

and worst: new signing feature and options are impossible to use until more boilerplate code has been added in each layer.

To avoid these issues, `rimage` parameters can bet set in `west config`. Here's a `workspace/.west/config` example:

```
[sign]
# Not needed when invoked from CMake
tool = rimage

[rimage]
# Quoting is optional and works like in Unix shells
# Not needed when rimage can be found in the default PATH
path = "/home/me/zworkspace/build-rimage/rimage"

# Not needed when using the default development key
extra-args = -i 4 -k 'keys/key argument with space.pem'
```

In order to support quoting, values are parsed by Python's `shlex.split()` like in *One-Time CMake Arguments*.

The `extra-args` are passed directly to the `rimage` command. The example above has the same effect as appending them on command line after `--` like this: `west sign --tool rimage -- -i 4 -k 'keys/key argument with space.pem'`. In case both are used, the command-line arguments go last.

silabs_commander

The `silabs_commander` tool is used to apply sign or MIC or encrypt binaries for Silicon Labs devices. It can be invoked either by `west sign` when the `sign.tool` configuration is set to `silabs_commander` or by `west build` if `CONFIG_SIWX91X_SIGN_KEY` or `CONFIG_SIWX91X_MIC_KEY` is set.

If one of `CONFIG_SIWX91X_SIGN_KEY` or `CONFIG_SIWX91X_MIC_KEY` is set, `west flash` will automatically flash the signed version of the binary.

`silabs_commander` require Simplicity Commander to be install on the host. The provisionning of the key on the device is described in UG574 SiWx917 SoC Manufacturing Utility User Guide.

2.11.13 Additional Zephyr extension commands

This page documents miscellaneous *Zephyr Extensions*.

Listing boards: `west boards`

The `boards` command can be used to list the boards that are supported by Zephyr without having to resort to additional sources of information.

It can be run by typing:

```
west boards
```

This command lists all supported boards in a default format. If you prefer to specify the display format yourself you can use the `--format` (or `-f`) flag:

```
west boards -f "{arch}:{name}"
```

Additional help about the formatting options can be found by running:

```
west boards -h
```

Shell completion scripts: `west completion`

The `completion` extension command outputs shell completion scripts that can then be used directly to enable shell completion for the supported shells.

It currently supports the following shells:

- bash
- zsh
- fish
- powershell (board qualifiers only)

Additional instructions are available in the command's help:

```
west help completion
```

Installing CMake packages: `west zephyr-export`

This command registers the current Zephyr installation as a CMake config package in the CMake user package registry.

In Windows, the CMake user package registry is found in `HKEY_CURRENT_USER\Software\Kitware\CMake\Packages`.

In Linux and MacOS, the CMake user package registry is found in. `~/.cmake/packages`.

You may run this command when setting up a Zephyr workspace. If you do, application CMakeLists.txt files that are outside of your workspace will be able to find the Zephyr repository with the following:

```
find_package(Zephyr REQUIRED HINTS $ENV{ZEPHYR_BASE})
```

See share/zephyr-package/cmake for details.

Software bill of materials: `west spdx`

This command generates a Software Bill of Materials (SBOM) for a Zephyr build as a set of SPDX documents. It records the source files that went into the build, the build artifacts they produced, and the relationships between them. The license and copyright of every file are scanned and filled into the documents, together with file hashes.

Choosing an SPDX version `west spdx` can emit either of the two major SPDX specification families. SPDX 2.3 is the default; select another version with the `--spdx-version` option.

SPDX 2.3 is a superset of 2.2 and adds fields such as `PrimaryPackagePurpose`. Pick SPDX 2.x for compatibility with tooling that does not yet understand SPDX 3; pick SPDX 3.0 or above for the richer, machine-readable build provenance described in *Build profile (SPDX 3.0)*.

> **Note**
>
> SPDX 3.1 support is experimental: the SPDX 3.1 specification is still in development.

Generating SPDX documents

1. Enable `CONFIG_BUILD_OUTPUT_META` in your project, so that the build records what `west spdx` needs.
2. Build your application:

```
west build -d BUILD_DIR [...]
```

3. Generate SPDX documents using this build directory:

   ```
   west spdx -d BUILD_DIR
   ```

   This generates SPDX 2.3 tag-value documents by default. To generate SPDX 2.2 or 3.0 documents instead, pass `--spdx-version`:

   ```
   west spdx -d BUILD_DIR --spdx-version 3.0
   ```

Note

When building with *Sysbuild (System build)*, make sure you target the actual application which you want to generate the SBOM for. For example, if the application is named `hello_world`:

```
west build --sysbuild -d BUILD_DIR
west spdx -d BUILD_DIR/hello_world
```

Output documents The documents are written to `BUILD_DIR/spdx/` (override with `-s`). The same set of bill-of-materials (BOM) documents is produced regardless of the SPDX version; only the file extension differs: `.spdx` for the SPDX 2.x tag-value format and `.jsonld` for the SPDX 3.0 JSON-LD format:

- `app`: BOM for the application source files used for the build
- `zephyr`: BOM for the specific Zephyr source code files used for the build
- `build`: BOM for the built output files
- `modules-deps`: BOM for modules dependencies. Check *modules* for more details.

For SPDX 3.0, every document declares conformance to the Core, Software and Simple Licensing profiles, and `build.jsonld` additionally declares the *Build profile* that captures how the artifacts were produced.

Every file in the bill-of-materials is scanned so that its hashes (SHA256, SHA1 and MD5) can be recorded, together with its license and copyright.

Both are resolved with the third-party `reuse` tool from the REUSE group, so `west spdx` honours every way the REUSE specification allows them to be declared: an `SPDX-License-Identifier` and `SPDX-FileCopyrightText` comment in the file itself, a `.license` file sitting next to it, or a `REUSE.toml` at the root of the repository annotating whole sets of paths at once. That last form is the only way to license a file that cannot hold a comment of its own, binary blobs in particular.

What is found is written out as `LicenseInfoInFile`, `LicenseConcluded` and `FileCopyrightText` (SPDX 2.x), or as the element's license and copyright properties (SPDX 3.0).

Note

Copyright extraction uses heuristics that may not capture complete notice text, so `FileCopyrightText` content is best-effort. This aligns with SPDX specification recommendations.

Relationships SPDX relationships are created to indicate dependencies between CMake build targets, build targets that are linked together, and source files that are compiled to generate the built library files.

The two specification families express build provenance differently:

- In **SPDX 2.x**, each generated artifact carries file-level `GENERATED_FROM` relationships pointing back at the source (and, with `--analyze-includes`, header) files it was compiled from.
- In **SPDX 3.0**, that provenance is carried by the *Build profile* instead, using `hasInput`/`hasOutput`/`usesTool` relationships scoped to the `build` lifecycle.

Build profile (SPDX 3.0) When generating SPDX 3.0 documents, `west spdx` populates the SPDX 3.0 Build profile so the SBOM records not just *what* was built but *how* it was built. The information is collected automatically from the CMake file-API, and lives in `build.jsonld`.

The profile adds a `build_Build` element describing the overall build: its build type, the CMake generator and build configuration, and selected environment variables such as `BOARD` and `ARCH`. The toolchain (CMake, the compilers, assembler, linker and archiver) is recorded as `Tool` elements, each with its path and version. Build-scoped relationships then link the build to its inputs (the source packages and compiled files), its outputs (the final image) and the tools it used.

Each intermediate target, such as a static library, also gets its own sub-build capturing the exact sources, tools and compile flags that produced its artifact, so any output can be traced back to how it was built.

Command-line options `west spdx` accepts these additional options:

- `-i`, `--init`: create the CMake file-based API query in a build directory before it is configured. Deprecated, and to be removed in Zephyr 5.0: a build with `CONFIG_BUILD_OUTPUT_META` now requests the query itself.
- `-n PREFIX`: a prefix for the Document Namespaces that will be included in the generated SPDX documents. See SPDX specification clause 6 for details. If `-n` is omitted, a default namespace will be generated according to the default format described in section 2.5 using a random UUID.
- `-s SPDX_DIR`: specifies an alternate directory where the SPDX documents should be written instead of `BUILD_DIR/spdx/`.
- `--spdx-version {2.2,2.3,3.0,3.1}`: specifies which SPDX specification version to use. Defaults to `2.3`. See *Choosing an SPDX version* for the differences between the versions.
- `--analyze-includes`: in addition to recording the compiled source code files (e.g. `.c`, `.S`) in the bills-of-materials, also attempt to determine the specific header files that are included for each `.c` file.

  This takes longer, as it performs a dry run using the C compiler for each `.c` file using the same arguments that were passed to it for the actual build.
- `--include-sdk`: with `--analyze-includes`, also create a fourth SPDX document, `sdk.spdx` (or `sdk.jsonld`), which lists header files included from the SDK.

Warning

The generation of SBOM documents for the `native_sim` platform is currently not supported.

Working with binary blobs: `west blobs`

The `blobs` command allows users to interact with *binary blobs* declared in one or more *modules* via their *module.yml* file.

The `blobs` command has three sub-commands, used to list, fetch or clean (i.e. delete) the binary blobs themselves.

You can list binary blobs while specifying the format of the output:

```
west blobs list -f '{module}: {type} {path}'
```

For the full set of variables available in `-f/--format` run `west blobs -h`.

Fetching blobs works in a similar manner:

```
west blobs fetch
```

Note that, as described in *the modules section*, fetched blobs are stored in a `zephyr/blobs/` folder relative to the root of the corresponding module repository.

As does deleting them:

```
west blobs clean
```

Additionally the tool allows you to specify the modules you want to list, fetch or clean blobs for by typing the module names as a command-line parameter.

The argument `--allow-regex` can be passed `west blobs fetch` to restrict the specific blobs that are fetched, by passing a regular expression:

```
# For example, only download esp32 blobs, skip the other variants
west blobs fetch hal_espressif --allow-regex 'lib/esp32/.*'
```

An auto-cache directory can be provided via the `--auto-cache` cli argument or via the `blobs.auto-cache` config option. When enabled, the auto-cache directory is automatically populated whenever a blob is missing and downloaded.

One or more additional cache directories (separated by `;`) can be provided in `--cache-dirs` cli argument or `blobs.cache-dirs` config option.

`west blobs fetch` searches all configured cache directories (including the auto-cache) for a matching blob filename. Cached files may be stored either under their original filename or with a SHA-256 suffix (`<filename>.<sha>`). If found, the blob is copied from the cache to the blob path; otherwise it is downloaded from its URL(s) to the blob path.

One or more download mirrors can be configured via the `blobs.mirrors` config option. Its value is a JSON object that contains one or more key-value pairs, where each key is a remote URL prefix (a string) and each value is either a single mirror URL prefix (a string) or a list of mirror URL prefixes (an array of strings).

A single mirror for a remote URL prefix:

```
west config blobs.mirrors '{"https://github.com/":
↪"https://example.com/github-mirror/"}'
```

More than one mirror for the same remote URL prefix, tried in list order:

```
west config blobs.mirrors '{
  "https://github.com/": [
    "https://example.com/github1-mirror/",
    "https://example.com/github2-mirror/"
  ]
}'
```

For each blob URL, every mirror whose remote URL prefix matches is tried, ordered so that the *longest* (most specific) matching remote URL prefix is tried first (like git's `insteadOf`); mirrors for shorter, less specific matches are tried afterward. Mirrors configured for the same remote URL prefix are tried in the order they are listed. The original URL is tried last, as a fallback if every mirror fails.

Twister wrapper: `west twister`

This command is a wrapper for *twister*.

Twister can then be invoked via west as follows:

```
west twister -help
west twister -T tests/ztest/base
```

Working with binary descriptors: `west bindesc`

The `bindesc` command allows users to read *binary descriptors* of executable files. It currently supports `.bin`, `.hex`, `.elf` and `.uf2` files as input.

You can search for a specific descriptor in an image, for example:

```
west bindesc search KERNEL_VERSION_STRING build/zephyr/zephyr.bin
```

You can search for a custom descriptor by type and ID, for example:

```
west bindesc custom_search STR 0x200 build/zephyr/zephyr.bin
```

You can dump all of the descriptors in an image using:

```
west bindesc dump build/zephyr/zephyr.bin
```

You can extract the descriptor data area of the image to a file using:

```
west bindesc extract
```

You can list all known standard descriptor names using:

```
west bindesc list
```

You can print the offset of the descriptors inside the image using:

```
west bindesc get_offset
```

Indexing the sources with GNU Global: `west gtags`

Important

You must install the `gtags` and `global` programs provided by GNU Global to use this command.

The `west gtags` command lets you create a GNU Global tags file for the entire west workspace:

```
west gtags
```

This will create a tags file named `GTAGS` in the workspace *topdir* (it will also create other Global-related metadata files named `GPATH` and `GRTAGS` in the same place).

You can then run the `global` command anywhere inside the workspace to search for symbol locations using this tags file.

For example, to search for definitions of the `arch_system_halt()` function, starting from the `zephyr/drivers` directory:

```
$ cd zephyr/drivers
$ global -x arch_system_halt
arch_system_halt   65 ../arch/arc/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt  455 ../arch/arm64/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt  137 ../arch/nios2/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt   18 ../arch/posix/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt   17 ../arch/x86/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt  126 ../arch/xtensa/core/fatal.c FUNC_NORETURN void␣
↪arch_system_halt(unsigned int reason)
arch_system_halt   21 ../kernel/fatal.c FUNC_NORETURN __weak void␣
↪arch_system_halt(unsigned int reason)
```

This prints the search symbol, the line it is defined on, a relative path to the file it is defined in, and the line itself, for all places where the symbol is defined.

Additional tips:

- This can also be useful to search for vendor HAL function definitions.
- See the `global` command's manual page for more information on how to use this tool.
- You should run `global`, **not** `west global`. There is no need for a separate `west global` command since `global` already searches for the `GTAGS` file starting from your current working directory. This is why you need to run `global` from inside the workspace.

Working with patches: `west patch`

The `patch` command allows users to apply patches to Zephyr or Zephyr modules in a controlled manner that makes automation and tracking easier for external applications that use the *T2 star topology*. The *patches.yml* file stores metadata about patch files and fills-in the gaps between official Zephyr releases, so that users can easily see the status of any upstreaming efforts, and determine which patches to drop before upgrading to the next Zephyr release.

There are several sub-commands available to manage patches for Zephyr or other modules in the workspace:

- `apply`: apply patches listed in `patches.yml`
- `reverse`: reverse patches listed in `patches.yml` that have been previously applied
- `clean`: remove all patches that have been applied, and reset to the manifest checkout state
- `list`: list all patches in `patches.yml`
- `gh-fetch`: fetch patches from a GitHub pull request

```
west-workspace/
└── application/
   ...
   ├── west.yml
   └── zephyr
       ├── module.yml
       ├── patches
       │   ├── bootloader
       │   │   └── mcuboot
       │   │       └── my-tweak-for-mcuboot.patch
       │   └── zephyr
```

(continues on next page)

(continued from previous page)

```
|       └── my-zephyr-change.patch
└── patches.yml
```

In this example, the *west manifest* file, `west.yml`, would pin to a specific Zephyr revision (e.g. `v4.1.0`) and apply patches against that revision of Zephyr and the specific revisions of other modules used in the application. However, this application needs two changes in order to meet requirements; one for Zephyr and another for MCUBoot.

```
patches:
  - path: zephyr/my-zephyr-change.patch

    issue: https://github.com/zephyrproject-rtos/zephyr/issues/<issue-number>
    merge-status: true
    merge-commit: 1234567890abcdef1234567890abcdef12345678
    merge-date: 2025-05-06
    apply-command: git apply
    comments: |
      A change to mcuboot that has been merged already. We can remove this
      patch when we are ready to upgrade to the next Zephyr release.
```

Patches can easily be applied in an automated manner. For example:

```
west init -m <manifest repo> <workspace>
cd <workspace>
west update
west patch apply
```

When it is time to update to a newer version of Zephyr, the `west.yml` file can be updated to point at the next Zephyr release, e.g. `v4.2.0`. Patches that are no longer needed, like `my-tweak-for-mcuboot.patch` in the example above, can be removed from `patches.yml` and from the external application repository, and then the following commands can be run.

```
west patch clean
west update
west patch apply --roll-back # roll-back all patches if one does not apply cleanly
```

Optionally, patches can be reversed rather than cleaning all modules. This leaves non-conflicting, unrelated edits to modules in place, but removes only the changes made by patches. This is useful when developing patches and testing them in an application, but not wanting to clean all patches and lose any manual edits made to the module.

```
west patch reverse
```

If a patch needs to be reworked, remember to update the `patches.yml` file with the new SHA256

checksum.

```
sha256sum zephyr/patches/zephyr/my-zephyr-change.patch
7d57ca78d5214f422172cc47fed9d0faa6d97a0796c02485bff0bf29455765e9
```

It is also possible to use `west patch gh-fetch` to fetch patches from a GitHub pull request and automatically create or update the `patches.yml` file. This can be useful when the author already has a number of changes captured in existing upstream pull requests.

```
west patch gh-fetch --owner zephyrproject-rtos --repo zephyr --pull-request
↪<pr-number> \
  --module zephyr --split-commits
```

The above command will create the directory and file structure below, which includes patches for each individual commit associated with the given pull request.

```
zephyr
├── patches
|   ├── first-commit-from-pr.patch
|   ├── second-commit-from-pr.patch
|   └── third-commit-from-pr.patch
└── patches.yml
```

Working with the Zephyr SDK: `west sdk`

The `west sdk` command is a Zephyr-specific west command used to list and install the Zephyr SDK and its toolchains.

Listing SDKs and toolchains To list installed Zephyr SDKs as well as available SDK releases and toolchains, run:

```
west sdk list
```

This command shows:

- Installed SDK versions
- Available SDK releases
- Toolchains included in each SDK

Installing the Zephyr SDK To install the Zephyr SDK, run:

```
west sdk install
```

This command may run in interactive mode and prompt for SDK or toolchain selection. When specific toolchains are provided via `--toolchains`, the command runs non-interactively, which is recommended for automation.

To install specific toolchains only, use the `--toolchains` option:

```
west sdk install --toolchains arm-zephyr-eabi riscv64-zephyr-elf
```

If you are unsure which toolchains you need, run `west sdk list` first to see the available options and avoid downloading unnecessary toolchains, which can save gigabytes of disk space and download time.

2.11.14 History and Motivation

West was added to the Zephyr project to fulfill two fundamental requirements:

- The ability to work with multiple Git repositories
- The ability to provide an extensible and user-friendly command-line interface for basic Zephyr workflows

During the development of west, a set of *Design Constraints* were identified to avoid the common pitfalls of tools of this kind.

Requirements

Although the motivation behind splitting the Zephyr codebase into multiple repositories is outside of the scope of this page, the fundamental requirements, along with a clear justification of the choice not to use existing tools and instead develop a new one, do belong here.

The basic requirements are:

- **R1**: Keep externally maintained code in separately maintained repositories outside of the main zephyr repository, without requiring users to manually clone each of the external repositories
- **R2**: Provide a tool that both Zephyr users and distributors can make use of to benefit from and extend
- **R3**: Allow users and downstream distributions to override or remove repositories without having to make changes to the zephyr repository
- **R4**: Support both continuous tracking and commit-based (bisectable) project updating

Rationale for a custom tool

Some of west's features are similar to those provided by Git Submodules and Google's repo.

Existing tools were considered during west's initial design and development. None were found suitable for Zephyr's requirements. In particular, these were examined in detail:

- Google repo
  - Does not cleanly support using zephyr as the manifest repository (**R4**)
  - Python 2 only
  - Does not play well with Windows
  - Assumes Gerrit is used for code review
- Git submodules
  - Does not fully support **R1**, since the externally maintained repositories would still need to be inside the main zephyr Git tree
  - Does not support **R3**, since downstream copies would need to either delete or replace submodule definitions
  - Does not support continuous tracking of the latest `HEAD` in external repositories (**R4**)
  - Requires hardcoding of the paths/locations of the external repositories

Multiple Git Repositories

Zephyr intends to provide all required building blocks needed to deploy complex IoT applications. This in turn means that the Zephyr project is much more than an RTOS kernel, and is instead a collection of components that work together. In this context, there are a few reasons to work with multiple Git repositories in a standardized manner within the project:

- Clean separation of Zephyr original code and imported projects and libraries
- Avoidance of license incompatibilities between original and imported code
- Reduction in size and scope of the core Zephyr codebase, with additional repositories containing optional components instead of being imported directly into the tree
- Safety and security certifications
- Enforcement of modularization of the components
- Out-of-tree development based on subsets of the supported boards and SoCs

See *Basics* for information on how west workspaces manage multiple git repositories.

Design Constraints

West is:

- **Optional**: it is always *possible* to drop back to "raw" command-line tools, i.e. use Zephyr without using west (although west itself might need to be installed and accessible to the build system). It may not always be *convenient* to do so, however. (If all of west's features were already conveniently available, there would be no reason to develop it.)
- **Compatible with CMake**: building, flashing and debugging, and emulator support will always remain compatible with direct use of CMake.
- **Cross-platform**: West is written in Python 3, and works on all platforms supported by Zephyr.
- **Usable as a Library**: whenever possible, west features are implemented as libraries that can be used standalone in other programs, along with separate command line interfaces that wrap them. West itself is a Python package named `west`; its libraries are implemented as subpackages.
- **Conservative about features**: no features will be accepted without strong and compelling motivation.
- **Clearly specified**: West's behavior in cases where it wraps other commands is clearly specified and documented. This enables interoperability with third party tools, and means Zephyr developers can always find out what is happening "under the hood" when using west.

See Zephyr issue #6205 and for more details and discussion.

`west update` detached HEADs

The use of detached git `HEAD` revisions documented in the *update procedure* confuses and even frustrates some users.

Specifically, users often ask why `west update` doesn't leave existing local branches checked out by default.

This section explains why `west update` behaves the way it does by default, and mentions some other options you have for managing projects that you modified locally.

Two core requirements for `west update` are:

1. safety: the command should not lose any of the user's work
2. determinism: two users running `west update` on the same manifest should get the exact same *workspace* contents

Using detached HEADs helps preserve safety. As documented in the update procedure, using `git checkout --detach` on the updated project to get a detached `HEAD` is a generally safe operation that won't lose the user's work:

- if your work is all safely committed in a local git branch, that branch will be left as-is (see the `git help checkout` output for details)
- if you have uncommitted work, it will be safely kept in your working tree by git if that's possible
- if that's not possible, the entire command will fail, and you can decide what to do with your work before re-running `west update`

Detached HEADs also help ensure determinism:

- Checking out exactly the project revision that's specified in your manifest file is needed to make sure your workspace's files match what's specified in the main manifest. If west did not check out the manifest revision by default, your workspace could be invisibly different from what you would expect given the contents of the manifest files in your working copy. Even worse, the way it was different would depend on exactly what was in your branch before you ran `west update`.
- There is a subtle interaction with *Manifest Imports*. If your project itself has one or more manifest files that are being imported by `west update`, then west needs to check out those files into the working tree so it can resolve the entire imported manifest. If `west update` left a branch checked out in your project, the manifest files in your working tree could be out of date. If west then used those out-of-date files to finish the import, the process could fail unexpectedly or produce other nondeterministic results.

West does not check out the *manifest-rev* branch directly for reasons explained in the documentation for that branch.

This default behavior was chosen a long time ago and it's too late to change it now, since users are depending on it. However, there are other ways to run `west update` if this default doesn't work for you. To learn more, run `west help update` and read the `checked out branch behavior` option group text. For example:

- if you're actively writing some code in your project and you want to keep it up to date after potential changes in the upstream manifest, use `west update --rebase`
- if you've got some local code you'd like to keep around as long as the upstream revision for your project hasn't moved on to something newer, use `west update --keep-descendants`

You can use *West aliases* if you want to set up a shorter way to type one of these commands in your workspace. You can also contribute new options to this option group by sending a pull request to:

https://github.com/zephyrproject-rtos/west

2.11.15 Using Zephyr without west

This page provides information on using Zephyr without west. This is not recommended for beginners due to the extra effort involved. In particular, you will have to do work "by hand" to replace these features:

- cloning the additional source code repositories used by Zephyr in addition to the main zephyr repository, and keeping them up to date
- specifying the locations of these repositories to the Zephyr build system
- flashing and debugging without understanding detailed usage of the relevant host tools

Note

If you have previously installed west and want to stop using it, uninstall it first:

```
pip3 uninstall west
```

Otherwise, Zephyr's build system will find it and may try to use it.

Getting the Source

In addition to downloading the zephyr source code repository itself, you will need to manually clone the additional projects listed in the *west manifest* file inside that repository.

```
mkdir zephyrproject
cd zephyrproject
git clone https://github.com/zephyrproject-rtos/zephyr
# clone additional repositories listed in zephyr/west.yml,
# and check out the specified revisions as well.
```

As you pull changes in the zephyr repository, you will also need to maintain those additional repositories, adding new ones as necessary and keeping existing ones up to date at the latest revisions.

Building applications

You can build a Zephyr application using CMake and Ninja (or make) directly without west installed if you specify any modules manually.

```
cmake -Bbuild -GNinja -DZEPHYR_MODULES=module1;module2;... samples/hello_world
ninja -Cbuild
```

When building with west installed, the Zephyr build system will use it to set *ZEPHYR_MODULES*.

If you don't have west installed and your application does not need any of these repositories, the build will still work.

If you don't have west installed and your application *does* need one of these repositories, you must set **ZEPHYR_MODULES** yourself as shown above.

See *Modules (External projects)* for more details.

Similarly, if your application requires binary blobs and you are not using west, you will need to download and place those blobs in the right places instead of using `west blobs`. See *Binary Blobs* for more details.

Flashing and Debugging

Flashing and debugging are done with the `west flash`, `west debug`, `west debugserver`, `west attach` and `west rtt` commands, which are documented in *Building, Flashing and Debugging*. These commands require west, so they are not available if you are using Zephyr without it.

Without west, you can still flash and debug using any of the *Flash & Debug Host Tools* which work for your board (and which those west commands wrap), but you will have to invoke them yourself, with the right options for your board and application.

For details on west's Python APIs, see west-apis.

2.12 Test Runner (Twister)

Twister scans for the set of test applications in the git repository and attempts to execute them. By default, it tries to build each test application on boards marked as default in the board definition file.

The default options will build the majority of the test applications on a defined set of boards and will run in an emulated environment if available for the architecture or configuration being tested.

Because of the limited test execution coverage, twister cannot guarantee local changes will succeed in the full build environment, but it does sufficient testing by building samples and tests for different boards and different configurations to help keep the complete code tree buildable.

When using (at least) one `-v` option, twister's console output shows for every test application how the test is run (qemu, native_sim, etc.) or whether the binary was just built. The resultant *status* of a test is likewise reported in the `twister.json` and other report files. There are a few reasons why twister only builds a test and doesn't run it:

- The test is marked as `build_only: true` in its `.yaml` configuration file.
- The test configuration has defined a `harness` but you don't have it or haven't set it up.
- The target device is not connected and not available for flashing
- You or some higher level automation invoked twister with `--build-only`.

To run Twister in the local tree, follow the steps below:

```
$ west twister
```

Note

The examples in this document invoke Twister as `west twister`, the *west* extension command, which works the same on all host operating systems. The following invocations are equivalent:

- `west twister ...` (recommended).
- `python .\scripts\twister ...` (Windows): invoking the script directly. This requires the Zephyr environment to be set up first (`source zephyr-env.sh` or `zephyr-env.cmd`).

All forms accept the same command line options.

If you want to run tests on one or more specific platforms, you can use the `--platform` option, it is a platform filter for testing, with this option, test suites will only be built/run on the platforms specified. This option also supports different revisions of one same board, you can use `--platform board@revision` to test on a specific revision.

The list of command line options supported by twister can be viewed with `west twister --help`. See *Command Line Options* for the full set of options.

The following pages cover additional Twister topics:

2.12.1 Command Line Options

The list of command line options supported by Twister can be viewed with `west twister --help`. The full set of options is shown below (rendered at documentation build time):

```
$ $ZEPHYR_BASE/scripts/twister --help
usage: twister [-h] [-E FILENAME] [-F FILENAME] [-T TESTSUITE_ROOT] [-f]

                [-X FIXTURE] [-x EXTRA_ARGS] [-y]
                [--alt-config-root ALT_CONFIG_ROOT]
                ...

positional arguments:
  extra_test_args       Additional args following a '--' are passed to the
                        test binary

options:
  -h, --help            show this help message and exit
  -G, --integration     Run integration tests
  --emulation-only      Only build and run emulation platforms
  --simulation
↪{mdb-nsim,nsim,renode,qemu,tsim,armfvp,xt-sim,native,custom,simics,whisper}
```

(continues on next page)

(continued from previous page)

```
                      Selects which simulation to use. Must match one of the
                      names defined in the board's manifest. If multiple
                      simulator are specified in the selected board and this
                      argument is not passed, then the first simulator is
                      selected.
  --device-testing    Test on device directly. Specify the serial device to
                      use with the --device-serial option.
  --pre-script PRE_SCRIPT
                      specify a pre script. This will be executed before
                      device handler open serial port and invoke runner.
  --device-serial DEVICE_SERIAL
                      Serial device for accessing the board (e.g.,
                      /dev/ttyACM0)
  --device-serial-baud DEVICE_SERIAL_BAUD
                      Serial device baud rate (default 115200)
  --device-serial-pty DEVICE_SERIAL_PTY
                      Script for controlling pseudoterminal. Twister
                      believes that it interacts with a terminal when it
                      actually interacts with the script. E.g "twister
                      --device-testing --device-serial-pty <script>
  --generate-hardware-map GENERATE_HARDWARE_MAP
                      Probe serial devices connected to this platform and
                      create a hardware map file to be used with --device-
                      testing
  --hardware-map HARDWARE_MAP
                      Load hardware map from a file. This will be used for
                      testing on hardware that is listed in the file.
  --persistent-hardware-map
                      With --generate-hardware-map, tries to use persistent
                      names for serial devices on platforms that support
                      this feature (currently only Linux).
  --device-flash-with-test
                      Add a test case timeout to the flash operation timeout
                      when flash operation also executes test case on the
                      platform.
  --device-flash-timeout DEVICE_FLASH_TIMEOUT
                      Set timeout for the device flash operation in seconds.
  --flash-before      Flash device before attaching to serial port. This is
                      useful for devices that share the same port for
                      programming and serial console, or use soft-USB, where
                      flash must come first. Also, it skips reading
                      remaining logs from the old image run.
  --flash-command FLASH_COMMAND
                      Instead of 'west flash', uses a custom flash command
                      to flash when running with --device-testing. Supports
                      comma-separated argument list, the script is also
                      passed a --build-dir flag with the build directory as
                      an argument, and a --board-id flag with the board or
                      probe id if available.
  --west-flash [WEST_FLASH]
                      Comma separated list of additional flags passed to
                      west when running with --device-testing. E.g "twister
                      --device-testing --device-serial /dev/ttyACM0 --west-
                      flash="--board-id=foobar,--erase" will translate to
                      "west flash -- --board-id=foobar --erase"
  --west-runner WEST_RUNNER
```

(continues on next page)

(continued from previous page)

```
                      Uses the specified west runner instead of default when
                      running with --west-flash. E.g "twister --device-
                      testing --device-serial /dev/ttyACM0 --west-flash
                      --west-runner=pyocd" will translate to "west flash
                      --runner pyocd"
--west-flash-cmd {flash,debug}
                      Uses the specified west command. twister will use
                      flash if not set E.g "twister --device-testing
                      --device-serial /dev/ttyACM0 --west-flash-cmd="flash"
                      will translate to "west flash ..."
-a ARCH, --arch ARCH  Arch filter for testing. Takes precedence over
                      --platform. If unspecified, test all arches. Multiple
                      invocations are treated as a logical 'or' relationship
--vendor VENDOR       Vendor filter for testing
-p PLATFORM, --platform PLATFORM
                      Platform filter for testing. This option may be used
                      multiple times. Test suites will only be built/run on
                      the platforms specified. If this option is not used,
                      then platforms marked as default in the platform
                      metadata file will be chosen to build and test.
-P EXCLUDE_PLATFORM, --exclude-platform EXCLUDE_PLATFORM
                      Exclude platforms and do not build or run any tests on
                      those platforms. This option can be called multiple
                      times.
--platform-pattern PLATFORM_PATTERN
                      Platform regular expression filter for testing. This
                      option may be used multiple times. Test suites will
                      only be built/run on the platforms matching the
                      specified patterns. If this option is not used, then
                      platforms marked as default in the platform metadata
                      file will be chosen to build and test.
--test-pattern TEST_PATTERN
                      Run only the tests matching the specified pattern. The
                      pattern can include regular expressions.
--filter {buildable,runnable}
                      Filter tests to be built and executed. By default
                      everything is built and if a test is runnable
                      (emulation or a connected device), it is run. This
                      option allows for example to only build tests that can
                      actually be run. Runnable is a subset of buildable.
-t TAG, --tag TAG     Specify tags to restrict which tests to run by tag
                      value. Default is to not do any tag filtering.
                      Multiple invocations are treated as a logical 'or'
                      relationship.
-e EXCLUDE_TAG, --exclude-tag EXCLUDE_TAG
                      Specify tags of tests that should not run. Default is
                      to run all tests with all tags.
-K, --force-platform  Force testing on selected platforms, even if they are
                      excluded in the test configuration (testcase.yaml).
--ignore-platform-key
                      Do not filter based on platform key
--level LEVEL         Test level to be used. By default, no levels are used
                      for filtering and do the selection based on existing
                      filters.
-b, --build-only      Only build the code, do not attempt to run the code on
                      targets.
```

(continues on next page)

(continued from previous page)

```
  --prep-artifacts-for-testing
                        Generate artifacts for testing, do not attempt to run
                        the code on targets.
  --package-artifacts PACKAGE_ARTIFACTS
                        Package artifacts needed for flashing in a file to be
                        used with --test-only
  --test-only           Only run device tests with current artifacts, do not
                        build the code
  --post-build-checks   Run post-build checks on each build directory once a
                        build completes, for example detecting git
                        repositories accidentally cloned into a build
                        directory. Disabled by default; intended to be enabled
                        in CI.
  --timeout-multiplier TIMEOUT_MULTIPLIER
                        Globally adjust tests timeouts by specified
                        multiplier. The resulting test timeout would be
                        multiplication of test timeout value, board-level
                        timeout multiplier and global timeout multiplier (this
                        parameter)
  --pytest-args PYTEST_ARGS
                        Pass additional arguments to the pytest subprocess.
                        This parameter will extend the pytest_args from the
                        harness_config in YAML file.
  --ctest-args CTEST_ARGS
                        Pass additional arguments to the ctest subprocess.
                        This parameter will extend the ctest_args from the
                        harness_config in YAML file.
  --enable-valgrind     Run binary through valgrind and check for several
                        memory access errors. Valgrind needs to be installed
                        on the host. This option only works with host binaries
                        such as those generated for the native_sim
                        configuration and is mutual exclusive with --enable-
                        asan.
  --enable-asan         Enable address sanitizer to check for several memory
                        access errors. Libasan needs to be installed on the
                        host. This option only works with host binaries such
                        as those generated for the native_sim configuration
                        and is mutual exclusive with --enable-valgrind.
  -A BOARD_ROOT, --board-root BOARD_ROOT
                        Directory to search for board configuration files. All
                        .yaml files in the directory will be processed. The
                        directory should have the same structure in the main
                        Zephyr tree: boards/<vendor>/<board_name>/
  --allow-installed-plugin
                        Allow to use pytest plugin installed by pip for pytest
                        tests.
  -B SUBSET, --subset SUBSET
                        Only run a subset of the tests, 1/4 for running the
                        first 25%, 3/5 means run the 3rd fifth of the total.
                        This option is useful when running a large number of
                        tests on different hosts to speed up execution time.
  --shuffle-tests       Shuffle test execution order to get randomly
                        distributed tests.
  --shuffle-tests-seed SHUFFLE_TESTS_SEED
                        Seed value for random generator used to shuffle tests.
                        If not provided, seed in generated by system. Used
```

(continues on next page)

(continued from previous page)

```
                        only when --shuffle-tests is provided.
  -c, --clobber-output  Cleaning the output directory will simply delete it
                        instead of the default policy of renaming.
  --cmake-only          Only run cmake, do not build or run.
  --test-config TEST_CONFIG
                        Path to file with plans and test configurations.
  --disable-suite-name-check
                        Disable extended test suite name verification at the
                        beginning of Ztest test. This option could be useful
                        for tests or platforms, which from some reasons cannot
                        print early logs.
  --enable-lsan         Enable leak sanitizer to check for heap memory leaks.
                        Libasan needs to be installed on the host. This option
                        only works with host binaries such as those generated
                        for the native_sim configuration and when --enable-
                        asan is given.
  --enable-ubsan        Enable undefined behavior sanitizer to check for
                        undefined behaviour during program execution. It uses
                        an optional runtime library to provide better error
                        diagnostics. This option only works with host binaries
                        such as those generated for the native_sim
                        configuration.
  --force-color         Always output ANSI color escape sequences even when
                        the output is redirected (not a tty)
  --force-toolchain     Do not filter based on toolchain, use the set
                        toolchain unconditionally
  -i, --inline-logs     Upon test failure, print relevant log data to stdout
                        instead of just a path to it.
  -j JOBS, --jobs JOBS  Number of jobs for building, defaults to number of CPU
                        threads, overcommitted by factor 2 when --build-only.
  -l, --all             Build/test on all platforms. Any --platform arguments
                        ignored.
  --log-file FILENAME   Specify a file where to save logs.
  -M [{pass,all}], --runtime-artifact-cleanup [{pass,all}]
                        Cleanup test artifacts. The default behavior is 'pass'
                        which only removes artifacts of passing tests. If you
                        wish to remove all artificats including those of
                        failed tests, use 'all'.
  --keep-artifacts KEEP_ARTIFACTS
                        Keep specified artifacts when cleaning up at runtime.
                        Multiple invocations are possible.
  -n, --no-clean        Re-use the outdir before building. Will result in
                        faster compilation since builds will be incremental.
  --aggressive-no-clean
                        Re-use the outdir before building and do not re-run
                        cmake. Will result in much faster compilation since
                        builds will be incremental. This option might result
                        in build failures and inconsistencies if dependencies
                        change or when applied on a significantly changed code
                        base. Use on your own risk. It is recommended to only
                        use this option for local development and when testing
                        localized change in a subsystem.
  --detailed-test-id    Compose each test Suite name from its configuration
                        path (relative to root) and the appropriate Scenario
                        name using PATH_TO_TEST_CONFIG/SCENARIO_NAME schema.
  --no-detailed-test-id
```

(continues on next page)

(continued from previous page)

```
                      Don't prefix each test Suite name with its
                      configuration path, so it is the same as the
                      appropriate Scenario name.
  --detailed-skipped-report
                      Generate a detailed report with all skipped test cases
                      including those that are filtered based on testsuite
                      definition.
  -O OUTDIR, --outdir OUTDIR
                      Output directory for logs and binaries. Default is
                      'twister-out' in the current directory. This directory
                      will be cleaned unless '--no-clean' is set. The '--
                      clobber-output' option controls what cleaning does.
  -o REPORT_DIR, --report-dir REPORT_DIR
                      Output reports containing results of the test run into
                      the specified directory. The output will be both in
                      JSON and JUNIT format (twister.json and twister.xml).
  --overflow-as-errors  Treat RAM/SRAM overflows as errors.
  --report-filtered     Include filtered tests in the reports.
  --platform-reports    Create individual reports for each platform.
  --quarantine-list FILENAME
                      Load list of test scenarios under quarantine. The
                      entries in the file need to correspond to the test
                      scenarios names as in corresponding tests .yaml files.
                      These scenarios will be skipped with quarantine as the
                      reason.
  --quarantine-verify   Use the list of test scenarios under quarantine and
                      run them to verify their current status.
  --quit-on-failure     quit twister once there is build / run failure
  --report-name REPORT_NAME
                      Create a report with a custom name.
  --report-summary [REPORT_SUMMARY]
                      Show failed/error report from latest run. Default
                      shows all items found. However, you can specify the
                      number of items (e.g. --report-summary 15). It also
                      works well with the --outdir switch.
  --report-suffix REPORT_SUFFIX
                      Add a suffix to all generated file names, for example
                      to add a version or a commit ID.
  --report-all-options  Show all command line options applied, including
                      defaults, as environment.options object in
                      twister.json. Default: show only non-default settings.
  --retry-failed RETRY_FAILED
                      Retry failing tests again, up to the number of times
                      specified.
  --retry-interval RETRY_INTERVAL
                      Retry failing tests after specified period of time.
  --retry-build-errors  Retry build errors as well.
  -S, --enable-slow     Execute time-consuming test cases that have been
                      marked as 'slow' in testcase.yaml. Normally these are
                      only built.
  --enable-slow-only    Execute time-consuming test cases that have been
                      marked as 'slow' in testcase.yaml only. This also set
                      the option --enable-slow
  --seed SEED           Seed for native_sim pseudo-random number generator
  --short-build-path    Create shorter build directory paths based on symbolic
                      links. The shortened build path will be used by CMake
```

(continues on next page)

(continued from previous page)

```
                        for generating the build system and executing the
                        build. Use this option if you experience build
                        failures related to path length, for example on
                        Windows OS. This option can be used only with '--
                        ninja' argument (to use Ninja build generator).
  --timestamps          Print all messages with time stamps.
  -u, --no-update       Do not update the results of the last run. This option
                        is only useful when reusing the same output directory
                        of twister, for example when re-running failed tests
                        with --only-failed or --no-clean. This option is for
                        debugging purposes only.
  -v, --verbose         Call multiple times to increase verbosity.
  --console-monitor     Show a live full-screen dashboard for the run in this
                        terminal instead of the normal scrolling output:
                        progress, in-flight jobs with their pipeline stage,
                        and a filterable instance table with per-instance
                        details and logs. Requires an interactive terminal
                        (ignored otherwise). Press q to leave the dashboard;
                        while the run is still going, normal console output
                        resumes, and after it finishes, reports are written as
                        usual. Normal log output goes to twister.log while the
                        dashboard is shown.
  -ll {NOTSET,DEBUG,INFO,WARNING,ERROR,CRITICAL}, --log-level
↪{NOTSET,DEBUG,INFO,WARNING,ERROR,CRITICAL}
                        Select the threshold event severity for which you'd
                        like to receive logs in console. Default is INFO.
  -W, --disable-warnings-as-errors
                        Do not treat warning conditions as errors.
  -X FIXTURE, --fixture FIXTURE
                        Specify a fixture that a board might support.
  -x EXTRA_ARGS, --extra-args EXTRA_ARGS
                        Extra CMake cache entries to define when building test
                        cases. May be called multiple times. The key-value
                        entries will be prefixed with -D before being passed
                        to CMake. E.g "twister -x=USE_CCACHE=0" will translate
                        to "cmake -DUSE_CCACHE=0" which will ultimately
                        disable ccache.
  -y, --dry-run         Create the filtered list of test cases, but don't
                        actually run them. Useful if you're just interested in
                        the test plan generated for every run and saved in the
                        specified output directory (testplan.json).
  --alt-config-root ALT_CONFIG_ROOT
                        Alternative test configuration root/s. When a test is
                        found, Twister will check if a test configuration file
                        exist in any of the alternative test configuration
                        root folders. For example, given
                        $test_root/tests/foo/testcase.yaml, Twister will use
                        $alt_config_root/tests/foo/testcase.yaml if it exists

Test case selection:

  Artificially long but functional example:
      $ ./scripts/twister -v     \
        --testsuite-root tests/ztest/base    \
        --testsuite-root tests/kernel   \
        --test      tests/ztest/base/testing.ztest.verbose_0  \
```

(continues on next page)

(continued from previous page)

```
       --test      tests/kernel/fifo/fifo_api/kernel.fifo

    "kernel.fifo.poll" is one of the test section names in
                                __/fifo_api/testcase.yaml

  -F FILENAME, --load-tests FILENAME
                        Load a list of tests and platforms to be run from a
                        JSON file ('testplan.json' schema).
  -T TESTSUITE_ROOT, --testsuite-root TESTSUITE_ROOT
                        Base directory to recursively search for test cases.
                        All testcase.yaml files under here will be processed.
                        May be called multiple times. Defaults to the
                        'samples/' and 'tests/' directories at the base of the
                        Zephyr tree.
  -f, --only-failed     Run only those tests that failed the previous twister
                        run invocation.
  -s TEST, --test TEST, --scenario TEST
                        Run only the specified test suite scenario. These are
                        named by 'path/relative/to/Zephyr/base/section.subsect
                        ion_in_testcase_yaml', or just 'section.subsection'
                        identifier. With '--testsuite-root' option the
                        scenario will be found faster.
  --sub-test SUB_TEST   Recursively find sub-test functions (test cases) and
                        run the entire test scenario (section.subsection)
                        where they were found, including all sibling test
                        functions. Sub-tests are named by: 'section.subsection
                        _in_testcase_yaml.ztest_suite.ztest_without_test_prefi
                        x'. Example_1: 'kernel.fifo.fifo_api_1cpu.fifo_loop'
                        where 'kernel.fifo' is a test scenario name
                        (section.subsection) and 'fifo_api_1cpu.fifo_loop' is
                        a Ztest 'suite_name.test_name'. Example_2:
                        'debug.coredump.logging_backend' is a standalone test
                        scenario name. Note: This selection mechanism works
                        only for Ztest suite and test function names in the
                        source files which are not generated by macro-
                        substitutions.
  -N, --ninja           Use the Ninja generator with CMake. (This is the
                        default)
  -k, --make            Use the unix Makefile generator with CMake.

Test plan reporting:
  Report the composed test plan details and exit (dry-run).

  -E FILENAME, --save-tests FILENAME
                        Write a list of tests and platforms to be run to
                        FILENAME file and stop execution. The resulting file
                        will have the same content as 'testplan.json'.
  --list-tests          List of all sub-test functions recursively found in
                        all --testsuite-root arguments. The output is
                        flattened and reports detailed sub-test names without
                        their directories. Note: sub-test names can share the
                        same test scenario identifier prefix
                        (section.subsection) even if they are from different
                        test projects.
  --test-tree           Output the test plan in a tree form.
```

(continues on next page)

```
  --list-tags           List all tags occurring in selected tests.

Memory footprint:
  Collect and report ROM/RAM size footprint for the test instance images built.

  --create-rom-ram-report
                        Generate detailed json reports with ROM/RAM symbol
                        sizes for each test image built using additional build
                        option `--target footprint`.
  --footprint-report [{all,ROM,RAM}]
                        Select which memory area symbols' data to collect as
                        'footprint' property of each test suite built, and
                        report in 'twister_footprint.json' together with the
                        relevant execution metadata the same way as in
                        `twister.json`. Implies '--create-rom-ram-report' to
                        generate the footprint data files. No value means
                        'all'. Default: None
  --enable-size-report  Collect and report ROM/RAM section sizes for each test
                        image built.
  --footprint-from-buildlog
                        Take ROM/RAM sections footprint summary values from
                        the 'build.log' instead of 'objdump' results used
                        otherwise.Requires --enable-size-report or one of the
                        baseline comparison modes.Warning: the feature will
                        not work correctly with sysbuild.
  -m, --last-metrics    Compare footprints to the previous twister invocation
                        as a baseline running in the same output directory.
                        Implies --enable-size-report option.
  --compare-report COMPARE_REPORT
                        Use this report file as a baseline for footprint
                        comparison. The file should be of 'twister.json'
                        schema. Implies --enable-size-report option.
  --show-footprint      With footprint comparison to a baseline, log ROM/RAM
                        section deltas.
  -H FOOTPRINT_THRESHOLD, --footprint-threshold FOOTPRINT_THRESHOLD
                        With footprint comparison to a baseline, warn the user
                        for any of the footprint metric change which is
                        greater or equal to the specified percentage value.
                        Default is 5.0 for 5.0% delta from the new footprint
                        value. Use zero to warn on any footprint metric
                        increase.
  -D, --all-deltas      With footprint comparison to a baseline, warn on any
                        footprint change, increase or decrease. Implies
                        --footprint-threshold=0
  -z FILENAME, --size FILENAME
                        Ignore all other command line options and just produce
                        a report to stdout with ROM/RAM section sizes on the
                        specified binary images.

Code coverage:
  Build with code coverage support, collect code coverage statistics executing␣
↪tests, compose code coverage report at the end.
  Effective for devices with 'HAS_COVERAGE_SUPPORT'.

  --enable-coverage     Enable code coverage collection using gcov.
  -C, --coverage        Generate coverage reports. Implies --enable-coverage
                        to collect the coverage data first.
```

(continues on next page)

(continued from previous page)

```
  --gcov-tool GCOV_TOOL
                        Path to the 'gcov' tool to use for code coverage
                        reports. By default it will be chosen in the following
                        order: using ZEPHYR_TOOLCHAIN_VARIANT ('llvm': from
                        LLVM_TOOLCHAIN_PATH), gcov installed on the host - for
                        'native' or 'unit' platform types, using
                        ZEPHYR_SDK_INSTALL_DIR.
  --coverage-basedir COVERAGE_BASEDIR
                        Base source directory for coverage report.
  --coverage-platform COVERAGE_PLATFORM
                        Platforms to run coverage reports on. This option may
                        be used multiple times. Default to what was selected
                        with --platform.
  --coverage-tool {lcov,gcovr}
                        Tool to use to generate coverage reports (gcovr -
                        default).
  --coverage-formats COVERAGE_FORMATS
                        Output formats to use for generated coverage reports
                        as a comma-separated list without spaces. Valid
                        options for 'gcovr' tool are:
                        html,xml,csv,txt,coveralls,sonarqube (html - default).
                        Valid options for 'lcov' tool are: html,lcov
                        (html,lcov - default).
  --coverage-per-instance
                        Compose individual coverage reports for each test
                        suite when coverage reporting is enabled; it might run
                        in addition to the default aggregation mode which
                        produces one coverage report for all executed test
                        suites. Default: False
  --disable-coverage-aggregation
                        Don't aggregate coverage report statistics for all the
                        test suites selected to run with enabled coverage.
                        Requires another reporting mode to be active
                        (`--coverage-per-instance`) to have at least one of
                        these reporting modes. Default: False
  --coverage-per-test   Collect a separate coverage artifact for every
                        individual Ztest test case, enabling a per-test to
                        source-code coverage matrix. Requires the 'lcov'
                        coverage tool. Implies --coverage. On platforms that
                        support semihosting (e.g. mps2/*) the per-test data is
                        written straight to the host filesystem, avoiding
                        console traffic. Default: False
```

2.12.2 Integration with pytest test framework

Please mind that integration of twister with pytest is still work in progress. Not every platform type is supported in pytest (yet). If you find any issue with the integration or have an idea for an improvement, please, let us know about it and open a GitHub issue/enhancement.

Introduction

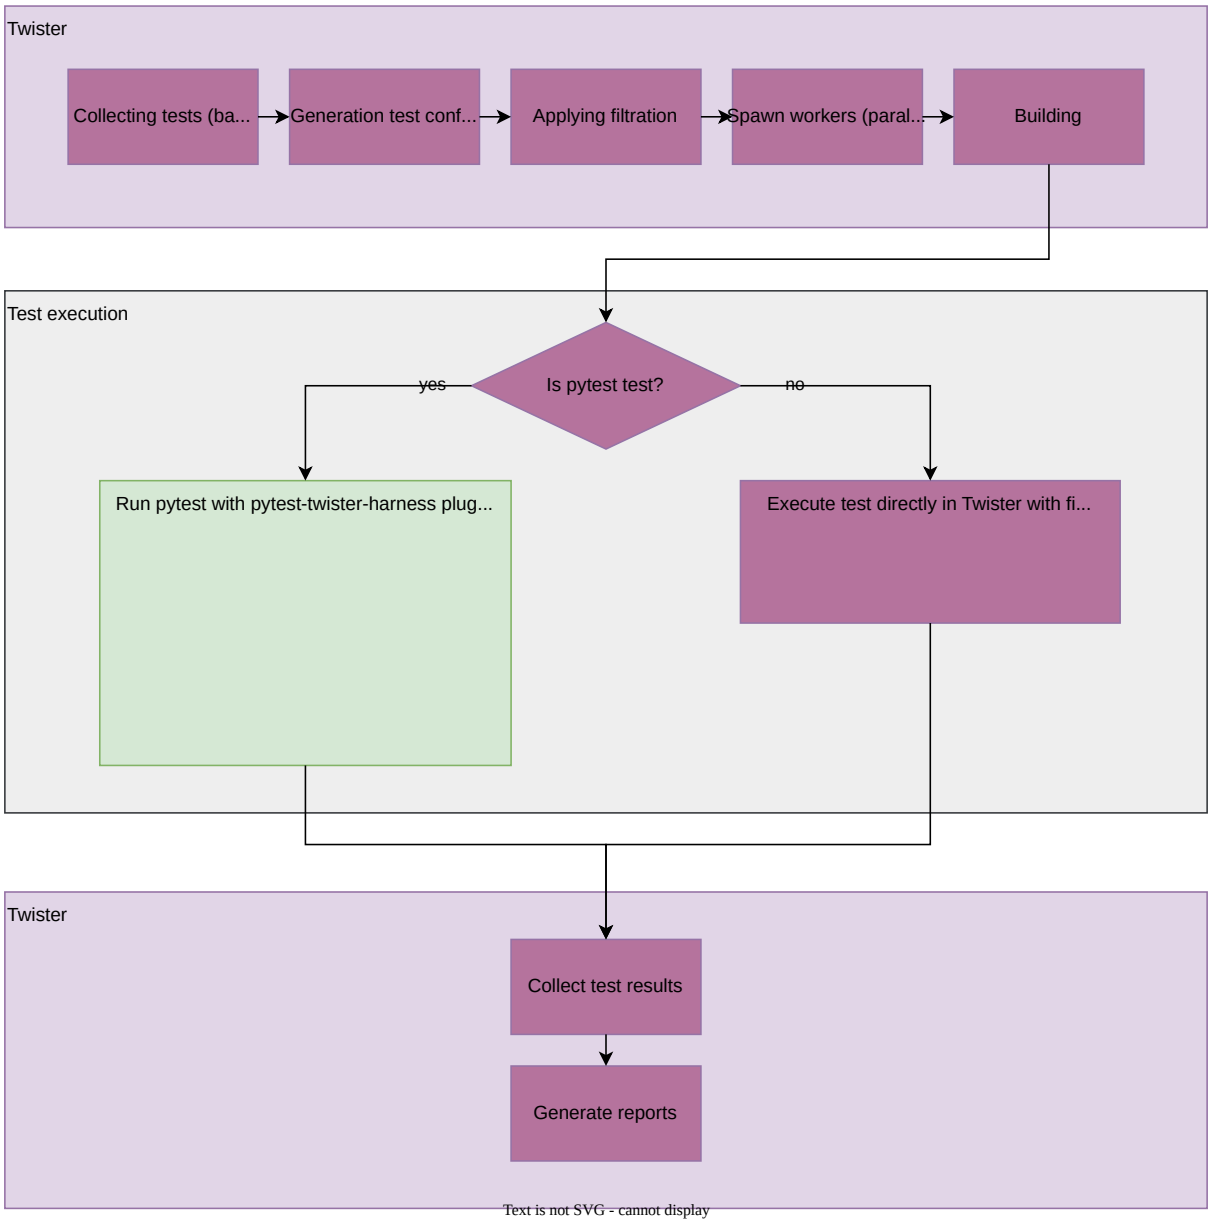
Pytest is a python framework that *"makes it easy to write small, readable tests, and can scale to support complex functional testing for applications and libraries"* (https://docs.pytest.org/en/7.3.x/). Python is known for its free libraries and ease of using it for scripting. In addition, pytest utilizes the concept of plugins and fixtures, increasing its expendability and reusability. A pytest plugin `pytest-twister-harness` was introduced to provide an integration between pytest and

twister, allowing Zephyr's community to utilize pytest functionality with keeping twister as the main framework.

Integration with twister

By default, there is nothing to be done to enable pytest support in twister. The plugin is developed as a part of Zephyr's tree. To enable install-less operation, twister first extends `PYTHONPATH` with path to this plugin, and then during pytest call, it appends the command with `-p twister_harness.plugin` argument. If one prefers to use the installed version of the plugin, they must add `--allow-installed-plugin` flag to twister's call.

Pytest-based test suites are discovered the same way as other twister tests, i.e., by a presence of tests.yaml file. Inside, a keyword `harness` tells twister how to handle a given test. In the case of `harness: pytest`, most of twister workflow (test suites discovery, parallelization, building and reporting) remains the same as for other harnesses. The change happens during the execution step. The below picture presents a simplified overview of the integration.



If `harness: pytest` is used, twister delegates the test execution to pytest, by calling it as a subprocess. Required parameters (such as build directory, device to be used, etc.) are passed through a

YAML configuration file. When pytest is done, twister looks for a pytest report (results.xml) and sets the test result accordingly.

How to create a pytest test

An example folder containing a pytest test, application source code and Twister configuration .yaml file can look like the following:

```
test_foo/
├── pytest/
│   └── test_foo.py
├── src/
│   └── main.c
├── CMakeList.txt
├── prj.conf
└── testcase.yaml
```

An example of a pytest test is given at samples/subsys/testsuite/pytest/shell/pytest/test_shell.py. Using the configuration provided in the `testcase.yaml` file, Twister builds the application from `src` and then, if the .yaml file contains a `harness: pytest` entry, it calls pytest in a separate subprocess. A sample configuration file may look like this:

```
tests:
  some.foo.test:
    harness: pytest
    tags: foo
```

By default, pytest tries to look for tests in a `pytest` directory located next to a directory with binary sources. A keyword `pytest_root` placed under `harness_config` section in .yaml file can be used to point to other files, directories or subtests (more info *here*).

Pytest scans the given locations looking for tests, following its default discovery rules.

Passing extra arguments There are two ways for passing extra arguments to the called pytest subprocess:

1. From .yaml file, using `pytest_args` placed under `harness_config` section - more info *here*.
2. Through Twister command line interface as `--pytest-args` argument. This can be particularly useful when one wants to select a specific testcase from a test suite. For instance, one can use a command:

   ```
   $ west twister --platform native_sim -T samples/subsys/testsuite/pytest/shell␣
   ↪\
   -s samples/subsys/testsuite/pytest/shell/sample.pytest.shell \
   --pytest-args='-k test_shell_print_version'
   ```

   The command line arguments will extend those from the .yaml file. If the same argument is present in both places, the one from the command line will take precedence.

Fixtures

dut Give access to a *DeviceAdapter* type object, that represents Device Under Test. This fixture is the core of pytest harness plugin. It is required to launch DUT (initialize logging, flash device, connect serial etc). This fixture yields a device prepared according to the requested type (`native`, `qemu`, `hardware`, etc.). All types of devices share the same API. This allows for writing tests which are device-type-agnostic. Scope of this fixture is determined by the `pytest_dut_scope` keyword placed under `harness_config` section (more info *here*).

```
from twister_harness import DeviceAdapter

def test_sample(dut: DeviceAdapter):
   dut.readlines_until(regex='Hello world')
```

shell Provide a *Shell* class object with methods used to interact with shell application. It calls `wait_for_promt` method, to not start scenario until DUT is ready. The shell fixture calls `dut` fixture, hence has access to all its methods. The `shell` fixture adds methods optimized for interactions with a shell. It can be used instead of `dut` for tests. Scope of this fixture is determined by the `pytest_dut_scope` keyword placed under `harness_config` section (more info *here*).

```
from twister_harness import Shell

def test_shell(shell: Shell):
   shell.exec_command('help')
```

mcumgr Sample fixture to wrap `mcumgr` command-line tool used to manage remote devices. More information about MCUmgr can be found here *MCUmgr*.

> **Note**
>
> This fixture requires the `mcumgr` available in the system PATH

Only selected functionality of MCUmgr is wrapped by this fixture. For example, here is a test with a fixture `mcumgr`

```
from twister_harness import DeviceAdapter, Shell, McuMgr

def test_upgrade(dut: DeviceAdapter, shell: Shell, mcumgr: McuMgr):
   # free the serial port for mcumgr
   dut.disconnect()
   # upload the signed image
   mcumgr.image_upload('path/to/zephyr.signed.bin')
   # obtain the hash of uploaded image from the device
   second_hash = mcumgr.get_hash_to_test()
   # test a new upgrade image
   mcumgr.image_test(second_hash)
   # reset the device remotely
   mcumgr.reset_device()
   # continue test scenario, check version etc.
```

unlaunched_dut Similar to the `dut` fixture, but it does not initialize the device. It can be used when a finer control over the build process is needed. It becomes responsibility of the test to initialize the device.

```
from twister_harness import DeviceAdapter

def test_sample(unlaunched_dut: DeviceAdapter):
   unlaunched_dut.launch()
   unlaunched_dut.readlines_until(regex='Hello world')
```

Fixtures for Multi-DUT scenarios

Multi-DUT fixtures mirror the single-DUT fixtures (`unlaunched_dut`, `dut`, `shell`) but operate on lists of devices. They work for both hardware and `native_sim` targets; QEMU is not supported. They require `duts` entries to be present in `twister_pytest_config.yaml`. Twister generates this file automatically — for simulation targets it creates placeholder DUT entries so no hardware map is needed — and then calls pytest. When re-running pytest manually without Twister (see FAQ), that same config file is reused. See *Multi-DUTs testing support* section in the Twister documentation for configuration details.

unlaunched_duts Analogous to `unlaunched_dut`, but returns a list of *DeviceAdapter* objects - one per reserved DUT - with log files initialized but devices not yet launched.

```
from twister_harness import DeviceAdapter

def test_sample(unlaunched_duts: list[DeviceAdapter]):
   for dut in unlaunched_duts:
      dut.launch()
   unlaunched_duts[0].readlines_until(regex='Hello world')
```

duts Analogous to `dut`, but returns a list of launched *DeviceAdapter* objects. All devices are flashed concurrently to reduce setup time. If sequential flashing is required, override this fixture in your `conftest.py`.

```
from twister_harness import DeviceAdapter

def test_sample(duts: list[DeviceAdapter]):
   assert len(duts) > 1
   duts[0].readlines_until(regex='Hello world')
   duts[1].readlines_until(regex='Hello world')
```

shells Analogous to `shell`, but returns a list of *Shell* objects - one per reserved DUT - each already waiting for the shell prompt.

```
from twister_harness import Shell

def test_sample(shells: list[Shell]):
   assert len(shells) > 1
   shells[0].exec_command('help')
   shells[1].exec_command('help')
```

Classes

DeviceAdapter

class twister_harness.**DeviceAdapter**(*device_config: DeviceConfig*)

This class defines a common interface for all device types (hardware, simulator, QEMU) used in tests to gathering device output and send data to it.

launch() → None

Launch the test application on the target device.

This method performs the complete device initialization sequence:

- Close any previously running application (cleanup)
- Generate the execution command if not already set
- Add any extra test arguments to the command

- Start reader threads to capture device output
- Launch the application (flash for hardware, execute for simulators)

The launch process varies by device type:

- Hardware devices: Flash the application and establish serial communication. May connect before or after flashing depending on device configuration.
- QEMU/simulators: Start subprocess and establish FIFO/pipe communication
- Native simulators: Execute binary and connect via process pipes

`close`() → None

Disconnect, close device and close reader threads.

`readline`(*connection_index: int = 0*, ***kwargs*) → str

Read a single line from device output.

Parameters

- `connection_index` – Connection port to read from (0=main UART, 1=second core, etc.)
- `kwargs` – Additional keyword arguments (timeout, print_output)

Returns

Single line of text without trailing newlines

`readlines`(*connection_index: int = 0*, ***kwargs*) → list[str]

Read all available output lines produced by device from internal buffer.

`readlines_until`(*connection_index: int = 0*, ***kwargs*) → list[str]

Read lines from device output until a specific condition is met.

This method provides flexible ways to collect device output: wait for a specific pattern, collect a fixed number of lines, or get all currently available lines.

Parameters

- `connection_index` – Index of the connection/port to read from (default: 0). For hardware devices: 0 = main UART, 1 = second core UART, etc. For QEMU and native: always use 0 (only one connection available)
- `kwargs` – Keyword arguments passed to underlying connection including:
  - regex - Regular expression pattern to search for
  - num_of_lines - Exact number of lines to read
  - timeout - Maximum time in seconds to wait (uses base_timeout if not provided)
  - print_output - Whether to log each line as it's read (default: True)

Returns

List of output lines without trailing newlines

Raises

`AssertionError` – If timeout expires before condition is met

`write`(*data: bytes*, *connection_index: int = 0*) → None

Write data bytes to the target device.

Sends raw bytes to the device through the appropriate communication channel. The underlying transport mechanism varies by device type: Hardware devices write to serial/UART port, QEMU devices write to FIFO queue, and Native simulators write to process stdin pipes.

Parameters

- **data** – Raw bytes to send to the device
- **connection_index** – Index of the connection/port to write to (default: 0)

Shell

class twister_harness.**Shell**(*device:* DeviceAdapter, *prompt: str = 'uart:~$', timeout: float | None = None*)

Helper class that provides methods used to interact with shell application.

exec_command(*command: str*, *timeout: float | None = None*, *print_output: bool = True*, ** (Keyword-only parameters separator (PEP 3102))*, *get_full_output: bool = False*, *full_output_timeout: float | None = None*) → list[str]

Send shell command to a device and return response. Passed command is extended by double enter sings - first one to execute this command on a device, second one to receive next prompt what is a signal that execution was finished. Method returns printout of the executed command.

Parameters

- **get_full_output** – If True, after the shell prompt is seen, keep reading lines until `full_output_timeout` elapses (wall clock). Use this when output (e.g. decoded logs) continues to arrive after the prompt.
- **full_output_timeout** – Seconds to spend draining additional lines after the prompt. When `get_full_output` is True and this is omitted, `timeout` (or `base_timeout`) is used.

wait_for_prompt(*timeout: float | None = None*) → bool

Send every 0.5 second “enter” command to the device until shell prompt statement will occur (return True) or timeout will be exceeded (return False).

get_filtered_output(*command_lines: list[str]*) → list[str]

Filter out prompts and log messages

Take the output of exec_command, which can contain log messages and command prompts, and filter them to obtain only the command output.

Example:

```
>>> # equivalent to `lines = shell.exec_command("kernel version")`
>>> lines = [
>>>     'uart:~$',                    # filter prompts
>>>     'Zephyr version 3.6.0',       # keep this line
>>>     'uart:~$ <dbg> debug message' # filter log messages
>>> ]
>>> filtered_output = shell.get_filtered_output(output)
>>> filtered_output
['Zephyr version 3.6.0']
```

Parameters
command_lines – List of strings i.e. the output of *exec_command*.

Returns
A list of strings containing, excluding prompts and log messages.

Examples of pytest tests in the Zephyr project

- pytest_shell
- MCUmgr tests - tests/boot/with_mcumgr
- LwM2M tests - tests/net/lib/lwm2m/interop

- GDB stub tests - tests/subsys/debug/gdbstub

FAQ

How to flash/run application only once per pytest session?

`dut` is a fixture responsible for flashing/running application. By default, its scope is set as `function`. This can be changed by adding to .yaml file `pytest_dut_scope` keyword placed under `harness_config` section:

```
harness: pytest
harness_config:
   pytest_dut_scope: session
```

More info can be found *here*.

How to run only one particular test from a python file?

This can be achieved in several ways. In .yaml file it can be added using a `pytest_root` entry placed under `harness_config` with list of tests which should be run:

```
harness: pytest
harness_config:
   pytest_root:
      - "pytest/test_shell.py::test_shell_print_help"
```

Particular tests can be also chosen by pytest `-k` option (more info about pytest keyword filter can be found here). It can be applied by adding `-k` filter in `pytest_args` in .yaml file:

```
harness: pytest
harness_config:
   pytest_args:
      - "-k test_shell_print_help"
```

or by adding it to Twister command overriding parameters from the .yaml file:

```
$ west twister ... --pytest-args='-k test_shell_print_help'
```

How to get information about used device type in test?

This can be taken from `dut` fixture (which represents *DeviceAdapter* object):

```
device_type: str = dut.device_config.type
if device_type == 'hardware':
   ...
elif device_type == 'native':
   ...
```

How to rerun locally pytest tests without rebuilding application by Twister?

This can be achieved by running Twister once again with `--test-only` argument added to Twister command. Another way is running Twister with highest verbosity level (`-vv`) and then copy-pasting from logs command dedicated for spawning pytest (log started by `Running pytest command: ...`).

First, run scenario with Twister:

```
$ west twister -vv -ll debug -T samples/subsys/testsuite/pytest/shell \
-s sample.pytest.shell --device-testing -p nrf54l15dk/nrf54l15/cpuapp --
↪device-serial \
/dev/ttyACM1 --west-flash=--erase
```

Twister automatically generates a configuration file `twister_pytest_config.yaml` in the build directory containing all test parameters including device configuration etc.

Then export the required PYTHONPATH environment variable if not already set:

```
$ export PYTHONPATH=$ZEPHYR_BASE/scripts/pylib/pytest-twister-harness/src
```

Finally, run pytest command:

```
$ pytest -s -v -p twister_harness.plugin \
--
↪twister-config=twister-out/.../sample.pytest.shell/twister_pytest_config.yaml␣
↪\
samples/subsys/testsuite/pytest/shell/pytest
```

Is this possible to run pytest tests in parallel?

Basically `pytest-harness-plugin` wasn't written with intention of running pytest tests in parallel. Especially those one dedicated for hardware. There was assumption that parallelization of tests is made by Twister, and it is responsible for managing available sources (jobs and hardwares). If anyone is interested in doing this for some reasons (for example via pytest-xdist plugin) they do so at their own risk.

Limitations

- Not every platform type is supported in the plugin (yet).

2.12.3 Twister Status

What is a Twister Status?

Twister Status formulates the current state of

- `Harness`
- `TestCase`
- `TestSuite`
- `TestInstance`

in a comprehensive and easy-to understand way. In practice, most users will be interested in Statuses of Instances and Cases after the conclusion of their Twister runs.

Tip

Nomenclature reminder:

`Harness`

`Harness` is a Python class inside Twister that allows us to capture and analyse output from a program external to Twister. It has been excised from this page for clarity, as it does not appear in final reports.

`TestCase`

`TestCase`, also called Case, is a piece of code that aims to verify some assertion. It is the smallest subdivision of testing in Zephyr.

`TestSuite`

`TestSuite`, also called Suite, is a grouping of Cases. One can modify Twister's behaviour on a per-Suite basis via `testcase.yaml` files. Such grouped Cases should have enough in common for it to make sense to treat them all the same by Twister.

`TestInstance`

`TestInstance`, also called Instance, is a Suite on some platform. Twister typically reports its results for Instances, despite them being called "Suites" there. If a status is marked as applicable for Suites, it is also applicable for Instances. As the distinction between them is not useful in this section, whenever you read "Suite", assume the same for Instances.

More detailed explanation can be found *here*.

Possible Twister Statuses

Table 6: Twister Statuses

In-code	In-text	Description	Suite	Case
FIL-TER	fil-tered	A static or runtime filter has eliminated the test from the list of tests to use.	✓	✓
NOTRUN	not run	The test wasn't run because it was not runnable in current configuration. It was, however, built correctly.	✓	✓
BLOCK	blocked	The test was not run because of an error or crash in the test suite.	×	✓
SKIP	skipped	Test was skipped by some other reason than previously delineated.	✓	✓
ERROR	error	The test produced an error in running the test itself.	✓	✓
FAIL	failed	The test produced results different than expected.	✓	✓
PASS	passed	The test produced results as expected.	✓	✓

In-code and **In-text** are the naming contexts of a given status: the former is rather internal for Twister and appears in logs, whereas the latter is used in the JSON reports.

Note

There are two more Statuses that are internal to Twister. `NONE` (A starting status for Cases and Suites) and `STARTED` (Indicating an in-progress Case). Those should not appear in the final Twister report. Appearance of those non-terminal Statuses in one's report files indicates a problem with Twister.

Case and Suite Status combinations

Table 7: Case and Suite Status combinations

□ Case\Suite □	FILTER	ERROR	FAIL	PASS	NOTRUN	SKIP
FILTER	✓	×	×	×	×	×
ERROR	×	✓	×	×	×	×
BLOCK	×	✓	✓	×	×	×
FAIL	×	✓	✓	×	×	×
PASS	×	✓	✓	✓	×	×
NOTRUN	×	×	×	×	✓	×
SKIP	×	✓	✓	✓	×	✓

× indicates that such a combination should not happen in a proper Twister run. In other words, no Suite of a status indicated by the table column should contain any Cases of a status indicated by the table row.

✓ indicates a proper combination.

Detailed explanation, per Suite Status

`FILTER`:
: This status indicates that the whole Suite has been statically filtered out of a given Twister run. Thus, any Case within it should also have such a status.

`ERROR`:
: Suite encountered a problem when running the test. It requires at least one case with `ERROR` or `BLOCK` status. As this takes precedence over all other Case statuses, all valid terminal Case statuses can be within such a Suite.

`FAIL`:
: Suite has at least one Case that did not meet its assertions. This takes precedence over all other Case statuses, given that the conditions for an ERROR status have not been met.

`PASS`:
: Suite has passed properly. It cannot contain any Cases with `BLOCK`, `ERROR`, or `FAIL` statuses, as those indicate a problem when running the Suite.

`NOTRUN`:
: Whole suite was not run, but only built. It requires than all Cases within were not run. As runnability is decided on a per-Suite basis, only `NOTRUN` is applicable for its Cases.

`SKIP`:
: Whole Suite has been skipped at runtime. All Cases need to have `SKIP` status as well.

2.12.4 Twister blackbox tests

This guide aims to explain the structure of a test file so the reader will be able to understand existing files and create their own. All developers should fix any tests they break and create new ones when introducing new features, so this knowledge is important for any Twister developer.

Basics

Twister blackbox tests are written in python, using the `pytest` library. Read up on it *here* . Auxiliary test data follows whichever format it was in originally. Tests and data are wholly contained in the scripts/tests/twister_blackbox directory and prepended with `test_`.

Blackbox tests should not be aware of the internal twister code. Instead, they should call twister as user would and check the results.

Sample test file

```
#!/usr/bin/env python3
# Copyright (c) 2024 Intel Corporation
#
# SPDX-License-Identifier: Apache-2.0

import importlib
import json
import os
import sys
from unittest import mock

import pytest
from conftest import TEST_DATA, ZEPHYR_BASE, test_filename_mock
from twisterlib.testplan import TestPlan

class TestDummy:
    TESTDATA_X = [
        ("smoke", 5),
        ("acceptance", 6),
    ]

    @classmethod
    def setup_class(cls):
        apath = os.path.join(ZEPHYR_BASE, "scripts", "twister")
        cls.loader = importlib.machinery.SourceFileLoader("__main__", apath)
        cls.spec = importlib.util.spec_from_loader(cls.loader.name, cls.loader)
        cls.twister_module = importlib.util.module_from_spec(cls.spec)

    @classmethod
    def teardown_class(cls):
        pass

    @pytest.mark.parametrize(
        "level, expected_tests", TESTDATA_X, ids=["smoke", "acceptance"]
    )
    @mock.patch.object(TestPlan, "TEST_DEFINITION_FILENAME", test_filename_mock)
    def test_level(self, capfd, out_path, level, expected_tests):
        # Select platforms used for the tests
        test_platforms = ["qemu_x86", "frdm_k64f"]
        # Select test root
        path = os.path.join(TEST_DATA, "tests")
        config_path = os.path.join(TEST_DATA, "test_config.yaml")

        # Set flags for our Twister command as a list of strs
        args = (
            # Flags related to the generic test setup:
```

(continues on next page)

(continued from previous page)

```
            # * Control the level of detail in stdout/err
            # * Establish the output directory
            # * Select Zephyr tests to use
            # * Control whether to only build or build and run aforementioned tests
            ["-i", "--outdir", out_path, "-T", path, "-y"]
            # Flags under test
            + ["--level", level]
            # Flags required for the test
            + ["--test-config", config_path]
            # Flags related to platform selection
            + [
                val
                for pair in zip(["-p"] * len(test_platforms), test_platforms, strict=False)
                for val in pair
            ]
        )

        # First, provide the args variable as our Twister command line arguments.
        # Then, catch the exit code in the sys_exit variable.
        with mock.patch.object(sys, "argv", [sys.argv[0]] + args), pytest.raises(
            SystemExit
        ) as sys_exit:
            # Execute the Twister call itself.
            self.loader.exec_module(self.twister_module)

        # Check whether the Twister call succeeded
        assert str(sys_exit.value) == "0"

        # Access to the test file output
        with open(os.path.join(out_path, "testplan.json")) as f:
            j = json.load(f)
        filtered_j = [
            (ts["platform"], ts["name"], tc["identifier"])
            for ts in j["testsuites"]
            for tc in ts["testcases"]
            if "reason" not in tc
        ]

        # Read stdout and stderr to out and err variables respectively
        out, err = capfd.readouterr()
        # Rewrite the captured buffers to stdout and stderr so the user can still read them
        sys.stdout.write(out)
        sys.stderr.write(err)

        # Test-relevant checks
        assert expected_tests == len(filtered_j)
```

Comparison with CLI

Test above runs the command

```
twister -i --outdir $OUTDIR -T $TEST_DATA/tests -y --level $LEVEL
--test-config $TEST_DATA/test_config.yaml -p qemu_x86 -p frdm_k64f
```

It presumes a CLI with the `zephyr-env.sh` or `zephyr-env.cmd` already run.

Such a test provides us with all the outputs we typically expect of a Twister run thanks to `importlib` 's `exec_module()`[1] . We can easily set up all flags that we expect from a Twister call via `args` variable[2] . We can check the standard output or stderr in `out` and `err` variables.

Beside the standard outputs, we can also investigate the file outputs, normally placed in `twister-out` directories. Most of the time, we will use the `out_path` fixture in conjunction with `--outdir` flag (L52) to keep test-generated files in temporary directories. Typical files read in blackbox tests are `testplan.json` , `twister.xml` and `twister.log` .

Other functionalities

Decorators

- `@pytest.mark.usefixtures('clear_log')`
  - allows us to use `clear_log` fixture from `conftest.py` . The fixture is to become `autouse` in the future. After that, this decorator can be removed.
- `@pytest.mark.parametrize('level, expected_tests', TESTDATA_X, ids=['smoke', 'acceptance'])`
  - this is an example of `pytest` 's test parametrization. Read up on it here. TESTDATAs are most often declared as class fields.
- `@mock.patch.object(TestPlan, 'TEST_DEFINITION_FILENAME', test_filename_mock)`
  - this decorator allows us to use only tests defined in the `test_data` and ignore the Zephyr testcases in the `tests` directory. **Note that all "test_data" tests use `test_data.yaml` as a filename, not `testcase.yaml` !** Read up on the `mock` library here.

Fixtures Blackbox tests use `pytest` 's fixtures, further reading on which is available here.

If you would like to add your own fixtures, consider whether they will be used in just one test file, or in many.

- If in many, create such a fixture in the scripts/tests/twister_blackbox/conftest.py file.
  - scripts/tests/twister_blackbox/conftest.py already contains some fixtures - take a look there for an example.
- If in just one, declare it in that file.
  - Consider using class fields instead - look at TESTDATAs for an example.

How do I...

Call Twister multiple times in one test? Sometimes we want to test something that requires prior Twister use. `--test-only` flag would be a typical example, as it is to be coupled with previous `--build-only` Twister call. How should we approach that?

If we just call the `importlib` 's `exec_module` two times, we will experience log duplication. `twister.log` will duplicate every line (triplicate if we call it three times, etc.) instead of overwriting the log or appending to the end of it.

It is caused by the use of logger module variables in the Twister files. Thus us executing the module again causes the loggers to have multiple handles.

To overcome this, between the calls you ought to use

[1] Take note of the `setup_class()` class function, which allows us to run `twister` python file as if it were called directly (bypassing the `__name__ == '__main__'` check).

[2] We advise you to keep the first section of `args` definition intact in almost all of your tests, as it is used for the common test setup.

```
capfd.readouterr()   # To remove output from the buffer
                     # Note that if you want output from all runs after each other,
                     # skip this line.
clear_log_in_test()  # To remove log duplication
```

2.12.5 Board Configuration

To build tests for a specific board and to execute some of the tests on real hardware or in an emulation environment such as QEMU a board configuration file is required which is generic enough to be used for other tasks that require a board inventory with details about the board and its configuration that is only available during build time otherwise.

The board metadata file is located in the board directory and is structured using the YAML markup language. The example below shows a board with a data required for best test coverage for this specific board:

```
identifier: frdm_k64f
name: NXP FRDM-K64F
type: mcu
arch: arm
toolchain:
  - zephyr
  - gnuarmemb
supported:
  - arduino_gpio
  - arduino_i2c
  - netif:eth
  - adc
  - i2c
  - nvs
  - spi
  - gpio
  - usb_device
  - watchdog
  - can
  - pwm
testing:
  default: true
```

identifier:
A string that matches how the board is defined in the build system. This same string is used when building, for example when calling `west build` or `cmake`:

```
# with west
west build -b reel_board
# with cmake
cmake -DBOARD=reel_board ..
```

name:
The actual name of the board as it appears in marketing material.

vendor:
The board vendor. Used by the `vendor_allow` and `vendor_exclude` test scenario filters.

tier:
An optional integer indicating the board support tier. Used for reporting and to group platforms by their level of support.

type:
Type of the board or configuration. One of `mcu`, `qemu`, `sim`, `unit` or `native`.

simulation:
Simulator(s) used to simulate the platform, e.g. qemu.

```
simulation:
  - name: qemu
  - name: armfvp
    exec: FVP_Some_Platform
  - name: custom
    exec: AnotherBinary
```

By default, tests will be executed using the first entry in the simulation array. Another simulation can be selected with `--simulation <simulation_name>`. The `exec` attribute is optional. If it is set but the required simulator is not available, the tests will be built only. If it is not set and the required simulator is not available the tests will fail to run. The simulation name must match one of the elements of `SUPPORTED_EMU_PLATFORMS`.

arch:
Architecture of the board

toolchain:
The list of supported toolchains that can build this board. This should match one of the values used for *ZEPHYR_TOOLCHAIN_VARIANT* when building on the command line. Twister filters out any test instance whose toolchain is not in this list, unless `--force-toolchain` is given. This list says which toolchains *may* build the board, it does not select one; see *Toolchain Selection*.

preferred_toolchain:
The toolchain Twister should use for this platform when nothing else selects one. This is useful for boards that are nominally buildable with several toolchains but should be tested with a specific one. See *Toolchain Selection*.

build_toolchains:
An optional list of toolchains that every test assigned to this platform should be built with. Twister creates one test instance per toolchain in the list, each in its own build directory, instead of picking a single toolchain for the platform. For example, to build everything on `native_sim` with both GCC and Clang:

```
build_toolchains:
  - host/gnu
  - host/llvm
```

Because this multiplies build time, it is usually better to leave it out of the board definition and enable it only for CI, using the `build_toolchains` option of the *Twister configuration file*. See *Toolchain Selection*.

ram:
Available RAM on the board (specified in KB). This is used to match test scenario requirements. If not specified we default to 128KB.

flash:
Available FLASH on the board (specified in KB). This is used to match test scenario requirements. If not specified we default to 512KB.

sysbuild: [True|False] (default False)
If true, applications for this platform are built using *sysbuild* by default.

twister: [True|False] (default True)
If false, Twister ignores this platform entirely and never builds or runs tests on it.

supported:
A list of features this board supports. This can be specified as a single word feature or as a

variant of a feature class. For example:

```
supported:
  - pci
```

This indicates the board does support PCI. You can make a test scenario build or run only on such boards, or:

```
supported:
  - netif:eth
  - sensor:bmi16
```

A test scenario can depend on 'eth' to only test ethernet or on 'netif' to run on any board with a networking interface.

testing:
testing relating keywords to provide best coverage for the features of this board.

binaries:
A list of custom binaries to be kept for device testing.

default: [True|False]:
This is a default board, it will tested with the highest priority and is covered when invoking the simplified twister without any additional arguments.

ignore_tags:
Do not attempt to build (and therefore run) tests marked with this list of tags.

only_tags:
Only execute tests with this list of tags on a specific platform.

timeout_multiplier: <float> (default 1)
Multiply each test scenario timeout by specified ratio. This option allows to tune timeouts only for required platform. It can be useful in case naturally slow platform I.e.: HW board with power-efficient but slow CPU or simulation platform which can perform instruction accurate simulation but does it slowly.

flash_before: [True|False] (default False)
For pytest/shell harness hardware testing, flash the device before opening the serial port. This prevents serial port disconnection issues during flashing on some boards (e.g., those with USB CDC that reset during flash operations).

renode:
Configuration for the Renode simulator. Supports two keys: `uart`, the UART peripheral the harness connects to (e.g. `sysbus.uart0`), and `resc`, the Renode script (`.resc`) used to set up the simulated machine.

env:
A list of environment variables. Twister will check if all these environment variables are set, and otherwise skip this platform. This allows the user to define a platform which should be used, for example, only if some required software or hardware is present, and to signal that presence to twister using these environment variables.

variants:
A mapping of board variant (qualifier) names to per-variant overrides. Each entry is itself a platform definition and may override any of the keys above for that specific variant, while inheriting the remaining values from the top-level definition.

2.12.6 Toolchain Selection

Several options influence which toolchain a test is built with. They fall into three groups: options that *select* a toolchain, options that *filter* out test instances whose toolchain is not usable, and options that *multiply* a test into several builds.

Twister first determines a default toolchain for the whole run by invoking `cmake/verify-toolchain.cmake`, which honors the *ZEPHYR_TOOLCHAIN_VARIANT* environment variable. This value is reported at the start of the run as `Using '<toolchain>' toolchain variant.`

For every test scenario and platform pair, the toolchain is then selected using the first of the following that applies:

1. The test scenario's `integration_toolchains`, if set. The test is built once per listed toolchain.
2. The platform's `build_toolchains`, if set, either in the board configuration or in the *Twister configuration file*. The test is built once per listed toolchain.
3. For `posix` and `unit` platforms, `host/llvm` if the run default is `host/llvm`, otherwise `host/gnu`.
4. The platform's `preferred_toolchain`, if set.
5. The run default described above, or `zephyr` if it could not be determined.

Note that *ZEPHYR_TOOLCHAIN_VARIANT* only changes the run default, which is the last entry in this list. It does not override a platform's `preferred_toolchain` or `build_toolchains`, nor a scenario's `integration_toolchains`.

Once a toolchain is selected, the resulting test instance can still be filtered out:

- If the toolchain is not in the platform's `toolchain` list of supported toolchains, the instance is filtered. `--force-toolchain` disables this check and uses the selected toolchain unconditionally. The comparison also succeeds on the part before the `/`, so `host/gnu` matches a platform listing `host`.
- The scenario's `toolchain_allow` and `toolchain_exclude` options filter instances by the selected toolchain.

Because `integration_toolchains` and `build_toolchains` produce one test instance per toolchain, they multiply build time. `build_toolchains` is therefore normally left out of the board configuration and enabled only for the configuration file used by CI.

2.12.7 Tests

Tests are detected by the presence of a `tests.yaml` (`sample.yaml` and `testcase.yaml` support is deprecated) files in the application's project directory. This test application configuration file may contain one or more entries in the `tests:` section each identifying a Test Scenario.

Test application configurations are written using the YAML syntax and share the same structure as samples.

A Test Scenario is a set of conditions and variables defined in a Test Scenario entry, under which a set of Test Suites will be built and executed.

A Test Suite is a collection of Test Cases which are intended to be used to test a software program to ensure it meets certain requirements. The Test Cases in a Test Suite are either related or meant to be executed together.

Test Scenario, Test Suite, and Test Case names must follow to these basic rules:

1. The format of the Test Scenario identifier shall be a string without any spaces or special characters (allowed characters: alphanumeric and [_=]) consisting of multiple sections delimited with a dot (`.`).
2. Each Test Scenario identifier shall start with a section name followed by a subsection names delimited with a dot (`.`). For example, a test scenario that covers semaphores in the kernel shall start with `kernel.semaphore`.
3. All Test Scenario names must be unique for the Twister execution scope.
4. The full canonical name of a Test Suite is: `<Test Application Project path>/<Test Scenario identifier>`

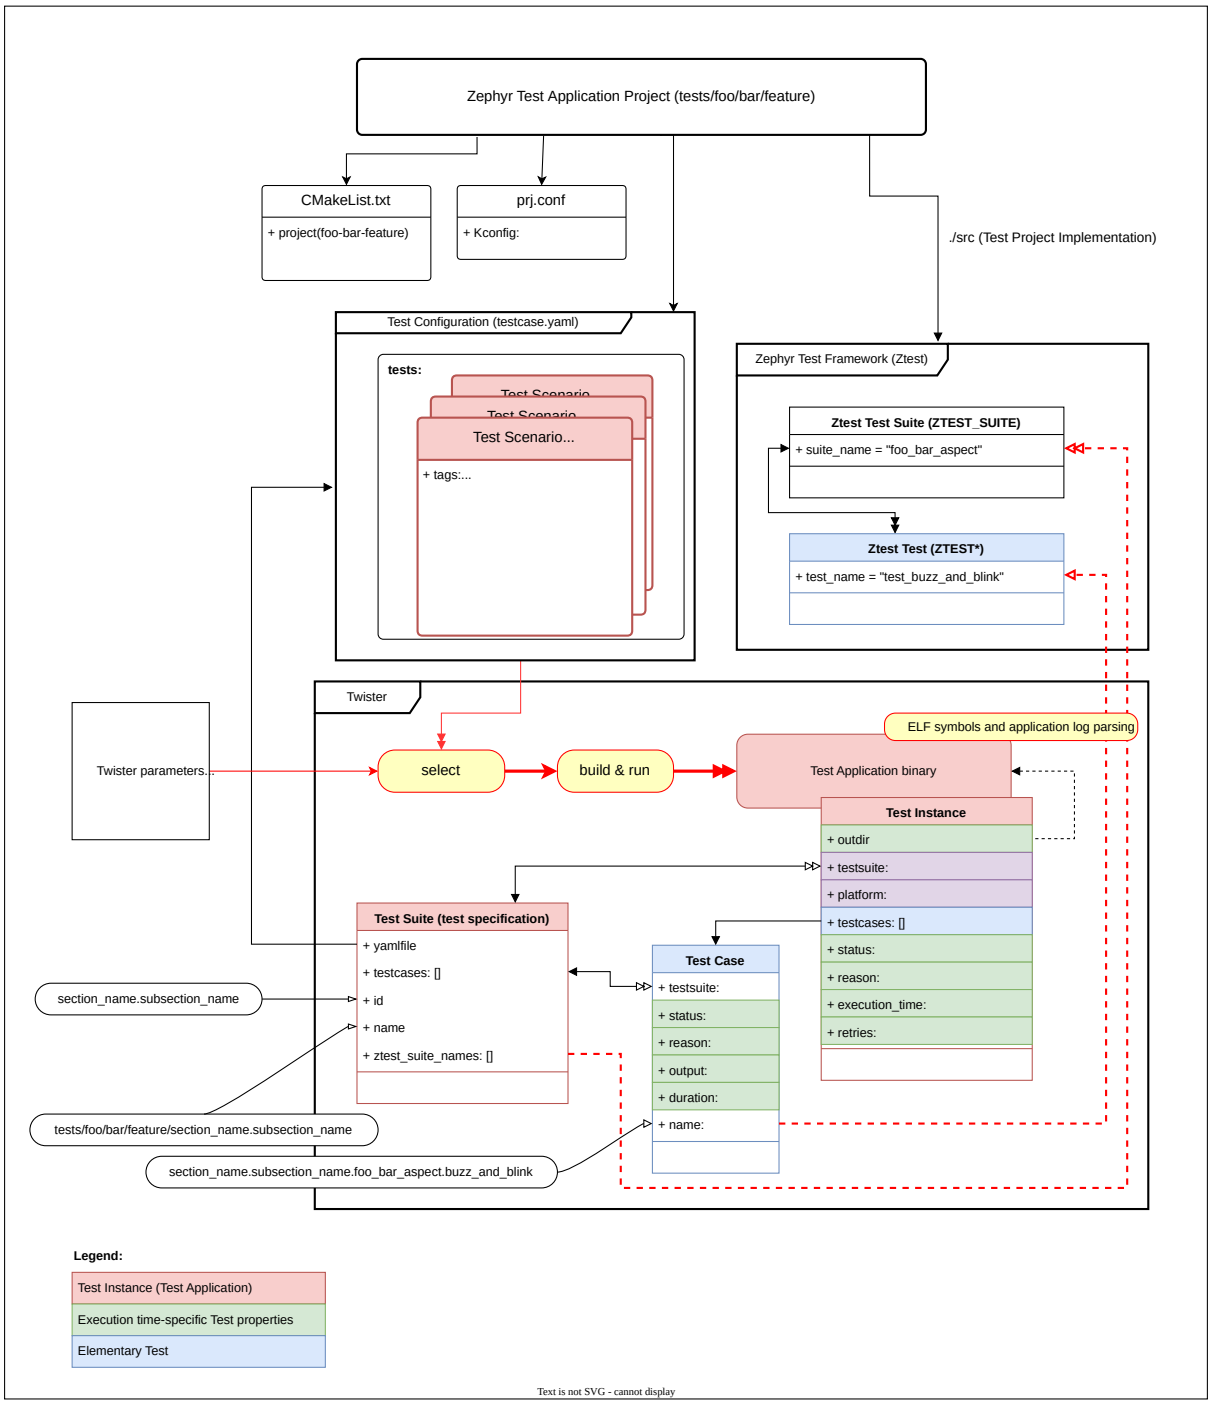


Fig. 4: Twister and a Test application project.

5. Depending on the Test Suite implementation, its Test Case identifiers consist of **at least three sections** delimited with a dot (`.`):

   - **Ztest tests**: a Test Scenario identifier from the corresponding `testcase.yaml` file, a Ztest suite name, and a Ztest test name: `<Test Scenario identifier>.<Ztest suite name>.<Ztest test name>`
   - **Standalone tests and samples**: a Test Scenario identifier from the corresponding `tests.yaml` file where the last section signifies the standalone Test Case name, for example: `debug.coredump.logging_backend`.

The following is an example test configuration with a few options that are explained in this document.

```
tests:
  bluetooth.gatt:
    build_only: true
    platform_allow:
      - qemu_cortex_m3
      - qemu_x86
    tags:
      - bluetooth
  bluetooth.gatt.br:
    build_only: true
    extra_args:
      -CONF_FILE="prj_br.conf"
    filter: not CONFIG_DEBUG
    platform_exclude:
      -up_squared
    platform_allow:
      - qemu_cortex_m3 qemu_x86
    tags:
      - bluetooth
```

A sample with tests will have the same structure with additional information related to the sample and what is being demonstrated:

```
sample:
  name: hello world
  description: Hello World sample, the simplest Zephyr application
tests:
  sample.basic.hello_world:
    build_only: true
    tags:
      - tests
    min_ram: 16
  sample.basic.hello_world.singlethread:
    build_only: true
    extra_args: CONF_FILE=prj_single.conf
    filter: not CONFIG_BT
    tags:
      - tests
    min_ram: 16
```

A Test Scenario entry in the `tests:` YAML dictionary has its Test Scenario identifier as a key.

Each Test Scenario entry in the Test Application configuration can define the following key/value pairs:

tags: <list of tags> (required)
A set of string tags for the test scenario. Usually pertains to functional domains but can be

anything. Command line invocations of this script can filter the set of tests to run based on tag.

skip: <True|False> (default False)
skip test scenario unconditionally. This can be used for broken tests for example.

slow: <True|False> (default False)
Don't run this test scenario unless `--enable-slow` or `--enable-slow-only` was passed in on the command line. Intended for time-consuming test scenarios that are only run under certain circumstances, like daily builds. These test scenarios are still compiled.

extra_args: <list of extra arguments>
Extra arguments to pass to build tool when building or running the test scenario.

Using namespacing, it is possible to apply extra_args only to some hardware. Currently architectures/platforms/simulation are supported:

```
common:
  tags:
   - drivers
   - adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_args:
      - arch:x86:CONFIG_ADC_ASYNC=y
      - platform:qemu_x86:CONFIG_DEBUG=y
      - platform:mimxrt1060_evk:SHIELD=rk043fn66hs_ctg
      - simulation:qemu:CONFIG_MPU=y
```

extra_configs: <list of extra configurations>
Extra configuration options to be merged with a main prj.conf when building or running the test scenario. For example:

```
common:
  tags:
    - drivers
    - adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - CONFIG_ADC_ASYNC=y
```

Using namespacing, it is possible to apply a configuration only to some hardware. Currently both architectures and platforms are supported:

```
common:
  tags:
    - drivers
    - adc
tests:
  test:
    depends_on: adc
  test_async:
    extra_configs:
      - arch:x86:CONFIG_ADC_ASYNC=y
      - platform:qemu_x86:CONFIG_DEBUG=y
```

extra_conf_files: <list of configuration files>
Extra Kconfig fragment files to merge into the build, as an alternative to passing `CONF_FILE=` through `extra_args`. Entries from `common` and the test scenario are concatenated. Prefer this field over `extra_args` for configuration files.

extra_overlay_confs: <list of overlay configuration files>
Extra Kconfig overlay fragments to merge into the build, as an alternative to passing `OVERLAY_CONFIG=` through `extra_args`. Entries from `common` and the test scenario are concatenated.

extra_dtc_overlay_files: <list of devicetree overlay files>
Extra devicetree overlay files to apply to the build, as an alternative to passing `DTC_OVERLAY_FILE=` through `extra_args`. Entries from `common` and the test scenario are concatenated.

build_only: <True|False> (default False)
If true, twister will not try to run the test even if the test is runnable on the platform.

This keyword is reserved for tests that are used to test if some code actually builds. A `build_only` test is not designed to be run in any environment and should not be testing any functionality, it only verifies that the code builds.

This option is often used to test drivers and the fact that they are correctly enabled in Zephyr and that the code builds, for example sensor drivers. Such test shall not be used to verify the functionality of the driver.

build_on_all: <True|False> (default False)
If true, attempt to build test scenario on all available platforms. This is mostly used in CI for increased coverage. Do not use this flag in new tests.

depends_on: <list of features>
A board or platform can announce what features it supports, this option will enable the test only those platforms that provide this feature.

levels: <list of levels>
Test levels this test should be part of. If a level is present, this test will be selectable using the command line option `--level <level name>`

min_ram: <integer>
estimated minimum amount of RAM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

min_flash: <integer>
estimated minimum amount of ROM in KB needed for this test to build and run. This is compared with information provided by the board metadata.

timeout: <number of seconds>
Length of time to run test before automatically killing it. Default to 60 seconds.

arch_allow: <list of arches, such as x86, arm, arc>
Set of architectures that this test scenario should only be run for.

arch_exclude: <list of arches, such as x86, arm, arc>
Set of architectures that this test scenario should not run on.

toolchain_allow: <list of toolchain variants>
Set of toolchain variants that this test scenario should only be run for. The toolchain is the one configured for the run (see *ZEPHYR_TOOLCHAIN_VARIANT*). Platforms built with any other toolchain are filtered out.

toolchain_exclude: <list of toolchain variants>
Set of toolchain variants that this test scenario should not be run for.

vendor_allow: <list of vendors>
Set of platform vendors that this test scenario should only be run for. The vendor is defined

as part of the board definition. Boards associated with this vendors will be included. Other boards, including those without a vendor will be excluded.

vendor_exclude: <list of vendors>
Set of platform vendors that this test scenario should not run on. The vendor is defined as part of the board. Boards associated with this vendors will be excluded.

platform_allow: <list of platforms>
Set of platforms that this test scenario should only be run for. Do not use this option to limit testing or building in CI due to time or resource constraints, this option should only be used if the test or sample can only be run on the allowed platform and nothing else.

integration_platforms: <YML list of platforms/boards>
This option limits the scope to the listed platforms when twister is invoked with the `--integration` option. Use this instead of platform_allow if the goal is to limit scope due to timing or resource constraints.

integration_toolchains: <YML list of toolchain variants>
This option expands the scope to all the listed toolchains variants and adds another vector of testing where desired. By default, test configurations are generated based on the toolchain configured in the environment:

test scenario -> platforms1 -> toolchain1 test scenario -> platforms2 -> toolchain1

When a platform supports multiple toolchains that are available during the twister run, it is possible to expand the test configurations to include additional tests for each toolchain. For example, if a platform supports toolchains `toolchain1` and `toolchain2`, and the test scenario includes:

```
integration_toolchains:
  - toolchain1
  - toolchain2
```

the following configurations are generated:

test scenario -> platforms1 -> toolchain1 test scenario -> platforms1 -> toolchain2 test scenario -> platforms2 -> toolchain1 test scenario -> platforms2 -> toolchain2

> **Note**
> This functionality is evaluated always and is not limited to the `--integration` option.

This option takes precedence over a platform's `build_toolchains`. To expand the toolchain scope for every test on a platform instead of per test scenario, use `build_toolchains`. See *Toolchain Selection*.

platform_exclude: <list of platforms>
Set of platforms that this test scenario should not run on.

platform_type: <list of platform types>
Restrict this test scenario to platforms of the given type(s). A platform's type is declared via the `type:` key in its board metadata. Supported values are `mcu`, `qemu`, `sim`, `unit` and `native`. Platforms whose type is not in this list are filtered out.

simulation_exclude: <list of simulators>
Set of simulators that this test scenario should not run on. Supported values are `qemu`, `simics`, `xt-sim`, `renode`, `nsim`, `mdb-nsim`, `tsim`, `armfvp`, `native` and `custom`.

extra_sections: <list of extra binary sections>
When computing sizes, twister will report errors if it finds extra, unexpected sections in the Zephyr binary unless they are named here. They will not be included in the size calculation.

sysbuild: <True|False> (default False)
Build the project using sysbuild infrastructure. Only the main project's generated device-tree and Kconfig will be used for filtering tests. on device testing must use the hardware map, or west flash to load the images onto the target. The `--erase` option of west flash is not supported with this option. Usage of unsupported options will result in tests requiring sysbuild support being skipped.

harness: <string>
A harness keyword in the `testcase.yaml` file identifies a Twister harness needed to run a test successfully. A harness is a feature of Twister and implemented by Twister, some harnesses are defined as placeholders and have no implementation yet.

A harness can be seen as the handler that needs to be implemented in Twister to be able to evaluate if a test passes criteria. For example, a keyboard harness is set on tests that require keyboard interaction to reach verdict on whether a test has passed or failed, however, Twister lack this harness implementation at the moment.

Supported harnesses:

- ztest
- test
- console
- pytest
- gtest
- robot
- ctest
- shell
- power
- display_capture
- script
- bsim

See *Harnesses* for more information.

platform_key: <list of platform attributes>
Often a test needs to only be built and run once to qualify as passing. Imagine a library of code that depends on the platform architecture where passing the test on a single platform for each arch is enough to qualify the tests and code as passing. The platform_key attribute enables doing just that.

For example to key on (arch, simulation) to ensure a test is run once per arch and simulation (as would be most common):

```
platform_key:
  - arch
  - simulation
```

Adding platform (board) attributes to include things such as soc name, soc family, and perhaps sets of IP blocks implementing each peripheral interface would enable other interesting uses. For example, this could enable building and running SPI tests once for each unique IP block.

harness_config: <harness configuration options>
Extra harness configuration options to be used to select a board and/or for handling generic Console with regex matching. Config can announce what features it supports. This option will enable the test to run on only those platforms that fulfill this external dependency.

fixture: <string or list>
Specify a test scenario dependency on an external device(e.g., sensor), and identify setups that fulfill this dependency. It depends on specific test setup and board selection logic to pick the particular board(s) out of multiple boards that fulfill the dependency in an automation setup based on `fixture` keyword. Some sample fixture names are i2c_hts221, i2c_bme280, i2c_FRAM, ble_fw and gpio_loop.

ztest_suite_repeat: <int> (default 1)
This parameter specifies the number of times the entire test suite should be repeated.

ztest_test_repeat: <int> (default 1)
This parameter specifies the number of times each individual test within the test suite should be repeated.

ztest_test_shuffle: <True|False> (default False)
This parameter indicates whether the order of the tests within the test suite should be shuffled. When set to `true`, the tests will be executed in a random order.

The following is an example yaml file with robot harness_config options.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite: [robot file path]
```

It can be more than one test suite using a list.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite:
        - [robot file path 1]
        - [robot file path 2]
        - [robot file path n]
```

One or more options can be passed to robotframework.

```
tests:
  robot.example:
    harness: robot
    harness_config:
      robot_testsuite: [robot file path]
      robot_option:
        - --exclude tag
        - --stop-on-error
```

filter: <expression>
Filter whether the test scenario should be run by evaluating an expression against an environment containing the following values:

```
{ ARCH : <architecture>,
  PLATFORM : <platform>,
  <all CONFIG_* key/value pairs in the test's generated defconfig>,
  *<env>: any environment variable available
}
```

Twister will first evaluate the expression to find if a “limited” cmake call, i.e. using package_helper cmake script, can be done.

Existence of "dt_*" entries indicates devicetree is needed. Refer to *Devicetree Filtering Expressions* for detailed description of the different DT expressions available.

Existence of "CONFIG*" entries indicates kconfig is needed. If there are no other types of entries in the expression a filtration can be done without creating a complete build system. If there are entries of other types a full cmake is required.

The grammar for the expression language is as follows:

```
expression : expression 'and' expression
           | expression 'or' expression
           | 'not' expression
           | '(' expression ')'
           | symbol '==' constant
           | symbol '!=' constant
           | symbol '<' NUMBER
           | symbol '>' NUMBER
           | symbol '>=' NUMBER
           | symbol '<=' NUMBER
           | symbol 'in' list
           | symbol ':' STRING
           | symbol
           ;

list : '[' list_contents ']';

list_contents : constant (',' constant)*;

constant : NUMBER | STRING;
```

For the case where `expression ::= symbol`, it evaluates to `true` if the symbol is defined to a non-empty string.

Operator precedence, starting from lowest to highest:

- or (left associative)
- and (left associative)
- not (right associative)
- all comparison operators (non-associative)

`arch_allow`, `arch_exclude`, `platform_allow`, `platform_exclude` are all syntactic sugar for these expressions. For instance:

```
arch_exclude = x86 arc
```

Is the same as:

```
filter = not ARCH in ["x86", "arc"]
```

The `:` operator compiles the string argument as a regular expression, and then returns a true value only if the symbol's value in the environment matches. For example, if `CONFIG_SOC="stm32f107xc"` then

```
filter = CONFIG_SOC : "stm.*"
```

Would match it.

required_snippets: <list of needed snippets>
Snippets are supported in twister for test scenarios that require them. As with normal applications, twister supports using the base zephyr snippet directory and test application

directory for finding snippets. Listed snippets will filter supported tests for boards (snippets must be compatible with a board for the test to run on them, they are not optional).

The following is an example yaml file with 2 required snippets.

```
tests:
  snippet.example:
    required_snippets:
      - cdc-acm-console
      - user-snippet-example
```

required_applications: <list of required applications> (default empty)

Specify a list of test applications that must be built before current test can run. It enables sharing of built applications between test scenarios, allowing tests to access build artifacts from other applications.

Each required application entry supports:

- `application`: Test scenario identifier (required)
- `name`: Deprecated alias for `application` (still accepted for backward compatibility, but `application` should be used in new configurations)
- `platform`: Target platform (optional, defaults to current test's platform)
- `path`: Directory path where Twister should search for the application (optional). Can be an absolute path or a path relative to the directory containing the test's YAML file. Environment variables and Zephyr module directory variables are expanded (see *Expanding paths with module directory variables*). If not specified, Twister searches in the same directory as the referring test's YAML file.

Required applications are automatically discovered and built by Twister. If a required application is not already loaded, Twister searches for it in the directory specified by `path` or, if `path` is not set, in the same directory as the referring test's YAML file. When reusing build directories (e.g., with `--no-clean`), Twister can find required applications in the current build directory.

How it works:

- Twister builds the required applications first
- The main test application waits for required applications to complete
- Build directories of required applications are made available to the test harness
- For pytest harness, build directories are passed via `--required-build` arguments and accessible through the `required_build_dirs` fixture

When combined with `build: false`, the current test scenario skips its own build step entirely and uses the first required application's build artifacts as its image. This is useful for scenarios that serve purely as test harnesses for an image built elsewhere.

Example configuration:

```
tests:
  # Requires two applications, second one from a different path and with a␣
↪fixed platform
  sample.required_app_demo:
    harness: pytest
    required_applications:
      - application: sample.shared_app
      - application: other.app
        path: ../other_app
        platform: native_sim
  # No self build, use the first required application as the test image
```

(continues on next page)

(continued from previous page)

```
sample.no_self_build:
  build: false
  harness: pytest
  required_applications:
    - application: sample.basic.helloworld
      path: $ZEPHYR_BASE/samples/hello_world
sample.shared_app:
  build_only: true
```

Limitations:

- Not supported with `--runtime-artifact-cleanup`, as build artifacts of required applications must be retained for use by the main test application.
- Not supported with `--subset`: a required application and the test depending on it may be assigned to different subsets, making build artifacts unavailable at test execution time.

build: <True|False> (default True)
If false, the test scenario skips its own build step and uses the build artifacts from the first entry in `required_applications` as its image. This is useful for scenarios that serve purely as a test harness for an image built by another scenario.

Constraints:

- `required_applications` must be non-empty.
- Supported harnesses: pytest-based (e.g. `pytest`, `shell`) and `bsim`.
- QEMU platforms are not supported.

expect_reboot: <True|False> (default False)
Notify twister that the test scenario is expected to reboot while executing. When enabled, twister will suppress warnings about unexpected multiple runs of a testsuite or testcase.

modules: <list of module names>
Build and run this test scenario only when all of the listed *modules* are present in the workspace. Scenarios that require a module which is not available are filtered out.

type: <string> (default integration)
Test type of the scenario. Set to `unit` for unit tests that are built for the *unit_testing board* and run on the host without the full Zephyr build system.

testcases: <list of test case names>
Explicitly declare the list of test case names that make up this scenario. This is normally detected automatically (for example from the ztest source) and only needs to be set for harnesses that cannot be introspected.

ignore_faults: <True|False> (default False)
Do not mark the test scenario as failed if a fault is detected in the output while the test is running.

ignore_qemu_crash: <True|False> (default False)
Do not mark the test scenario as failed if QEMU crashes while the test is running.

The set of test scenarios that actually run depends on directives in the test scenario file and options passed in on the command line. If there is any confusion, running with `-v` or examining the *test plan* (`testplan.json`) can help show why particular test scenarios were filtered out.

To load arguments from a file, add + before the file name, e.g., `+file_name`. File content must be one or more valid arguments separated by line break instead of white spaces.

Most everyday users will run with no arguments.

Expanding paths with module directory variables

Path options in the test scenario file (e.g. `required_applications`, `harness_config: pytest_root`) are expanded before use. In addition to environment variables, Twister expands Zephyr module directory variables, which mirror the CMake variables defined for every module:

- `ZEPHYR_<MODULE>_MODULE_DIR` - absolute path to the module's root.
- `ZEPHYR_<MODULE>_MODULE_NAME` - the module's name.

`<MODULE>` is upper-cased with non-alphanumeric characters replaced by _, exactly as CMake does (for example `$ZEPHYR_HAL_NORDIC_MODULE_DIR` for the `hal_nordic` module). Unknown references are left unchanged.

Managing tests timeouts

There are several parameters which control tests timeouts on various levels:

- `timeout` option in each test scenario. See *here* for more details.
- `timeout_multiplier` option in board configuration. See *here* for more details.
- `--timeout-multiplier` twister option which can be used to adjust timeouts in exact twister run. It can be useful in case of simulation platform as simulation time may depend on the host speed & load or we may select different simulation method (i.e. cycle accurate but slower one), etc...

Overall test scenario timeout is a multiplication of these three parameters.

Devicetree Filtering Expressions

Expressions starting with "dt_*" are used to filter boards based on specific devicetree properties, such as compatibles, aliases, node labels, node properties, chosen nodes, etc. when selecting test scenarios.

> **Note**
>
> The source code for these expressions can be found at scripts/pylib/twister/expr_parser.py.

Expressions

`dt_compat_enabled(compat)`

Purpose:
Checks if any DT node with the specified compatible string (`compat`) is enabled.

Parameters:

- `compat`: The compatible string to match.

`dt_alias_exists(alias)`

Purpose:
Checks if any DT node with the specified alias exists and is enabled.

Parameters:

- `alias`: The alias (defined in `aliases` node) to match.

`dt_enabled_alias_with_parent_compat(alias, compat)`

Purpose:
Checks if the DT has an enabled alias node whose parent has the specified compatible string. Useful for nodes like `gpio-leds` child nodes, which may not have their own compatible.

Parameters:

- `alias`: The alias (defined in `aliases` node) to match.
- `compat`: The parent node's compatible string to match.

`dt_label_with_parent_compat_enabled(label, compat)`

Purpose:
Checks if a DT node with the specified label exists, is enabled, and its parent has the specified compatible string.

Parameters:

- `label`: The node label to match.
- `compat`: The parent node's compatible string to match.

`dt_label_compat_enabled(label, compat)`

Purpose:
Checks if a DT node with the specified label exists, is enabled, and has the specified compatible string.

Parameters:

- `label`: The node label to match.
- `compat`: The node compatible string to match.

`dt_chosen_enabled(chosen)`

Purpose:
Checks if a DT chosen property with the specified name exists and the node assigned to it is enabled.

Parameters:

- `chosen`: The name of the chosen property.

`dt_nodelabel_enabled(label)`

Purpose:
Checks if a DT node with the specified label exists and is enabled.

Parameters:

- `label`: The node label to match.

`dt_nodelabel_prop_enabled(label, prop)`

Purpose:
Checks if a DT node with the specified label exists, is enabled, and has the specified property with a non-empty value.

Parameters:

- `label`: The node label to match.
- `prop`: The node's property to check.

`dt_node_has_prop(node_id, prop)`

Purpose:
Checks if a DT node (specified by alias or path) has the specified property, regardless of its status. Useful for nodes that do not have a status, like `zephyr,user` node.

Parameters:

- `node_id`: The node alias (defined in `aliases` node) or node path to match.
- `prop`: The node's property to check.

Usage These expressions are used in Twister's test scenarios filtering logic to select boards that match specific DT conditions. For example:

```
tests:
  - test: my_test
    filter: dt_compat_enabled("my-compat-string")
```

The test scenario `my_test` will only build for boards where a DT node with `my-compat-string` is enabled.

2.12.8 Harnesses

A *harness* is the mechanism Twister uses to run a test and decide whether it passed or failed. After a test image is built and started on its target (real hardware, an emulator, or the host), the harness drives the interaction with the running image – providing input, capturing output, or handing execution over to an external test runner – and interprets the result to assign a *status* to each test case.

A test scenario selects a harness with the `harness:` entry in its `tests.yaml` and tunes its behavior through `harness_config`. When no harness is specified, the default `test` harness is used. Different harnesses serve different needs: some parse the device's console output against expected patterns, while others delegate execution to an external framework such as pytest, Robot Framework, or ctest. The pages linked below describe each supported harness and its `harness_config` options.

Harnesses `ztest`, `gtest` and `console` are based on parsing of the output and matching certain phrases. `ztest` and `gtest` harnesses look for pass/fail/etc. frames defined in those frameworks.

Some widely used harnesses that are not supported yet:

- keyboard
- net
- bluetooth

The following is an example yaml file with a few harness_config options.

```
sample:
  name: HTS221 Temperature and Humidity Monitor
common:
  tags:
    - sensor
  harness: console
  harness_config:
    type: multi_line
    ordered: false
    regex:
      - "Temperature:(.*)C"
      - "Relative Humidity:(.*)%"
    fixture: i2c_hts221
```

(continues on next page)

(continued from previous page)

```
tests:
  test:
    tags:
      - sensors
    depends_on: i2c
```

Ctest

ctest_args: <list of arguments> (default empty)
Specify a list of additional arguments to pass to `ctest` e.g.: `ctest_args: ['--repeat until-pass:5']`. Note that `--ctest-args` can be passed multiple times to pass several arguments to the ctest.

Gtest

Use `gtest` harness if you've already got tests written in the gTest framework and do not wish to update them to zTest.

Pytest

The *pytest harness* is used to execute pytest test suites in the Zephyr test. The following options apply to the pytest harness:

pytest_root: <list of pytest testpaths> (default pytest)
Specify a list of pytest directories, files or subtests that need to be executed when a test scenario begins to run. The default pytest directory is `pytest`. After the pytest run is finished, Twister will check if the test scenario passed or failed according to the pytest report. Environment variables and Zephyr module directory variables are expanded (see *Expanding paths with module directory variables*). As an example, a list of valid pytest roots is presented below:

```
harness_config:
  pytest_root:
    - "pytest/test_shell_help.py"
    - "../shell/pytest/test_shell.py"
    - "/tmp/test_shell.py"
    - "~/tmp/test_shell.py"
    - "$ZEPHYR_BASE/samples/subsys/testsuite/pytest/shell/pytest/test_shell.py
↪"
    - "$ZEPHYR_HAL_NORDIC_MODULE_DIR/tests/pytest/test_hal.py"  # path inside␣
↪a module
    - "pytest/test_shell_help.py::test_shell2_sample"  # select pytest subtest
    - "pytest/test_shell_help.py::test_shell2_sample[param_a]"  # select␣
↪pytest parametrized subtest
```

pytest_args: <list of arguments> (default empty)
Specify a list of additional arguments to pass to `pytest` e.g.: `pytest_args: ['-k=test_method', '--log-level=DEBUG']`. Note that `--pytest-args` can be passed multiple times to pass several arguments to the pytest.

pytest_dut_scope: <function|class|module|package|session> (default function)

The scope for which `dut` and `shell` pytest fixtures are shared. If the scope is set to `function`, DUT is launched for every test case in python script. For `session` scope, DUT is launched only once.

The following is an example yaml file with pytest harness_config options, default pytest_root name "pytest" will be used if pytest_root not specified. please refer the examples in samples/subsys/testsuite/pytest/.

```
common:
  harness: pytest
tests:
  pytest.example.directories:
    harness_config:
      pytest_root:
        - pytest_dir1
        - $ENV_VAR/samples/test/pytest_dir2
  pytest.example.files_and_subtests:
    harness_config:
      pytest_root:
        - pytest/test_file_1.py
        - test_file_2.py::test_A
        - test_file_2.py::test_B[param_a]
```

required_devices: <list of required device entries> (default empty)
Specify additional DUTs required for a multi-DUT test scenario. Each entry configures one extra device to reserve and flash alongside the main DUT. An empty entry `{}` reserves a second device with the same platform and application as the main DUT.

Multi-DUT testing is supported for hardware device testing and `native_sim` simulation. QEMU is not supported. For simulation targets, Twister automatically creates the required placeholder DUT entries, no hardware map is needed. For hardware testing, provide a hardware map file (`--hardware-map`) with a matching entry per required device. More details in *Multi-DUTs testing support* section.

Each entry supports the following optional fields:

platform: <string> (optional, defaults to current test's platform)
Platform to use for this required device. If not specified, the same platform as the main DUT is used.

application: <string> (optional, defaults to current test application)
Test application ID to flash on this required device. When specified, Twister builds the application separately and assigns its build directory to the reserved DUT before flashing. If not specified, the same application as the main DUT is used.

It uses same mechanism as *required_applications*.

path: <string> (optional)
Directory path where Twister should search for the application specified in `application`. Can be an absolute path or a path relative to the directory containing the test's YAML file. Environment variables and Zephyr module directory variables are expanded (see *Expanding paths with module directory variables*). If not specified, Twister searches in the same directory as the referring test's YAML file.

fixture: <list of fixture names> (optional, defaults to empty)
List of fixture names that must be present on the reserved device. See *Fixtures* for details.

Fixtures support an optional parameter suffix using the `name:param` syntax (e.g., `io_adapter:channel_a`). When the main DUT has a fixture with a parameter, Twister uses that parameter value to match required devices - only devices carrying the **same parameter** for that fixture name are considered. This ensures that physically connected DUT pairs (e.g., two boards wired together and registered with the same fixture parameter in the hardware map) are always reserved together and not mixed with unrelated boards.

Example hardware map entries for a paired setup:

```
- id: "01"
  platform: nrf52840dk/nrf52840
  serial: /dev/ttyACM0
  fixtures:
    - io_adapter:channel_a
- id: "02"
  platform: nrf52840dk/nrf52840
  serial: /dev/ttyACM1
  fixtures:
    - io_adapter:channel_a
```

With `fixture: [io_adapter]` on both the main DUT and the required device, Twister selects only boards sharing the same `channel_a` parameter, guaranteeing the physically paired boards are picked.

Example configurations with multiple required devices:

```
tests:
  # Two DUTs, same platform and application
  multidut.basic:
    harness_config:
      required_devices:
        - {}
  # Second DUT fixed to a specific platform
  multidut.fixed_platform:
    harness_config:
      required_devices:
        - platform: nrf52840dk/nrf52840
  # Second DUT flashed with a different application
  multidut.other_app:
    harness_config:
      required_devices:
        - application: multidut.basic
```

Console

The `console` harness tells Twister to parse a test's text output for a regex defined in the test's YAML file.

The following options are currently supported:

type: <one_line|multi_line> (required)
Depends on the regex string to be matched

regex: <list of regular expressions> (required)
Strings with regular expressions to match with the test's output to confirm the test runs as expected.

ordered: <True|False> (default False)
Check the regular expression strings in orderly or randomly fashion

record: <recording options> (optional)

regex: <list of regular expressions> (required)
Regular expressions with named subgroups to match data fields found in the test instance's output lines where it provides some custom data for further analysis. These records will be written into the build directory `recording.csv` file as well as `recording` property of the test suite object in `twister.json`.

With several regular expressions given, each of them will be applied to each output line producing either several different records from the same output line, or different

records from different lines, or similar records from different lines.

The .CSV file will have as many columns as there are fields detected in all records; missing values are filled by empty strings.

For example, to extract three data fields `metric`, `cycles`, `nanoseconds`:

```
record:
  regex:
    - "(?P<metric>.*):(?P<cycles>.*) cycles, (?P<nanoseconds>.*) ns"
```

merge: <True|False> (default False)
Allows to keep only one record in a test instance with all the data fields extracted by the regular expressions. Fields with the same name will be put into lists ordered as their appearance in recordings. It is possible for such multi value fields to have different number of values depending on the regex rules and the test's output.

as_json: <list of regex subgroup names> (optional)
Data fields, extracted by the regular expressions into named subgroups, which will be additionally parsed as JSON encoded strings and written into `twister.json` as nested `recording` object properties. The corresponding `recording.csv` columns will contain JSON strings as-is.

Using this option, a test log can convey layered data structures passed from the test image for further analysis with summary results, traces, statistics, etc.

For example, this configuration:

```
record:
  regex: "RECORD:(?P<type>.*):DATA:(?P<metrics>.*)"
  as_json: [metrics]
```

when matched to a test log string:

```
RECORD:jitter_drift:DATA:{"rollovers":0, "mean_us":1000.0}
```

will be reported in `twister.json` as:

```
"recording":[
    {
          "type":"jitter_drift",
          "metrics":{
              "rollovers":0,
              "mean_us":1000.0
          }
    }
]
```

Robot

Zephyr supports Robot Framework as one of solutions for automated testing.

Robot files allow you to express interactive test scenarios in human-readable text format and execute them in simulation or against hardware. At this moment Zephyr integration supports running Robot tests in the Renode simulation framework, QEMU and Native Simulator.

To execute a Robot test suite with twister, run the following command:

```
$ west twister --platform hifive1 --test␣
↪samples/subsys/shell/shell_module/sample.shell.shell_module.robot
```

Writing Robot tests For the list of keywords provided by the Robot Framework itself, refer to the official Robot documentation.

Information on writing and running Robot Framework tests in Renode can be found in the testing section of Renode documentation. It provides a list of the most commonly used keywords together with links to the source code where those are defined.

It's possible to extend the framework by adding new keywords expressed directly in Robot test suite files, as an external Python library or, like Renode does it, dynamically via XML-RPC. For details see the extending Robot Framework section in the official Robot documentation.

Running a single testsuite To run a single testsuite instead of a whole group of test you can run:

```
$ west twister -p qemu_riscv32 -s arch.shared_interrupt
```

The `robot` harness is used to execute Robot Framework test suites in simulation target (Qemu, Native Simulator, Renode).

robot_testsuite: <robot file path> (default empty)
Specify one or more paths to a file containing a Robot Framework test suite to be run.

robot_option: <robot option> (default empty)
One or more options to be send to robotframework.

Power

The `power` harness is used to measure and validate the current consumption. It integrates with 'pytest' to perform automated data collection and analysis using a hardware power monitor.

The harness executes the following steps:

1. Initializes a power monitoring device (e.g., `stm_powershield`) via the `PowerMonitor` abstract interface.
2. Starts current measurement for a defined `measurement_duration`.
3. Collects raw current waveform data.
4. Uses a peak detection algorithm to segment data into defined execution phases based on power transitions.
5. Computes RMS current values for each phase using a utility function.
6. Compares the computed values with user-defined expected RMS values.

```
harness: power
harness_config:
  fixture: pm_probe
  power_measurements:
    elements_to_trim: 100
    min_peak_distance: 40
    min_peak_height: 0.008
    peak_padding: 40
    measurement_duration: 6
    num_of_transitions: 4
    expected_rms_values: [56.0, 4.0, 1.2, 0.26, 140]
    tolerance_percentage: 20
```

- **elements_to_trim** – Number of samples to discard at the start of measurement to eliminate noise.
- **min_peak_distance** – Minimum distance between detected current peaks (helps detect distinct transitions).

- **min_peak_height** – Minimum current threshold to qualify as a peak (in amps).
- **peak_padding** – Number of samples to extend around each detected peak.
- **measurement_duration** – Total time (in seconds) to record current data.
- **num_of_transitions** – Expected number of power state transitions in the DUT during test execution.
- **expected_rms_values** – Target RMS values for each identified execution phase (in milliamps).
- **tolerance_percentage** – Allowed deviation percentage from the expected RMS values.

Display capture

The `display_capture` harness is used to verify display driver functionality by capturing and analyzing display output using a camera. It integrates with pytest to perform automated visual testing using video fingerprints.

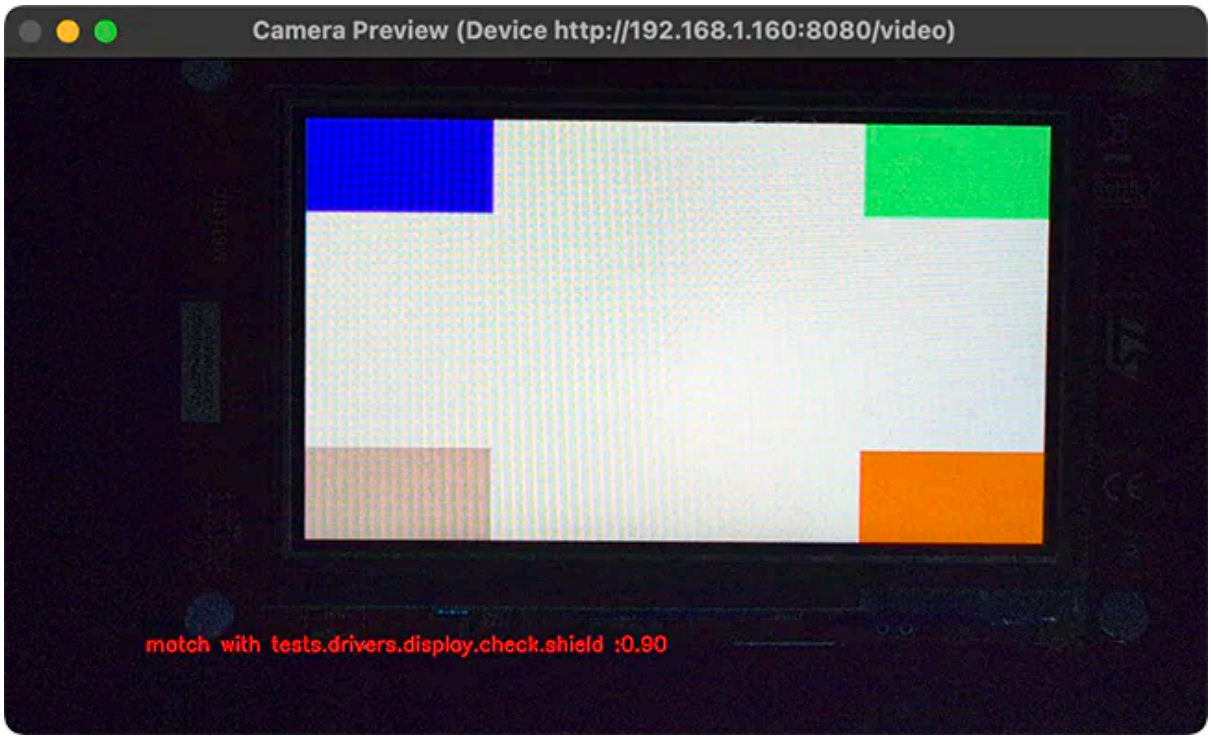

Fig. 5: Window being displayed for a “compare” run where fingerprint is a 90% match with the reference.

Hardware setup The display capture harness requires:

- UVC compatible camera with at least 2 megapixels (e.g., 1080p resolution)
- Light-blocking enclosure or black curtain to ensure consistent lighting
- PC host with camera connection for capturing display output
- DUT connected to the same PC for flashing and serial console access

Configuration The harness uses a YAML configuration file that defines camera settings, test parameters, and video signature analysis options. A typical configuration is shown below:

Listing 1: display_config.yaml

```yaml
case_config:
  device_id: 0
  res_x: 1280
  res_y: 720
  fps: 30
  run_time: 20
test:
  timeout: 30
  prompt: "screen starts"
  expect: ["tests.drivers.display.check.shield"]
plugins:
  - name: signature
    module: plugins.signature_plugin
    class: VideoSignaturePlugin
    status: enable
    config:
      operations: "compare"  # or "generate"
      metadata:
        name: "tests.drivers.display.check.shield"
        platform: "frdm_mcxn947"
      directory: "./fingerprints"
      duration: 100
      method: "combined"
      threshold: 0.65
      phash_weight: 0.35
      dhash_weight: 0.25
      histogram_weight: 0.2
      edge_ratio_weight: 0.1
      gradient_hist_weight: 0.1
```

- `case_config` - This section defines to the general camera settings and duration of the test.
  - `device_id` - The camera device ID (defaults to 0). Any valid OpenCV camera identifier, which can be:
    - An integer for local cameras (use 0 for the first camera, 1 for the second, etc).
    - A device path string such as `/dev/video0` on Linux.
    - An IP video stream URL such as `rtsp://192.168.1.100:8554/stream` for network cameras.
  - `res_x` - The horizontal resolution of the camera (integer, defaults to 1280).
  - `res_y` - The vertical resolution of the camera (integer, defaults to 720).
  - `fps` - The frames per second of the camera (integer, defaults to 30).
  - `run_time` - The duration of the test in seconds (integer, defaults to 20).
- `test` - This section contains the test configuration for device interaction.
  - `timeout` - Maximum time in seconds to wait for the prompt to appear on the device UART output (integer, defaults to 30).
  - `prompt` - The string pattern to wait for in the device UART output before starting the display capture. This can be a regular expression (string, defaults to `uart:~$`).
  - `expect` - A list of expected test result strings that must match the results returned by the application. The test passes if the captured results match this list (list of strings, defaults to `['PASS']`).

- `plugins` - This section contains the configuration for the plugins processing the camera frames. Only the `VideoSignaturePlugin` plugin is currently supported, and it takes the following configuration options:
  - `operations` - The operation to perform when running the test (string). Must be set to either `generate` to capture fingerprints or `compare` to compare the captured fingerprints with the reference fingerprints.
  - `metadata` - Metadata information for fingerprint identification (optional).
    - `name` - Test case name identifier (string).
    - `platform` - Target platform identifier (string).
  - `directory` - The directory where the fingerprints are stored (string, defaults to `./fingerprints`).
  - `duration` - The number of frames to analyze (integer). More frames takes longer but generate more accurate fingerprints).
  - `method` - The method used to generate display fingerprints (string, defaults to `combined`). Must be set to either of the following values: `phash`, `dhash`, `histogram`, or `combined`.

    `phash` (Perceptual Hash)
    Captures overall visual structure and layout. Best for detecting major rendering issues, e.g. UI elements being positioned incorrectly.

    `dhash` (Difference Hash)
    Detects brightness patterns and gradients. Sensitive to contrast changes, e.g. brightness or contrast problems.

    `histogram` (Color Histogram)
    Analyzes color distribution. Fast at detecting obvious color problems, e.g. color swap bugs.

    `combined` (recommended method)
    Weights all methods together (see *method*`_weight` option below) for robust comparison. Provides balanced detection of both major and subtle visual issues.
  - `threshold` - The similarity score above which it is considered that there is a match between the reference and the captured fingerprints (optional float, defaults to 0.65).
  - `phash_weight` - The weight for the phash method (optional float, defaults to 0.35)
  - `dhash_weight` - The weight for the dhash method (optional float, defaults to 0.25)
  - `histogram_weight` - The weight for the histogram method (optional float, defaults to 0.2)
  - `gradient_hist_weight` - The weight for the gradient histogram method (optional float, defaults to 0.1)
  - `edge_ratio_weight` - The weight for the edge ratio method (optional float, defaults to 0.1)

The configuration file path is specified in the test's `testcase.yaml` via the `display_capture_config` harness configuration option using the `DISPLAY_TEST_DIR` environment variable:

```
harness: display_capture
harness_config:
  pytest_dut_scope: session
  fixture: fixture_display
  display_capture_config: "${DISPLAY_TEST_DIR}/display_config.yaml"
```

Workflow First, generate **reference fingerprints** for a known-good display output:

```
# Build and flash the display test
west build -b <board> tests/drivers/display/display_check
west flash

# Configure for fingerprint generation mode by setting the 'operations' field to
↪'generate'
# in the configuration file.

# Generate fingerprints
export DISPLAY_TEST_DIR=<path-to-config-directory>
west twister --device-testing --hardware-map map.yml \
    -T tests/drivers/display/display_check/
```

Fingerprints are stored in the directory specified in the `directory` field of the configuration file, and organized by test name and platform as defined in the `metadata` field of the configuration file.

Once the fingerprints have been generated, you can run the test(s) again, this time in **comparison mode**:

```
# Set the 'operations' field to 'compare' in the configuration file.

export DISPLAY_TEST_DIR=<path-to-fingerprints-parent-directory>
west twister --device-testing --hardware-map map.yml \
    -T tests/drivers/display/display_check/
```

The harness compares captured video against reference fingerprints using the configured signature methods and thresholds. If the similarity score between reference and captured fingerprints exceeds the configured `threshold`, the test passes.

Note

- The test name in the DUT's `testcase.yaml` must match the `name` field in the fingerprint's metadata configuration.
- Multiple fingerprints can be stored in one directory for comprehensive validation, though this increases comparison time.
- Fingerprints are specific to both the test scenario and platform.

Script

The `script` harness executes shell scripts as test cases. It resolves scripts from the `tests_scripts` harness configuration option, runs each script as a subprocess, and reports individual pass/fail results based on the script exit code.

The `script` harness also serves as a base class for the *bsim*, *pytest*, and *ctest* harnesses, providing shared subprocess execution, output streaming, and log handling.

tests_scripts: <list of script paths> (default tests_scripts)
: Specify a list of shell script paths, relative to the test source directory, that need to be executed when a test scenario runs. Each entry can be a path to a single file, a directory, or a glob pattern. When a directory is specified, all `.sh` files in that directory, including its subdirectories, are collected (excluding files starting with _). The default is the `tests_scripts` directory.

```
harness: script
harness_config:
  tests_scripts:
    - tests_scripts/test_a.sh
    - ../../test/test_b.sh
    - $ENV_VAR/tests_scripts
```

Any extra command-line arguments passed to Twister after `--` are forwarded to every script as additional positional arguments.

Bsim

The `bsim` harness extends the *script harness* to support BabbleSim tests. During the build phase it copies the final executable (`zephyr.exe`) from the build directory to BabbleSim's `bin` directory (`${BSIM_OUT_PATH}/bin`). During the run phase it executes the test scripts listed in `tests_scripts`.

By default, the executable file name is (with dots and slashes replaced by underscores): `bs_<platform_name>_<test_path>_<test_scenario_name>`. This name can be overridden with the `bsim_exe_name` option in `harness_config` section.

Additional `bsim` harness keys extending the *script harness*:

bsim_exe_name: <string>
: If provided, the executable filename when copying to BabbleSim's bin directory, will be `bs_<platform_name>_<bsim_exe_name>` instead of the default based on the test path and scenario name.

Example configuration with a multi-images BabbleSim test where the advertiser is build-only and the scanner references it via *required_applications*:

```
common:
  platform_allow:
    - nrf52_bsim/native
  harness: bsim
tests:
  bluetooth.host.adv.extended.advertiser:
    build_only: true
    harness_config:
      bsim_exe_name: tests_bsim_bluetooth_host_adv_extended_prj_advertiser_conf
    extra_args:
      CONF_FILE=prj_advertiser.conf
  bluetooth.host.adv.extended.scanner:
    harness_config:
      bsim_exe_name: tests_bsim_bluetooth_host_adv_extended_prj_scanner_conf
      tests_scripts:
        - tests_scripts/run_adv_extended.sh
    extra_args:
      CONF_FILE=prj_scanner.conf
    required_applications:
      - application: bluetooth.host.adv.extended.advertiser
```

Shell

The shell harness is used to execute shell commands and parse the output and utilizes the pytest framework and the pytest harness of twister.

The following options apply to the shell harness:

shell_commands: <list of pairs of commands and their expected output> (default empty)
Specify a list of shell commands to be executed and their expected output. For example:

```
harness_config:
  shell_commands:
  - command: "kernel cycles"
    expected: "cycles: .* hw cycles"
  - command: "kernel version"
    expected: "Zephyr version .*"
  - command: "kernel sleep 100"
```

If expected output is not provided, the command will be executed and the output will be logged.

shell_commands_file: <string> (default empty)
Specify a file containing test parameters to be used in the test. The file should contain a list of commands and their expected output. For example:

```
- command: "mpu mtest 1"
  expected: "The value is: 0x.*"
- command: "mpu mtest 2"
  expected: "The value is: 0x.*"
```

If no file is specified, the shell harness will use the default file `test_shell.yml` in the test directory. `shell_commands` will take precedence over `shell_commands_file`.

2.12.9 Sidecars

Some tests need a host-side resource to exist for the duration of a run: a daemon the emulated guest talks to, a shared memory region the host reads back afterwards, or a network interface the guest attaches to. A *sidecar* models this. It is selected with the `sidecar:` entry in a test scenario's `tests.yaml` and is orthogonal to the harness: the harness interprets the guest's output while the sidecar provisions the host side around the run. Any harness (`console` for a sample, `ztest` for a test, ...) can therefore be paired with any sidecar.

```
tests:
  some.test:
    harness: ztest
    sidecar: <name>
```

A sidecar has a small lifecycle, driven by Twister for each test instance:

1. **configure** – the sidecar reads what it needs from the instance and its `sidecar_config` block before anything is provisioned.
2. **host check** – at test-plan time the sidecar reports whether the host provides what it needs (for example, that a required daemon binary is installed). When it does not, the test is *built only* and not executed, exactly like a platform whose simulator is not installed.
3. **setup** – called just before the handler runs the test image; it brings the host resource up (starts a daemon, creates an interface, ...). If the host side still turns out to be unavailable – for example bringing the resource up needs privileges that are not present – setup reports this and Twister *skips* execution instead of failing the test.
4. **teardown** – called after the handler returns, in a `finally` block, so it always runs even if the test failed or timed out. It releases the resource and may also collect data the guest left behind (for example reading a shared memory region back into the build directory).

Because provisioning is decoupled from output processing, Twister can also attach a sidecar to an instance itself, without the test opting in – for example to route coverage data off a guest that has no other host transport.

Each sidecar defines its own configuration keys under a block of `sidecar_config` named after the sidecar. Namespacing by sidecar name keeps each sidecar's keys separate, so only the block matching the scenario's `sidecar:` value is consumed. For example, the `virtiofs` sidecar shares a host directory seeded from a template with:

```
tests:
  some.test:
    harness: console
    sidecar: virtiofs
    sidecar_config:
      virtiofs:
        shared: shared
```

2.12.10 Selecting platform scope

One of the key features of Twister is its ability to decide on which platforms a given test scenario should run. This behavior has its roots in Twister being developed as a test runner for Zephyr's CI. With hundreds of available platforms and thousands of tests, the testing tools should be able to adapt the scope and select/filter out what is relevant and what is not.

Twister always prepares an initial list of platforms in scope for a given test, based on command line arguments and the *test's configuration*. Then, platforms that don't fulfill the conditions required in the configuration yaml (e.g. minimum ram) are filtered out from the scope. Using `--force-platform` allows to override filtering caused by `platform_allow`, `platform_exclude`, `arch_allow` and `arch_exclude` keys in test configuration files.

Command line arguments define the initial scope in the following way:

- `-p/--platform <platform_name>` (can be used multiple times): only platforms passed with this argument;
- `-l/--all`: all available platforms;
- `-G/--integration`: all platforms from an `integration_platforms` list in a given test configuration file. If a test has no `integration_platforms` *"scope presumption"* will happen;
- No scope argument: *"scope presumption"* will happen.

"Scope presumption": A list of Twister's *default platforms* is used as the initial list. If nothing is left after the filtration, the `platform_allow` list is used as the initial scope.

2.12.11 Running in Integration Mode

This mode is used in continuous integration (CI) and other automated environments used to give developers fast feedback on changes. The mode can be activated using the `--integration` option of twister and narrows down the scope of builds and tests if applicable to platforms defined under the integration keyword in the test configuration file (`tests.yaml`).

2.12.12 Running tests on custom emulator

Apart from the already supported QEMU and other simulated environments, Twister supports running any out-of-tree custom emulator defined in the board's `board.cmake`. To use this type of simulation, add the following properties to `custom_board/custom_board.yaml`:

```
simulation:
  - name: custom
    exec: <name_of_emu_binary>
```

This tells Twister that the board is using a custom emulator called `<name_of_emu_binary>`, make sure this binary exists in the PATH.

Then, in `custom_board/board.cmake`, set the supported emulation platforms to `custom`:

```
set(SUPPORTED_EMU_PLATFORMS custom)
```

Finally, implement the `run_custom` target in `custom_board/board.cmake`. It should look something like this:

```
add_custom_target(run_custom
  COMMAND
  <name_of_emu_binary to invoke during 'run'>
  <any args to be passed to the command, i.e. ${BOARD}, $
↪{APPLICATION_BINARY_DIR}/zephyr/zephyr.elf>
  WORKING_DIRECTORY ${APPLICATION_BINARY_DIR}
  DEPENDS ${logical_target_for_zephyr_elf}
  USES_TERMINAL
  )
```

2.12.13 Running Tests in Random Order

Enable ZTEST framework's `CONFIG_ZTEST_SHUFFLE` config option to run your tests in random order. This can be beneficial for identifying dependencies between test cases. For native_sim platforms, you can provide the seed to the random number generator by providing `--seed=value` as an argument to twister. See *Shuffling Test Sequence* for more details.

2.12.14 Running Tests on Hardware

Beside being able to run tests in QEMU and other simulated environments, twister supports running most of the tests on real devices and produces reports for each run with detailed FAIL/PASS results.

Executing tests on a single device

To use this feature on a single connected device, run twister with the following new options:

Linux

```
west twister --device-testing --device-serial /dev/ttyACM0 \
--device-serial-baud 115200 -p frdm_k64f  -T tests/kernel
```

Windows

```
west twister --device-testing --device-serial COM1 \
--device-serial-baud 115200 -p frdm_k64f  -T tests/kernel
```

The `--device-serial` option denotes the serial device the board is connected to. This needs to be accessible by the user running twister. You can run this on only one board at a time, specified using the `--platform` option. If the platform supports multiple serial ports, you can provide `--device-serial` multiple times, and it will be passed to the pytest harness. Alternatively you can use the hardware map, see *multi-core testing* for more details

The `--device-serial-baud` option is only needed if your device does not run at 115200 baud.

To support devices without a physical serial port, use the `--device-serial-pty` option. In this cases, log messages are captured for example using a script. In this case you can run twister with the following options:

Linux

```
west twister --device-testing --device-serial-pty "script.py" \
-p intel_adsp/cavs25 -T tests/kernel
```

Windows

Note

Not supported on Windows OS

The script is user-defined and handles delivering the messages which can be used by twister to determine the test execution status.

The `--device-flash-timeout` option allows to set explicit timeout on the device flash operation, for example when device flashing takes significantly large time.

The `--device-flash-with-test` option indicates that on the platform the flash operation also executes a test scenario, so the flash timeout is increased by a test scenario timeout.

Executing tests on multiple devices

To build and execute tests on multiple devices connected to the host PC, a hardware map needs to be created with all connected devices and their details such as the serial device, baud and their IDs if available. Run the following command to produce the hardware map:

```
$ west twister --generate-hardware-map map.yml
```

The generated hardware map file (map.yml) will have the list of connected devices, for example:

Linux

```
- connected: true
  id: "OSHW000032254e4500128002ab98002784d1000097969900"
  platform: unknown
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
- connected: true
  id: "000683759358"
  platform: unknown
  product: J-Link
  runner: unknown
  serial: /dev/cu.usbmodem0006837593581
```

Windows

```
- connected: true
  id: "OSHW000032254e4500128002ab98002784d1000097969900"
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM1
- connected: true
  id: "000683759358"
  platform: unknown
  product: unknown
  runner: unknown
  serial: COM2
```

Any options marked as `unknown` need to be changed and set with the correct values, in the above example the platform names, the products and the runners need to be replaced with the correct values corresponding to the connected hardware. In this example we are using a reel_board and an nrf52840dk/nrf52840:

Linux

```
- connected: true
  id: "OSHW000032254e4500128002ab98002784d1000097969900"
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/cu.usbmodem146114202
  baud: 9600
- connected: true
  id: "000683759358"
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: nrfjprog
  serial: /dev/cu.usbmodem0006837593581
  baud: 9600
```

Windows

```
- connected: true
  id: "OSHW000032254e4500128002ab98002784d1000097969900"
  platform: reel_board
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: COM1
  baud: 9600
- connected: true
  id: "000683759358"
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: nrfjprog
  serial: COM2
  baud: 9600
```

The baud entry is only needed if not running at 115200.

If the map file already exists, then new entries are added and existing entries will be updated. This way you can use one single master hardware map and update it for every run to get the correct serial devices and status of the devices.

With the hardware map ready, you can run any tests by pointing to the map

Linux

```
west twister --device-testing --hardware-map map.yml -T samples/hello_world/
```

Windows

```
west twister --device-testing --hardware-map map.yml -T samples\hello_world
```

The above command will result in twister building tests for the platforms defined in the hardware map and subsequently flashing and running the tests on those platforms.

Note

Currently only boards with support for pyocd, nrfjprog, jlink, openocd, or dediprog are supported with the hardware map features. Boards that require other runners to flash the Zephyr binary are still work in progress.

Hardware map allows to set `--device-flash-timeout` and `--device-flash-with-test` command line options as `flash-timeout` and `flash-with-test` fields respectively. These hardware

map values override command line options for the particular platform.

Serial PTY support using `--device-serial-pty` can also be used in the hardware map:

```
- connected: true
  id: None
  platform: intel_adsp/cavs25
  product: None
  runner: intel_adsp
  serial_pty: path/to/script.py
  runner_params:
    - --remote-host=remote_host_ip_addr
    - --key=/path/to/key.pem
```

The runner_params field indicates the parameters you want to pass to the west runner. For some boards the west runner needs some extra parameters to work. It is equivalent to following west and twister commands.

Linux

```
west flash --remote-host remote_host_ip_addr --key /path/to/key.pem

west twister -p intel_adsp/cavs25 --device-testing --device-serial-pty script.py
--west-flash="--remote-host=remote_host_ip_addr,--key=/path/to/key.pem"
```

Windows

Note

Not supported on Windows OS

Note

For serial PTY, the “–generate-hardware-map” option cannot scan it out and generate a correct hardware map automatically. You have to edit it manually according to above example. This is because the serial port of the PTY is not fixed and being allocated in the system at runtime.

If west is not available or does not know how to flash your system, a custom flash command can be specified using the `flash-command` flag. The script is called with a `--build-dir` with the path of the current build, as well as a `--board-id` flag to identify the specific device when multiple are available in a hardware map.

Linux

```
west twister -p npcx9m6f_evb --device-testing --device-serial /dev/ttyACM0
--flash-command './custom_flash_script.py,--flag,"complex, argument"'
```

Windows

Note

west twister -p npcx9m6f_evb –device-testing –device-serial COM1 –flash-command ‘custom_flash_script.py,–flag,”complex, argument”’

Would result in calling `./custom_flash_script.py --build-dir <build directory> --board-id <board identification> --flag "complex, argument"`.

Fixtures Some tests require additional setup or special wiring specific to the test. Running the tests without this setup or test fixture may fail. A test scenario can specify the fixture it needs which can then be matched with hardware capability of a board and the fixtures it supports via the command line or using the hardware map file.

Fixtures are defined in the hardware map file as a list:

```
- connected: true
  fixtures:
    - gpio_loopback
  id: "0240000026334e450015400f5e0e000b4eb1000097969900"
  platform: frdm_k64f
  product: DAPLink CMSIS-DAP
  runner: pyocd
  serial: /dev/ttyACM9
```

When running `twister` with `--device-testing`, the configured fixture in the hardware map file will be matched to test scenarios requesting the same fixtures and these tests will be executed on the boards that provide this fixture.

To reserve a board for fixture-dependent tests, set `run_with_fixture_only` to `true`. Twister will select that board only for test scenarios that request matching fixtures; it will not select the board for scenarios without fixture requirements.

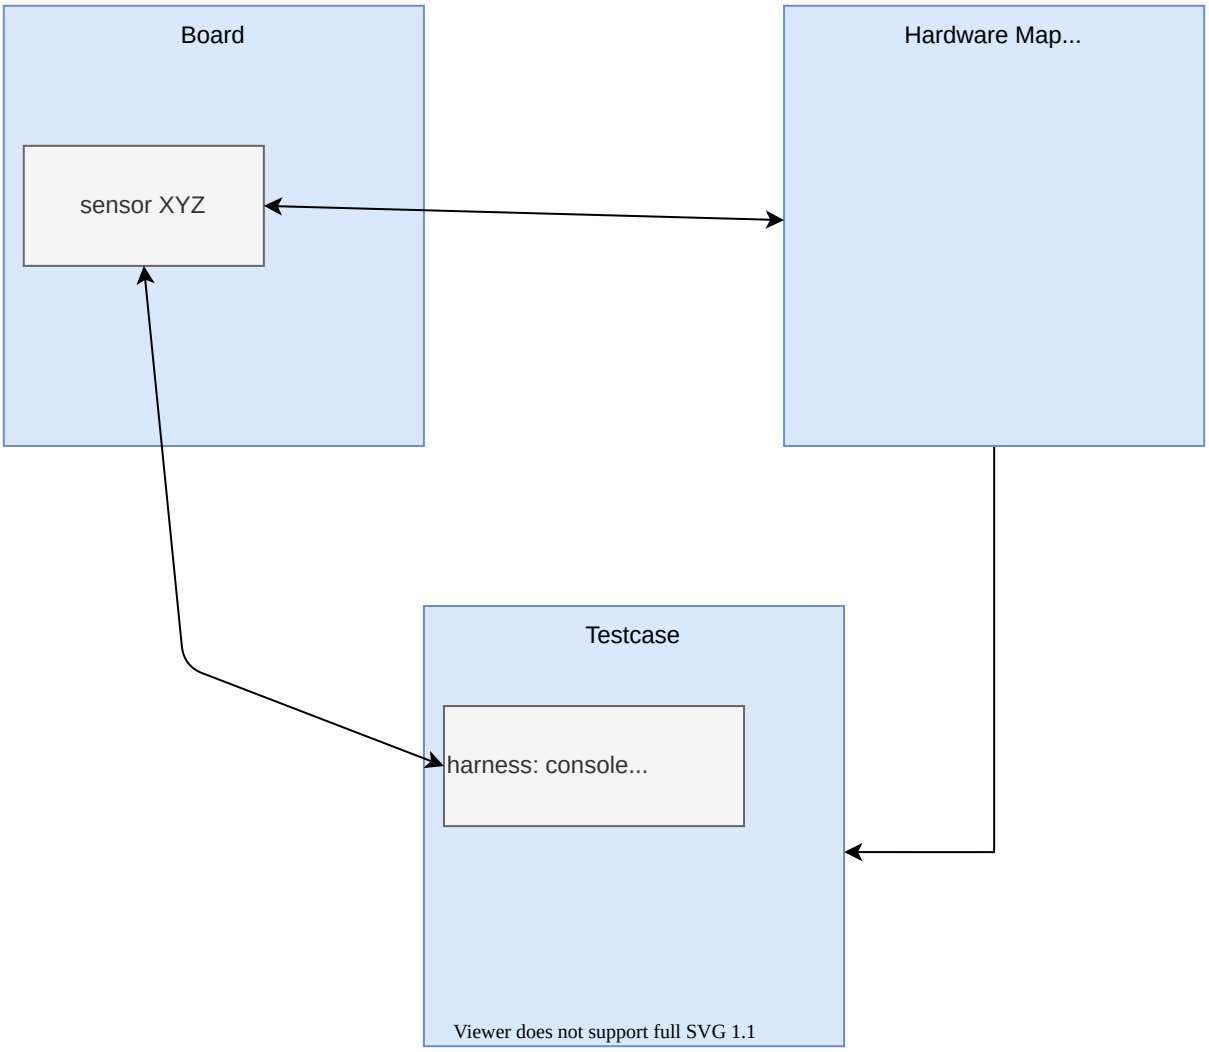
```
- connected: true
  fixtures:
    - gpio_loopback
  run_with_fixture_only: true
  id: 0240000026334e450015400f5e0e000b4eb1000097969900
  platform: frdm_k64f
```

Fixtures can also be provided via twister command option `--fixture`, this option can be used multiple times and all given fixtures will be appended as a list. And the given fixtures will be assigned to all boards, this means that all boards set by current twister command can run those test scenarios which request the same fixtures.

Some fixtures allow for configuration strings to be appended, separated from the fixture name by a `:`. Only the fixture name is matched against the fixtures requested by test scenarios.

Notes It may be useful to annotate board descriptions in the hardware map file with additional information. Use the `notes` keyword to do this. For example:

```
- connected: false
  fixtures:
    - gpio_loopback
  id: "000683290670"
  notes: An nrf5340dk/nrf5340 is detected as an nrf52840dk/nrf52840 with no serial
    port, and three serial ports with an unknown platform.  The board id of the␣
↪serial
    ports is not the same as the board id of the development kit.  If you␣
↪regenerate
    this file you will need to update serial to reference the third port, and␣
↪platform
    to nrf5340dk/nrf5340/cpuapp or another supported board target.
  platform: nrf52840dk/nrf52840
  product: J-Link
  runner: jlink
  serial: null
```



Board

Hardware Map...
Testcase
harness: console...
Viewer does not support full SVG 1.1

Overriding Board Identifier When (re-)generated the hardware map file will contain an `id` keyword that serves as the argument to `--board-id` when flashing. In some cases the detected ID is not the correct one to use, for example when using an external J-Link probe. The `probe_id` keyword overrides the `id` keyword for this purpose. For example:

```
- connected: false
  id: "0229000005d9ebc600000000000000000000000097969905"
  platform: mimxrt1060_evk
  probe_id: "000609301751"
  product: DAPLink CMSIS-DAP
  runner: jlink
  serial: null
```

Using Single Board For Multiple Variants

The `platform` attribute can be a list of names or a string with names separated by spaces. This allows to run tests for different platform variants on the same physical board, without re-configuring the hardware map file for each variant. For example:

```
- connected: true
  id: "001234567890"
  platform:
  - nrf5340dk/nrf5340/cpuapp
  - nrf5340dk/nrf5340/cpuapp/ns
  product: J-Link
  runner: nrfjprog
  serial: /dev/ttyACM1
```

Multi-Core testing support Twister supports testing multi-core applications where different cores use separate UART interfaces. This feature works only with the pytest harness (`harness: pytest`). Generated hardware map should contain multiple entries for the same physical device, each representing a different core connection. For example:

```
- connected: true
  id: "001234567890"
  serial: /dev/ttyACM0
- connected: true
  id: "001234567890"
  platform:
  - nrf54l15dk/nrf54l15/cpuapp
  product: J-Link
  runner: nrfutil
  serial: /dev/ttyACM1
```

Both instances share the same device ID but have different serial ports, allowing tests to interact with multiple cores simultaneously. Each connection is handled independently with separate log files.

Multi-DUTs testing support Twister supports test scenarios that require more than one device. This feature works only with the pytest harness (`harness: pytest`). Hardware and `native_sim` execution environments are supported.

To declare that a test needs an additional device, add `required_devices` under `harness_config` in the test's YAML file. Each entry in the list describes one extra DUT. An empty entry `{}` reserves a second device with the same platform and application as the main DUT. See *required_devices* for all available options.

Example test configuration:

```
tests:
  multidut.basic:
    harness: pytest
    harness_config:
      required_devices:
        - {}
```

The hardware map must contain at least one entry per required device. Each entry needs a matching platform and a serial connection:

```
- connected: true
  id: "01"
  platform: nrf52840dk/nrf52840
  serial: /dev/ttyACM0
- connected: true
  id: "02"
  platform: nrf52840dk/nrf52840
  serial: /dev/ttyACM1
```

Run the test on hardware with:

```
$ west twister -vv -ll debug -T tests/subsys/testsuite/multidut \
  --device-testing --hardware-map map.yaml
```

Run the test on `native_sim` (no hardware map required):

```
$ west twister -vv -ll debug -T tests/subsys/testsuite/multidut -p native_sim
```

Twister reserves all required devices (or creates placeholder entries if `native_sim` is used), then passes them to pytest with all necessary information (platform, serial connection, build artifacts to flash, etc.) so the test can interact with all devices.

An example multi-DUT test can be found at tests/subsys/testsuite/multidut.

Quarantine Twister allows user to provide configuration files defining a list of tests or platforms to be put under quarantine. Such tests will be skipped and marked accordingly in the output reports. This feature is especially useful when running larger test suits, where a failure of one test can affect the execution of other tests (e.g. putting the physical board in a corrupted state).

To use the quarantine feature one has to add the argument `--quarantine-list <PATH_TO_QUARANTINE_YAML>` to a twister call. Multiple quarantine files can be used. The current status of tests on the quarantine list can also be verified by adding `--quarantine-verify` to the above argument. This will make twister skip all tests which are not on the given list.

A quarantine yaml is a sequence of dictionaries. Each dictionary must have at least one of the following keys: `scenarios`, `platforms`, `architectures` or `simulations`. A combination of these entries is allowed. An optional `comment` entry can be used to provide more details (e.g., a link to a reported issue). These comments will also be added to the output reports.

When quarantining a class of tests or many scenarios in a single testsuite or when dealing with multiple issues within a subsystem, it is possible to use regular expressions, for example, **kernel.*** would quarantine all kernel tests.

An example of entries in a quarantine yaml:

```
- scenarios:
    - sample.basic.helloworld
  comment: "Link to the issue:␣
↪https://github.com/zephyrproject-rtos/zephyr/pull/33287"
```

(continues on next page)

(continued from previous page)

```
- scenarios:
    - kernel.common
    - kernel.common.(misra|tls)
    - kernel.common.nano64
  platforms:
    - .*_cortex_.*
    - native_sim

- platforms:
    - qemu_x86
  comment: "filter out qemu_x86"

- architectures:
    - riscv

- simulations:
    - armfvp
```

2.12.15 Test Output and Reports

By default, Twister writes all of its output to a `twister-out` directory created in the current working directory. Use `-O`/`--outdir` to choose a different location. On each run this directory is cleaned, unless `--no-clean` is given; `--clobber-output` controls what cleaning does.

Top-level reports

The following files are written at the root of the output directory:

`twister.json`
: The primary machine-readable report. It contains an entry for every selected test suite and test case with its *status*, target platform, execution time, memory footprint, any *recorded data*, and the environment and options used for the run.

`testplan.json`
: The resolved test plan: every test instance (test scenario times platform) that Twister considered, including those that were filtered out together with the reason. This is the file to inspect to understand why a given scenario did or did not run. It can be reused with `--load-tests` to replay the same selection.

`twister.xml`
: JUnit XML summary suitable for CI systems.

`twister_report.xml`
: JUnit XML report including all test cases (not just the summary).

`twister_suite_report.xml`
: JUnit XML report grouped by test suite.

`twister.log`
: Human-readable log of the whole run.

`twister_footprint.json`
: ROM/RAM footprint report. Only generated when `--footprint-report` is used.

The report base name (`twister`) can be changed with `--report-name`, and `--report-suffix` appends a suffix (for example a version or commit ID) to all generated file names. Use `-o`/`--report-dir` to write the reports to a directory other than the output directory, and `--platform-reports` to additionally emit a per-platform `<platform>.json` and `<platform>.xml`. `--report-summary` prints a summary of the failures from the latest run without rebuilding.

Per-test artifacts

Each test instance has its own build directory under the output directory, named after the platform and the test: `twister-out/<platform>/<test path>/<scenario>/`. In addition to the normal Zephyr build artifacts (for example `zephyr/zephyr.elf`), it may contain:

`build.log`
: Output of the build for this instance.

`handler.log`
: Console output captured from the device or emulator while running the test.

`twister_harness.log`
: Log produced by pytest-based harnesses (for example `pytest` and `shell`).

`recording.csv`
: Data fields captured by the `record` option of the *console harness*, when configured.

2.12.16 Live Run Monitoring

For long runs it can be hard to tell from the scrolling console output what twister is actually doing: what is queued, what each job is building or running right now, and which tests have already failed and why. The `--console-monitor` option replaces the normal output with a live full-screen dashboard in the terminal for the duration of the run:

```
$ west twister -T tests/kernel --console-monitor
```

The dashboard shows overall progress with pass/fail/error/filtered breakdowns and an estimated time to completion, the set of test instances currently *in flight* with the pipeline stage each one is in (`cmake`, `build`, `run`, ...), and a scrollable table of every test instance in the plan, including statically filtered ones. Normal log output goes to `twister.log` in the meantime.

Navigation: `Tab` cycles the table filter (all/active/failures/passed/queued/filtered), `f` jumps straight to the failures view, and `/` starts an incremental text search over instance names and failure reasons (`Esc` clears it). Move the selection with the arrow keys or `j`/`k` and press `Enter` to open the detail view for an instance: its pipeline stage timeline, the list of failing test cases with their reasons, and the tail of its log files (`l` switches between the available logs, `j`/`k` or the arrow keys scroll, `g`/`G` jump to the top/end, and the view follows new output while pinned to the end) – particularly useful for inspecting failures while the rest of the run continues.

When the run finishes the dashboard stays up so failures can be inspected; pressing `q` leaves it, after which reports are written and twister exits as usual. Pressing `q` while the run is still going leaves the dashboard early and resumes the normal console output. The option requires an interactive terminal and is ignored otherwise (e.g. in CI).

The monitor observes the run without influencing it: monitoring events are delivered on a best-effort basis and are dropped rather than ever delaying the build/run pipeline.

2.12.17 Twister Configuration File

The Twister configuration file (`test_config.yaml`, passed with `--test-config`) can be used to customize various aspects of twister and the default enabled options and features. This allows tweaking the filtering capabilities depending on the environment and makes it possible to adapt and improve coverage when targeting different sets of platforms.

Note

This file (selected with `--test-config`) configures a whole Twister run. It is distinct from the per-application test configuration in `tests.yaml`, which describes individual *test scenarios*.

The Twister configuration file also adds support for test levels and the ability to assign a specific test to one or more levels. Using command line options of twister it is then possible to select a level and just execute the tests included in this level.

Additionally, the configuration file allows defining level dependencies and additional inclusion of tests into a specific level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels easier.

To help with testing outside of upstream CI infrastructure, additional options are available in the configuration file, which can be hosted locally. As of now, those options are available:

- Ability to ignore default platforms as defined in board definitions (Those are mostly emulation platforms used to run tests in upstream CI)
- Option to specify your own list of default platforms overriding what upstream defines.
- Ability to override `build_on_all` options used in some test scenarios. This will treat tests or sample as any other just build for default platforms you specify in the configuration file or on the command line.
- Ignore some logic in twister to expand platform coverage in cases where default platforms are not in scope.

Platform Configuration

The following options control platform filtering in twister:

- `override_default_platforms`: override default key a platform sets in board configuration and instead use the list of platforms provided in the configuration file as the list of default platforms. This option is set to False by default.
- `increased_platform_scope`: This option is set to True by default, when disabled, twister will not increase platform coverage automatically and will only build and run tests on the specified platforms.
- `default_platforms`: A list of additional default platforms to add. This list can either be used to replace the existing default platforms or can extend it depending on the value of `override_default_platforms`.
- `build_toolchains`: A mapping of platform names to the list of toolchains every test assigned to that platform should be built with. Twister creates one test instance per toolchain, each in its own build directory. This sets, or overrides, the `build_toolchains` option of the board definition; an empty list disables multi-toolchain builds for a platform that requests them. Since this multiplies build time, it is typically enabled only in the configuration file used by CI (`tests/test_config_ci.yaml`) so that local runs keep building each test once. See *Toolchain Selection*.

And example platforms configuration:

```
platforms:
  override_default_platforms: true
  increased_platform_scope: false
  default_platforms:
    - qemu_x86
  build_toolchains:
    native_sim:
      - host/gnu
      - host/llvm
```

Test Level Configuration

The test configuration allows defining test levels, level dependencies and additional inclusion of tests into a specific test level if the test itself does not have this information already.

In the configuration file you can include complete components using regular expressions and you can specify which test level to import from the same file, making management of levels simple.

And example test level configuration:

```
levels:
  - name: my-test-level
    description: >
      my custom test level
    adds:
      - kernel.threads.*
      - kernel.timer.behavior
      - arch.interrupt
      - boards.*
```

Combined configuration

To mix the Platform and level configuration, you can take an example as below:

An example platforms plus level configuration:

```
platforms:
  override_default_platforms: true
  default_platforms:
    - frdm_k64f
levels:
  - name: smoke
    description: >
        A plan to be used verifying basic zephyr features.
  - name: unit
    description: >
        A plan to be used verifying unit test.
  - name: integration
    description: >
        A plan to be used verifying integration.
  - name: acceptance
    description: >
        A plan to be used verifying acceptance.
  - name: system
    description: >
        A plan to be used verifying system.
  - name: regression
    description: >
        A plan to be used verifying regression.
```

To run with above test_config.yaml file, only default_platforms with given test level test scenarios will run.

```
$ west twister --test-config=<path to>/test_config.yaml -T tests --level="smoke"
```

2.13 Testing

2.13.1 Test Framework

The Zephyr Test Framework (Ztest) provides a simple testing framework intended to be used during development. It provides basic assertion macros and a generic test structure.

The framework can be used in two ways, either as a generic framework for integration testing, or for unit testing specific modules.

- *Quick start - Integration testing*
- *Quick start - Unit testing*
- *Creating a test suite*
- *Adding tests to a suite*
- *Advanced features*
- *Best practices for declaring the test suite*
- *Stress test framework*
- *API reference*
- *Customizing Test Output*
- *Shuffling Test Sequence*
- *Repeating Tests*
- *Test Selection*
- *FFF Extensions*

Quick start - Integration testing

A simple working base is located at samples/subsys/testsuite/integration. To make a test application for the **bar** component of **foo**, you should copy the sample folder to `tests/foo/bar` and edit files there adjusting for your test application's purposes.

To build and execute all applicable test scenarios defined in your test application use the *Twister* tool, for example:

```
west twister -T tests/foo/bar/
```

To select just one of the test scenarios, run Twister with `--scenario` command:

```
west twister --scenario tests/foo/bar/your.test.scenario.name
```

In the command line above `tests/foo/bar` is the path to your test application and `your.test.scenario.name` references a test scenario defined in `tests.yaml` file, which is like `sample.testing.ztest` in the boilerplate test suite sample.

See *Twister test project diagram* for more details on how Twister deals with Ztest application.

The sample contains the following files:

Listing 2: CMakeLists.txt

```

5   */
6
7  #include <zephyr/ztest.h>
8
9
10 ZTEST_SUITE(framework_tests, NULL, NULL, NULL, NULL, NULL);
11
12 /**
13  * @brief Test Asserts
14  *
15  * This test verifies various assert macros provided by ztest.
16  *
17  */
18 ZTEST(framework_tests, test_assert)
19 {
20         zassert_true(1, "1 was false");
21         zassert_false(0, "0 was true");
22         zassert_is_null(NULL, "NULL was not NULL");
23         zassert_not_null("foo", "\"foo\" was NULL");
24         zassert_equal(1, 1, "1 was not equal to 1");
25         zassert_equal_ptr(NULL, NULL, "NULL was not equal to NULL");
26 }
```

A test application may consist of multiple test suites that either can be testing functionality or APIs. Functions implementing a test case should follow the guidelines below:

- Test cases function names should be prefixed with **test_**
- Test cases should be documented using doxygen
- Test case function names should be unique within the section or component being tested

For example:

```
/**
 * @brief Test Asserts
 *
 * This test case verifies the zassert_true macro.
 */
ZTEST(my_suite, test_assert)
{
        zassert_true(1, "1 was false");
}
```

Listing Tests Tests (test applications) in the Zephyr tree consist of many test scenarios that run as part of a project and test similar functionality, for example an API or a feature. The `twister` script can parse the test scenarios, suites and cases in all test applications or a subset of them, and can generate reports on a granular level, i.e. if test cases have passed or failed or if they were blocked or skipped.

Twister parses the source files looking for test case names, so you can list all kernel test cases, for example, by running:

```
west twister --list-tests -T tests/kernel
```

Skipping Tests Special- or architecture-specific tests cannot run on all platforms and architectures, however we still want to count those and report them as being skipped. Because the test inventory and the list of tests is extracted from the code, adding conditionals inside the test suite is sub-optimal. Tests that need to be skipped for a certain platform or feature need to explicitly report a skip using `ztest_test_skip()` or `Z_TEST_SKIP_IFDEF`. If the test runs, it needs to report either a pass or fail. For example:

```
#ifdef CONFIG_TEST1
ZTEST(common, test_test1)
{
     zassert_true(1, "true");
}
#else
ZTEST(common, test_test1)
{
     ztest_test_skip();
}
#endif

ZTEST(common, test_test2)
{
     Z_TEST_SKIP_IFDEF(CONFIG_BUGxxxxx);
     zassert_equal(1, 0, NULL);
}

ZTEST_SUITE(common, NULL, NULL, NULL, NULL, NULL);
```

Quick start - Unit testing

Ztest can be used for unit testing. This means that rather than including the entire Zephyr OS for testing a single function, you can focus the testing efforts into the specific module in question. This will speed up testing since only the module will have to be compiled in, and the tested functions will be called directly.

To setup unit tests you have to add a CMakeLists.txt, a tests.yaml and a prj.conf to the directory containing the unit test source files. The resulting binary from this

directory is built using -DBOARD=unit_testing. When twister is invoked the script zephyr/scripts/pylib/twister/twisterlib/testplan.py filters out all tests.yaml in which type: unit is not set. Only unit tests are executed with a firmware build with BOARD=unit_testing.

> **Note**
>
> Unit tests are run as **native** applications on the host and are therefore subject to similar limitations as documented for the POSIX architecture. Running unit tests is therefore only supported for Linux. To run unit tests on Windows or macOS it is necessary to use containers or Virtual Machines running a Linux guest. Follow the same instructions as for the POSIX Arch dependencies.

The `unit_testing` board Unit tests are built for the special `unit_testing` board (subsys/testsuite/boards/unit_testing). It is not a real piece of hardware nor a simulated target: it is a pseudo-board with `arch: unit` that uses the host toolchain to produce a regular native executable. Selecting it with `-DBOARD=unit_testing` (which Twister does automatically for scenarios marked `type: unit`) builds and links only the source files you add to the `testbinary` target together with the Ztest unit-test harness.

Crucially, **the Zephyr kernel and operating system are not built at all**. There is no boot sequence, no scheduler, no devicetree-driven device initialization, and no driver model. The functions under test are compiled into the test binary and called directly. Any kernel API or other dependency that the module under test relies on must be supplied by the test itself, usually as a stub or a *mock*.

Difference from `native_sim` and other boards It is easy to confuse the `unit_testing` board with native_sim, since both run on the host. They are fundamentally different:

- native_sim builds the **complete Zephyr OS** – kernel, devicetree, Kconfig, drivers and subsystems – into a host binary that boots and runs exactly like a Zephyr image on real hardware, only compiled for the host instead of a target SoC. Use it to run full applications and integration tests on the host. Tests for these boards do **not** set `type: unit`.
- `unit_testing` builds **none** of that. It links only the code under test plus Ztest, with everything else stubbed or mocked, and calls the tested functions directly. This makes builds and runs fast and keeps the focus on a single module, at the cost of having to provide stubs for every dependency. These tests must set `type: unit` (see *below*).

In short, reach for `native_sim` to exercise code in the context of a running Zephyr system, and for `unit_testing` to test an isolated module without pulling in the kernel.

CMakeLists.txt In order to declare the unit tests present in a source folder, you need to add the relevant source files to the `testbinary` target from the CMake unittest component. See a minimal example below:

```
cmake_minimum_required(VERSION 3.28.0)

project(app)
find_package(Zephyr COMPONENTS unittest REQUIRED HINTS $ENV{ZEPHYR_BASE})
target_sources(testbinary PRIVATE main.c)
```

Since you won't be including basic kernel data structures that most code depends on, you have to provide function stubs in the test. Ztest provides some helpers for mocking functions, as demonstrated below.

In a unit test, mock objects can simulate the behavior of complex real objects and are used to decide whether a test failed or passed by verifying whether an interaction with an object occurred, and if required, to assert the order of that interaction.

tests.yaml You have to set the value for the key “type” to “unit” in the tests.yaml

```
tests:
   testscenario.testsuite:
      tags: your_tag
      type: unit
```

prj.conf For unit tests this contains usually only

```
CONFIG_ZTEST=y
```

If your unit tests require additional libraries (e.g. math-lib) you will have to add them either via the CMakeLists.txt or in the tests.yaml:

```
tests:
   testscenario.testsuite:
      tags: your_tag
      type: unit

```

Examples of unit tests can be found in the tests/unit/ folder.

Creating a test suite

Using Ztest to create a test suite is as easy as calling the `ZTEST_SUITE`. The macro accepts the following arguments:

- `suite_name` - The name of the suite. This name must be unique within a single binary.
- `ztest_suite_predicate_t` - An optional predicate function to allow choosing when the test will run. The predicate will get a pointer to the global state passed in through `ztest_run_all()` and should return a boolean to decide if the suite should run.
- `ztest_suite_setup_t` - An optional setup function which returns a test fixture. This will be called and run once per test suite run.
- `ztest_suite_before_t` - An optional before function which will run before every single test in this suite.
- `ztest_suite_after_t` - An optional after function which will run after every single test in this suite.
- `ztest_suite_teardown_t` - An optional teardown function which will run at the end of all the tests in the suite.

Below is an example of a test suite using a predicate:

```
#include <zephyr/ztest.h>
#include "test_state.h"

static bool predicate(const void *global_state)
{
     return ((const struct test_state*)global_state)->x == 5;
}

ZTEST_SUITE(alternating_suite, predicate, NULL, NULL, NULL, NULL);
```

Adding tests to a suite

There are 5 macros used to add a test to a suite, they are:

- ZTEST (suite_name, test_name) - Which can be used to add a test by test_name to a given suite by suite_name.
- ZTEST_P (suite_name, test_name) - Add a value-parameterized test to a given suite. The test body is executed once per registered parameter value. Inside the body, call ztest_get_current_param() or use the ZTEST_GET_PARAM typed helper to retrieve the current value. The suite fixture (data argument) is independent from the parameter and is never overwritten. See *Value-parameterized tests* for the full API.
- ZTEST_USER (suite_name, test_name) - Which behaves the same as ZTEST, only that when CONFIG_USERSPACE is enabled, then the test will be run in a userspace thread.
- ZTEST_F (suite_name, test_name) - Which behaves the same as ZTEST, only that the test function will already include a variable named fixture with the type <suite_name>_fixture.
- ZTEST_USER_F (suite_name, test_name) - Which combines the fixture feature of ZTEST_F with the userspace threading for the test.

Test fixtures Test fixtures can be used to help simplify repeated test setup operations. In many cases, tests in the same suite will require some initial setup followed by some form of reset between each test. This is achieved via fixtures in the following way:

```
#include <zephyr/ztest.h>

struct my_suite_fixture {
     size_t max_size;
     size_t size;
     uint8_t buff[1];
};

static void *my_suite_setup(void)
{
     /* Allocate the fixture with 256 byte buffer */
     struct my_suite_fixture *fixture = malloc(sizeof(struct my_suite_fixture) +␣
↪255);

     zassume_not_null(fixture, NULL);
     fixture->max_size = 256;

     return fixture;
}

static void my_suite_before(void *f)
{
     struct my_suite_fixture *fixture = (struct my_suite_fixture *)f;
     memset(fixture->buff, 0, fixture->max_size);
     fixture->size = 0;
}

static void my_suite_teardown(void *f)
{
     free(f);
}

ZTEST_SUITE(my_suite, NULL, my_suite_setup, my_suite_before, NULL,␣
↪my_suite_teardown);

ZTEST_F(my_suite, test_feature_x)
```

(continues on next page)

(continued from previous page)

```
{
     zassert_equal(0, fixture->size);
     zassert_equal(256, fixture->max_size);
}
```

Using memory allocated by a test fixture in a userspace thread, such as during execution of `ZTEST_USER` or `ZTEST_USER_F`, requires that memory to be declared userspace accessible. This is because the fixture memory is owned and initialized by kernel space. The Ztest framework provides the `ZTEST_DMEM` and `ZTEST_BMEM` macros for use of such user/kernel space shared memory.

Advanced features

Value-parameterized tests Value-parameterized tests allow a single test body to be executed once for each value in a supplied list, similar to GoogleTest's `TEST_P` / `INSTANTIATE_TEST_SUITE_P` pattern. The fixture and the parameter are completely independent: the suite's `setup()` return value is always passed as `data` and is never overwritten by a parameter value.

Declaring a parameterized test body Use `ZTEST_P` in the same way as `ZTEST`. Inside the body, the `data` pointer carries the suite fixture (identical to `ZTEST_F`). The current parameter value is retrieved through the run-time accessors:

```
#include <zephyr/ztest.h>

struct my_suite_fixture {
     int initial_value;
};

static void *my_suite_setup(void) {
     static struct my_suite_fixture f = { .initial_value = 42 };
     return &f;
}

ZTEST_SUITE(my_suite, NULL, my_suite_setup, NULL, NULL, NULL);

ZTEST_P(my_suite, test_multiply)
{
     struct my_suite_fixture *f = (struct my_suite_fixture *)data;
     int factor = ZTEST_GET_PARAM(int);

     /* fixture is always intact, regardless of parameter */
     zassert_equal(f->initial_value, 42, "fixture corrupted");
     zassert_true(f->initial_value * factor > 0, "product must be positive");
}
```

Declaring parameter values Use `ZTEST_DEFINE_PARAM_VALUES` to create a static value set from literal values:

```
ZTEST_DEFINE_PARAM_VALUES(small_factors, int, 1, 2, 3);
```

For values already stored in an array use `ZTEST_DEFINE_PARAM_VALUES_ARRAY`:

```
static const int big_factors[] = { 10, 100, 1000 };
ZTEST_DEFINE_PARAM_VALUES_ARRAY(big_factor_vals, big_factors);
```

For a numeric range use `ZTEST_DEFINE_PARAM_RANGE`, which mirrors GoogleTest's `testing::Range(begin, end [, step])` semantics. Values are {`begin`, `begin+step`, ...

} up to but **not** including end. No backing array is allocated, so large ranges have zero RAM overhead:

```
/* {0, 2, 4, 6, 8} - 5 values, step is supplied explicitly */
ZTEST_DEFINE_PARAM_RANGE(even_vals, int, 0, 10, 2);

/* {1, 2, 3, 4, 5} - step=1 is the common case */
ZTEST_DEFINE_PARAM_RANGE(one_to_five, int, 1, 6, 1);
```

Note

ZTEST_DEFINE_PARAM_RANGE requires end > begin and step > 0, both enforced at compile time via BUILD_ASSERT.

For values that must be **computed at runtime** — for instance random numbers, hardware sensor readings, or values produced by a custom algorithm — use ZTEST_DEFINE_PARAM_GENERATOR or ZTEST_DEFINE_PARAM_GENERATOR_WITH_SETUP. Both accept a user-provided generator callback with the signature void gen(size_t index, void *out) that writes one value per invocation. Like ranges, no backing array is allocated.

The _WITH_SETUP variant additionally calls a void setup(void) hook **once** before the dispatch loop. This is the right place to seed a PRNG, reset a stateful counter, or open any resource needed by the generator:

```
#include <zephyr/random/random.h>

/* Seed the RNG before the first iteration so failures are reproducible. */
static void seed_rng(void)
{
	sys_rand_seed(MY_FUZZ_SEED);
}

static void rand_u32_gen(size_t idx, void *out)
{
	ARG_UNUSED(idx);
	*(uint32_t *)out = sys_rand32_get();
}

ZTEST_DEFINE_PARAM_GENERATOR_WITH_SETUP(fuzz_vals, uint32_t, MY_FUZZ_ITERATIONS,
                                        seed_rng, rand_u32_gen);
```

When no setup is needed, use the simpler form:

```
static void deterministic_gen(size_t idx, void *out)
{
	/* Deterministic but computed at runtime (e.g. based on hardware ID). */
	*(uint32_t *)out = get_device_seed() ^ (uint32_t)idx;
}

ZTEST_DEFINE_PARAM_GENERATOR(hw_vals, uint32_t, 16U, deterministic_gen);
```

Note

The count_ argument to both generator macros must be a constant expression (a numeric literal, a #define, or a Kconfig symbol such as MY_FUZZ_ITERATIONS). Truly dynamic counts are not supported.

Struct-typed parameters work the same way:

```
struct point { int x; int y; };

static const struct point corners[] = { {0,0}, {1,0}, {0,1}, {1,1} };
ZTEST_DEFINE_PARAM_VALUES_ARRAY(corner_vals, corners);

ZTEST_P(my_suite, test_in_unit_square)
{
     const struct point *p = ZTEST_GET_PARAM_PTR(struct point);
     zassert_true(p->x >= 0 && p->x <= 1 && p->y >= 0 && p->y <= 1,
                  "point (%d, %d) outside unit square", p->x, p->y);
}
```

Instantiating a parameterized test `ZTEST_INSTANTIATE_TEST_SUITE_P` binds a value set to a test body. Each call creates a separate named instantiation; the same test body may be instantiated multiple times with different value sets:

```
ZTEST_INSTANTIATE_TEST_SUITE_P(small, my_suite, test_multiply, small_factors);
ZTEST_INSTANTIATE_TEST_SUITE_P(big,   my_suite, test_multiply, big_factor_vals);
```

The first argument (`small` / `big`) is an arbitrary unique identifier within the compilation unit; it is recorded in the test metadata but does not affect test naming as reported by Twister.

Retrieving the current parameter Inside a `ZTEST_P` body the following helpers are available:

Helper	Description
`ztest_has_current_param()`	Returns `true` when called inside a parameterized invocation.
`ztest_get_current_param()`	Returns a `const void *` pointer to the current value.
`ZTEST_GET_PARAM_PTR(type)`	Returns a `const type *` pointer to the current value.
`ZTEST_GET_PARAM(type)`	Dereferences and returns the current value as `type`.
`ztest_get_current_param_index()`	Returns the zero-based index of the current value within its set.
`ztest_get_current_param_size()`	Returns the size in bytes of one parameter element.

Non-parameterized tests (`ZTEST`, `ZTEST_F`) always see `ztest_has_current_param()` return `false` and `ztest_get_current_param()` return `NULL`.

Test result expectations Some tests were made to be broken. In cases where the test is expected to fail or skip due to the nature of the code, it's possible to annotate the test as such. For example:

```
#include <zephyr/ztest.h>

ZTEST_SUITE(my_suite, NULL, NULL, NULL, NULL, NULL);

ZTEST_EXPECT_FAIL(my_suite, test_fail);
ZTEST(my_suite, test_fail)
{
  /** This will fail the test */
  zassert_true(false, NULL);
}

ZTEST_EXPECT_SKIP(my_suite, test_skip);
```

(continues on next page)

(continued from previous page)

```
ZTEST(my_suite, test_skip)
{
  /** This will skip the test */
  zassume_true(false, NULL);
}
```

In this example, the above tests should be marked as failed and skipped respectively. Instead, Ztest will mark both as passed due to the expectation.

Test rules Test rules are a way to run the same logic for every test and every suite. There are a lot of cases where you might want to reset some state for every test in the binary (regardless of which suite is currently running). As an example, this could be to reset mocks, reset emulators, flush the UART, etc.:

```
#include <zephyr/fff.h>
#include <zephyr/ztest.h>

#include "test_mocks.h"

DEFINE_FFF_GLOBALS;

DEFINE_FAKE_VOID_FUN(my_weak_func);

static void fff_reset_rule_before(const struct ztest_unit_test *test, void␣
↪*fixture)
{
     ARG_UNUSED(test);
     ARG_UNUSED(fixture);

     RESET_FAKE(my_weak_func);
}

ZTEST_RULE(fff_reset_rule, fff_reset_rule_before, NULL);
```

A custom `test_main` While the Ztest framework provides a default `test_main()` function, it's possible that some applications will want to provide custom behavior. This is particularly true if there's some global state that the tests depend on and that state either cannot be replicated or is difficult to replicate without starting the process over. For example, one such state could be a power sequence. Assuming there's a board with several steps in the power-on sequence a test suite can be written using the `predicate` to control when it would run. In that case, the `test_main()` function can be written as follows:

```
#include <zephyr/ztest.h>

#include "my_test.h"

void test_main(void)
{
     struct power_sequence_state state;

     /* Only suites that use a predicate checking for phase == PWR_PHASE_0 will␣
↪run. */
     state.phase = PWR_PHASE_0;
     ztest_run_all(&state, false, 1, 1);
```

(continues on next page)

(continued from previous page)

```
    /* Only suites that use a predicate checking for phase == PWR_PHASE_1 will␣
↪run. */
    state.phase = PWR_PHASE_1;
    ztest_run_all(&state, false, 1, 1);

    /* Only suites that use a predicate checking for phase == PWR_PHASE_2 will␣
↪run. */
    state.phase = PWR_PHASE_2;
    ztest_run_all(&state, false, 1, 1);

    /* Check that all the suites in this binary ran at least once. */
    ztest_verify_all_test_suites_ran();
}
```

The signature of `ztest_run_all()` is `ztest_run_all(const void *state, bool shuffle, int suite_iter, int case_iter)`:

- `state` - Pointer to the global state passed to each suite's `predicate`.
- `shuffle` - When `true`, randomize the order in which suites and tests run (requires `CONFIG_ZTEST_SHUFFLE`); `false` keeps the default alphanumerical order.
- `suite_iter` - Number of times to repeat each test suite.
- `case_iter` - Number of times to repeat each test case.

In the example above each call runs the matching suites once, in order, without shuffling.

Best practices for declaring the test suite

twister and other validation tools need to obtain the list of test cases that a Zephyr *ztest* test image will expose.

Rationale

This all is for the purpose of traceability. It's not enough to have only a semaphore test application. We also need to show that we have testpoints for all APIs and functionality, and we trace back to documentation of the API, and functional requirements.

The idea is that test reports show results for every test case as passed, failed, blocked, or skipped. Reporting on only the high-level test application, particularly when tests do too many things, is too vague.

Other questions:

- Why not pre-scan with CPP and then parse? or post scan the ELF file?

  If C pre-processing or building fails because of any issue, then we won't be able to tell the subcases.

- Why not declare them in the YAML test configuration?

  A separate test case description file would be harder to maintain than just keeping the information in the test source files themselves – only one file to update when changes are made eliminates duplication.

Stress test framework

Zephyr stress test framework (Ztress) provides an environment for executing user functions in multiple priority contexts. It can be used to validate that code is resilient to preemptions. The framework tracks the number of executions and preemptions for each context. Execution can

have various completion conditions like timeout, number of executions or number of preemptions.

The framework is setting up the environment by creating the requested number of threads (each on different priority), optionally starting a timer. For each context, a user function (different for each context) is called and then the context sleeps for a randomized amount of system ticks. The framework is tracking CPU load and adjusts sleeping periods to achieve higher CPU load. In order to increase the probability of preemptions, the system clock frequency should be relatively high. The default 100 Hz on QEMU x86 is much too low and it is recommended to increase it to 100 kHz.

The stress test environment is setup and executed using `ZTRESS_EXECUTE` which accepts a variable number of arguments. Each argument is a context that is specified by `ZTRESS_TIMER` or `ZTRESS_THREAD` macros. Contexts are specified in priority descending order. Each context specifies completion conditions by providing the minimum number of executions and preemptions. When all conditions are met and the execution has completed, an execution report is printed and the macro returns. Note that while the test is executing, a progress report is periodically printed.

Execution can be prematurely completed by specifying a test timeout (`ztress_set_timeout()`) or an explicit abort (`ztress_abort()`).

User function parameters contains an execution counter and a flag indicating if it is the last execution.

The example below presents how to setup and run 3 contexts (one of which is k_timer interrupt handler context). Completion criteria is set to at least 10000 executions of each context and 1000 preemptions of the lowest priority context. Additionally, the timeout is configured to complete after 10 seconds if those conditions are not met. The last argument of each context is the initial sleep time which will be adjusted throughout the test to achieve the highest CPU load.

```
ztress_set_timeout(K_MSEC(10000));
ZTRESS_EXECUTE(ZTRESS_TIMER(foo_0, user_data_0, 10000, Z_TIMEOUT_TICKS(20)),
               ZTRESS_THREAD(foo_1, user_data_1, 10000, 0, Z_TIMEOUT_TICKS(20)),
               ZTRESS_THREAD(foo_2, user_data_2, 10000, 1000,␣
↪Z_TIMEOUT_TICKS(20)));
```

Configuration Static configuration of Ztress contains:

- `CONFIG_ZTRESS_MAX_THREADS` - number of supported threads.
- `CONFIG_ZTRESS_STACK_SIZE` - Stack size of created threads.
- `CONFIG_ZTRESS_REPORT_PROGRESS_MS` - Test progress report interval.

API reference

Running tests

Ztest testing macros

Assertions These macros will instantly fail the test if the related assertion fails. When an assertion fails, it will print the current file, line and function, alongside a reason for the failure and an optional message. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assertions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassert_equal(buf->ref, 2, "Invalid refcount")`:

```
Assertion failed at main.c:62: test_get_single_buffer: Invalid refcount (buf->ref␣
↪not equal to 2)
Aborted at unit test function
```

Ztest assertion macros

Expectations These macros will continue test execution if the related expectation fails and subsequently fail the test at the end of its execution. When an expectation fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message but continue executing the test. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the expectations will only print the file and line numbers, reducing the binary size of the test.

For example, if the following expectations fail:

```
zexpect_equal(buf->ref, 2, "Invalid refcount");
zexpect_equal(buf->ref, 1337, "Invalid refcount");
```

The output will look something like:

```
START - test_get_single_buffer
    Expectation failed at main.c:62: test_get_single_buffer: Invalid refcount␣
↪(buf->ref not equal to 2)
    Expectation failed at main.c:63: test_get_single_buffer: Invalid refcount␣
↪(buf->ref not equal to 1337)
 FAIL - test_get_single_buffer in 0.0 seconds
```

Ztest expectation macros

Assumptions These macros will instantly skip the test or suite if the related assumption fails. When an assumption fails, it will print the current file, line, and function, alongside a reason for the failure and an optional message. If the config `CONFIG_ZTEST_ASSERT_VERBOSE` is 0, the assumptions will only print the file and line numbers, reducing the binary size of the test.

Example output for a failed macro from `zassume_equal(buf->ref, 2, "Invalid refcount")`:

```
START - test_get_single_buffer
    Assumption failed at main.c:62: test_get_single_buffer: Invalid refcount␣
↪(buf->ref not equal to 2)
 SKIP - test_get_single_buffer in 0.0 seconds
```

Ztest assumption macros

Ztress

Ztest ztress macros

Mocking via FFF Zephyr has integrated with FFF for mocking. See FFF for documentation. To use it, include the relevant header:

```
#include <zephyr/fff.h>
```

Zephyr provides several FFF-based fake drivers which can be used as either stubs or mocks. Fake driver instances are configured via *Devicetree* and *Configuration System (Kconfig)*. See the following devicetree bindings for more information:

- `zephyr,fake-can`
- `zephyr,fake-comp`
- `zephyr,fake-eeprom`
- `zephyr,fake-leds`
- `zephyr,fake-pwm`
- `zephyr,fake-regulator`

- `zephyr,fake-rtc`
- `zephyr,fake-stepper-ctrl`
- `zephyr,fake-stepper-driver`

Zephyr also has defined extensions to FFF for simplified declarations of fake functions. See *FFF Extensions*.

Customizing Test Output

Customization is enabled by setting `CONFIG_ZTEST_TC_UTIL_USER_OVERRIDE` to "y" and adding a file `tc_util_user_override.h` with your overrides.

Add the line `zephyr_include_directories(my_folder)` to your project's `CMakeLists.txt` to let Zephyr find your header file during builds.

See the file subsys/testsuite/include/zephyr/tc_util.h to see which macros and/or defines can be overridden. These will be surrounded by blocks such as:

```
#ifndef SOMETHING
#define SOMETHING <default implementation>
#endif /* SOMETHING */
```

Shuffling Test Sequence

By default the tests are sorted and ran in alphanumerical order. Test cases may be dependent on this sequence. Enable `CONFIG_ZTEST_SHUFFLE` to randomize the order. The output from the test will display the seed for failed tests. For native simulator builds you can provide the seed as an argument to twister with `--seed`.

Repeating Tests

By default the tests are executed once. The test cases and test suites may be executed multiple times. Enable `CONFIG_ZTEST_REPEAT` to execute the tests multiple times. By default the multiplication factors are 3, which means every test suite is executed 3 times and every test case is executed 3 times. This can be changed by the `CONFIG_ZTEST_SUITE_REPEAT_COUNT` and `CONFIG_ZTEST_TEST_REPEAT_COUNT` Kconfig options.

Test Selection

For tests built for native simulator, use command line arguments to list or select tests to run. The test argument expects a comma separated list of `suite::test` . You can substitute the test name with an `*` to run all tests within a suite.

For example

```
$ zephyr.exe -list
$ zephyr.exe -test=
↪"fixture_tests::test_fixture_pointer,framework_tests::test_assert_mem_equal"
$ zephyr.exe -test="framework_tests::*"
```

FFF extensions

2.13.2 Benchmarking Framework

The Zephyr benchmarking framework provides cycle-accurate performance measurements. It automates data collection and statistical calculation, offering a standardized way to evaluate execution metrics across the Zephyr ecosystem.

Overview

This framework helps identify regressions and optimize critical paths by providing:

- **Standardized API**: Macros that align with existing `ztest` conventions.
- **Statistical Analysis**: Calculations of Mean, Standard Deviation, Standard Error, and Min/Max values.
- **Overhead Compensation**: Inclusion of a control test to account for the benchmarking frameworks own execution time. The control is subtracted from every reported statistic identically, so the corrected values are real numbers that generally do not coincide with any single measurement.

Configuration

To use the benchmarking framework, you must enable the following Kconfig options:

```
CONFIG_ZTEST=y
CONFIG_ZTEST_BENCHMARK=y
```

Usage

A benchmark suite is defined similarly to the normal ztest testsuite by first defining the suite with `ZTEST_BENCHMARK_SUITE` and then adding individual benchmark tests to the suite using either `ZTEST_BENCHMARK` or `ZTEST_BENCHMARK_TIMED` macros.

```
#include <zephyr/ztest.h>

ZTEST_BENCHMARK_SUITE(<test suite name>, <setup_fn>, <teardown_fn>);
```

Standard Benchmarks Standard benchmarks are sample-based, meaning they execute the test a specified number of times and measure the total cycles taken. This is useful for benchmarking critical paths where you want to understand the raw CPU performance in terms of cycles. It provides insights into the efficiency of the code and helps identify bottlenecks in terms of CPU usage. This benchmarking method is suitable for code that has consistent execution times and is not heavily influenced by external factors such as I/O operations or context switches.

```
#include <zephyr/ztest.h>

ZTEST_BENCHMARK_SUITE(<suite name>, NULL, NULL);

ZTEST_BENCHMARK(<suite name>, <benchmark name>, <number of samples>, <setup_fn>,
↪<teardown_fn>)
{
    /* Code to benchmark */
}
```

A standard benchmark follows a flow where the setup function is called before each sample, the test function is executed for the specified number of samples, and the teardown function is called after each sample.

Timed Benchmarks Timed benchmarks in contrast to the standard benchmarks measures execution time of the code instead of cycles. This is useful for benchmarking code that may have variable execution times or when you want to measure the actual time taken rather than just CPU cycles of a critical path. It provides a broader view of performance characteristics, especially for code that involves I/O operations, context switches, or other factors that can influence execution time beyond raw CPU performance.

```
ZTEST_BENCHMARK_TIMED(<suite name>, <benchmark name>, <time in ms>, <setup_fn>,
↪<teardown_fn>)
{
      /* Code to benchmark */
}
```

Unlike standard benchmarks that favor isolation, Timed Benchmarks executes setup and teardown functions only once allowing the test function to run hot within a dedicated time window. This will give a more realistic measurements as it includes the overhead of the system as it would be in a real-world scenario, such as interrupts, context switches, and other background tasks.

Manual Benchmarks Standard and timed benchmarks are timed by the framework itself, which takes both timestamps in thread context around each invocation of the benchmark body. Some measurements cannot be expressed that way because their endpoints are captured in different execution contexts: for example the latency from raising an interrupt to the first instruction of its ISR, or from the end of an ISR to a woken thread running.

Manual benchmarks keep the loop, the setup and the teardown in the framework and hand the body only the choice of what is measured, by bracketing it with `ztest_benchmark_start()` and `ztest_benchmark_end()`. The framework computes and reports the same statistics as for standard benchmarks.

```
ZTEST_BENCHMARK_MANUAL(<suite name>, <benchmark name>, <samples>, <setup_fn>,
↪<teardown_fn>)
{
      prepare();

      ztest_benchmark_start();
      operation_under_test();
      ztest_benchmark_end();
}
```

Both hooks only take a timestamp, so either may be called from an ISR and the span need not begin and end in the same execution context. For the latency from an interrupt to the thread it wakes, the ISR marks the start and the thread ends the span:

```
static void my_isr(const void *arg)
{
      ztest_benchmark_start();
}

ZTEST_BENCHMARK_MANUAL(<suite name>, isr_exit_latency, 1000, NULL, NULL)
{
      trigger_the_interrupt();

      ztest_benchmark_end();
}
```

The sample itself is computed once the body has returned, which is what keeps the statistics out of interrupt context: updating them uses floating point, which is not allowed in an ISR on every architecture. An iteration whose body marks no span contributes no sample.

Manual benchmarks are corrected against a control of their own rather than the one the sampled benchmarks use. A manual span costs the two timestamps that bracket it and nothing else, where the sampled control also measures the indirect call to the benchmark body, which is not part of a manual span. A span whose ends are captured in two different contexts pays neither exactly, and no control can express that.

The warmup applies here exactly as it does to a sampled benchmark: the framework runs the body `CONFIG_ZTEST_BENCHMARK_WARMUP` extra times and discards those spans, keeping the first as the cold cost. The body never has to distinguish between the two phases, and every measured iteration is preceded by exactly the same work as the one before it.

Understanding Results

Standard Benchmarking Results

```
<suite name> ###############################################
<benchmark name> ===========================================
   Sample size:<number of samples>, total cycles: <total amount of cycles>
   Mean(u): <mean cycles per sample>
   Standard deviation(s): <cycles>
   Standard Error(SE): <cycles>
   Min: <cycles> (run #<sample number>)
   Max: <cycles> (run #<sample number>)
```

Note

`CONFIG_ZTEST_BENCHMARK_OUTLIERS` replaces the standard error line with the number of samples that exceed the median by more than `CONFIG_ZTEST_BENCHMARK_OUTLIER_MARGIN_DIV` allows, and that number as a percentage. The margin matters because the counter resolution spreads the baseline over a few counts; without it about half of any distribution would be reported. A latency distribution is usually a baseline plus a handful of disturbed runs rather than samples of one stochastic population, and a standard error over the two suggests an average that no single execution ever produced – ten thousand runs of 760 cycles and one of 1240 give a standard error of 0.048, which reads as precision and is not, where `1 / 10000 (0.010%)` says what happened. Only the report changes; the standard error keeps its CSV column.

Statistical Metrics

- **Mean (u)**: The average number of cycles taken per sample. It provides a central value representing the expected cost of execution.
- **Standard Deviation (s)**: Measures the amount of variation or fluctuation of the execution cost from the mean. A low standard deviation indicates that the behavior is deterministic and consistent.
- **Standard Error (SE)**: Estimates how far the sample mean is likely to be from the "true" mean of the system. It provides insight into the statistical reliability of the test. A lower SE indicates higher confidence in the result.
- **Min/Max**: The minimum and maximum cycle counts observed, along with which sample they occurred on.

Warmup and the cold cost A benchmark is defined as three phases: the setup, then `CONFIG_ZTEST_BENCHMARK_WARMUP` iterations that are executed but not recorded, then the measured samples. The warmup applies to every benchmark in the image.

The very first execution is always unrecorded, whatever the warmup is set to. It runs with cold caches, branch predictors and TLBs and can be an order of magnitude slower than the steady

state, and rather than discard that information the framework reports it on its own as the **cold cost**. The two answer different questions — what an operation costs the first time it is reached, and what it costs thereafter — and an application that runs a path once at startup cares about the first.

Keeping it out of the distribution is what makes the distribution mean anything at the tail. A benchmark that reported the cold start in both places would have it decide the far percentiles: at ten thousand samples the nearest-rank p99.99 is the second largest value, so one cold start would be read as the steady-state tail.

Raising the warmup beyond that costs accuracy on a micro benchmark whose whole cost is comparable to a cache miss, and with a large enough sample count the early iterations have no measurable effect on the mean, so the default of zero is the right starting point. Raise it when the benchmark is large enough for cache state to matter and the steady state is what you are after.

Latency percentiles The mean and the standard error describe how precisely the average was estimated. That is the right question for throughput, but not for latency: a real-time system is characterised by how bad an individual operation can be, and that lives in the tail of the distribution rather than near the mean.

Enable `CONFIG_ZTEST_BENCHMARK_PERCENTILES` to retain the individual samples and report `min`, `p50`, `p90`, `p99`, `p99.9`, `p99.99` and `max` alongside the usual statistics. In CSV mode each sampled and manual benchmark emits an additional `P` row; see `CONFIG_ZTEST_BENCHMARK_OUTPUT_CSV` for the columns.

The difference this makes is clearest on a distribution with a tail. Measuring interrupt entry latency on a loaded system gives a mean of 1264 cycles with a standard error of 34, which describes no interrupt that actually occurred: the percentiles show 1216 cycles all the way out to p99, and 25184 beyond it.

A percentile has to be resolvable by the number of samples taken. p99 needs at least 100 samples, p99.9 at least 1000 and p99.99 at least 10000; with fewer, the reported value degenerates to the maximum. Samples are retained in a buffer of `CONFIG_ZTEST_BENCHMARK_MAX_SAMPLES` entries of 8 bytes each, which has to be at least as large as the sample count of the largest benchmark. The retained samples are the first ones taken rather than a sample of the whole run, so percentiles over a truncated prefix would miss whatever happened after the buffer filled, which is where the tail tends to live. A benchmark that overruns the buffer therefore reports no percentiles at all, and says how many samples did not fit.

Plainly speaking, lower values are better for all metrics. Lower mean, min, and max values indicates better raw performance. Lower standard deviation and standard error values indicate more consistent and therefore reliable performance.

Timed Benchmarking Results

```
<benchmark name> ============================================
   Samples: <Number of samples executed during the benchmark>
   Total Time: <Gross execution time>
   Work Time: <Net execution time> ns (Net)
   Ops/Sec: <average operations per second>
   Cycles/Op: <average cycles per operation>
```

Statistical Metrics

- **Total Time**: The total time taken for all samples of the benchmark, including overhead.
- **Work Time**: The total time taken for the code under test, excluding the overhead of the benchmarking framework itself. This provides a more accurate measure of the actual performance of the code being benchmarked.

- **Ops/Sec**: The number of operations (samples) that can be performed per second, calculated by dividing the number of samples by the net work time (in seconds). This metric is particularly useful for understanding the throughput of the code being benchmarked.
- **Cycles/Op**: The average number of CPU cycles taken per operation, calculated by dividing the net number of cycles by the number of samples. This metric provides insight into the efficiency of the code in terms of CPU usage.

In general higher values for Ops/Sec are better as it indicates higher throughput, just as lower values for Cycles/Op are better. As the Cycles/Op and Ops/Sec metrics are derived from the same underlying data, they are reflecting the same performance characteristics from different perspectives. A high Ops/Sec should correspond to a low Cycles/Op, and vice versa.

Benchmark Output Options The benchmarking framework provides several options for outputting results of benchmarking data. By default, results are printed in a verbose human-readable format that is easy to understand and interpret. Alternatively, you can enable the `CONFIG_ZTEST_BENCHMARK_OUTPUT_CSV` Kconfig option to output results in a CSV format that can be easily imported by scripts for further analysis. The CSV output includes all the same metrics as the verbose output, but in a format that is more conducive to automated analysis and reporting.

The standard benchmark csv output format is as follows:

```
S,<suite name>,<benchmark name>,<sample size>,<total␣
↪cycles>,<mean>,<stddev>,<stderr>,<min>,<min sample>,<max>,<max sample>
```

The timed benchmark csv output format is as follows:

```
T,<suite name>,<benchmark name>,<samples>,<total time>,<work␣
↪time>,<ops/sec>,<cycles/op>
```

Important Considerations

- **Noise**: Benchmarking is inherently sensitive to system noise. To obtain as accurate results as possible, disable unnecessary background tasks and interrupts that may interfere with timing.
- **Cache Warming**: The first sample of a benchmark may often be slower due to cache misses and this can skew results slightly on small sample sizes, choose a sufficiently large number of samples to mitigate this effect.
- **Use setup/teardown functions**: It is *highly* encouraged to utilize the setup and teardown functions to isolate the code under test as much as possible. Excessive setup/teardown code in the benchmark code can introduce noise and skew results *significantly* for small critical paths.

API Reference

Zephyr Benchmarking Framework

2.13.3 Generating coverage reports

With Zephyr, you can generate code coverage reports to analyze which parts of the code are covered by a given test or application.

You can do this in two ways:

- In a real embedded target or QEMU, using Zephyr's gcov integration
- Directly in your host computer, by compiling your application targeting the POSIX architecture

Test coverage reports in embedded devices or QEMU

Overview GCC GCOV is a test coverage program used together with the GCC compiler to analyze and create test coverage reports for your programs, helping you create more efficient, faster running code and discovering untested code paths

In Zephyr, gcov collects coverage profiling data in RAM (and not to a file system) while your application is running. Support for gcov collection and reporting is limited by available RAM size and so is currently enabled only for QEMU emulation of embedded targets.

Details There are 2 parts to enable this feature. The first is to enable the coverage for the device and the second to enable in the test application. As explained earlier the code coverage with gcov is a function of RAM available. Therefore ensure that the device has enough RAM when enabling the coverage for it. For example a small device like frdm_k64f can run a simple test application but the more complex test cases which consume more RAM will crash when coverage is enabled.

To enable the device for coverage, select `CONFIG_HAS_COVERAGE_SUPPORT` in the Kconfig.board file.

To report the coverage for the particular test application set `CONFIG_COVERAGE`.

Steps to generate code coverage reports These steps will produce an HTML coverage report for a single application.

1. Build the code with CONFIG_COVERAGE=y.

```
west build -b mps2/an385 -- -DCONFIG_COVERAGE=y -DCONFIG_COVERAGE_DUMP=y
```

2. Capture the emulator output into a log file. You may need to terminate the emulator with `Ctrl-A X` for this to complete after the coverage dump has been printed:

```
$ ninja -Cbuild run | tee log.log
```

3. Generate the gcov `.gcda` and `.gcno` files from the log file that was saved:

```
$ python3 scripts/gen_gcov_files.py -i log.log
```

4. Find the gcov binary placed in the SDK. You will need to pass the path to the gcov binary for the appropriate architecture when you later invoke `gcovr`:

```
$ find $ZEPHYR_SDK_INSTALL_DIR -iregex ".*gcov"
```

5. Create an output directory for the reports:

```
$ mkdir -p coverage-report
```

6. Run `gcovr` to get the reports:

```
$ gcovr -r $ZEPHYR_BASE . --html -o coverage-report/coverage.html --
↪html-details --gcov-executable <gcov_path_in_SDK>
```

Coverage reports using the POSIX architecture

When compiling for the POSIX architecture, you utilize your host native tooling to build a native executable which contains your application, the Zephyr OS, and some basic HW emulation.

That means you can use the same tools you would while developing any other desktop application.

To build your application with gcc's gcov, simply set `CONFIG_COVERAGE` before compiling it. When you run your application, `gcov` coverage data will be dumped into the respective `gcda` and `gcno` files. You may postprocess these with your preferred tools. For example:

```
west build -b native_sim samples/hello_world -- -DCONFIG_COVERAGE=y
```

```
$ ./build/zephyr/zephyr.exe
# Press Ctrl+C to exit
$ lcov --capture --directory ./ --output-file lcov.info -q --rc␣
↪lcov_branch_coverage=1
$ genhtml lcov.info --output-directory lcov_html -q --ignore-errors source --
↪branch-coverage --highlight --legend
```

Note

You need a recent version of lcov (at least 1.14) with support for intermediate text format. Such packages exist in recent Linux distributions.

Alternatively, you can use gcovr (at least version 4.2).

Coverage reports using Twister

Zephyr's *twister script* can automatically generate a coverage report from the tests which were executed. You just need to invoke it with the `--coverage` command line option.

For example, you may invoke:

```
$ west twister --coverage -p qemu_x86 -T tests/kernel
```

or:

```
$ west twister --coverage -p native_sim -T tests/bluetooth
```

which will produce `twister-out/coverage/index.html` report as well as the coverage data collected by `gcovr` tool in `twister-out/coverage.json`.

Other reports might be chosen with `--coverage-tool` and `--coverage-formats` command line options.

To generate code coverage report including Zephyr sources as well as your application code outside of Zephyr repository (see *Application Types*) call Twister from your project directory with `--coverage-basedir $ZEPHYR_BASE` command line option, for example:

```
$ west twister --coverage -p native_sim --coverage-basedir $ZEPHYR_BASE -T␣
↪your_project_dir
```

Note

By default, Twister calls `gcovr` tool which filters source files assuming real paths are everywhere with all symlinks resolved, so when your development environment has directories with symlinks then, to avoid incomplete `gcovr` reports, either your *ZEPHYR_BASE* should contain a real path, or `lcov` tool used instead of `gcovr` with additional Twister command line option `--coverage-tool lcov`.

The process differs for unit tests, which are built with the host toolchain and require a different board:

```
$ west twister --coverage -p unit_testing -T tests/unit
```

which produces a report in the same location as non-unit testing.

Per-test coverage matrix By default coverage is aggregated per test scenario. To attribute coverage down to individual *Ztest* test cases – for example to answer "which tests exercised line X of `foo.c`" – pass `--coverage-per-test`:

```
$ west twister -p mps2/an385 -T tests/kernel --coverage --coverage-tool lcov \
    --coverage-per-test
```

This enables `CONFIG_ZTEST_COVERAGE_PER_TEST`, which resets the gcov counters before each test case and dumps an isolated, test-tagged coverage artifact after it. On platforms that support semihosting (ARM, RISC-V and Xtensa targets under QEMU, such as `mps2/an385`) the per-test data is written straight to the host filesystem, avoiding the large amount of serial console traffic that per-test dumping would otherwise produce; other platforms fall back to the serial console transport.

In addition to the usual aggregated coverage report, this produces:

- one `<scenario>.<test>.info` tracefile per test under each build's `coverage/tests/` directory, and
- `twister-out/coverage/test_matrix.json`, a machine-readable matrix with a `by_line` view (`{file: {line: [tests]}}`) and a `by_test` view (`{test: {file: [lines]}}`).

Per-test attribution is carried by the matrix (and its dashboard), not by the aggregated lcov report: each instance's coverage is collapsed to a single tracefile before aggregation, so the end-of-run reporting stays proportional to the number of instances rather than the total number of test cases.

Note

`--coverage-per-test` requires the `lcov` coverage tool, because the matrix relies on lcov's per-test `TN` tracefile records; `gcovr` has no equivalent. It also implies `--coverage`.

Visualizing the matrix `test_matrix.json` can be turned into a self-contained, interactive HTML dashboard with the standalone scripts/gen_test_matrix_dashboard.py script (it has no dependency on Twister and can be run on any previously generated matrix):

```
$ scripts/gen_test_matrix_dashboard.py -i twister-out/coverage/test_matrix.json
```

This writes `twister-out/coverage/test_matrix.html`, which lists – per test – how many files and lines it covers and how many lines it covers *uniquely* (that no other test reaches, useful for spotting redundant or load-bearing tests), and lets you drill into the files a test covers or look up which tests cover a given file and line.

Using different toolchains Twister looks at the environment variable `ZEPHYR_TOOLCHAIN_VARIANT` to check which gcov tool to use by default. The following are used as the default for the Twister `--gcov-tool` argument default:

Toolchain	`--gcov-tool` value
host	`gcov`
llvm	`llvm-cov gcov`
zephyr	`gcov`

2.13.4 BabbleSim

BabbleSim and Zephyr

In the Zephyr project we use the Babblesim simulator to test some of the Zephyr radio protocols, including the Bluetooth LE stack, 802.15.4, and some of the networking stack.

BabbleSim is a physical layer simulator, which in combination with the Zephyr bsim boards can be used to simulate a network of Bluetooth LE and 15.4 devices. When we build Zephyr targeting a bsim board we produce a Linux executable, which includes the application, Zephyr OS, and models of the HW.

When there is radio activity, this Linux executable will connect to the BabbleSim Phy simulation to simulate the radio channel.

In the BabbleSim documentation you can find more information on how to get and build the simulator. In the nrf52_bsim, nrf5340bsim, and nrf54l15bsim boards documentation you can find more information about how to build Zephyr targeting these particular boards, and a few examples.

Types of tests

Tests without radio activity: bsim tests with twister The bsim boards can be used without radio activity, and in that case, it is not necessary to connect them to a physical layer simulation. Thanks to this, these target boards can be used just like native_sim with *twister*, to run all standard Zephyr twister tests, but with models of a real SOC HW, and their drivers.

Tests with radio activity When there is radio activity, BabbleSim tests require at the very least a physical layer simulation running, and most, more than 1 simulated device. Due to this, these tests are executed by running a dedicated script for each test which starts both the needed simulated devices, and the physical layer executable with their required parameters, and any other tool which may be required.

To be able to run them with twister, the *bsim harness* should be used.

These tests are kept in the tests/bsim/ folder.

Check the sub-sections below for more information about how to build and run them, as well as the conventions they follow.

There are two main sets of tests:

- Self checking embedded application/tests: In which some of the simulated devices applications are built with some checks which decide if the test is passing or failing. These embedded applications tests use the bs_tests system to report the pass or failure, and in many cases to build several tests into the same binary.
- Test using the EDTT tool, in which a EDTT (python) test controls the embedded applications over an RPC mechanism, and decides if the test passes or not. Today these tests include a very significant subset of the BT qualification test suite.

More information about how different tests types relate to BabbleSim and the bsim boards can be found in the bsim boards tests section.

Test coverage and BabbleSim

As the bsim boards are based on the POSIX architecture, you can easily collect test coverage information.

Check *the page on coverage generation* for more info, and note you can just pass the `--coverage` option to twister to automatically build with `CONFIG_COVERAGE` and generate the coverage report.

Building and running the tests

Check the nrf52_bsim page for instructions on how to set up the simulator.

You can build and run these tests with *twister*. To run multidevice tests, you will need to pass twister the option `--fixture bsim_multi_test`.

For example, from ${ZEPHYR_BASE}, you can build and run one of the BT tests with:

```
twister -p nrf52_bsim/native -T tests/bsim/bluetooth/host/adv/chain/ --fixture␣
↪bsim_multi_test
```

If the test binaries have already been built, you can also run a test directly using its individual test script. For example:

```
BOARD=nrf52_bsim/native␣
↪tests/bsim/bluetooth/host/adv/chain/tests_scripts/adv_chain.sh
```

Twister command line options like `-n`, `--no-clean`, `--aggressive-no-clean`, or `-b`, `--build-only` are likely to be useful when debugging or fixing issues.

Legacy batch scripts Until the twister bsim harness was added, building and running multi-device bsim tests relied on two scripts in the tests/bsim/ folder: `compile.sh` and `run_parallel.sh`. These scripts were used by the CI system to build the needed images and execute these tests in batch. They were also meant as utilities for users to build and execute their tests. These scripts can still be used, but users are recommended to transition to using *twister* and `tests.yaml` definitions.

These scripts expect a few environment variables to be set. For example, from Zephyr's root folder, you can run:

```
# Build all the tests
${ZEPHYR_BASE}/tests/bsim/compile.sh

# Run them (in parallel)
RESULTS_FILE=${ZEPHYR_BASE}/myresults.xml \
   SEARCH_PATH=${ZEPHYR_BASE}/tests/bsim \
      ${ZEPHYR_BASE}/tests/bsim/run_parallel.sh
```

Or to build and run only a specific subset, e.g. host advertising tests:

```
# Build the Bluetooth host advertising tests
${ZEPHYR_BASE}/tests/bsim/bluetooth/host/adv/compile.sh

# Run them (in parallel)
RESULTS_FILE=${ZEPHYR_BASE}/myresults.xml \
   SEARCH_PATH=${ZEPHYR_BASE}/tests/bsim/bluetooth/host/adv \
      ${ZEPHYR_BASE}/tests/bsim/run_parallel.sh
```

Check the `run_parallel.sh` help for more options and examples on how to use this script to run the tests in batch.

After building the tests' required binaries you can run a test directly using its individual test script.

For example you can build the required binaries for the networking tests with

```
WORK_DIR=${ZEPHYR_BASE}/bsim_out ${ZEPHYR_BASE}/tests/bsim/net/compile.sh
```

and then directly run one of the tests:

```
${ZEPHYR_BASE}/tests/bsim/net/sockets/echo_test/tests_scripts/echo_test_802154.sh
```

Conventions

Test code See the Bluetooth sample test for conventions that apply to test code.

Test scripts Please follow the existing conventions and do not design one-off bespoke runners (e.g. a python script, or another shell abstraction).

The rationale is that it is easier and faster for the maintainers to perform tree-wide updates for build system or compatibility changes if the tests are run in the same manner, with the same variables, etc..

If you have a good idea for improving your test script, please make a PR changing *all* the test scripts in order to benefit everyone and conserve homogeneity. You can of course discuss it first in an RFC issue or on the babblesim discord channel.

Scripts starting with an underscore (_) are not automatically discovered and run. They can serve as either helper functions for the main script, or can be used for local development utilities, e.g. building and running tests locally, debugging, etc..

Here are the conventions:

- Each test is defined by a shell script with the extension `.sh`, in a subfolder called `tests_scripts/`.
- It is recommended to run a single test per script file. It allows for better parallelization of the runs in CI.
- Scripts expect that the binaries they require are already built. They should not compile binaries.
- Scripts will spawn the processes for every simulated device and the physical layer simulation.
- Scripts must return 0 to the invoking shell if the test passes, and not 0 if the test fails.
- Each test must have a unique simulation id, to enable running different tests in parallel.
- Neither the scripts nor the images should modify the workstation filesystem content beyond the `${BSIM_OUT_PATH}/results/<simulation_id>/` or `/tmp/` folders. That is, they should not leave stray files behind.
- Tests that require several consecutive simulations (e.g, if simulating a device pairing, powering off, and powering up after as a new simulation) should use separate simulation ids for each simulation segment, ensuring that the radio activity of each segment can be inspected a posteriori.
- Avoid overly long tests. If the test takes over 20 seconds of runtime, consider if it is possible to split it in several separate tests.
- If the test takes over 5 seconds, set `EXECUTE_TIMEOUT` to a value that is at least 5 times bigger than the measured run-time.
- Do not set `EXECUTE_TIMEOUT` to a value lower than the default.
- Tests should not be overly verbose: less than a hundred lines are expected on the outputs. Do make use of `LOG_DBG()` extensively, but don't enable the `DBG` log level by default.
- Test scripts that use the Physical layer simulation are expected to pass any extra parameters passed to the test script directly to the Phy executable. This is used, for example, to run the Phy in check mode (`-c`), in which the Phy verifies that the last simulation and this one have produced the exact same radio traffic.

2.13.5 CI Test Plan Selector (test_plan_v2)

The CI test plan selector is a modular Python script located at `scripts/ci/test_plan_v2.py`. Its purpose is to analyse the set of files changed in a Pull Request and emit a targeted twister test plan — exercising only the tests that are plausibly affected by the change while avoiding a full tree-wide run on every commit.

The script writes two artefacts:

- `testplan.json` — passed to twister via `twister --load-tests`.
- `.testplan` — a plain `KEY=value` environment file consumed by CI orchestration scripts, containing `TWISTER_TESTS`, `TWISTER_NODES`, and `TWISTER_FULL`.

Architecture

The selector is built around a *strategy pipeline*. Each strategy is an independent analyser that:

1. Receives the list of changed files (or the subset not yet consumed by earlier strategies).
2. Inspects those files according to its own logic.
3. Returns a list of `TwisterCall` descriptors and the set of files it has *handled*.

The `Orchestrator` drives the pipeline, merges all results into a `PlanAccumulator`, deduplicates test suites, and writes the output files.

Strategy ordering

Strategies run in a fixed order that reflects two principles:

Specificity over generality. The most precise strategies run first. A file that lives inside `tests/kernel/sched/` is handled definitively by `DirectTestStrategy` (run exactly those tests) before the catch-all `MaintainerAreaStrategy` can add an entire Kernel area sweep.

Consume-before-additive. Consuming strategies run before additive ones. Once a consuming strategy claims a file, downstream strategies never see it. This prevents a change to a board file from also triggering a driver compat scan and a Kconfig sweep for the same path.

The current order is:

#	Strategy	Consumes	Rationale
0	`ComplexityStrategy`	No	Scores the patchset using pydriller and lizard. Must run first so the score is available to `RiskClassifierStrategy`. Emits no twister calls.
1	`IgnoreStrategy`	Yes	Silently drops files that can never affect tests (documentation, CI workflows, tooling). Runs early so later strategies never waste effort on ignored paths.
1b	`BoilerplateFilter`	Yes	Consumes files whose entire diff consists of whitespace adjustments, blank-line changes, SPDX licence identifiers, copyright notices, or bare comment delimiters. Such changes cannot affect runtime behaviour, so removing them early keeps the pool clean for substantive strategies. Requires a git commit range; no-op otherwise.
2	`DirectTestStrategy`	Yes	A changed test or sample file must trigger *only* that test, not an entire area-wide sweep. Consuming this file prevents `MaintainerAreaStrategy` from also adding every test in the Kernel area when `tests/kernel/sched/main.c` is modified.
3	`SnippetStrategy`	Yes	Snippet changes are self-contained: only tests that declare the snippet in `required_snippets` need to run. Consuming prevents downstream strategies from treating a snippet YAML as an unknown configuration file.
4	`BoardStrategy`	Yes	Board-specific changes require a targeted integration test on every board variant. Consuming prevents a board `.yaml` file from also matching Kconfig and Header strategies.
5	`SoCStrategy`	Yes	SoC-level changes affect every board built on that SoC family. Consuming prevents the same `soc/` path from reaching the Kconfig sweep.
6	`ManifestStrategy`	Yes	A changed `west.yml` requires module-tagged integration tests, not a generic maintainer-area run. Consuming the manifest file prevents the catch-all from adding unrelated tests.
7	`DriverCompatStrategy`	No	Additive: driver files may also be covered by area patterns, so the file is not consumed and `KconfigImpactStrategy` and `MaintainerAreaStrategy` can add further coverage.
8	`DtsBindingStrategy`	No	Additive: binding changes combine overlay-based test selection with board-targeted area calls.
9	`KconfigImpactStrategy`	No	Additive: Kconfig changes may affect many unrelated files; only consumes when a non-widespread symbol is found, leaving widespread-symbol files for the catch-all.
10	`HeaderImpactStrategy`	No	Additive: header changes trace include users back to maintainer areas. Widespread headers (included in more than the configured threshold) are skipped.
11	`MaintainerAreaStrategy`	No	Catch-all: matches any remaining file against `MAINTAINERS.yml` area patterns and emits `--test-pattern` calls for each matching area that has a non-empty `tests:` list.

Boilerplate filter

`BoilerplateFilter` runs immediately after `IgnoreStrategy` and before any test-selection strategy. It inspects the actual diff of each changed file (via `git diff`) and consumes those whose entire content change is non-substantive:

- **Whitespace and blank-line changes** — detected by `git diff -w --ignore-blank-lines`: if that command produces no output for a file, every changed line is whitespace or blank.
- **SPDX and copyright header edits** — lines that begin with `SPDX-License-Identifier:`,

`SPDX-FileCopyrightText:`, or the word `Copyright`.

- **Comment-delimiter-only lines** — lines whose non-whitespace content consists entirely of `/*`, `*/`, `//`, `#`, or `*` characters (e.g. reformatted block-comment borders).

A file is consumed only when **every** added or removed line in its diff falls into one of those categories. A single substantive line (a changed statement, macro, or declaration) causes the file to pass through to downstream strategies unchanged.

The filter is a no-op when `--commits` is not supplied (e.g. when using `--modified-files`), because the diff cannot be computed without a commit range. In that case all files remain in the pool.

Consume vs. additive behaviour

Every strategy subclass carries a class attribute `consumes: bool`.

When `consumes = True`:
Files returned in the *handled* set are removed from the `remaining` pool before the next strategy runs. Use this when the strategy is *authoritative* for its file type — i.e. when seeing the file in a later strategy would produce redundant or incorrect results.

When `consumes = False` (default):
Files remain in the pool regardless of what the strategy returns. All downstream strategies receive the same file list. Use this for additive strategies that contribute *additional* test coverage without claiming exclusive ownership.

> **Note**
>
> The `Orchestrator` skips a strategy entirely when the `remaining` pool is empty. Because non-consuming strategies see all files, "remaining" only shrinks through consuming strategies. As soon as the pool is empty the orchestrator stops calling strategies.

Full-run and fallback conditions

The orchestrator signals `TWISTER_FULL=True` in `.testplan` when either of the following is true:

1. **Unresolved files.** After all strategies have run, at least one changed file was not *handled* by any strategy. Rather than silently skipping coverage for an unknown path, the script falls back to requesting a full run so no regression slips through.
2. **Explicit full-run signal.** A strategy returns a `TwisterCall` with `full_run=True`. When the orchestrator encounters such a call, it immediately sets `TWISTER_FULL=True`, empties the remaining pool, and stops executing further calls. This mechanism allows a strategy to opt out of targeted selection (e.g. when a core subsystem header used by the entire tree is modified).

When `TWISTER_FULL=True` the CI script is expected to discard `testplan.json` and run twister without `--load-tests`.

Node count calculation

`TWISTER_NODES` in `.testplan` is computed as follows:

- `0` — no tests were selected.
- `1` — fewer than `--tests-per-builder` tests were selected (fits in one builder).
- `ceil(total / tests_per_builder)` — otherwise. The ceiling ensures that no builder is over-capacity when the division is not exact.

The default value of `--tests-per-builder` is `900`.

Adding a new strategy

1. **Subclass** `SelectionStrategy` and implement the two abstract members:

```
class MyStrategy(SelectionStrategy):

    consumes: bool = False  # or True if authoritative

    @property
    def name(self):
        return "MyStrategy"

    def analyze(self, changed_files):
        # inspect changed_files
        calls = [...]       # list of TwisterCall
        handled = {...}     # subset of changed_files this strategy owns
        return calls, handled
```

2. **Decide consume vs. additive.** Ask: "If a downstream strategy also sees this file, will it produce useful additional coverage, or redundant/wrong results?" If redundant/wrong: `consumes = True`.
3. **Insert in the correct position** in `build_strategies()`. As a rule of thumb:
   - Consuming strategies belong before all additive strategies.
   - More-specific strategies belong before less-specific ones.
   - Strategies with no side-effects on the file pool (additive) can be ordered by cost — cheapest first.
4. **Guard optional dependencies** with a late import inside `analyze` and return `[], set()` gracefully when the dependency is missing. Use the `# noqa: PLC0415` comment to silence the late-import warning.
5. **Write unit tests** in `scripts/tests/ci/test_test_plan_v2.py` covering:
   - The happy path (files correctly identified and routed).
   - The no-op path (irrelevant files produce no calls and no handled set).
   - Edge cases (missing files on disk, malformed YAML, empty inputs).

Shared pipeline context

`PipelineContext` is a dataclass threaded through all strategies via `build_strategies()`. It currently carries:

- `complexity_score` — aggregate patchset score written by `ComplexityStrategy` and read by `RiskClassifierStrategy`.
- `file_metrics` — per-file `ComplexityMetrics` mappings for detailed logging and downstream decision-making.

New cross-strategy state should be added as typed fields on `PipelineContext` rather than as strategy-level instance variables.

Test strategy for validating selection behaviour

The test suite lives in `scripts/tests/ci/test_test_plan_v2.py` and is run with pytest:

```
pytest scripts/tests/ci/test_test_plan_v2.py -v
```

Tests are organised into one class per strategy or shared component. The following categories of tests are expected for each new strategy:

Unit tests (no Zephyr tree required)
Use a `tmp_path` fixture to create the minimum filesystem structures (`board.yml`, `snippet.yml`, `testcase.yaml`, etc.) needed to exercise each code path. These tests should be fast and hermetic.

Helper method tests
Test internal methods (path-walking, YAML parsing, regex extraction) in isolation. Pass synthetic content rather than relying on real files in the repository.

Orchestrator integration tests
Use mock strategies and a mock `TwisterExecutor` to test the orchestrator's consume-vs-additive logic, full-run signalling, and `.testplan` output without invoking twister.

Real-tree integration tests (optional, `@pytest.mark.integration`)
May be added and marked with `@pytest.mark.integration` to be excluded from the default run. These are only meaningful on a complete Zephyr checkout.

Minimal test checklist for a new strategy

- The strategy returns no calls and no handled files when no relevant files are in the input list.
- The strategy correctly identifies and returns the expected `TwisterCall` for a known-good input.
- The strategy does not crash when required files are absent from the filesystem.
- For consuming strategies: the handled set equals the matched files and nothing else.
- For additive strategies: the handled set is empty or equals only the files the strategy is authoritative for.

CLI reference

```
usage: test_plan_v2.py [-c A..B] [-m FILE] [-f PATH]
                       [-o FILE] [-p PLATFORM] [--maintainers-file FILE]
                       [-T DIR] [--quarantine-list FILE]
                       [--tests-per-builder N] [--disable-strategy NAME]
                       [--detailed-test-id]

-c A..B              Git commit range (e.g. ``main..HEAD``).  Changed files
                     are derived from ``git diff --name-only A..B``.
-m FILE              JSON file containing a list of changed file paths.
-f PATH              Treat PATH as a changed file (repeatable).
-o FILE              Output JSON file (default: ``testplan.json``).
-p PLATFORM          Restrict all selections to this platform (repeatable).
--maintainers-file   Path to ``MAINTAINERS.yml``.
-T DIR               Extra testsuite root forwarded to every twister call.
--quarantine-list    Quarantine YAML forwarded to twister.
--tests-per-builder  Tests per CI builder node (default: 900).
--disable-strategy   Skip a strategy by name (repeatable).
--detailed-test-id   Pass ``--detailed-test-id`` to twister.
```

2.14 Static Code Analysis (SCA)

Support for static code analysis tools in Zephyr is possible through CMake.

The build setting **ZEPHYR_SCA_VARIANT** can be used to specify the SCA tool to use. ZEPHYR_SCA_VARIANT is also supported as *environment variable*.

Use -DZEPHYR_SCA_VARIANT=<tool>, for example -DZEPHYR_SCA_VARIANT=sparse to enable the static analysis tool sparse.

2.14.1 SCA Tool infrastructure

Support for an SCA tool is implemented in a sca.cmake file. The sca.cmake must be placed under *SCA_ROOT*/cmake/sca/*tool*/sca.cmake. Zephyr itself is always added as an **SCA_ROOT** but the build system offers the possibility to add additional folders to the **SCA_ROOT** setting.

You can provide support for out of tree SCA tools by creating the following structure:

```
<sca_root>/                 # Custom SCA root
└── cmake/
    └── sca/
        └── <tool>/         # Name of SCA tool, this is the value given to␣
↪ZEPHYR_SCA_VARIANT
            └── sca.cmake   # CMake code that configures the tool to be used with␣
↪Zephyr
```

To add foo under /path/to/my_tools/cmake/sca create the following structure:

```
/path/to/my_tools
        └── cmake/
            └── sca/
                └── foo/
                    └── sca.cmake
```

To use foo as SCA tool you must then specify -DZEPHYR_SCA_VARIANT=foo.

Remember to add /path/to/my_tools to **SCA_ROOT**.

SCA_TOOL can be set as a regular CMake setting using -DSCA_ROOT=<sca_root>, or added by a Zephyr module in its module.yml file, see *Zephyr Modules - Build settings*

Compiler and linker launchers

An SCA tool that needs to observe or wrap the compilation and link commands does so by setting the CMAKE_<LANG>_COMPILER_LAUNCHER and CMAKE_<LANG>_LINKER_LAUNCHER variables from its sca.cmake. They must be set as normal variables, not as cache entries.

A launcher set this way replaces any launcher that was already configured, ccache included. A tool that is a transparent wrapper, meaning it runs the command it is given unmodified, may instead keep the previous launcher by appending it:

```
set(CMAKE_C_COMPILER_LAUNCHER ${my_wrapper} ${CMAKE_C_COMPILER_LAUNCHER})
```

2.14.2 Native SCA Tool support

The following is a list of SCA tools natively supported by Zephyr build system.

Clang static analyzer support

Clang Static Analyzer is built on top of Clang and LLVM. Strictly speaking, the analyzer is part of Clang, as Clang consists of a set of reusable C++ libraries for building powerful source-level tools. The static analysis engine used by the Clang Static Analyzer is a Clang library, and has the capability to be reused in different contexts and by different clients.

LLVM provides various methods to run the analyzer on a codebase, through either a dedicated set of tools (scan-build and analyze-build), or via command line arguments when running clang ('–analyze').

- 'scan-build' utility comes as the most convenient way for projects using a simple $CC makefile variables, as it will wraps and replace the compiler calls to perform it's analysis.
- 'analyze-build' utility is a sub-tool from 'scan-build', it only relies on a 'compile_commands.json' database to perform the analysis.
- clang option '–analyze' will run the analyzer alongside the build, but objects files are not generated, making any link stage impossible. In our case the first link stage will fail and stop the analysis.

Because of it's complexe build infrastructure, invoking clang analyzer with 'analyze-build' is the most simple way to analyze a Zephyr project.

Clang static analyzer documentation

Installing clang analyzer 'scan-build' and its sub-tool 'analyze-build' come natively with llvm as part of the binaries. Make sure to have the binary directory accessible into your PATH.

'scan-build' is also available as a standalone python package available on pypi.

```
pip install scan-build
```

> **Note**
>
> The analyser requires that the project builds with a LLVM toolchain, and produces a 'compile_commands.json' database.

Run clang static analyzer To run clang static analyzer, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=clang` parameter, alongside the llvm toolchain parameters, e.g.

```
west build -b qemu_x86 samples/userspace/hello_world_user -- -
↪DZEPHYR_TOOLCHAIN_VARIANT=host/llvm -DLLVM_TOOLCHAIN_PATH=... -
↪DZEPHYR_SCA_VARIANT=clang
```

> **Note**
>
> By default, clang static analyzer produces a html report, but various other outputs can be selected with options (sarif, plist, html)

Configuring clang static analyzer Clang static analyzer can be controlled using specific options. To get an exhaustive list of available options, report to the 'analyze-build' helper and 'scan-build' helper.

```
analyze-build --help
```

Options already activated by default:

- –analyze-headers : Also analyze functions in #included files.

Parameter	Description
`CLANG_SCA_OPTS`	A semicolon separated list of 'analyze-build' options.

These parameters can be passed on the command line, or be set as environment variables.

```
west build -b stm32h573i_dk samples/hello_world -- -
↪DZEPHYR_TOOLCHAIN_VARIANT=host/llvm -DLLVM_TOOLCHAIN_PATH=... -
↪DZEPHYR_SCA_VARIANT=clang -DCLANG_SCA_OPTS="--sarif;--verbose"
```

CodeChecker support

CodeChecker is a static analysis infrastructure. It executes analysis tools available on the build system, such as Clang-Tidy, Clang Static Analyzer and Cppcheck. Refer to the analyzer's websites for installation instructions.

Installing CodeChecker CodeChecker itself is a python package available on pypi.

```
pip install codechecker
```

Building with CodeChecker To run CodeChecker, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=codechecker` parameter, e.g.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -
↪DZEPHYR_SCA_VARIANT=codechecker
```

Configuring CodeChecker CodeChecker uses different command steps, each with their respective configuration parameters. The following table lists all these options.

Parameter	Description
CODECHECKER_ANALY	The number of threads to use in analysis. (default: <CPU count>)
CODECHECKER_ANALY	Arguments passed to the `analyze` command directly. (e.g. `--timeout;360`)
CODECHECKER_CLEAN	Perform a cleanup after parsing/storing. This will remove all `plist` files.
CODECHECKER_CONFI	A JSON or YAML file with configuration options passed to all commands.
CODECHECKER_EXPOR	A comma separated list of report types. Allowed types are: `html,json,codeclimate,gerrit,baseline`.
CODECHECKER_NAME	The CodeChecker run metadata name. (default: `zephyr`)
CODECHECKER_PARSE	By default, CodeChecker identified issues will not fail the build, set this option to fail during analysis.
CODECHECKER_PARSE	Arguments passed to the `parse` command directly. (e.g. `--verbose;debug`)
CODECHECKER_PARSE	Skip parsing the analysis, useful if you simply want to store the results.
CODECHECKER_STORE	Run the `store` command after analysis.
CODECHECKER_STORE	Arguments passed to the `store` command directly. Implies `CODECHECKER_STORE`. (e.g. `--url;localhost:8001/Default`)
CODECHECKER_STORE	Pass an identifier `--tag` to the `store` command.
CODECHECKER_TRIM_	Trim the defined path from the analysis results, e.g. `/home/user/zephyrproject`. The value from `west topdir` is added by default.

These parameters can be passed on the command line, or be set as environment variables.

Running twister with CodeChecker When running CodeChecker as part of `twister` some default options are set as following:

Parameter	Value
CODECHECKER_ANALYZE_JOBS	1
CODECHECKER_NAME	<board target>:<testsuite name>
CODECHECKER_STORE_TAG	The value from `git describe` in the application source directory.

To override these values, set an environment variable or pass them as extra arguments.

Coverity

Coverity Scan is a service by which Black Duck provides the results of analysis on open source coding projects to open source code developers that have registered their products with Coverity Scan.

This integration was only tested with scan.coverity.com and the tool distribution available through this service.

Generating Build Data Files To use this integration, coverity tool distribution must be found in your *PATH* environment and *west build* should be called with a `-DZEPHYR_SCA_VARIANT=coverity` parameter, e.g.

```
west build -b qemu_cortex_m3 samples/hello_world -- -DZEPHYR_SCA_VARIANT=coverity
```

Results of the scan will be generated as `build/sca/coverity`.

You can also set `COVERITY_OUTPUT_DIR` as the destination for multiple and incremental scan results.

Result Analysis Follow the instructions on https://scan.coverity.com for uploading results.

Parasoft C/C++test support

Parasoft C/C++test is a software testing and static analysis tool for C and C++. It is a commercial software and you must acquire a commercial license to use it.

Documentation of C/C++test can be found at https://docs.parasoft.com/. Please refer to the documentation for how to use it.

Generating Build Data Files To use C/C++test, `cpptestscan` must be found in your *PATH* environment variable. And *west build* should be called with a `-DZEPHYR_SCA_VARIANT=cpptest` parameter, e.g.

```
west build -b qemu_cortex_m3 zephyr/samples/hello_world -- -
↪DZEPHYR_SCA_VARIANT=cpptest
```

A `.bdf` file will be generated as `build/sca/cpptest/cpptestscan.bdf`.

Generating a report file Please refer to Parasoft C/C++test documentation for more details.

To import and generate a report file, something like the following should work.

```
cpptestcli -data out -localsettings local.conf -bdf␣
↪build/sca/cpptest/cpptestscan.bdf -config "builtin://Recommended Rules" -report␣
↪out/report
```

You might need to set `bdf.import.c.compiler.exec`, `bdf.import.cpp.compiler.exec`, and `bdf.import.linker.exec` to the toolchain *west build* used.

Devicetree diagnostics (`dtdoctor`)

`dtdoctor` is a static analysis tool that helps diagnose Devicetree-related build errors.

It intercepts error messages from the compiler and linker and, when they refer to unresolved Devicetree device symbols (e.g. `__device_dts_ord_*`), provides detailed information about what might be causing the error and how to fix it.

Using dtdoctor To enable `dtdoctor`, build with `-DZEPHYR_SCA_VARIANT=dtdoctor`.

For example:

```
west build -b reel_board samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=dtdoctor
```

ECLAIR support

Bugseng ECLAIR is a certified static analysis tool and platform for software verification. Applications range from coding rule validation, with a particular emphasis on the MISRA and BARR-C coding standards, to the computation of software metrics, to the checking of independence and freedom from interference among software components, to the automatic detection of important classes of software errors.

Prerequisites The ECLAIR tool must be installed and made available in the operating system's PATH variable.

To verify the installation, you can run:

```
eclair -version
```

A valid license or trial license is required to use ECLAIR. To request a trial license, visit this page.

Running ECLAIR To run ECLAIR, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=eclair` parameter.

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=eclair
```

> **Note**
>
> This will only invoke the ECLAIR analysis with the predefined ruleset `first_analysis`. If you want to use a different ruleset, you need to provide a configuration file. See the next section for more information.

Configurations The configuration of the ECLAIR SCA environment can either be done via a CMake options file or with adapted options as command line arguments.

To invoke a CMake options file into the ECLAIR call, you can define the `ECLAIR_OPTIONS_FILE` variable, for example:

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=eclair -
↪DECLAIR_OPTIONS_FILE=my_options.cmake
```

The default (if no config file is given) configuration is always `first_analysis`, which is a tiny selection of rules to verify that everything is correctly working.

If the default configuration wants to be overwritten via the command line and not via an options file, that can be achieved by giving the argument `-DOption=ON|OFF`.

For example:

```
west build -b mimxrt1064_evk samples/basic/blinky -- -DZEPHYR_SCA_VARIANT=eclair -
↪DECLAIR_REPORTS_SARIF=ON
```

Zephyr is a large and complex project, so the configuration sets are split into the Zephyr's guidelines selection (taken from https://docs.zephyrproject.org/latest/contribute/coding_guidelines/index.html) in five sets to make it more digestible to use on a private machine:

- first_analysis (default): a tiny selection of the project's coding guidelines to verify that everything is correctly working.
- STU: Selection of the project's coding guidelines, which can be verified by analyzing the single translation units independently.
- STU_heavy: Selection of complex STU project coding guidelines that require a significant amount of time.
- WP: All whole program project coding guidelines ("system" in MISRA's parlance).
- std_lib: Project coding guidelines about the C Standard Library.

In addition, the zephyr_guidelines ruleset contains all the main rules listed in the Coding Guidelines.

Related CMake options:

- `ECLAIR_RULESET_FIRST_ANALYSIS`
- `ECLAIR_RULESET_STU`
- `ECLAIR_RULESET_STU_HEAVY`
- `ECLAIR_RULESET_WP`
- `ECLAIR_RULESET_STD_LIB`
- `ECLAIR_RULESET_ZEPHYR_GUIDELINES`

User-defined ruleset If you want to use your own defined ruleset instead of the predefined Zephyr coding guidelines rulesets, you can do so by setting `ECLAIR_RULESET_USER=ON`. Create your own ruleset file for ECLAIR with the following naming format: `analysis_<RULESET>.ecl`. After creating the file, define the name of the ruleset for ECLAIR with the CMake variable `ECLAIR_USER_RULESET_NAME`. If the ruleset file is not in the application source directory, you can define the path to the ruleset file with the CMake variable `ECLAIR_USER_RULESET_PATH`. This configuration takes relative paths and absolute paths.

Related CMake options and variables:

- `ECLAIR_RULESET_USER`
- `ECLAIR_USER_RULESET_NAME`
- `ECLAIR_USER_RULESET_PATH`

Generate additional report formats ECLAIR can generate additional report formats (e.g., DOC, ODT, XLSX) and different variants of reports in addition to the default ecd file. Following additional reports and report formats can be generated:

- Metrics in spreadsheet format.
- Findings in spreadsheet format.
- Findings in SARIF format.
- Summary report in plain textual format.
- Summary report in DOC format.
- Summary report in ODT format.
- Summary report in HTML format.
- Detailed reports in txt format.
- Detailed report in DOC format.
- Detailed report in ODT format.
- Detailed report in HTML format.

Related CMake options:

- ECLAIR_METRICS_TAB
- ECLAIR_REPORTS_TAB
- ECLAIR_REPORTS_SARIF
- ECLAIR_SUMMARY_TXT
- ECLAIR_SUMMARY_DOC
- ECLAIR_SUMMARY_ODT
- ECLAIR_SUMMARY_HTML
- ECLAIR_FULL_TXT
- ECLAIR_FULL_DOC
- ECLAIR_FULL_ODT
- ECLAIR_FULL_HTML

Detail level of full reports The detail level of the txt and doc full reports can also be adapted by a configuration. In this case, the following configurations are available:

- Show all areas
- Show only the first area

Related CMake options:

- ECLAIR_FULL_DOC_ALL_AREAS
- ECLAIR_FULL_DOC_FIRST_AREA
- ECLAIR_FULL_TXT_ALL_AREAS
- ECLAIR_FULL_TXT_FIRST_AREA

GCC static analysis support

Static analysis was introduced in GCC 10 and it is enabled with the option `-fanalyzer`. This option performs a much more expensive and thorough analysis of the code than traditional warnings.

Run GCC static analysis To run GCC static analysis, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=gcc` parameter, e.g.

```
west build -b qemu_x86 samples/userspace/hello_world_user -- -
↪DZEPHYR_SCA_VARIANT=gcc
```

Configuring GCC static analyzer GCC static analyzer can be controlled using specific options.

- Options controlling the analyzer
- Options controlling the diagnostic message formatting

Parameter	Description
GCC_SCA_OPTS	A semicolon separated list of GCC analyzer options.

These parameters can be passed on the command line, or be set as environment variables.

```
west build -b stm32h573i_dk samples/hello_world -- -DZEPHYR_SCA_VARIANT=gcc -
↪DGCC_SCA_OPTS="-fdiagnostics-format=json;-fanalyzer-verbosity=3"
```

> **Note**
>
> GCC static analyzer is under active development, and each new release comes with new options. This page gives an overview of options and fix introduced with each new release of the analyzer.

Latest version of the analyzer Since the Zephyr toolchain may not include the most recent version of the GCC static analyzer, the GCC static analysis can be run with a more recent GNU Arm embedded toolchain to take advantage of the latest analyzer version.

```
west build -b stm32h573i_dk samples/hello_world -- -DZEPHYR_SCA_VARIANT=gcc -
↪DZEPHYR_TOOLCHAIN_VARIANT=gnuarmemb -DGNUARMEMB_TOOLCHAIN_PATH=...
```

IAR C-STAT support

IAR C-STAT is a comprehensive static analysis tool for C/C++ source code. It can find errors and vulnerabilities supporting a number of coding standards such as MISRA C, MISRA C++, CERT C/C++ and CWE.

Installing IAR C-STAT IAR C-STAT comes pre-installed with the IAR Build Tools and with the IAR Embedded Workbench. Refer to your respective product's documentation for details.

Building with IAR C-STAT To run IAR C-STAT, you will need CMake 4.1.0 or later. When building with *west build* append the additional parameter to select IAR C-STAT `-DZEPHYR_SCA_VARIANT=iar_c_stat`, e.g.

```
west build -b stm32f429ii_aca samples/basic/blinky -- -
↪DZEPHYR_SCA_VARIANT=iar_c_stat
```

Configuring IAR C-STAT The IAR C-STAT accepts parameters for customizing the analysis. The following table lists the supported options.

Parameter	Description
CSTAT_RULESE	The pre-defined ruleset to be used. (default: `stdchecks`, accepted values: `all`, `cert`,`misrac2004`,`misrac2012`,`misrac++2008`,`stdchecks`,`security`)
CSTAT_ANALYZI	The number of threads to use in analysis. (default: <CPU count>)
CSTAT_ANALYZI	Arguments passed to the `analyze` command directly. (e.g. `--timeout=900`; `--deterministic`;`--fpe`)
CSTAT_DB	Override the default location of the C-STAT SQLite database. (e.g. `/home/user/cstat.db`)
CSTAT_CLEANUI	Perform a cleanup of the C-STAT SQLite database. (e.g. `true`)

These parameters can be passed on the command line, or be set as environment variables. Below you will find an example of how to enable and combine non-standard rulesets at will:

```
# From the root of the zephyr repository
west build -b stm32f429ii_aca samples/basic/blinky -- -
↪DZEPHYR_SCA_VARIANT=iar_c_stat -DCSTAT_RULESET=misrac2012,cert
```

include-what-you-use (IWYU) support

include-what-you-use (IWYU) is a tool built on top of Clang and LLVM that analyzes `#include` directives in C and C++ source files. For every translation unit it reports headers that are included

but not used, and symbols that are used but whose defining header is only included transitively. Acting on its suggestions keeps the set of includes minimal and explicit.

Installing include-what-you-use `include-what-you-use` is distributed by most Linux distributions, on ubuntu:

```
sudo apt-get install iwyu
```

Make sure the `include-what-you-use` binary is available in your *PATH*.

> **Note**
>
> IWYU is built on Clang, so building with the LLVM toolchain produces the most accurate results.

Run include-what-you-use To run include-what-you-use, *west build* should be called with a `-DZEPHYR_SCA_VARIANT=iwyu` parameter, e.g.

```
west build -b native_sim samples/hello_world -- -DZEPHYR_SCA_VARIANT=iwyu
```

The analysis runs alongside the compilation of each source file, and the suggested include changes are printed to the build output (stderr).

Configuring include-what-you-use include-what-you-use can be controlled using specific options. Refer to the IWYU documentation for the full list of options.

Parameter	Description
IWYU_OI	A semicolon separated list of include-what-you-use options. Each option is forwarded to the tool with the required `-Xiwyu` prefix automatically.

These parameters can be passed on the command line, or be set as environment variables.

```
west build -b native_sim samples/hello_world -- -DZEPHYR_SCA_VARIANT=iwyu -
↪DIWYU_OPTS="--no_comments;--verbose=3"
```

Polyspace support

Polyspace® is a commercial static code analysis tool from MathWorks, which is certified for use in highest safety contexts. It can check compliance to coding guidelines like MISRA C and CERT C, find CWEs, detect bugs and calculate code complexity metrics. Optionally, it can run a formal proof to verify the absence of run-time errors like array out of bounds access, overflows, race conditions and more, and thus help achieving memory safety.

Installing The Polyspace tools must be installed and made available in the operating system's or container's PATH variable. Specifically, the path `<polyspace_root>/polyspace/bin` must be on the list.

For installation instructions, see here. To use formal verification (proving the *absence* of defects), you additionally need to install this.

A license file must be available in the installation folder. To request a trial license, visit this page.

Running The code analysis can be triggered through the `west` command by appending the option `-DZEPHYR_SCA_VARIANT=polyspace` to the build, for example:

```
west build -b qemu_x86 samples/hello_world -- -DZEPHYR_SCA_VARIANT=polyspace
```

Reviewing results The identified issues are summarized at the end of the build and printed in the console window, along with the path of the folder containing detailed results.

For an efficient review, the folder should be opened in the Polyspace user interface or uploaded to the web interface and reviewed there.

For programmatic access of the results, e.g., in the CI pipeline, the individual issues are also described in a CSV file in the results folder.

Configuration By default, Polyspace scans for typical programming defects on all C and C++ sources. The following options are available to customize the default behavior:

Option	Effect	Example
POLYSPACE_ONLY_API	If set, only user code is analyzed and Zephyr sources are ignored.	-DPOLYSPACE_ONLY_APP=1
POLYSPACE_OPTIONS	Provide additional command line flags, e.g., for selection of coding rules. Separate the options and their values by semicolon. For a list of options, see here.	-DPOLYSPACE_OPTIONS="-misra3; mandatory-required; -checkers;all"
POLYSPACE_OPTIONS_	Command line flags can also be provided in a text file, line by line. Provide the absolute path to the file.	-DPOLYSPACE_OPTIONS_FILE=/workdir/zephyr/myoptions.txt
POLYSPACE_MODE	Switch between bugfinding and proving mode. Default is bugfinding. See here for more details.	-DPOLYSPACE_MODE=prove
POLYSPACE_PROG_NAI	Override the name of the analyzed application. Default is board and application name.	-DPOLYSPACE_PROG_NAME=myapp
POLYSPACE_PROG_VEI	Override the version of the analyzed application. Default is taken from git-describe.	-DPOLYSPACE_PROG_VERSION=v1.0b-28f023

Sparse support

Sparse is a static code analysis tool. Apart from performing common code analysis tasks it also supports an `address_space` attribute, which allows introduction of distinct address spaces in C code with subsequent verification that pointers to different address spaces do not get confused. Additionally it supports a `force` attribute which should be used to cast pointers between different address spaces. At the moment Zephyr introduces a single custom address space `__cache` used to identify pointers from the cached address range on the Xtensa architecture. This helps identify cases where cached and uncached addresses are confused.

Running with sparse To run a sparse verification build *west build* should be called with a `-DZEPHYR_SCA_VARIANT=sparse` parameter, e.g.

```
west build -d hello -b intel_adsp/cavs25 zephyr/samples/hello_world -- -
↪DZEPHYR_SCA_VARIANT=sparse
```

2.15 Toolchains

Guides on how to set up toolchains for Zephyr development.

2.15.1 Zephyr SDK

The Zephyr Software Development Kit (SDK) contains GNU and LLVM toolchains for each of Zephyr's supported architectures. It also includes additional host tools, such as custom QEMU and OpenOCD.

Use of the Zephyr SDK is highly recommended and may even be required under certain conditions (for example, running tests in QEMU for some architectures).

Supported architectures

The Zephyr SDK supports the following target architectures:

- ARC (32-bit and 64-bit; ARCv1, ARCv2, ARCv3)
- ARM (32-bit and 64-bit; ARMv6, ARMv7, ARMv8; A/R/M Profiles)
- Microblaze (32-bit)
- MIPS (32-bit and 64-bit)
- RISC-V (32-bit and 64-bit; RV32I, RV32E, RV64I)
- RX
- SPARC (32-bit and 64-bit; SPARC V8, SPARC V9)
- x86 (32-bit and 64-bit)
- Xtensa

Installation bundle and variables

The Zephyr SDK bundle supports all major operating systems (Linux, macOS and Windows) and is delivered as a compressed file.

To ease distribution, the SDK is pre-packed in three different variants you can download:

Table 8: SDK Bundle Variants

Variant	Host Tools	Toolchains Included
`gnu`	Yes	GNU (Binutils, GCC, and GDB) for all supported architectures
`llvm`	Yes	LLVM/Clang
`minimal`	Yes	None

The installation process consists of extracting the downloaded bundle file and running the included setup script.

Independently of which bundle you download, during installation you will be prompted for which of the toolchains you want to install, and if it is not found in the local directory where the setup script is being executed it will be downloaded during installation. It is also possible to download and uncompress both the GNU and LLVM SDK bundles into the same directory tree and in that way install both without the need to download either during the setup script execution.

Additional OS-specific instructions are described in the sections below.

If no toolchain is selected, the build system looks for Zephyr SDK and uses the toolchain from there. You can enforce this by setting the environment variable *ZEPHYR_TOOLCHAIN_VARIANT* to `zephyr`.

If you install the Zephyr SDK outside any of the default locations (listed in the operating system specific instructions below) and you want automatic discovery of the Zephyr SDK, then you must register the Zephyr SDK in the CMake package registry by running the setup script. If you decide not to register the Zephyr SDK in the CMake registry, then the *ZEPHYR_SDK_INSTALL_DIR* can be used to point to the Zephyr SDK installation directory.

You can also set *ZEPHYR_SDK_INSTALL_DIR* to point to a directory containing multiple Zephyr SDKs, allowing for automatic toolchain selection. For example, you can set `ZEPHYR_SDK_INSTALL_DIR` to `/company/tools`, where the `company/tools` folder contains the following subfolders:

- `/company/tools/zephyr-sdk-0.13.2`
- `/company/tools/zephyr-sdk-a.b.c`
- `/company/tools/zephyr-sdk-x.y.z`

This allows the Zephyr build system to choose the correct version of the SDK, while allowing multiple Zephyr SDKs to be grouped together at a specific path.

Zephyr SDK version compatibility

In general, the Zephyr SDK version referenced in this page should be considered the recommended version for the corresponding Zephyr version.

For the full list of compatible Zephyr and Zephyr SDK versions, refer to the Zephyr SDK Version Compatibility Matrix.

Zephyr SDK installation

Note

You can change `1.0.1` to another version in the instructions below if needed; the Zephyr SDK Releases page contains all available SDK releases.

Note

The instructions below are for installing using the Zephyr GNU SDK bundle, which includes the GNU toolchains for all supported architectures and the host tools. To install using the Zephyr LLVM SDK bundle, replace the `_gnu` suffix with `_llvm` in the SDK bundle file name.

Note

If you want to uninstall the SDK, you may simply remove the directory where you installed it.

Linux

1. Download and verify the Zephyr SDK bundle:

```
cd ~
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v1.0.1/
↪zephyr-sdk-1.0.1_linux-x86_64_gnu.tar.xz
```

```
wget -O - https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v1.0.
↪1/sha256.sum | shasum --check --ignore-missing
```

If your host architecture is 64-bit ARM (for example, Raspberry Pi), replace `x86_64` with `aarch64` in order to download the 64-bit ARM Linux SDK.

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-1.0.1_linux-x86_64_gnu.tar.xz
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `$HOME`
> - `$HOME/.local`
> - `$HOME/.local/opt`
> - `$HOME/bin`
> - `/opt`
> - `/usr/local`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-1.0.1
./setup.sh
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

4. Install udev rules, which allow you to flash most Zephyr boards as a regular user:

```
sudo cp ~/zephyr-sdk-1.0.1/hosttools/sysroots/x86_64-pokysdk-linux/usr/share/
↪openocd/contrib/60-openocd.rules /etc/udev/rules.d
sudo udevadm control --reload
```

macOS

1. Download and verify the Zephyr SDK bundle:

```
cd ~
curl -L -O https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v1.
↪0.1/zephyr-sdk-1.0.1_macos-aarch64_gnu.tar.xz
curl -L https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v1.0.1/
↪sha256.sum | shasum --check --ignore-missing
```

2. Extract the Zephyr SDK bundle archive:

```
tar xvf zephyr-sdk-1.0.1_macos-aarch64_gnu.tar.xz
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `$HOME`
> - `$HOME/.local`
> - `$HOME/.local/opt`
> - `$HOME/bin`
> - `/opt`
> - `/usr/local`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `$HOME`, the resulting installation path will be `$HOME/zephyr-sdk-<version>`.

3. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-1.0.1
./setup.sh
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

Windows

1. Open a `cmd.exe` terminal window **as a regular user**
2. Download the Zephyr SDK bundle:

```
cd %HOMEPATH%
wget https://github.com/zephyrproject-rtos/sdk-ng/releases/download/v1.0.1/
↪zephyr-sdk-1.0.1_windows-x86_64_gnu.7z
```

3. Extract the Zephyr SDK bundle archive:

```
7z x zephyr-sdk-1.0.1_windows-x86_64_gnu.7z
```

> **Note**
>
> It is recommended to extract the Zephyr SDK bundle at one of the following locations:
>
> - `%HOMEPATH%`
> - `%PROGRAMFILES%`
>
> The Zephyr SDK bundle archive contains the `zephyr-sdk-<version>` directory and, when extracted under `%HOMEPATH%`, the resulting installation path will be `%HOMEPATH%\zephyr-sdk-<version>`.

4. Run the Zephyr SDK bundle setup script:

```
cd zephyr-sdk-1.0.1
setup.cmd
```

> **Note**
>
> You only need to run the setup script once after extracting the Zephyr SDK bundle.
>
> You must rerun the setup script if you relocate the Zephyr SDK bundle directory after the initial setup.

2.15.2 Arm Compiler 6

1. Download and install a development suite containing the Arm Compiler 6 for your operating system.
2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `armclang`.
   - Set `ARMCLANG_TOOLCHAIN_PATH` to the toolchain installation directory.
3. The Arm Compiler 6 needs the `ARMLMD_LICENSE_FILE` environment variable to point to your license file or server.

For example:

```
# Linux, macOS, license file:
export ARMLMD_LICENSE_FILE=/<path>/license_armds.dat
# Linux, macOS, license server:
export ARMLMD_LICENSE_FILE=8224@myserver
```

```
# Windows, license file:
set ARMLMD_LICENSE_FILE=c:\<path>\license_armds.dat
# Windows, license server:
set ARMLMD_LICENSE_FILE=8224@myserver
```

1. If the Arm Compiler 6 was installed as part of an Arm Development Studio, then you must set the `ARM_PRODUCT_DEF` to point to the product definition file: See also: Product and toolkit configuration. For example if the Arm Development Studio is installed in: `/opt/armds-2020-1` with a Gold license, then set `ARM_PRODUCT_DEF` to point to `/opt/armds-2020-1/gold.elmap`.

> **Note**
>
> The Arm Compiler 6 uses `armlink` for linking. This is incompatible with Zephyr's linker script template, which works with GNU ld. Zephyr's Arm Compiler 6 support Zephyr's CMake linker script generator, which supports generating scatter files. Basic scatter file support is in place, but there are still areas covered in ld templates which are not fully supported by the CMake linker script generator.
>
> Some Zephyr subsystems or modules may also contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `armclang`.

2.15.3 Arm Toolchain for Embedded (ATfE)

Arm Toolchain for Embedded (ATfE) is a C and C++ toolchain from Arm based
on the free and open-source LLVM Compiler Infrastructure and the Picolib C library for baremetal targets.

ATfE is fined-tuned with a particular focus on performance for newer
ARM products (post 2024) like 64-bit Arm Architectures (AArch64), or the M-Profile Vector Extension (MVE, a 32-bit Armv8.1-M extension).

Installation

1. Download and install a Arm toolchain for embedded build for your operating system and extract it on your file system.
2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `host/llvm`.
   - Set `LLVM_TOOLCHAIN_PATH` to the toolchain installation directory.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `LLVM_TOOLCHAIN_PATH` values may be different on your system):

   Ubuntu

   ```
   echo $ZEPHYR_TOOLCHAIN_VARIANT
   host/llvm
   echo $LLVM_TOOLCHAIN_PATH
   /home/you/Downloads/ATfE
   ```

   macOS

   ```
   echo $ZEPHYR_TOOLCHAIN_VARIANT
   host/llvm
   echo $LLVM_TOOLCHAIN_PATH
   /home/you/Downloads/ATfE
   ```

   Windows

   ```
   > echo %ZEPHYR_TOOLCHAIN_VARIANT%
   host/llvm
   > echo %LLVM_TOOLCHAIN_PATH%
   C:\ATfE
   ```

4. You can also set `ZEPHYR_TOOLCHAIN_VARIANT` and `LLVM_TOOLCHAIN_PATH` as CMake variables when generating a build system for a Zephyr application, like so:

   ```
   west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=host/llvm -
   ↪DLLVM_TOOLCHAIN_PATH=...
   ```

Toolchain settings

Because LLVM is widely compatible with GNU tools, When builiding with any LLVM toolchain, you have to specify some settings to let the compiler know what tools to use:

Linker

- Set `CONFIG_LLVM_USE_LLD=y` to use LLVM linker.
- Set `CONFIG_LLVM_USE_LD=y` to use the GNU LD linker.

Runtime library

- Set `CONFIG_COMPILER_RT_RTLIB=y` to use LLVM runtime library.
- Set `CONFIG_LIBGCC_RTLIB=y` to use LibGCC runtime library.

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=host/llvm -DLLVM_TOOLCHAIN_PATH=... -
↪DCONFIG_LLVM_USE_LLD=y -DCONFIG_COMPILER_RT_RTLIB=y
```

2.15.4 Cadence Tensilica Xtensa C/C++ Compiler (XCC)

1. Obtain Tensilica Software Development Toolkit targeting the specific SoC on hand. This usually contains two parts:
   - The Xtensa Xplorer which contains the necessary executables and libraries.
   - A SoC-specific add-on to be installed on top of Xtensa Xplorer.
     - This add-on allows the compiler to generate code for the SoC on hand.
2. Install Xtensa Xplorer and then the SoC add-on.
   - Follow the instruction from Cadence on how to install the SDK.
   - Depending on the SDK, there are two set of compilers:
     - GCC-based compiler: `xt-xcc` and its friends.
     - Clang-based compiler: `xt-clang` and its friends.
3. Make sure you have obtained a license to use the SDK, or has access to a remote licensing server.
4. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xcc` or `xt-clang`.
   - Set `XTENSA_TOOLCHAIN_PATH` to the toolchain installation directory.
   - There are two ways to specify the SoC ID and the SDK version to use. They are mutually exclusive, and cannot be used together.
     1. When building for a single SoC:
        - Set `XTENSA_CORE` to the SoC ID where application is being targeted.
        - Set `TOOLCHAIN_VER` to the Xtensa SDK version.
     2. When building for multiple SoCs, for each SoC and board combination:
        - Set `XTENSA_CORE_{normalized_board_target}` to the SoC ID where application is being targeted.
        - Set `TOOLCHAIN_VAR_{normalized_board_target}` to the Xtensa SDK version.
5. For example, assuming the SDK is installed in `/opt/xtensa`, and using the SDK for application development on `intel_adsp/ace15_mtpm`, setup the environment using the two above mentioned ways:
   1. Single SoC:

```
# Linux
export ZEPHYR_TOOLCHAIN_VARIANT=xt-clang
export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
export XTENSA_CORE=ace10_LX7HiFi4_2022_10
export TOOLCHAIN_VER=RI-2022.10-linux
```

   2. Multiple SoCs:

```
# Linux
export ZEPHYR_TOOLCHAIN_VARIANT=xt-clang
export XTENSA_TOOLCHAIN_PATH=/opt/xtensa/XtDevTools/install/tools/
export TOOLCHAIN_VER_intel_adsp_ace15_mtpm=RI-2022.10-linux
export XTENSA_CORE_intel_adsp_ace15_mtpm=ace10_LX7HiFi4_2022_10
```

6. To use Clang-based compiler:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xt-clang`.

- Note that the Clang-based compiler may contain an old LLVM bug which results in the following error:

```
/tmp/file.s: Assembler messages:
/tmp/file.s:20: Error: file number 1 already allocated
clang-3.9: error: Xtensa-as command failed with exit code 1
```

If this happens, set `XCC_NO_G_FLAG` to `1`.

  - For example:

```
# Linux
export XCC_NO_G_FLAG=1
```

2.15.5 DesignWare ARC MetaWare Development Toolkit (MWDT)

1. You need to have ARC MWDT installed on your host.
2. You need to have *Zephyr SDK* installed on your host.

> **Note**
>
> A Zephyr SDK is used as a source of tools like device tree compiler (DTC), QEMU, etc... Even though ARC MWDT toolchain is used for Zephyr RTOS build, still the GNU preprocessor & GNU objcopy might be used for some steps like device tree preprocessing and `.bin` file generation. We used Zephyr SDK as a source of these ARC GNU tools as well. To setup ARC GNU toolchain please use SDK Bundle (Full or Minimal) instead of manual installation of separate tarballs. It installs and registers toolchain and host tools in the system, that allows you to avoid toolchain related issues while building Zephyr.

3. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `arcmwdt`.
   - Set `ARCMWDT_TOOLCHAIN_PATH` to the toolchain installation directory. MWDT installation provides `METAWARE_ROOT` so simply set `ARCMWDT_TOOLCHAIN_PATH` to `$METAWARE_ROOT/../` (Linux) or `%METAWARE_ROOT%\..\` (Windows).

> **Tip**
>
> If you have only one ARC MWDT toolchain version installed on your machine you may skip setting `ARCMWDT_TOOLCHAIN_PATH` - it would be detected automatically.

4. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `ARCMWDT_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
arcmwdt
$ echo $ARCMWDT_TOOLCHAIN_PATH
/home/you/ARC/MWDT_2023.03/

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
arcmwdt
> echo %ARCMWDT_TOOLCHAIN_PATH%
C:\ARC\MWDT_2023.03\
```

2.15.6 GNU Arm Embedded

1. Download and install a GNU Arm Embedded build for your operating system and extract it on your file system.

   Note

   On Windows, we'll assume for this guide that you install into the directory `C:\gnu_arm_embedded`. You can also choose the default installation path used by the ARM GCC installer, in which case you will need to adjust the path accordingly in the guide below.

   Warning

   On macOS Catalina or later you might need to *change a security policy* for the toolchain to be able to run from the terminal.

2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `gnuarmemb`.
   - Set `GNUARMEMB_TOOLCHAIN_PATH` to the toolchain installation directory.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `GNUARMEMB_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
gnuarmemb
$ echo $GNUARMEMB_TOOLCHAIN_PATH
/home/you/Downloads/gnu_arm_embedded

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
gnuarmemb
> echo %GNUARMEMB_TOOLCHAIN_PATH%
C:\gnu_arm_embedded
```

   Warning

   On macOS, if you are having trouble with the suggested procedure, there is an unofficial package on brew that might help you. Run `brew install gcc-arm-embedded` and configure the variables
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `gnuarmemb`.
   - Set `GNUARMEMB_TOOLCHAIN_PATH` to the brew installation directory (something like `/usr/local`)

2.15.7 Qualcomm Hexagon LLVM Toolchain

1. Download a pre-built Hexagon LLVM cross-toolchain from the toolchain_for_hexagon releases page and extract it, for example to `/opt/hexagon-toolchain`. The install directory is the one holding `bin/clang`.

   Use a release built from LLVM 23 or newer. Earlier releases miscompile the `~BIT(n)`. The fix landed in #205489.

2. Set *ZEPHYR_TOOLCHAIN_VARIANT* to hexagon and *HEXAGON_TOOLCHAIN_PATH* to that directory:

```
export ZEPHYR_TOOLCHAIN_VARIANT=hexagon
export HEXAGON_TOOLCHAIN_PATH=/opt/hexagon-toolchain
```

HEXAGON_TOOLCHAIN_PATH
: Install directory of the Hexagon LLVM cross-toolchain.

The toolchain is an ordinary LLVM installation, so this variant is the *Host Toolchains* `llvm` variant driving a different compiler. It has a path variable of its own because the Hexagon clang registers only the Hexagon target and so cannot build host-compiled targets such as native_sim; an environment that covers both has to name the two LLVM installations independently, as Zephyr's CI does when a single Twister run spans both kinds of platform.

Building a Hexagon target with `ZEPHYR_TOOLCHAIN_VARIANT=host/llvm` and `LLVM_TOOLCHAIN_PATH` is equivalent and remains supported, as long as the installation it names is the Hexagon one.

2.15.8 IAR Arm Toolchain

1. Download and install a release v9.70 or newer of IAR Arm Toolchain on your host (IAR Embedded Workbench or IAR Build Tools, perpetual or subscription licensing)
2. Make sure you have *Zephyr SDK* installed on your host.
3. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `iar`.
   - Set `IAR_TOOLCHAIN_PATH` to the toolchain installation directory.
4. The cloud licensed variant of the IAR Toolchain needs the `IAR_LMS_BEARER_TOKEN` environment variable to be set to a valid `license bearer token` (subscription licensing).

For example:

```
# Linux (default installation path):
export IAR_TOOLCHAIN_PATH=/opt/iar/cxarm-<version>/arm
export ZEPHYR_TOOLCHAIN_VARIANT=iar
export IAR_LMS_BEARER_TOKEN="<BEARER-TOKEN>"
```

```
# Windows:
set IAR_TOOLCHAIN_PATH=c:\<path>\cxarm-<version>\arm
set ZEPHYR_TOOLCHAIN_VARIANT=iar
set IAR_LMS_BEARER_TOKEN="<BEARER-TOKEN>"
```

Note

Known limitations:

- The IAR Toolchain uses `ilink` for linking and depends on Zephyr's CMAKE_LINKER_GENERATOR. `ilink` is incompatible with Zephyr's linker script template, which works with GNU ld.
- The GNU Assembler distributed with the Zephyr SDK is used for `.S-files`.
- C library support for `Minimal libc` only. C++ is not supported.
- Some Zephyr subsystems or modules may contain C or assembly code that relies on GNU intrinsics and have not yet been updated to work fully with `iar`.
- TrustedFirmware is not supported

2.15.9 Intel oneAPI Toolkit

1. Download Intel oneAPI Base Toolkit
2. Assuming the toolkit is installed in `/opt/intel/oneApi`, set environment using:

```
# Linux, macOS:
export ONEAPI_TOOLCHAIN_PATH=/opt/intel/oneapi
source $ONEAPI_TOOLCHAIN_PATH/compiler/latest/env/vars.sh

# Windows:
> set ONEAPI_TOOLCHAIN_PATH=C:\Users\Intel\oneapi
```

   To setup the complete oneApi environment, use:

```
source  /opt/intel/oneapi/setvars.sh
```

   The above will also change the python environment to the one used by the toolchain and might conflict with what Zephyr uses.

3. Set *ZEPHYR_TOOLCHAIN_VARIANT* to `oneApi`.

2.15.10 MPLAB XC32

1. Download and install MPLAB XC32 Compiler for your operating system.
2. *Set these environment variables*:
   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `xc32`.
   - Set `XC32_TOOLCHAIN_PATH` to the toolchain installation directory.
3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `XC32_TOOLCHAIN_PATH` values may be different on your system):

```
# Linux, macOS:
$ echo $ZEPHYR_TOOLCHAIN_VARIANT
xc32
$ echo $XC32_TOOLCHAIN_PATH
/opt/microchip/xc32/v5.00

# Windows:
> echo %ZEPHYR_TOOLCHAIN_VARIANT%
xc32
> echo %XC32_TOOLCHAIN_PATH%
C:\Microchip\xc32\v5.00
```

4. For Microchip SoCs, set `XC_PACK_DIR` to the root directory containing installed Microchip Device Family Packs (DFPs).

   Note

   Zephyr uses `XC_PACK_DIR` to find the DFP matching the selected SoC and to pass the required `-mdfp` and `-mprocessor` flag to the XC32 toolchain.

   For example:

```
# Linux, macOS:
$ export XC_PACK_DIR=/home/path/.packs/microchip
```

(continues on next page)

(continued from previous page)

```
# Windows:
> set XC_PACK_DIR=C:\Users\path\.mchp_packs\Microchip
```

2.15.11 Host Toolchains

In some specific configurations, like when building for non-MCU x86 targets on a Linux host, you may be able to reuse the native development tools provided by your operating system.

To use your host gcc, set the *ZEPHYR_TOOLCHAIN_VARIANT environment variable* to `host/gnu`. To use clang, set *ZEPHYR_TOOLCHAIN_VARIANT* to `host/llvm`.

2.15.12 Other Cross Compilers

This toolchain variant is borrowed from the Linux kernel build system's mechanism of using a `CROSS_COMPILE` environment variable to set up a GNU-based cross toolchain.

Examples of such "other cross compilers" are cross toolchains that your Linux distribution packaged, that you compiled on your own, or that you downloaded from the net. Unlike toolchains specifically listed in *Toolchains*, the Zephyr build system may not have been tested with them, and doesn't officially support them. (Nonetheless, the toolchain set-up mechanism itself is supported.)

Follow these steps to use one of these toolchains.

1. Install a cross compiler suitable for your host and target systems.

   For example, you might install the `gcc-arm-none-eabi` package on Debian-based Linux systems, or `arm-none-eabi-newlib` on Fedora or Red Hat:

   ```
   # On Debian or Ubuntu
   sudo apt-get install gcc-arm-none-eabi
   # On Fedora or Red Hat
   sudo dnf install arm-none-eabi-newlib
   ```

2. *Set these environment variables*:

   - Set *ZEPHYR_TOOLCHAIN_VARIANT* to `cross-compile`.
   - Set `CROSS_COMPILE` to the common path prefix which your toolchain's binaries have, e.g. the path to the directory containing the compiler binaries plus the target triplet and trailing dash.

3. To check that you have set these variables correctly in your current environment, follow these example shell sessions (the `CROSS_COMPILE` value may be different on your system):

   ```
   # Linux, macOS:
   $ echo $ZEPHYR_TOOLCHAIN_VARIANT
   cross-compile
   $ echo $CROSS_COMPILE
   /usr/bin/arm-none-eabi-
   ```

   You can also set `CROSS_COMPILE` as a CMake variable.

When using this option, all of your toolchain binaries must reside in the same directory and have a common file name prefix. The `CROSS_COMPILE` variable is set to the directory concatenated with the file name prefix. In the Debian example above, the `gcc-arm-none-eabi` package installs binaries such as `arm-none-eabi-gcc` and `arm-none-eabi-ld` in directory `/usr/bin/`, so the common prefix is `/usr/bin/arm-none-eabi-` (including the trailing dash, `-`). If your toolchain is installed in `/opt/mytoolchain/bin` with binary names based on target triplet `myarch-none-elf`, `CROSS_COMPILE` would be set to `/opt/mytoolchain/bin/myarch-none-elf-`.

2.15.13 Custom CMake Toolchains

To use a custom toolchain defined in an external CMake file, *set these environment variables*:

- Set *ZEPHYR_TOOLCHAIN_VARIANT* to your toolchain's name
- Set TOOLCHAIN_ROOT to the path to the directory containing your toolchain's CMake configuration files.

Zephyr will then include the toolchain cmake files located in the TOOLCHAIN_ROOT directory:

- cmake/toolchain/<toolchain name>/generic.cmake: configures the toolchain for "generic" use, which mostly means running the C preprocessor on the generated *Devicetree* file.
- cmake/toolchain/<toolchain name>/target.cmake: configures the toolchain for "target" use, i.e. building Zephyr and your application's source code.

Here <toolchain name> is the same as the name provided in *ZEPHYR_TOOLCHAIN_VARIANT* See the zephyr files cmake/modules/FindHostTools.cmake and cmake/modules/FindTargetTools.cmake for more details on what your generic.cmake and target.cmake files should contain.

You can also set ZEPHYR_TOOLCHAIN_VARIANT and TOOLCHAIN_ROOT as CMake variables when generating a build system for a Zephyr application, like so:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

```
cmake -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=...
```

If you do this, -C <initial-cache> cmake option may useful. If you save your **ZEPHYR_TOOLCHAIN_VARIANT**, **TOOLCHAIN_ROOT**, and other settings in a file named my-toolchain.cmake, you can then invoke cmake as cmake -C my-toolchain.cmake ... to save typing.

Zephyr includes include/zephyr/toolchain.h which again includes a toolchain specific header based on the compiler identifier, such as __llvm__ or __GNUC__. Some custom compilers identify themselves as the compiler on which they are based, for example llvm which then gets the toolchain/llvm.h included. This included file may though not be right for the custom toolchain. In order to solve this, and thus to get the include/other.h included instead, add the set(TOOLCHAIN_USE_CUSTOM 1) cmake line to the generic.cmake and/or target.cmake files located under <TOOLCHAIN_ROOT>/cmake/toolchain/<toolchain name>/.

When **TOOLCHAIN_USE_CUSTOM** is set, the other.h must be available out-of-tree and it must include the correct header for the custom toolchain. A good location for the other.h header file, would be a directory under the directory specified in TOOLCHAIN_ROOT as include/zephyr/toolchain. To get the toolchain header included in zephyr's build, the **USERINCLUDE** can be set to point to the include directory, as shown here:

```
west build -- -DZEPHYR_TOOLCHAIN_VARIANT=... -DTOOLCHAIN_ROOT=... -DUSERINCLUDE=...
```

2.15.14 Embedded Linker (ELD)

ELD is Qualcomm's open-source, LLVM-based, GNU-compatible linker. It can be used as an alternative to LLD or GNU ld when building Zephyr with an LLVM toolchain (for example *Arm Toolchain for Embedded* or a host clang). See the ELD user guide for details on ELD itself.

ELD is just a linker (ld.eld); a separate C/C++ toolchain is still required to compile sources.

Installation

There are three ways to obtain ELD:

1. **Nightly binary release.** Prebuilt ld.eld binaries are published on the ELD releases page.

2. **Build from source.** Build ELD against an LLVM tree as described in the ELD README; an integrated `llvm-project` build produces `ld.eld` under the build tree's `bin/` directory.
3. **Full toolchain via cpullvm.** The cpullvm toolchain is a complete LLVM toolchain for Arm, AArch64 and RISC-V embedded targets that bundles both `ld.eld` and `ld.lld` along with clang, the runtime libraries and headers. Prebuilt cpullvm archives are published on its cpullvm releases page for Linux and Windows, and cpullvm 22.1.1 has been tested with Zephyr in the ELD CI.

Options 1 and 2 only provide `ld.eld`; a separate LLVM toolchain (clang, runtime libraries and headers) is still needed to build Zephyr.

Verify the installation:

```
$ ld.eld --version
eld 22.0 (GNU Compatible linker)
```

ELD 22.0 or later is required.

Usage

ELD is selected through the `host/llvm` toolchain variant. Point `LLVM_TOOLCHAIN_PATH` at the LLVM toolchain (for example a cpullvm installation, or another toolchain with `ld.eld` on its `bin/` directory or *PATH*), then enable ELD by setting `CONFIG_LLVM_USE_ELD` to `y`.

For example:

```
west build ... -- -DZEPHYR_TOOLCHAIN_VARIANT=host/llvm \
                  -DLLVM_TOOLCHAIN_PATH=<path-to-llvm-toolchain> \
                  -DCONFIG_LLVM_USE_ELD=y
```

See *Arm Toolchain for Embedded (ATfE)* or *Zephyr SDK* for more on configuring an LLVM toolchain.

2.16 Tools and IDEs

2.16.1 CLion

Note

This guide describes how to set up, build, and debug Zephyr's sample application in CLion, using the IDE's CMake integration. This approach is no longer optimal.

CLion now features native Zephyr West integration which provides an easier and more intuitive way to open, build, and run/debug Zephyr projects. This guide will be updated soon, but is still valid if you prefer to use CMake.

CLion is a cross-platform C/C++ IDE that supports multi-threaded RTOS debugging.

This guide describes the process of setting up, building, and debugging Zephyr's multi-thread-blinky sample in CLion.

The instructions have been tested on Windows. In terms of the CLion workflow, the steps would be the same for macOS and Linux, but make sure to select the correct environment file and to adjust the paths.

Get CLion

Download CLion and install it.

Initialize a new workspace

This guide gives details on how to build and debug the multi-thread-blinky sample application, but the instructions would be similar for any Zephyr project and *workspace layout*.

Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.

Open the project in CLion

1. In CLion, click *Open* on the Welcome screen or select *File* ▸ *Open* from the main menu.
2. Navigate to your Zephyr workspace (i.e.the `zephyrproject` folder in your HOME directory if you have followed the Getting Started instructions), then select `zephyr/samples/basic/threads` or another sample project folder.

   Click *OK*.
3. If prompted, click *Trust Project*.

   See the Project security section in CLion web help for more information on project security.

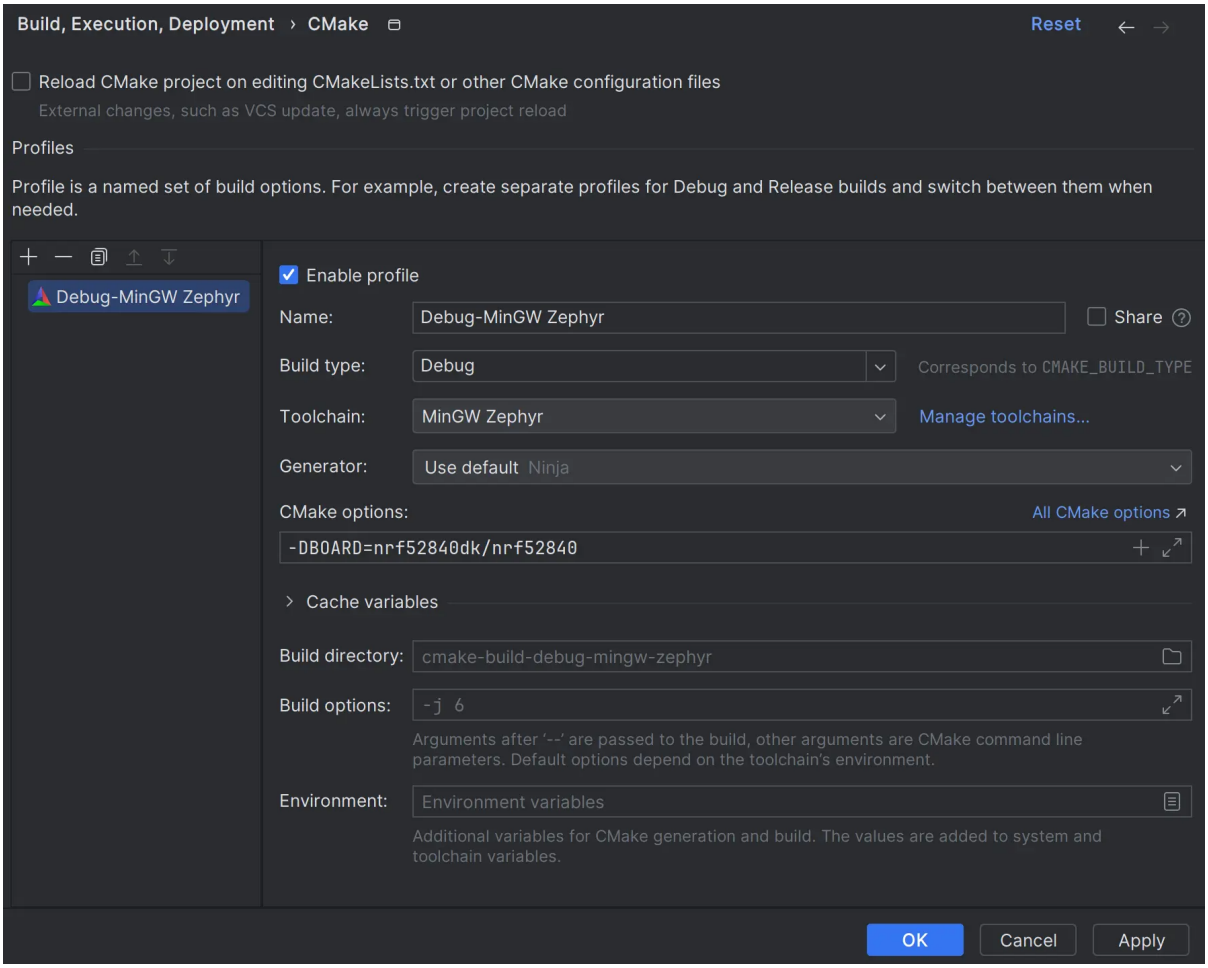
Configure the toolchain and CMake profile

CLion will open the *Open Project Wizard* with the CMake profile settings. If that does not happen, go to *Settings* ▸ *Build, Execution, Deployment* ▸ *CMake*.

1. Click *Manage Toolchains* next to the *Toolchain* field. This will open the *Toolchain* settings dialog.
2. We recommend that you use the *Bundled MinGW* toolchain with default settings on Windows, or the *System* (default) toolchain on Unix machines.
3. Click *Add environment* ▸ *From file* and select `..\.venv\Scripts\activate.bat`.

   Click *Apply* to save the changes.
4. Back in the CMake profile settings dialog, specify your board in the *CMake options* field. For example:

```
-DBOARD=nrf52840dk/nrf52840
```



5. Click *Apply* to save the changes.

   CMake load should finish successfully.

Configure Zephyr parameters for debug

1. In the configuration switcher on the top right, select *guiconfig* and click the hammer icon.
2. Use the GUI application to set the following flags:

```
DEBUG_THREAD_INFO
THREAD_RUNTIME_STATS
DEBUG_OPTIMIZATIONS
```

Build the project

In the configuration switcher, select **zephyr_final** and click the hammer icon.

Note that other CMake targets like `puncover` or `hardenconfig` can also be called at this point.

Enable RTOS integration

1. Go to *Settings* ▸ *Build, Execution, Deployment* ▸ *Embedded Development* ▸ *RTOS Integration*.
2. Set the *Enable RTOS Integration* checkbox.

This option enables Zephyr tasks view during debugging. See Multi-threaded RTOS debug in CLion web help for more information.

You can leave the option set to *Auto*. CLion will detect Zephyr automatically.

Create an Embedded GDB Server configuration

In order to debug a Zephyr application in CLion, you need to create a run/debug configuration out of the Embedded GDB Server template.

Instructions below show the case of a Nordic Semiconductor board and a Segger J-Link debug probe. If your setup is different, make sure to adjust the configuration settings accordingly.

1. Select *Run* ▸ *New Embedded Configuration* from the main menu.
2. Configure the settings:

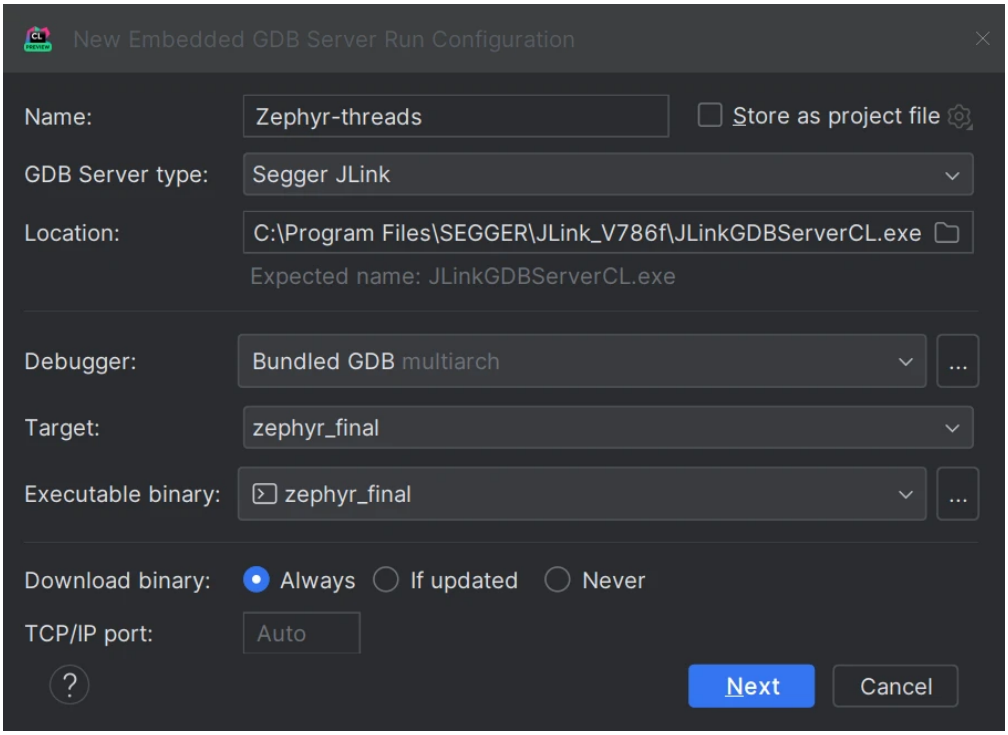
Option	Value
Nam (optiona	Zephyr-threads
GDB Serv Type	Segger JLink
Location	The path to `JLinkGDBServerCL.exe` on Windows or the `JLinkGDBServer` binary on macOS/Linux.
Debugger	Bundled GDB **Note** For non-ARM and non-x86 architectures, use a GDB executable from Zephyr SDK. Make sure to pick a version with Python support (for example, **riscv64-zephyr-elf-gdb-py**) and check that Python is present in the system `PATH`.
Target	zephyr-final
Executa binary	zephyr-final
Download binary	Always
TCP/ port	Auto

3. Click *Next* to set the Segger J-Link parameters.

4. Click *Create* when ready.

Start debugging

1. Place breakpoints by clicking in the left gutter next to the code lines.



New Embedded GDB Server Run Configuration
Name:

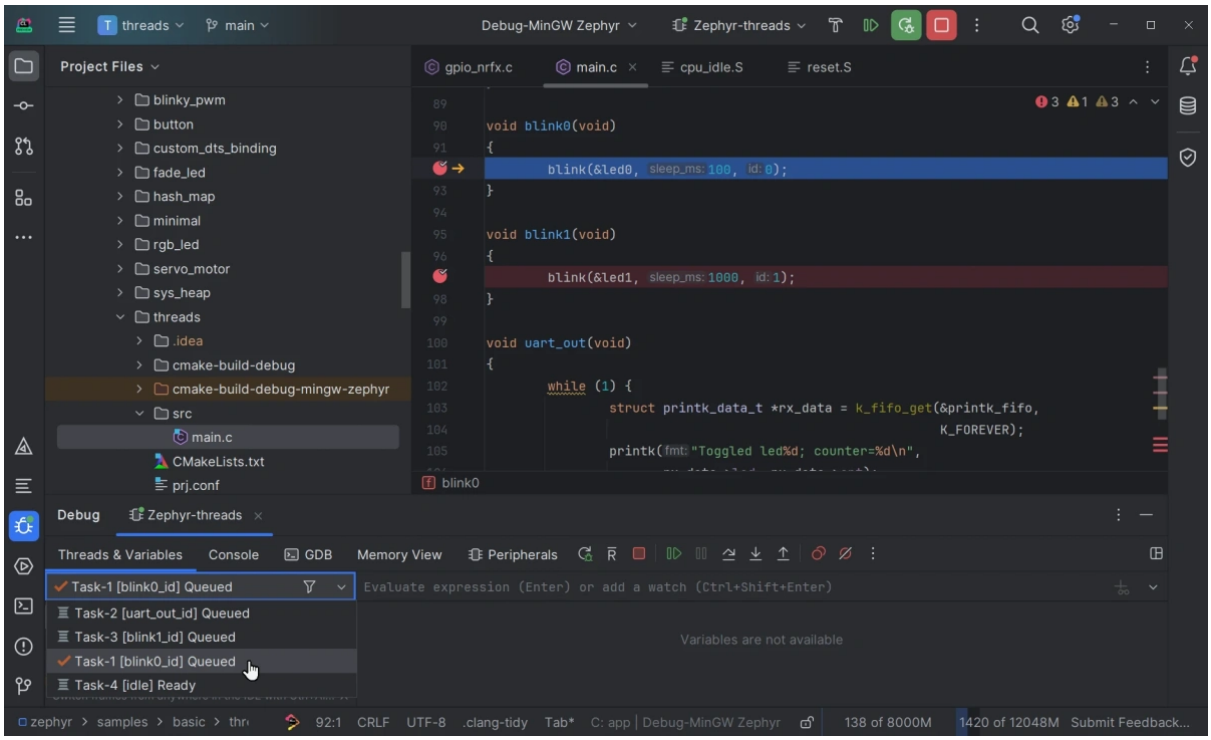
nRF53
nRF91
Nuclei System
Previous
Create
Cancel

2. Make sure that **Zephyr-threads** is selected in the configuration switcher and click the bug icon or press `Ctrl+D`.
3. When a breakpoint is hit, CLion opens the Debug tool window.

   Zephyr tasks are listed in the *Threads & Variables* pane. You can switch between them and inspect the variables for each task.



Refer to CLion web help for detailed description of the IDE debug capabilities.

2.16.2 Coccinelle

Coccinelle is a tool for pattern matching and text transformation that has many uses in kernel development, including the application of complex, tree-wide patches and detection of problematic programming patterns.

> **Note**
>
> Linux and macOS development environments are supported, but not Windows.

Getting Coccinelle

The semantic patches included in the kernel use features and options which are provided by Coccinelle version 1.0.0-rc11 and above. Using earlier versions will fail as the option names used by the Coccinelle files and `coccicheck` have been updated.

Coccinelle is available through the package manager of many distributions, e.g. :

- Debian
- Fedora
- Ubuntu
- OpenSUSE

- Arch Linux
- NetBSD
- FreeBSD

Some distribution packages are obsolete and it is recommended to use the latest version released from the Coccinelle homepage at https://coccinelle.lip6.fr/

Or from Github at:

https://github.com/coccinelle/coccinelle

Once you have it, run the following commands:

```
./autogen
./configure
make
```

as a regular user, and install it with:

```
sudo make install
```

More detailed installation instructions to build from source can be found at:

https://github.com/coccinelle/coccinelle/blob/master/install.txt

Supplemental documentation

For Semantic Patch Language(SmPL) grammar documentation refer to:

https://coccinelle.gitlabpages.inria.fr/website/documentation.html

Using Coccinelle on Zephyr

`coccicheck` checker is the front-end to the Coccinelle infrastructure and has various modes:

Four basic modes are defined: `patch`, `report`, `context`, and `org`. The mode to use is specified by setting `--mode=<mode>` or `-m=<mode>`.

- `patch` proposes a fix, when possible.
- `report` generates a list in the following format: file:line:column-column: message
- `context` highlights lines of interest and their context in a diff-like style.Lines of interest are indicated with `-`.
- `org` generates a report in the Org mode format of Emacs.

Note that not all semantic patches implement all modes. For easy use of Coccinelle, the default mode is `report`.

Two other modes provide some common combinations of these modes.

- `chain` tries the previous modes in the order above until one succeeds.
- `rep+ctxt` runs successively the report mode and the context mode. It should be used with the C option (described later) which checks the code on a file basis.

Examples

To make a report for every semantic patch, run the following command:

```
./scripts/coccicheck --mode=report
```

To produce patches, run:

```
./scripts/coccicheck --mode=patch
```

The `coccicheck` target applies every semantic patch available in the sub-directories of `scripts/coccinelle` to the entire source code tree.

For each semantic patch, a commit message is proposed. It gives a description of the problem being checked by the semantic patch, and includes a reference to Coccinelle.

As any static code analyzer, Coccinelle produces false positives. Thus, reports must be carefully checked, and patches reviewed.

To enable verbose messages set `--verbose=1` option, for example:

```
./scripts/coccicheck --mode=report --verbose=1
```

Coccinelle parallelization

By default, `coccicheck` tries to run as parallel as possible. To change the parallelism, set the `--jobs=<number>` option. For example, to run across 4 CPUs:

```
./scripts/coccicheck --mode=report --jobs=4
```

As of Coccinelle 1.0.2 Coccinelle uses Ocaml parmap for parallelization, if support for this is detected you will benefit from parmap parallelization.

When parmap is enabled `coccicheck` will enable dynamic load balancing by using `--chunksize 1` argument, this ensures we keep feeding threads with work one by one, so that we avoid the situation where most work gets done by only a few threads. With dynamic load balancing, if a thread finishes early we keep feeding it more work.

When parmap is enabled, if an error occurs in Coccinelle, this error value is propagated back, the return value of the `coccicheck` command captures this return value.

Using Coccinelle with a single semantic patch

The option `--cocci` can be used to check a single semantic patch. In that case, the variable must be initialized with the name of the semantic patch to apply.

For instance:

```
./scripts/coccicheck --mode=report --cocci=<example.cocci>
```

or:

```
./scripts/coccicheck --mode=report --cocci=./path/to/<example.cocci>
```

Controlling which files are processed by Coccinelle

By default the entire source tree is checked.

To apply Coccinelle to a specific directory, pass the path of specific directory as an argument.

For example, to check `drivers/usb/` one may write:

```
./scripts/coccicheck --mode=patch drivers/usb/
```

The `report` mode is the default. You can select another one with the `--mode=<mode>` option explained above.

Debugging Coccinelle SmPL patches

Using `coccicheck` is best as it provides in the spatch command line include options matching the options used when we compile the kernel. You can learn what these options are by using verbose option, you could then manually run Coccinelle with debug options added.

Alternatively you can debug running Coccinelle against SmPL patches by asking for stderr to be redirected to stderr, by default stderr is redirected to /dev/null, if you'd like to capture stderr you can specify the `--debug=file.err` option to `coccicheck`. For instance:

```
rm -f cocci.err
./scripts/coccicheck --mode=patch --debug=cocci.err
cat cocci.err
```

Debugging support is only supported when using Coccinelle >= 1.0.2.

Additional Flags

Additional flags can be passed to spatch through the SPFLAGS variable. This works as Coccinelle respects the last flags given to it when options are in conflict.

```
./scripts/coccicheck --sp-flag="--use-glimpse"
```

Coccinelle supports idutils as well but requires coccinelle >= 1.0.6. When no ID file is specified coccinelle assumes your ID database file is in the file .id-utils.index on the top level of the kernel, coccinelle carries a script scripts/idutils_index.sh which creates the database with:

```
mkid -i C --output .id-utils.index
```

If you have another database filename you can also just symlink with this name.

```
./scripts/coccicheck --sp-flag="--use-idutils"
```

Alternatively you can specify the database filename explicitly, for instance:

```
./scripts/coccicheck --sp-flag="--use-idutils /full-path/to/ID"
```

Sometimes coccinelle doesn't recognize or parse complex macro variables due to insufficient definition. Therefore, to make it parsable we explicitly provide the prototype of the complex macro using the `---macro-file-builtins <headerfile.h>` flag.

The `<headerfile.h>` should contain the complete prototype of the complex macro from which spatch engine can extract the type information required during transformation.

For example:

`Z_SYSCALL_HANDLER` is not recognized by coccinelle. Therefore, we put its prototype in a header file, say for example `mymacros.h`.

```
$ cat mymacros.h
#define Z_SYSCALL_HANDLER int xxx
```

Now we pass the header file `mymacros.h` during transformation:

```
./scripts/coccicheck --sp-flag="---macro-file-builtins mymacros.h"
```

See `spatch --help` to learn more about spatch options.

Note that the `--use-glimpse` and `--use-idutils` options require external tools for indexing the code. None of them is thus active by default. However, by indexing the code with one of these tools, and according to the cocci file used, spatch could proceed the entire code base more quickly.

SmPL patch specific options

SmPL patches can have their own requirements for options passed to Coccinelle. SmPL patch specific options can be provided by providing them at the top of the SmPL patch, for instance:

```
// Options: --no-includes --include-headers
```

Proposing new semantic patches

New semantic patches can be proposed and submitted by kernel developers. For sake of clarity, they should be organized in the sub-directories of `scripts/coccinelle/`.

The cocci script should have the following properties:

- The script **must** have `report` mode.
- The first few lines should state the purpose of the script using `///` comments . Usually, this message would be used as the commit log when proposing a patch based on the script.

Example

```
/// Use ARRAY_SIZE instead of dividing sizeof array with sizeof an element
```

- A more detailed information about the script with exceptional cases or false positives (if any) can be listed using `//#` comments.

Example

```
//# This makes an effort to find cases where ARRAY_SIZE can be used such as
//# where there is a division of sizeof the array by the sizeof its first
//# element or by any indexed element or the element type. It replaces the
//# division of the two sizeofs by ARRAY_SIZE.
```

- Confidence: It is a property defined to specify the accuracy level of the script. It can be either `High`, `Moderate` or `Low` depending upon the number of false positives observed.

Example

```
// Confidence: High
```

- Virtual rules: These are required to support the various modes framed in the script. The virtual rule specified in the script should have the corresponding mode handling rule.

Example

```
virtual context

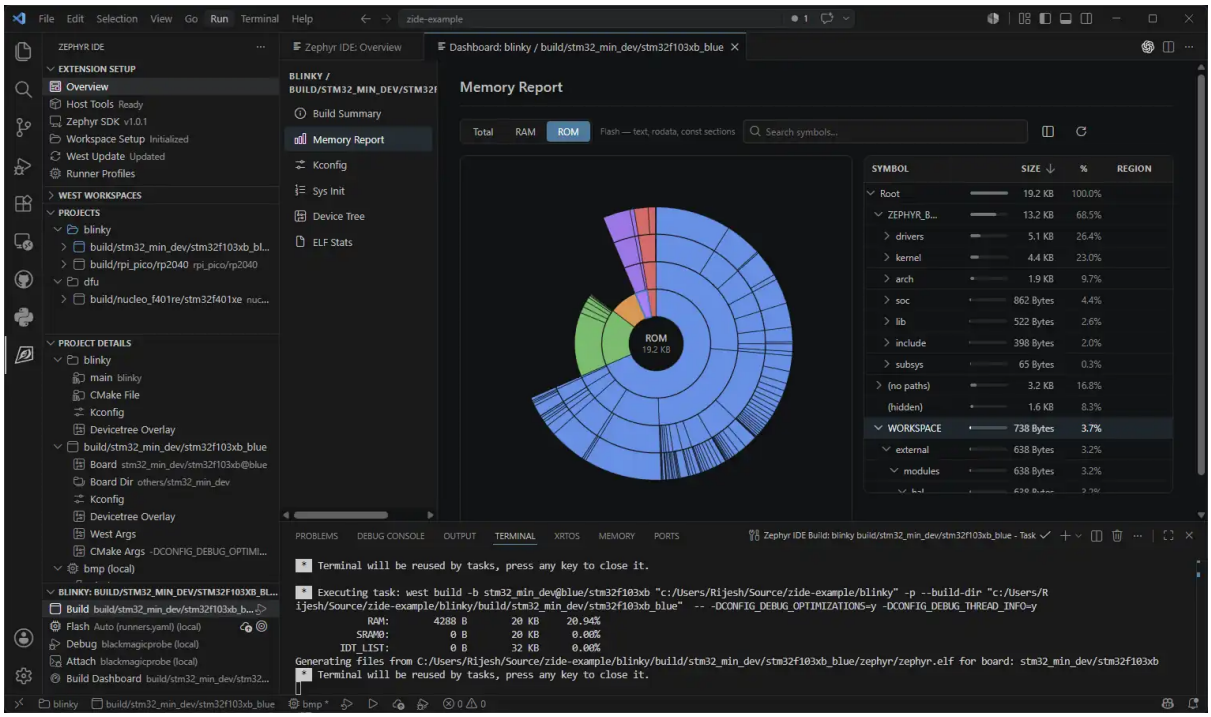
2.16.3 IDE for Zephyr (VS Code extension)

IDE for Zephyr is a Visual Studio Code (VS Code) extension for Zephyr RTOS development. It supports **host tool management**, **west workspace setup**, **SDK management**, **project creation**, **build/flash**, and **debugging**.



Key features

- Integrate with Cortex-Debug for ST-Link, J-Link, OpenOCD, Black Magic Probe, and other probes via the built-in `zephyr-ide-cortex` and `zephyr-ide-west` debugger types that auto-resolve ELF, GDB, and runner paths
- Integrate with clangd or C/C++ for IntelliSense
- Explore memory usage, Kconfig, and devicetree from the Build Dashboard; view ROM and RAM as a sunburst chart without leaving VS Code
- Edit Kconfig options interactively with the built-in editor
- Add, run, and reconfigure Twister tests from the project panel

- Install native host tools (CMake, Python 3, Ninja, DTC, GCC, etc.) automatically on Linux, macOS, and Windows
- Install and manage Zephyr SDK versions and per-architecture toolchains
- Add projects from existing applications or Zephyr samples, with multiple builds and per-build board and configuration overrides
- Store project configuration in a version-controllable `.vscode/zephyr-ide.json`, which can specify SDKs, packages, and blobs

Compatibility

- Windows
- Linux
- macOS

Getting started

1. Install the extension

   Install IDE for Zephyr from the VS Code Marketplace or the Open VSX Registry.

   An extension pack bundling Cortex-Debug, C/C++, Serial Monitor, Devicetree LSP, and CMake support is also available on the VS Code Marketplace (Extension Pack) and the Open VSX Registry (Extension Pack).

2. Open the Overview Page and Install Host Tools

   Click the *Host Tools* card. The extension verifies that the required build dependencies (CMake, Python 3, Ninja, DTC, GCC, etc.) are on the PATH and can install any missing tools automatically.

3. Configure a West workspace

   Click the *Workspace* card and choose a setup method:

   - **IDE for Zephyr Workspace from Git** — clone a repository that already contains a pre-configured IDE for Zephyr workspace.
   - **West Workspace from Git** — clone an existing west-based Zephyr repository.
   - **Standard Workspace** — create a fresh workspace with a Python virtual environment, west installation, and Zephyr repository initialization.
   - **Open Current Directory** — adopt an existing `.west` folder or link to an external Zephyr installation via *ZEPHYR_BASE*.

   This step also prompts you to install a Zephyr SDK if needed. You can manage SDKs later from the *Zephyr SDK* card on the Overview page.

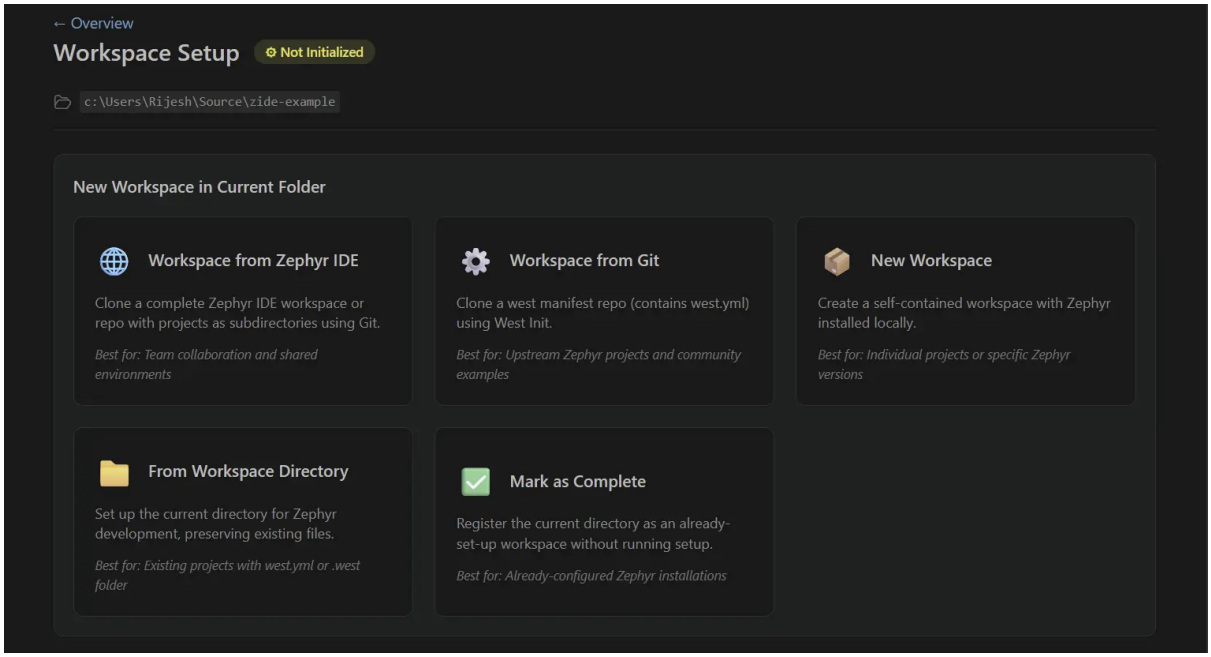
4. Add a project and a build

   In the Project panel, click *Add Project* to add an existing application or copy a Zephyr sample as a starting point.

   After adding a project, click *Add Build* to create a build configuration. Select the target board and, optionally, a runner profile. Each project can have multiple builds targeting different boards or configurations.

5. Build and flash the application

   Use the status bar buttons or the *Project Build* panel to build, flash, or run a pristine build. Build output is shown in the integrated terminal.



6. Configure and run a debug session

   IDE for Zephyr ships a built-in `zephyr-ide-west` debugger type that reads `runners.yaml` from the active build and translates it into a Cortex-Debug session automatically. No `.vscode/launch.json` entry is required to get started. The `zephyr-ide-west` provider accepts the arguments you would pass to `west debugserver`, while the `zephyr-ide-cortex` provider accepts the arguments you would pass to `cortex-debug` directly. You can also set up your own launch configuration and bind it to a build. The extension provides commands that can be resolved on launch.

   To add a launch configuration manually, use the minimal form:

   ```
   {
     "name": "Zephyr IDE: Debug",
     "type": "zephyr-ide-west",
     "request": "launch"
   }
   ```

   The built-in provider selects the runner from `runners.yaml`, resolves the ELF and GDB paths, and forwards the session to Cortex-Debug.

Sharing project configuration

Project settings, builds, runner profiles, Kconfig overlays, devicetree overlays, and per-build west and CMake arguments are stored in `.vscode/zephyr-ide.json`. The file is human-readable and can be committed to version control so team members share the same workspace configuration.

Useful links

- Explore the Extension repository

- Try the Sample project

2.16.4 Kapa.ai Documentation Assistant

The Zephyr documentation website is augmented with an AI assistant powered by Kapa.ai. The assistant is trained on Zephyr's own documentation, source code, and GitHub activity (see *Data sources* below) and can answer free-form questions in natural language, citing the documentation pages and resources it used to build each answer.

The same knowledge base is also exposed through a Model Context Protocol (MCP) server, so that external AI assistants and IDEs can query Zephyr knowledge directly (see *Using the MCP server*).

> **Note**
>
> Answers are AI-generated and may contain inaccuracies. Always verify important information against the official documentation, and treat the assistant as a starting point rather than an authoritative source.

Using the chatbot

The chatbot is available from every page of the documentation:

- Click the chatbot button displayed at the bottom of the page, or
- Press `Ctrl+K` (`Cmd+K` on macOS) to open it from anywhere.

The assistant opens in a sidebar where you can ask questions in plain language, for example *"How do I configure a UART device in the devicetree?"* or *"What is the difference between a workqueue and a thread?"*. Answers include links back to the relevant documentation pages, GitHub issues, or source files so you can dig deeper.

The first time you use the assistant, a one-time consent screen explains how the feature works and what data is collected. See the *Privacy* section below.

> **Tip**
>
> You don't have to ask your questions in English. The assistant detects the language you use and responds in the same language, so you can interact with it in your preferred language (English, Chinese, Spanish, Japanese, French, German, and many others).

AI-powered search

In addition to the chatbot, Kapa.ai can power the documentation search box:

1. Click the gear (*Search settings*) icon next to the search field.
2. Select *Kapa AI search* from the menu.
3. Type your query and press `Enter`.

Instead of the built-in keyword search, your query is answered by the AI assistant. Your selection is remembered, so subsequent searches keep using the engine you picked until you change it back.

Using the MCP server

Kapa.ai also exposes the Zephyr knowledge base as an MCP (Model Context Protocol) server. MCP is an open standard that lets AI assistants and AI-enabled IDEs connect to external tools and knowledge sources. By adding the Zephyr MCP server to your assistant, you give it the ability to query up-to-date Zephyr documentation, source code, and GitHub activity on your behalf.

The server is available at the following endpoint, using the streamable HTTP transport:

```
https://zephyrproject.mcp.kapa.ai
```

The exact configuration steps depend on the MCP client you use. Most clients read a JSON configuration file with an `mcpServers` section similar to the following:

```
{
  "mcpServers": {
    "zephyr-docs": {
      "url": "https://zephyrproject.mcp.kapa.ai"
    }
  }
}
```

Some clients instead expect the server to be launched through a local stdio bridge such as mcp-remote:

```
{
  "mcpServers": {
    "zephyr-docs": {
      "command": "npx", "args": ["-y", "mcp-remote",
↪"https://zephyrproject.mcp.kapa.ai"]
    }
  }
}
```

Refer to the documentation of your specific MCP client (AI coding assistant, IDE extension, etc.) for the precise location and syntax of its configuration.

Tip

Connecting the MCP server to an AI coding assistant lets it answer Zephyr questions and ground its code suggestions in the project's actual documentation and source, rather than relying solely on its training data.

Data sources

Kapa.ai builds its answers exclusively from the following Zephyr project sources, which are synchronized at the indicated frequencies:

Source	Details	Refresh frequency
Source code	`zephyrproject-rtos/zephyr` repository (excluding the `boards/` and `doc/` folders); C, Markdown, Python, and text files	Hourly
API reference	https://docs.zephyrproject.org/latest/doxygen/html/index.html	Daily
Devicetree bindings	https://docs.zephyrproject.org/latest/build/dts/api/bindings.html	Daily
Main documentation	https://docs.zephyrproject.org/latest/ (excluding the API reference and Devicetree bindings sections)	Daily
Project wiki	https://github.com/zephyrproject-rtos/zephyr/wiki	Daily
GitHub issues	`zephyrproject-rtos/zephyr` issues from the last 6 months	Every 5 minutes
GitHub pull requests	`zephyrproject-rtos/zephyr` pull requests from the last 6 months (excluding those closed without being merged)	Every 10 minutes

For the authoritative and most up-to-date configuration, refer to the Kapa.ai page on the Zephyr project infrastructure wiki.

Privacy

The assistant uses your questions to provide answers based on the Zephyr documentation, source code, and GitHub issues and pull requests. Questions and interactions may be anonymously collected and analyzed to help improve the documentation by identifying areas that need clarification. No personally identifiable information is collected.

2.16.5 STM32CubeIDE

STM32CubeIDE is an Eclipse-based integrated development environment from STMicroelectronics designed for the STM32 series of MCUs and MPUs.

This guide describes the process of setting up, building, and debugging Zephyr applications using the IDE.

A project must have already been created with Zephyr and west.

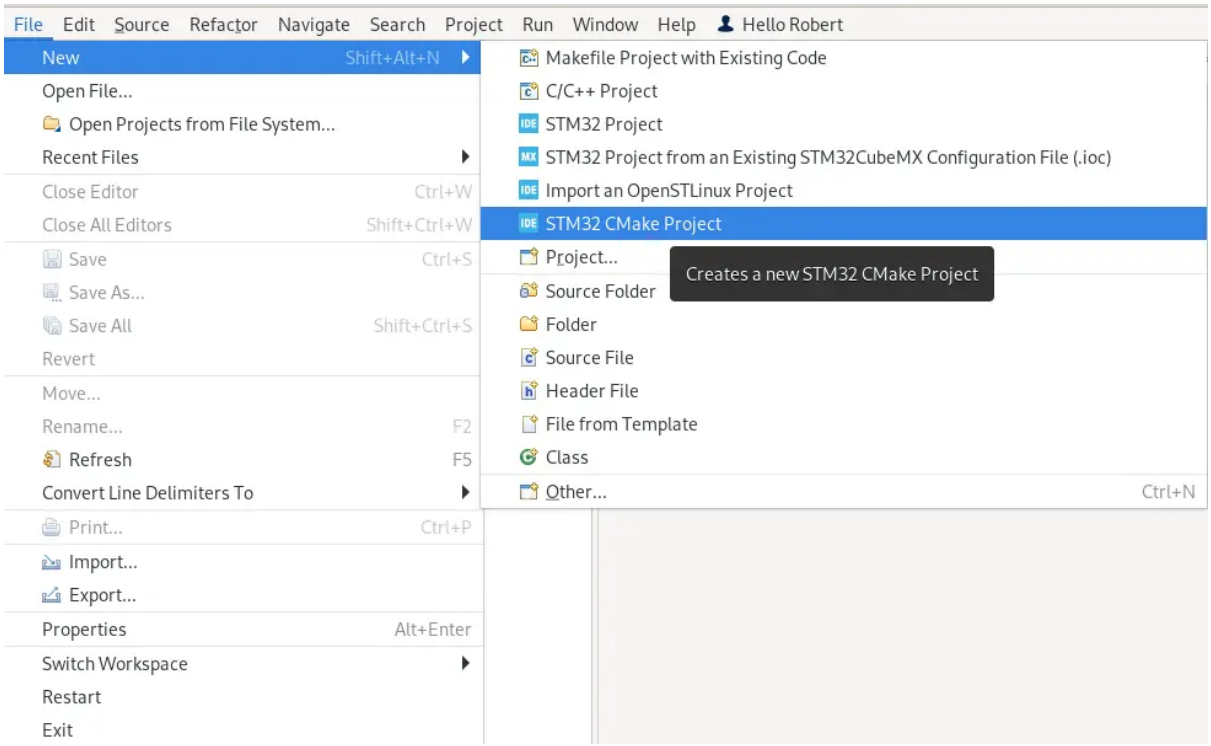
These directions have been validated to work with version 1.16.0 of the IDE on Linux.

Project Setup

1. Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.
2. Run STM32CubeIDE from your Zephyr environment. Example:

   ```
   $ /opt/st/stm32cubeide_1.16.0/stm32cubeide
   ```

3. Open your already existing project by going to *File* ▸ *New* ▸ *STM32 CMake Project*:
4. Select *Project with existing CMake sources*, then click *Next*.
5. Select *Next* and browse to the location of your sources. The folder that is opened should have the `CMakeLists.txt` and `prj.conf` files.
6. Select *Next* and select the appropriate MCU. Press *Finish* and your project should now be available. However, more actions must still be done in order to configure it properly.



7. Right-click on the newly created project in the workspace, and select *Properties*.
8. Go to the *C/C++ Build* page and set the Generator to `Ninja`. In *Other Options*, specify the target `BOARD` in CMake argument format. If an out-of-tree board is targeted, the `BOARD_ROOT` option must also be set. The resulting settings page should look similar to this:

   These options may or may not be needed depending on if you have an out-of-tree project or not.
9. Go to the *C/C++ General ▸ Preprocessor Include* page. Select the *GNU C* language, and click on the *CDT User Settings Entries* option.

   Click *Add* to add an *Include File* that points to Zephyr's `autoconf.h`, which is located in `<build dir>/zephyr/include/generated/autoconf.h`. This will ensure that STM32CubeIDE picks up Zephyr configuration options. The following dialog will be shown. Fill it in as follows:

   Once the include file has been added, your properties page should look similar to the following:
10. Click *Apply and Close*
11. You may now build the project using the *Build* button on the toolbar. The project can be run using the *Run* button, as well as debugged using the *Debug* button.

Debugging only

If you only want to use STM32CubeIDE to debug your project you can proceed as follows:

1. First, make sure to compile your project and have the `zephyr.elf` available.
2. Run STM32CubeIDE and import your project by going to *File ▸ Import...*:
3. Select *C/C++ ▸ STM32 Cortex-M Executable*, then click *Next*:
4. Click on *Browse* to browse to your build folder and select your `zephyr.elf`.
5. Click on *Select* to select your MCU. If relevant, choose also your CPU and/or core.
6. Click on *Finish*.

7. The project can now be debugged using the *Debug* button.

2.16.6 Visual Studio Code

Visual Studio Code (VS Code for short) is a popular cross-platform IDE that supports C projects and has a rich set of extensions.

This guide describes the process of setting up VS Code for Zephyr's blinky sample in VS Code.

The instructions have been tested on Linux, but the steps should be the same for macOS and Windows, just make sure to adjust the paths if needed.

Get VS Code

Download VS Code and install it.

Install the required extensions through the *Extensions* marketplace in the left panel. Search for the C/C++ Extension Pack and install it.

Initialize a new workspace

This guide gives details on how to configure the blinky sample application, but the instructions would be similar for any Zephyr project and *workspace layout*.

Before you start, make sure you have a working Zephyr development environment, as per the instructions in the *Getting Started Guide*.

Open the project in VS Code

1. In VS Code, select *File* ▸ *Open Folder* from the main menu.

2. Navigate to your Zephyr workspace and select it (i.e. the `zephyrproject` folder in your HOME directory if you have followed the Getting Started instructions).
3. If prompted, enable workspace trust.

Generate compile commands

In order to support code navigation and linting capabilities, you must compile your project once to generate the `compile_commands.json` file that will provide the C/C++ extension with the required information (ex. include paths). You may do it from VS Code embedded terminal; select *Terminal* ▸ *New Terminal* from the top menu or the command palette (`Ctrl+Shift+P`), then type:

```
$ cd zephyr
$ west build -p always -b native_sim/native/64 samples/basic/blinky
```

Configure the C/C++ extension

You'll now need to point to the generated `compile_commands.json` file to enable linting and code navigation in VS Code.

1. Go to the *File* ▸ *Preferences* ▸ *Settings* in the VS Code top menu.
2. Search for the parameter *C_Cpp* > *Default: Compile Commands* and set its value to: `zephyr/build/compile_commands.json`.

   Linting errors in the code should now be resolved, and you should be able to navigate through the code.

Additional resources

There are many other extensions that can be useful when working with Zephyr and VS Code. While this guide does not cover them yet, you may refer to their documentation to set them up:

Contribution tooling

- Checkpatch Extension
- EditorConfig Extension

Documentation languages extensions

- reStructuredText Extension Pack

IDE extensions

- CMake Extension documentation
- nRF Kconfig Extension
- nRF DeviceTree Extension
- GNU Linker Map files Extension

Additional guides

- How to Develop Zephyr Apps with a Modern, Visual IDE

> **Note**
>
> Please be aware that these extensions might not all have the same level of quality and maintenance.

2.16.7 Workbench for Zephyr

Workbench for Zephyr is a Visual Studio Code (VS Code) extension that adds Zephyr development support, including **SDK management**, **project creation wizard**, **build/flash**, and **debugging**.

Check the Getting started tutorial for a walkthrough.

Key features

- Install native Host Tools (Python, CMake, ...)
- Install and assign toolchains (Zephyr SDK, IAR, ...)
- Import West workspaces
- Create and import Zephyr applications
- Build and flash applications
- Debug applications
- Install runners automatically
- Perform memory and static analysis

Compatibility

- Windows 10-11
- Linux (x86_64)
  - Ubuntu
  - Debian
  - Fedora
  - Other distributions may also work (not tested)
- macOS

Getting started

1. Install the extension

   Install Workbench for Zephyr from the VS Code Marketplace.

2. Open the Workbench for Zephyr extension

   In the Activity Bar, click the *Workbench for Zephyr* icon.

3. Install Host Tools

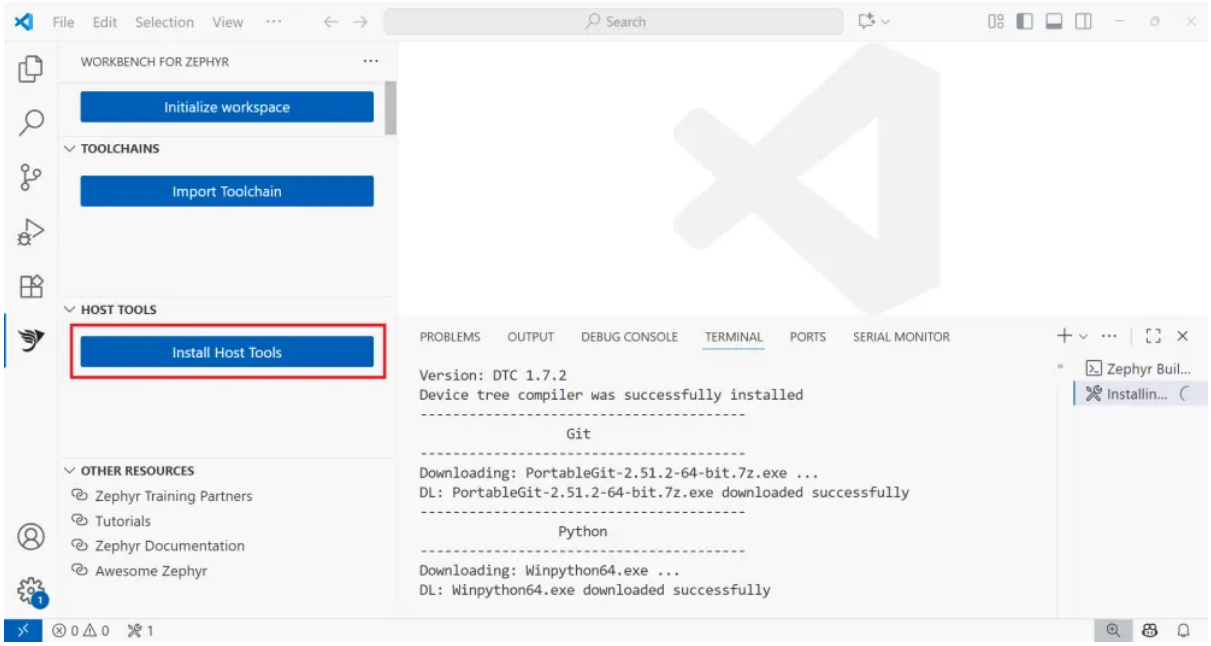
   Click *Install Host Tools* to download and install the native tools (typically into `${HOME}/.zinstaller`).

   > **Note**
   >
   > Some host tools may require administrator privileges. On Windows, this is required when installing 7z. On Linux, this is required when installing tools using the package manager, for example when running `apt install`.

4. Import a toolchain

   Click *Import Toolchain*, choose a toolchain, and select the destination folder.

   A toolchain provides the compiler and debugger required to build and debug Zephyr applications. The Zephyr SDK is the recommended option and can be installed as either the full



package or a minimal target-specific version. Workbench also supports other toolchains, such as IAR.

5. Initialize / Import a West workspace

   Click *Initialize workspace* and fill the workspace information.

   Workbench will create the workspace and parse the west manifest to configure projects.

6. Create a new application

   On Workbench for Zephyr, new projects are based on samples from Zephyr sources.

   - Click *Create New Application*.
   - Select the *West Workspace* to attach to.
   - Select the *Zephyr SDK* to use.
   - Select the target *Board* (for example, `ST STM32F4 Discovery`).
   - Select the *Sample* project to base on (for example, `hello_world`).
   - Enter the project name.
   - Enter the project location.

7. Build the application

   Click *Build* in the status bar, or select the application folder to build. Build output is shown in the integrated terminal.

8. Configure and run a debug session

   Use *Debug Manager* to generate/update a debug configuration (`.vscode/launch.json`):

   - Generated ELF (Program Path)
   - SVD file (optional)
   - GDB/port/address (if needed)
   - Debug server/runner (OpenOCD, J-Link, LinkServer, pyOCD, ...)

   Then start debugging normally via *Run and Debug*

Chapter 3

Kernel

3.1 Kernel Services

The Zephyr kernel lies at the heart of every Zephyr application. It provides a low footprint, high performance, multi-threaded execution environment with a rich set of available features. The rest of the Zephyr ecosystem, including device drivers, networking stack, and application-specific code, uses the kernel's features to create a complete application.

The configurable nature of the kernel allows you to incorporate only those features needed by your application, making it ideal for systems with limited amounts of memory (as little as 2 KB!) or with simple multi-threading requirements (such as a set of interrupt handlers and a single background task). Examples of such systems include: embedded sensor hubs, environmental sensors, simple LED wearable, and store inventory tags.

Applications requiring more memory (50 to 900 KB), multiple communication devices (like Wi-Fi and Bluetooth Low Energy), and complex multi-threading, can also be developed using the Zephyr kernel. Examples of such systems include: fitness wearables, smart watches, and IoT wireless gateways.

3.1.1 Scheduling, Interrupts, and Synchronization

These pages cover basic kernel services related to thread scheduling and synchronization.

Threads

Note

There is also limited support for using *Operation without Threads*.

  - *Terminating a Thread*
- *Runtime Statistics*
- *Runtime Stack Safety*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

This section describes kernel services for creating, scheduling, and deleting independently executable threads of instructions.

A *thread* is a kernel object that is used for application processing that is too lengthy or too complex to be performed by an ISR.

Any number of threads can be defined by an application (limited only by available RAM). Each thread is referenced by a *thread id* that is assigned when the thread is spawned.

A thread has the following key properties:

- A **stack area**, which is a region of memory used for the thread's stack. The **size** of the stack area can be tailored to conform to the actual needs of the thread's processing. Special macros exist to create and work with stack memory regions.
- A **thread control block** for private kernel bookkeeping of the thread's metadata. This is an instance of type `k_thread`.
- An **entry point function**, which is invoked when the thread is started. Up to 3 **argument values** can be passed to this function.
- A **scheduling priority**, which instructs the kernel's scheduler how to allocate CPU time to the thread. (See *Scheduling*.)
- A set of **thread options**, which allow the thread to receive special treatment by the kernel under specific circumstances. (See *Thread Options*.)
- A **start delay**, which specifies how long the kernel should wait before starting the thread.
- An **execution mode**, which can either be supervisor or user mode. By default, threads run in supervisor mode and allow access to privileged CPU instructions, the entire memory

address space, and peripherals. User mode threads have a reduced set of privileges. This depends on the CONFIG_USERSPACE option. See *User Mode*.

Lifecycle

Thread Creation A thread must be created before it can be used. The kernel initializes the thread control block as well as one end of the stack portion. The remainder of the thread's stack is typically left uninitialized.

Specifying a start delay of K_NO_WAIT instructs the kernel to start thread execution immediately. Alternatively, the kernel can be instructed to delay execution of the thread by specifying a timeout value – for example, to allow device hardware used by the thread to become available.

The kernel allows a delayed start to be canceled before the thread begins executing. A cancellation request has no effect if the thread has already started. A thread whose delayed start was successfully canceled must be re-spawned before it can be used.

Starting a Thread A thread that is created with K_FOREVER as its start delay is not added to the scheduler's ready queue and does not begin executing until it is explicitly started. The k_thread_start() function starts such an inactive thread, making it eligible for scheduling. Starting a thread that has already started has no effect.

This is useful when a thread object must be created at one point in time but its execution deferred until the application has completed additional setup.

Thread Termination Once a thread is started it typically executes forever. However, a thread may synchronously end its execution by returning from its entry point function. This is known as **termination**.

A thread that terminates is responsible for releasing any shared resources it may own (such as mutexes and dynamically allocated memory) prior to returning, since the kernel does *not* reclaim them automatically.

In some cases a thread may want to sleep until another thread terminates. This can be accomplished with the k_thread_join() API. This will block the calling thread until either the timeout expires, the target thread self-exits, or the target thread aborts (either due to a k_thread_abort() call or triggering a fatal error).

Once a thread has terminated, the kernel guarantees that no use will be made of the thread struct. The memory of such a struct can then be reused for any purpose, including spawning a new thread. Note that the thread must be fully terminated, which presents race conditions where a thread's own logic signals completion which is seen by another thread before the kernel processing is complete. Under normal circumstances, application code should use k_thread_join() or k_thread_abort() to synchronize on thread termination state and not rely on signaling from within application logic.

Thread Aborting A thread may asynchronously end its execution by **aborting**. The kernel automatically aborts a thread if the thread triggers a fatal error condition, such as dereferencing a null pointer.

A thread can also be aborted by another thread (or by itself) by calling k_thread_abort(). However, it is typically preferable to signal a thread to terminate itself gracefully, rather than aborting it.

As with thread termination, the kernel does not reclaim shared resources owned by an aborted thread.

> **Note**
>
> The kernel does not currently make any claims regarding an application's ability to respawn a thread that aborts.

Thread Suspension A thread can be prevented from executing for an indefinite period of time if it becomes **suspended**. The function `k_thread_suspend()` can be used to suspend any thread, including the calling thread. Suspending a thread that is already suspended has no additional effect.

Once suspended, a thread cannot be scheduled until another thread calls `k_thread_resume()` to remove the suspension.

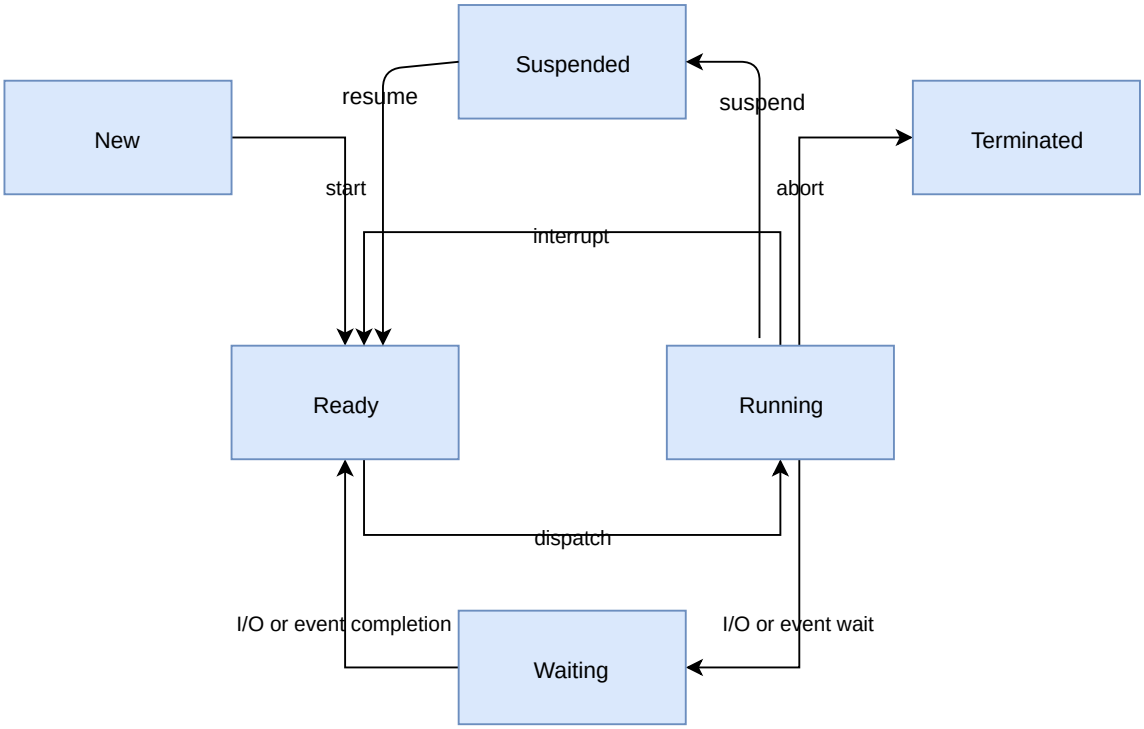
> **Note**
>
> A thread can prevent itself from executing for a specified period of time using `k_sleep()`. However, this is different from suspending a thread since a sleeping thread becomes executable automatically when the time limit is reached.

Thread States A thread that has no factors that prevent its execution is deemed to be **ready**, and is eligible to be selected as the current thread.

A thread that has one or more factors that prevent its execution is deemed to be **unready**, and cannot be selected as the current thread.

The following factors make a thread unready:

- The thread has not been started.
- The thread is waiting for a kernel object to complete an operation. (For example, the thread is taking a semaphore that is unavailable.)
- The thread is waiting for a timeout to occur.
- The thread has been suspended.
- The thread has terminated or aborted.



Note

Although the diagram above may appear to suggest that both **Ready** and **Running** are distinct thread states, that is not the correct interpretation. **Ready** is a thread state, and **Running** is a schedule state that only applies to **Ready** threads.

Thread Stack objects Every thread requires its own stack buffer for the CPU to push context. Depending on configuration, there are several constraints that must be met:

- There may need to be additional memory reserved for memory management structures
- If guard-based stack overflow detection is enabled, a small write-protected memory management region must immediately precede the stack buffer to catch overflows.
- If userspace is enabled, a separate fixed-size privilege elevation stack must be reserved to serve as a private kernel stack for handling system calls.
- If userspace is enabled, the thread's stack buffer must be appropriately sized and aligned such that a memory protection region may be programmed to exactly fit.

The alignment constraints can be quite restrictive, for example some MPUs require their regions to be of some power of two in size, and aligned to its own size.

Because of this, portable code can't simply pass an arbitrary character buffer to `k_thread_create()`. Special macros exist to instantiate stacks statically, prefixed with `K_KERNEL_STACK` and `K_THREAD_STACK`.

Additionally, stacks may be instantiated dynamically using `k_thread_stack_alloc()` and subsequently freed with `k_thread_stack_free()`.

Kernel-only Stacks If it is known that a thread will never run in user mode, or the stack is being used for special contexts like handling interrupts, it is best to define stacks using the `K_KERNEL_STACK` macros.

These stacks save memory because an MPU region will never need to be programmed to cover

the stack buffer itself, and the kernel will not need to reserve additional room for the privilege elevation stack, or memory management data structures which only pertain to user mode threads.

Attempts from user mode to use stacks declared in this way will result in a fatal error for the caller.

If `CONFIG_USERSPACE` is not enabled, the set of `K_THREAD_STACK` macros have an identical effect to the `K_KERNEL_STACK` macros.

Thread stacks If it is known that a stack will need to host user threads, or if this cannot be determined, define the stack with `K_THREAD_STACK` macros. This may use more memory but the stack object is suitable for hosting user threads.

If `CONFIG_USERSPACE` is not enabled, the set of `K_THREAD_STACK` macros have an identical effect to the `K_KERNEL_STACK` macros.

Thread Priorities A thread's priority is an integer value, and can be either negative or non-negative. Numerically lower priorities takes precedence over numerically higher values. For example, the scheduler gives thread A of priority 4 *higher* priority over thread B of priority 7; likewise thread C of priority -2 has higher priority than both thread A and thread B.

The scheduler distinguishes between two classes of threads, based on each thread's priority.

- A *cooperative thread* has a negative priority value. Once it becomes the current thread, a cooperative thread remains the current thread until it performs an action that makes it unready.
- A *preemptible thread* has a non-negative priority value. Once it becomes the current thread, a preemptible thread may be supplanted at any time if a cooperative thread, or a preemptible thread of higher or equal priority, becomes ready.

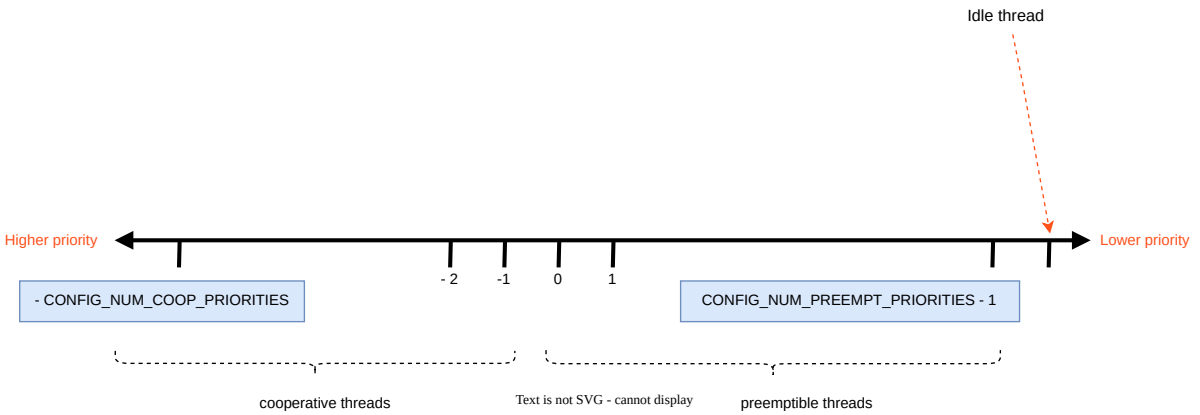
A thread's initial priority value can be altered up or down after the thread has been started. Thus it is possible for a preemptible thread to become a cooperative thread, and vice versa, by changing its priority.

Note

The scheduler does not make heuristic decisions to re-prioritize threads. Thread priorities are set and changed only at the application's request.

The kernel supports a virtually unlimited number of thread priority levels. The configuration options `CONFIG_NUM_COOP_PRIORITIES` and `CONFIG_NUM_PREEMPT_PRIORITIES` specify the number of priority levels for each class of thread, resulting in the following usable priority ranges:

- cooperative threads: (`-CONFIG_NUM_COOP_PRIORITIES`) to -1
- preemptive threads: 0 to (`CONFIG_NUM_PREEMPT_PRIORITIES` - 1)



For example, configuring 5 cooperative priorities and 10 preemptive priorities results in the ranges -5 to -1 and 0 to 9, respectively.

Meta-IRQ Priorities When enabled (see CONFIG_NUM_METAIRQ_PRIORITIES), there is a special subclass of cooperative priorities at the highest (numerically lowest) end of the priority space: meta-IRQ threads. These are scheduled according to their normal priority, but also have the special ability to preempt all other threads (and other meta-IRQ threads) at lower priorities, even if those threads are cooperative and/or have taken a scheduler lock. Meta-IRQ threads are still threads, however, and can still be interrupted by any hardware interrupt.

> **Note**
>
> When a cooperative (or schedule-locked) thread that was preempted by a meta-IRQ thread resumes its execution after the meta-IRQ thread completes, it will be on the same CPU–assuming it was neither suspended nor aborted. This helps ensure that these threads are not unexpectedly shuffled to another CPU while in the midst of querying the properties associated with their own CPU.

This behavior makes the act of unblocking a meta-IRQ thread (by any means, e.g. creating it, calling k_sem_give(), etc.) into the equivalent of a synchronous system call when done by a lower priority thread, or an ARM-like "pended IRQ" when done from true interrupt context. The intent is that this feature will be used to implement interrupt "bottom half" processing and/or "tasklet" features in driver subsystems. The thread, once woken, will be guaranteed to run before the current CPU returns into application code.

Unlike similar features in other OSes, meta-IRQ threads are true threads and run on their own stack (which must be allocated normally), not the per-CPU interrupt stack. Design work to enable the use of the IRQ stack on supported architectures is pending.

Note that because this breaks the promise made to cooperative threads by the Zephyr API (namely that the OS won't schedule other thread until the current thread deliberately blocks), it should be used only with great care from application code. These are not simply very high priority threads and should not be used as such.

Thread Options The kernel supports a small set of *thread options* that allow a thread to receive special treatment under specific circumstances. The set of options associated with a thread are specified when the thread is spawned.

A thread that does not require any thread option has an option value of zero. A thread that requires a thread option specifies it by name, using the | character as a separator if multiple options are needed (i.e. combine options using the bitwise OR operator).

The following thread options are supported.

K_ESSENTIAL
: This option tags the thread as an *essential thread*. This instructs the kernel to treat the termination or aborting of the thread as a fatal system error.

  By default, the thread is not considered to be an essential thread.

K_SSE_REGS
: This x86-specific option indicate that the thread uses the CPU's SSE registers. Also see K_FP_REGS.

  By default, the kernel does not attempt to save and restore the contents of these registers when scheduling the thread.

K_FP_REGS
: This option indicate that the thread uses the CPU's floating point registers. This instructs the kernel to take additional steps to save and restore the contents of these registers when scheduling the thread. (For more information see *Floating Point Services*.)

By default, the kernel does not attempt to save and restore the contents of this register when scheduling the thread.

K_USER
: If CONFIG_USERSPACE is enabled, this thread will be created in user mode and will have reduced privileges. See *User Mode*. Otherwise this flag does nothing.

K_INHERIT_PERMS
: If CONFIG_USERSPACE is enabled, this thread will inherit all kernel object permissions that the parent thread had, except the parent thread object. See *User Mode*.

Thread Custom Data Every thread has a 32-bit *custom data* area, accessible only by the thread itself, and may be used by the application for any purpose it chooses. The default custom data value for a thread is zero.

> **Note**
>
> Custom data support is not available to ISRs because they operate within a single shared kernel interrupt handling context.

By default, thread custom data support is disabled. The configuration option CONFIG_THREAD_CUSTOM_DATA can be used to enable support.

The k_thread_custom_data_set() and k_thread_custom_data_get() functions are used to write and read a thread's custom data, respectively. A thread can only access its own custom data, and not that of another thread.

The following code uses the custom data feature to record the number of times each thread calls a specific routine.

> **Note**
>
> Obviously, only a single routine can use this technique, since it monopolizes the use of the custom data feature.

```
int call_tracking_routine(void)
{
    uint32_t call_count;

    if (k_is_in_isr()) {
        /* ignore any call made by an ISR */
    } else {
        call_count = (uint32_t)k_thread_custom_data_get();
        call_count++;
        k_thread_custom_data_set((void *)call_count);
    }

    /* do rest of routine's processing */
    ...
}
```

Use thread custom data to allow a routine to access thread-specific information, by using the custom data as a pointer to a data structure owned by the thread.

Thread Name When CONFIG_THREAD_NAME is enabled, a human-readable name can be associated with each thread. Names are primarily an aid for debugging, logging, and shell introspection; the kernel does not use them for scheduling.

A thread name may be assigned in one of two ways:

- Statically, by passing a name to `K_THREAD_DEFINE`.
- At run time, using `k_thread_name_set()`. The supplied string must remain valid for the lifetime of the thread, as only a pointer to it is retained.

A thread's name can be retrieved with `k_thread_name_get()`, which returns a pointer to the name string, or with `k_thread_name_copy()`, which copies the name into a caller-supplied buffer. The copying variant is the safe choice from user mode, where the calling thread may not have access to the memory backing another thread's name.

If `CONFIG_THREAD_NAME` is not enabled, `k_thread_name_set()` returns an error and `k_thread_name_get()` returns `NULL`.

Thread Introspection The kernel provides several interfaces for inspecting threads at run time.

Identifying the current thread
`k_current_get()` returns the thread id (`k_tid_t`) of the thread that is currently executing. This id can be passed to the other thread APIs to operate on the calling thread.

Reading a thread's priority
`k_thread_priority_get()` returns the current scheduling priority of a thread. This reflects any changes made since the thread was created, for example by `k_thread_priority_set()`.

Obtaining a thread's state
`k_thread_state_str()` writes a human-readable representation of a thread's current state (for example `pending`, `suspended`, or `ready`) into a caller-supplied buffer. This is intended for diagnostic output and should not be parsed programmatically.

Iterating over all threads
When `CONFIG_THREAD_MONITOR` is enabled, `k_thread_foreach()` invokes a caller-supplied callback once for each thread in the system. It holds an internal lock that blocks thread creation and termination for the duration of the iteration, which guarantees a consistent snapshot of the thread list but can introduce latency proportional to the number of threads. `k_thread_foreach_unlocked()` is a lower-latency variant that releases the lock around each callback at the cost of a less strictly consistent view.

Querying stack usage
When `CONFIG_INIT_STACKS` and `CONFIG_THREAD_STACK_INFO` are enabled, `k_thread_stack_space_get()` reports the number of unused bytes remaining in a thread's stack, computed by scanning the stack for its unused (still-initialized) region. This complements the build-time stack analysis tools and the runtime stack safety feature described below.

Querying a pending timeout
A thread that is blocked on a timed operation (such as `k_sleep()` or a kernel object operation with a timeout) has a pending timeout. Its remaining duration can be queried in ticks with `k_thread_timeout_remaining_ticks()`, and the absolute system tick at which it will expire with `k_thread_timeout_expires_ticks()`. Both return zero if the thread has no pending timeout.

Implementation

Spawning a Thread A thread is spawned by defining its stack area and its thread control block, and then calling `k_thread_create()`.

The stack area may be statically allocated using `K_THREAD_STACK_DEFINE` or `K_KERNEL_STACK_DEFINE` to ensure it is properly set up in memory.

The size parameter for the stack must be one of three values:

- The original requested stack size passed to K_THREAD_STACK or K_KERNEL_STACK family of stack instantiation macros.
- For a stack object defined with the K_THREAD_STACK family of macros, the return value of K_THREAD_STACK_SIZEOF() for that object.
- For a stack object defined with the K_KERNEL_STACK family of macros, the return value of K_KERNEL_STACK_SIZEOF() for that object.

Alternatively, the stack area may be dynamically allocated using k_thread_stack_alloc() and freed using k_thread_stack_free().

The thread spawning function returns its thread id, which can be used to reference the thread.

The following code spawns a thread that starts immediately.

```
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);
struct k_thread my_thread_data;

k_tid_t my_tid = k_thread_create(&my_thread_data, my_stack_area,
                                 K_THREAD_STACK_SIZEOF(my_stack_area),
                                 my_entry_point,
                                 NULL, NULL, NULL,
                                 MY_PRIORITY, 0, K_NO_WAIT);
```

Alternatively, a thread can be declared at compile time by calling K_THREAD_DEFINE. Observe that the macro defines the stack area, control block, and thread id variables automatically.

The following code has the same effect as the code segment above.

```
#define MY_STACK_SIZE 500
#define MY_PRIORITY 5

extern void my_entry_point(void *, void *, void *);

K_THREAD_DEFINE(my_tid, MY_STACK_SIZE,
                my_entry_point, NULL, NULL, NULL,
                MY_PRIORITY, 0, 0);
```

Note

The delay parameter to k_thread_create() is a k_timeout_t value, so K_NO_WAIT means to start the thread immediately. The corresponding parameter to K_THREAD_DEFINE is a duration in integral milliseconds, so the equivalent argument is 0.

The following code dynamically allocates a thread stack, waits until the thread has joined, and then frees the dynamically allocated thread stack.

```
extern void my_entry_point(void *, void *, void *);

k_tid_t my_tid;
void *my_stack_area;

my_stack_area = k_thread_stack_alloc(CONFIG_DYNAMIC_THREAD_STACK_SIZE);
```

(continues on next page)

(continued from previous page)

```
my_tid = k_thread_create(&my_thread_data, my_stack_area,
                         CONFIG_DYNAMIC_THREAD_STACK_SIZE,
                         my_entry_point,
                         NULL, NULL, NULL,
                         MY_PRIORITY, 0, K_NO_WAIT);
k_thread_join(my_tid, K_FOREVER);
k_thread_stack_free(my_stack_area);
```

User Mode Constraints This section only applies if CONFIG_USERSPACE is enabled, and a user thread tries to create a new thread. The k_thread_create() API is still used, but there are additional constraints which must be met or the calling thread will be terminated:

- The calling thread must have permissions granted on both the child thread and stack parameters; both are tracked by the kernel as kernel objects.
- The child thread and stack objects must be in an uninitialized state, i.e. it is not currently running and the stack memory is unused.
- The stack size parameter passed in must be equal to or less than the bounds of the stack object when it was declared.
- The K_USER option must be used, as user threads can only create other user threads.
- The K_ESSENTIAL option must not be used, user threads may not be considered essential threads.
- The priority of the child thread must be a valid priority value, and equal to or lower than the parent thread.

Dropping Permissions If CONFIG_USERSPACE is enabled, a thread running in supervisor mode may perform a one-way transition to user mode using the k_thread_user_mode_enter() API. This is a one-way operation which will reset and zero the thread's stack memory. The thread will be marked as non-essential.

Terminating a Thread A thread terminates itself by returning from its entry point function.

The following code illustrates the ways a thread can terminate.

```
void my_entry_point(int unused1, int unused2, int unused3)
{
    while (1) {
        ...
        if (<some condition>) {
            return; /* thread terminates from mid-entry point function */
        }
        ...
    }

    /* thread terminates at end of entry point function */
}
```

If CONFIG_USERSPACE is enabled, aborting a thread will additionally mark the thread and stack objects as uninitialized so that they may be reused.

Runtime Statistics Thread runtime statistics can be gathered and retrieved if CONFIG_THREAD_RUNTIME_STATS is enabled, for example, total number of execution cycles of a thread.

By default, the runtime statistics are gathered using the default kernel timer. For some architectures, SoCs or boards, there are timers with higher resolution available via timing functions. Using of these timers can be enabled via CONFIG_THREAD_RUNTIME_STATS_USE_TIMING_FUNCTIONS.

Here is an example:

```
k_thread_runtime_stats_t rt_stats_thread;

k_thread_runtime_stats_get(k_current_get(), &rt_stats_thread);

printk("Cycles: %llu\n", rt_stats_thread.execution_cycles);
```

The combined statistics for every thread in the system can be retrieved with k_thread_runtime_stats_all_get(), which reports the aggregate runtime usage across all threads (including the idle thread). This is useful for computing overall CPU utilization.

When CONFIG_SCHED_THREAD_USAGE is enabled, statistics collection can be toggled at run time on a per-thread basis with k_thread_runtime_stats_enable() and k_thread_runtime_stats_disable(). Whether collection is currently active for a thread can be checked with k_thread_runtime_stats_is_enabled(). Disabling collection for threads that do not need to be measured reduces the bookkeeping overhead incurred on each context switch.

Runtime Stack Safety When CONFIG_THREAD_RUNTIME_STACK_SAFETY is enabled, the kernel provides routines that scan a thread's stack at runtime to determine how much of it remains unused. If the amount of unused stack space is found to have dropped below a configurable per-thread threshold, a user-defined handler is invoked.

This feature is intended for use by monitoring software. The handler may, for example, log a warning, suspend or abort the offending thread, or even reboot the system. It complements the build-time stack analysis tools and the hardware-based stack overflow detection by allowing a system to react *before* a stack is exhausted.

Each thread has an *unused stack threshold*, expressed in bytes. When a stack safety check finds that a thread's unused stack space is below this threshold, the supplied handler is called. A threshold of 0 bytes (the default) disables the check for that thread. The default threshold applied to newly created threads is derived from CONFIG_THREAD_RUNTIME_STACK_SAFETY_DEFAULT_UNUSED_THRESHOLD_PCT, which expresses it as a percentage of each thread's total stack size.

The threshold for an individual thread can be set or queried at runtime:

- k_thread_runtime_stack_unused_threshold_pct_set() sets the threshold as a percentage (0 to 99) of the thread's total stack size.
- k_thread_runtime_stack_unused_threshold_set() sets the threshold as an absolute number of bytes.
- k_thread_runtime_stack_unused_threshold_get() retrieves the current threshold (in bytes).

Two routines perform the actual check. Both accept a pointer that, on return, receives the amount of unused stack space, and a k_thread_stack_safety_handler_t handler (plus a user argument) that is invoked if the threshold has been crossed:

- k_thread_runtime_stack_safety_full_check() scans the entire stack to compute the exact amount of unused space.
- k_thread_runtime_stack_safety_threshold_check() performs an abbreviated scan that only looks for evidence that the thread has crossed its configured threshold. This is cheaper than a full check but does not yield an exact measure of unused space.

Here is an example that configures a thread to invoke a handler once its unused stack space drops below 10% of its total stack size:

```
void stack_safety_handler(const struct k_thread *thread,
                          size_t unused_space, void *arg)
{
        printk("Thread %p low on stack: %zu bytes unused\n",
               thread, unused_space);
}

/* Trigger the handler once less than 10% of the stack remains unused */
k_thread_runtime_stack_unused_threshold_pct_set(my_tid, 10);

/* Periodically check the thread from a monitoring context */
k_thread_runtime_stack_safety_full_check(my_tid, NULL,
                                         stack_safety_handler, NULL);
```

Suggested Uses Use threads to handle processing that cannot be handled in an ISR.

Use separate threads to handle logically distinct processing operations that can execute in parallel.

Configuration Options Related configuration options:

Thread Stack APIs

Scheduling

The kernel's priority-based scheduler allows an application's threads to share the CPU.

Concepts The scheduler determines which thread is allowed to execute at any point in time; this thread is known as the **current thread**.

There are various points in time when the scheduler is given an opportunity to change the identity of the current thread, meaning when the scheduler switches the CPU's execution from one thread to another. These points are called **reschedule points**. Some potential reschedule points are:

- transition of a thread from running state to a suspended or waiting state, for example by `k_sem_take()` or `k_sleep()`.
- transition of a thread to the *ready state*, for example by `k_sem_give()` or `k_thread_start()`
- return to thread context after processing an interrupt
- when a running thread invokes `k_yield()`

A thread **sleeps** when it voluntarily initiates an operation that transitions itself to a suspended or waiting state.

Whenever the scheduler changes the identity of the current thread, or when execution of the current thread is replaced by an ISR, the kernel first saves the current thread's CPU register values. These register values get restored when the thread later resumes execution.

Scheduling Algorithm The kernel's scheduler selects the highest priority ready thread to be the current thread. When multiple ready threads of the same priority exist, the scheduler chooses the one that has been waiting longest.

A thread's relative priority is primarily determined by its static priority. However, when both earliest-deadline-first scheduling is enabled (`CONFIG_SCHED_DEADLINE`) and a choice of threads have equal static priority, then the thread with the earlier deadline is considered to have the higher priority. Thus, when earliest-deadline-first scheduling is enabled, two threads are only considered to have the same priority when both their static priorities and deadlines are equal. The routine `k_thread_deadline_set()` is used to set a thread's deadline.

> **Note**
>
> Execution of ISRs takes precedence over thread execution, so the execution of the current thread may be replaced by an ISR at any time unless interrupts have been masked. This applies to both cooperative threads and preemptive threads.

The kernel can be built with one of several choices for the ready queue implementation, offering different choices between code size, constant factor runtime overhead and performance scaling when many threads are added.

- Simple linked-list ready queue (`CONFIG_SCHED_SIMPLE`)

  The scheduler ready queue will be implemented as a simple unordered list, with very fast constant time performance for single threads and very low code size. This implementation should be selected on systems with constrained code size that will never see more than a small number (3, maybe) of runnable threads in the queue at any given time. On most platforms (that are not otherwise using the red/black tree) this results in a savings of ~2k of code size.

- Red/black tree ready queue (`CONFIG_SCHED_SCALABLE`)

  The scheduler ready queue will be implemented as a red/black tree. This has rather slower constant-time insertion and removal overhead, and on most platforms (that are not oth-

erwise using the red/black tree somewhere) requires an extra ~2kb of code. The resulting behavior will scale cleanly and quickly into the many thousands of threads.

Use this for applications needing many concurrent runnable threads (> 20 or so). Most applications won't need this ready queue implementation.

- Traditional multi-queue ready queue (`CONFIG_SCHED_MULTIQ`)

  When selected, the scheduler ready queue will be implemented as the classic/textbook array of lists, one per priority.

  This corresponds to the scheduler algorithm used in Zephyr versions prior to 1.12.

  It incurs only a tiny code size overhead vs. the "dumb" scheduler and runs in O(1) time in almost all circumstances with very low constant factor. But it requires a fairly large RAM budget to store those list heads, and the limited features make it incompatible with features like deadline scheduling that need to sort threads more finely, and SMP affinity which need to traverse the list of threads.

  Typical applications with small numbers of runnable threads probably want the simple scheduler.

The wait_q abstraction used in IPC primitives to pend threads for later wakeup shares the same backend data structure choices as the scheduler, and can use the same options.

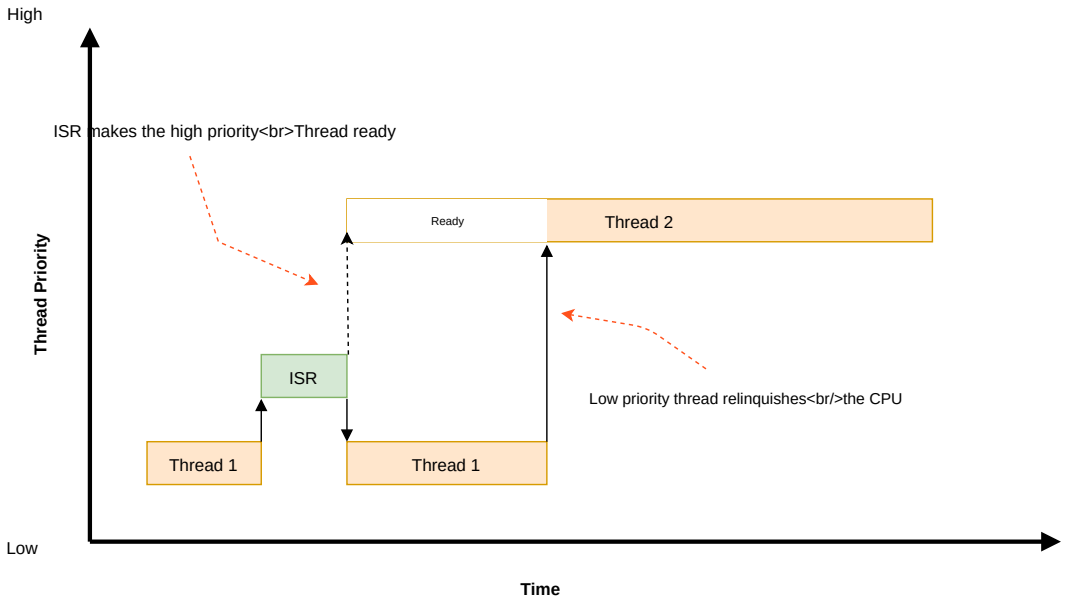
- Scalable wait_q implementation (`CONFIG_WAITQ_SCALABLE`)

  When selected, the wait_q will be implemented with a balanced tree. Choose this if you expect to have many threads waiting on individual primitives. There is a ~2kb code size increase over `CONFIG_WAITQ_SIMPLE` (which may be shared with `CONFIG_SCHED_SCALABLE`) if the red/black tree is not used elsewhere in the application, and pend/unpend operations on "small" queues will be somewhat slower (though this is not generally a performance path).

- Simple linked-list wait_q (`CONFIG_WAITQ_SIMPLE`)

  When selected, the wait_q will be implemented with a doubly-linked list. Choose this if you expect to have only a few threads blocked on any single IPC primitive.

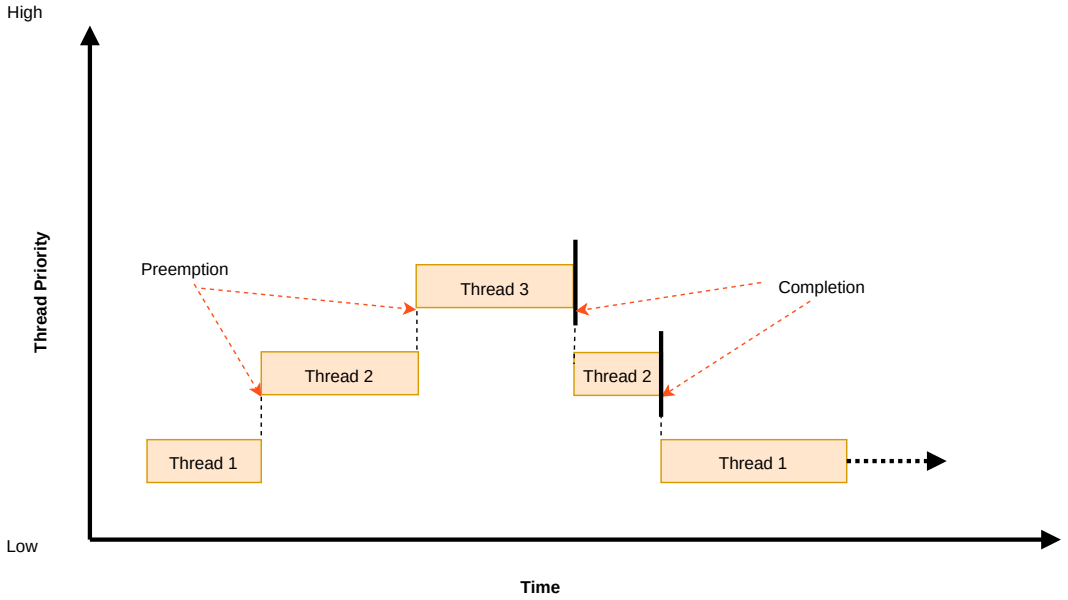
Cooperative Time Slicing Once a cooperative thread becomes the current thread, it remains the current thread until it performs an action that makes it unready. Consequently, if a cooperative thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of higher priority and equal priority.



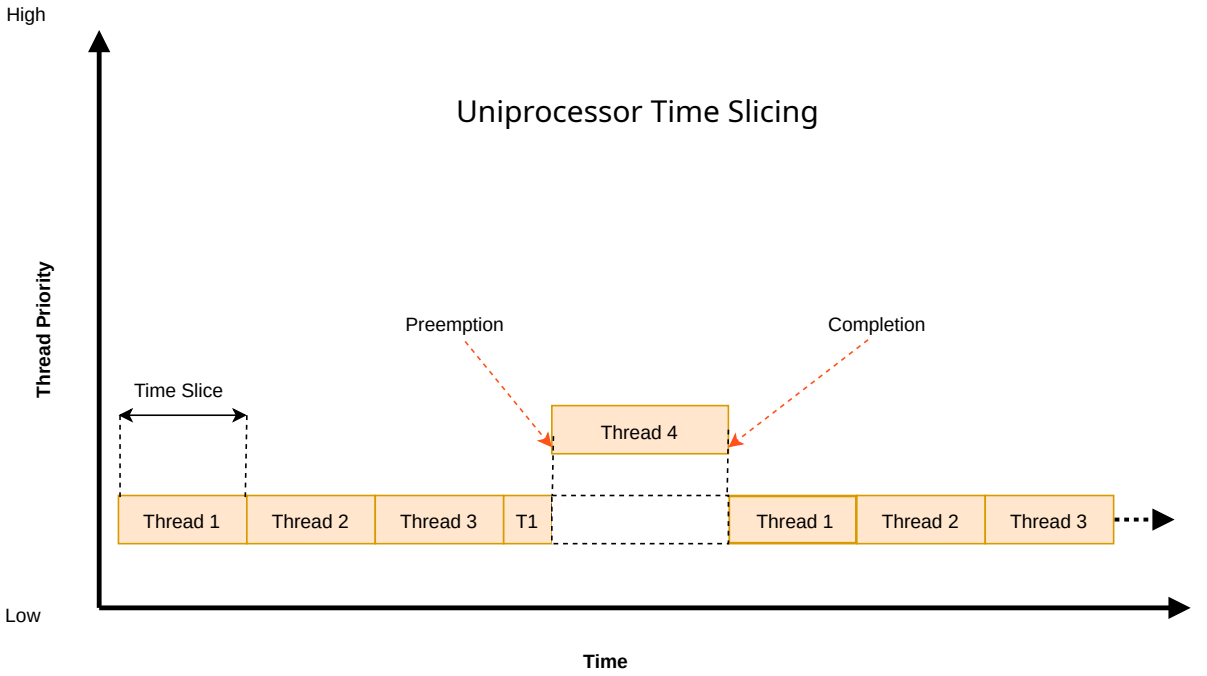
To overcome such problems, a cooperative thread can voluntarily relinquish the CPU from time to time to permit other threads to execute. A thread can relinquish the CPU in two ways:

- Calling `k_yield()` puts the thread at the back of the scheduler's prioritized list of ready threads, and then invokes the scheduler. All ready threads whose priority is higher or equal to that of the yielding thread are then allowed to execute before the yielding thread is rescheduled. If no such ready threads exist, the scheduler immediately reschedules the yielding thread without context switching.
- Calling `k_sleep()` makes the thread unready for a specified time period. Ready threads of *all* priorities are then allowed to execute; however, there is no guarantee that threads whose priority is lower than that of the sleeping thread will actually be scheduled before the sleeping thread becomes ready once again.

Preemptive Time Slicing Once a preemptive thread becomes the current thread, it remains the current thread until a higher priority thread becomes ready, or until the thread performs an action that makes it unready. Consequently, if a preemptive thread performs lengthy computations, it may cause an unacceptable delay in the scheduling of other threads, including those of equal priority.



To overcome such problems, a preemptive thread can perform cooperative time slicing (as described above), or the scheduler's time slicing capability can be used to allow other threads of the same priority to execute.



Note

For SMP, the behavior would be similar to the above UP image, except that Thread 1 would not immediately follow Thread 4. Instead it would be Thread 2, Thread 3, Thread 1, ...

The scheduler divides time on each CPU into a series of **time slices**, where slices are measured in system clock ticks. The time slice size is configurable, but this size can be changed while the application is running. Scheduling a new thread causes the time slice timer to be reset.

At the end of every time slice, the scheduler checks to see if the current thread is preemptible and, if so, implicitly invokes `k_yield()` on behalf of the thread. This gives other ready threads of the same priority the opportunity to execute before the current thread is scheduled again. If no other threads of equal priority are ready, then the current thread remains the current thread.

Threads with a priority higher than specified limit are exempt from preemptive time slicing, and are never preempted by a thread of equal priority. This allows an application to use preemptive time slicing only when dealing with lower priority threads that are less time-sensitive.

Note

The kernel's time slicing algorithm does *not* ensure that a set of equal-priority threads receive an equitable amount of CPU time, since it does not measure the amount of time a thread actually gets to execute. However, the algorithm *does* ensure that a thread never executes for longer than a single time slice without being required to yield.

Per-Thread Time Slicing The time slice configured with `k_sched_time_slice_set()` applies globally to every preemptible thread at or below a given priority. When `CONFIG_TIMESLICE_PER_THREAD` is enabled, an individual thread can instead be given its own time slice with `k_thread_time_slice_set()`. A per-thread slice takes precedence over the global value, and is applied even to threads whose priority is above the global time-slicing limit.

In addition to a slice duration (expressed in ticks), a per-thread slice registers a callback that the kernel invokes when the slice expires. This callback runs in interrupt context while the affected thread is still the current thread, and may, for example, adjust the thread's priority or slice for

its next execution, or suspend it.

Scheduler Locking A preemptible thread that does not wish to be preempted while performing a critical operation can instruct the scheduler to temporarily treat it as a cooperative thread by calling `k_sched_lock()`. This prevents other threads from interfering while the critical operation is being performed.

Once the critical operation is complete the preemptible thread must call `k_sched_unlock()` to restore its normal, preemptible status.

If a thread calls `k_sched_lock()` and subsequently performs an action that makes it unready, the scheduler will switch the locking thread out and allow other threads to execute. When the locking thread again becomes the current thread, its non-preemptible status is maintained.

> **Note**
>
> Locking out the scheduler is a more efficient way for a preemptible thread to prevent preemption than changing its priority level to a negative value.

Thread Sleeping A thread can call `k_sleep()` to delay its processing for a specified time period. During the time the thread is sleeping the CPU is relinquished to allow other ready threads to execute. Once the specified delay has elapsed the thread becomes ready and is eligible to be scheduled once again.

A sleeping thread can be woken up prematurely by another thread using `k_wakeup()`. This technique can sometimes be used to permit the secondary thread to signal the sleeping thread that something has occurred *without* requiring the threads to define a kernel synchronization object, such as a semaphore. Waking up a thread that is not sleeping is allowed, but has no effect.

Busy Waiting A thread can call `k_busy_wait()` to perform a `busy wait` that delays its processing for a specified time period *without* relinquishing the CPU to another ready thread.

A busy wait is typically used instead of thread sleeping when the required delay is too short to warrant having the scheduler context switch from the current thread to another thread and then back again.

Forcing a Scheduling Decision A thread can force the scheduler to make an immediate scheduling decision on the current CPU by calling `k_reschedule()`. When invoked from a thread (with interrupts unlocked) the scheduler runs immediately; when invoked from an ISR the decision is deferred until the ISR exits.

Unlike `k_yield()`, this routine does not guarantee a switch to a thread of equal or higher priority – it simply asks the kernel to re-evaluate which thread should run next given the current state. Most applications never need this routine.

Querying Preemptibility Code whose behavior depends on whether it can be preempted can query the current context with `k_is_preempt_thread()`. This returns a non-zero value only when the caller is a thread (not an ISR), the thread's priority is in the preemptible range, and the thread has not locked the scheduler.

The related `k_can_yield()` routine reports whether the current context is able to yield or invoke blocking APIs at all. It returns false in contexts such as ISRs, the pre-kernel initialization phase, or the idle thread, where yielding is not possible.

Suggested Uses Use cooperative threads for device drivers and other performance-critical work.

Use cooperative threads to implement mutual exclusion without the need for a kernel object, such as a mutex.

Use preemptive threads to give priority to time-sensitive processing over less time-sensitive processing.

Configuration Options

- CONFIG_TIMESLICING
- CONFIG_TIMESLICE_SIZE
- CONFIG_TIMESLICE_PRIORITY

CPU Idling

Although normally reserved for the idle thread, in certain special applications, a thread might want to make the CPU idle.

- *Concepts*
- *Implementation*
  - *Making the CPU idle*
  - *Making the CPU idle in an atomic fashion*
- *Suggested Uses*
- *API Reference*

Concepts Making the CPU idle causes the kernel to pause all operations until an event, normally an interrupt, wakes up the CPU. In a regular system, the idle thread is responsible for this. However, in some constrained systems, it is possible that another thread takes this duty.

Implementation

Making the CPU idle Making the CPU idle is simple: call the `k_cpu_idle()` API. The CPU will stop executing instructions until an event occurs. Most likely, the function will be called within a loop. Note that in certain architectures, upon return, `k_cpu_idle()` unconditionally unmasks interrupts.

```
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    /* wait for semaphore from ISR, then do related work */

    for (;;) {

        /* wait for ISR to trigger work to perform */
```

(continues on next page)

(continued from previous page)

```
        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {

            /* ... do processing */

        }

        /* put CPU to sleep to save power */
        k_cpu_idle();
    }
}
```

Making the CPU idle in an atomic fashion It is possible that there is a need to do some work atomically before making the CPU idle. In such a case, `k_cpu_atomic_idle()` should be used instead.

In fact, there is a race condition in the previous example: the interrupt could occur between the time the semaphore is taken, finding out it is not available and making the CPU idle again. In some systems, this can cause the CPU to idle until *another* interrupt occurs, which might be *never*, thus hanging the system completely. To prevent this, `k_cpu_atomic_idle()` should have been used, like in this example.

```
static k_sem my_sem;

void my_isr(void *unused)
{
    k_sem_give(&my_sem);
}

int main(void)
{
    k_sem_init(&my_sem, 0, 1);

    for (;;) {

        unsigned int key = irq_lock();

        /*
         * Wait for semaphore from ISR; if acquired, do related work, then
         * go to next loop iteration (the semaphore might have been given
         * again); else, make the CPU idle.
         */

        if (k_sem_take(&my_sem, K_NO_WAIT) == 0) {

            irq_unlock(key);

            /* ... do processing */

        } else {
            /* put CPU to sleep to save power */
            k_cpu_atomic_idle(key);
        }
    }
}
```

Suggested Uses Use `k_cpu_atomic_idle()` when a thread has to do some real work in addition to idling the CPU to wait for an event. See example above.

Use `k_cpu_idle()` only when a thread is only responsible for idling the CPU, i.e. not doing any real work, like in this example below.

```
int main(void)
{
    /* ... do some system/application initialization */

    /* thread is only used for CPU idling from this point on */
    for (;;) {
        k_cpu_idle();
    }
}
```

Note

Do not use these APIs unless absolutely necessary. In a normal system, the idle thread takes care of power management, including CPU idling.

CPU Idling APIs

System Threads

- *Implementation*
  - *Writing a main() function*
- *Suggested Uses*

A *system thread* is a thread that the kernel spawns automatically during system initialization.

The kernel spawns the following system threads:

Main thread
: This thread performs kernel initialization, then calls the application's `main()` function (if one is defined).

  By default, the main thread uses the highest configured preemptible thread priority (i.e. 0). If the kernel is not configured to support preemptible threads, the main thread uses the lowest configured cooperative thread priority (i.e. -1).

  The main thread is an essential thread while it is performing kernel initialization or executing the application's `main()` function; this means a fatal system error is raised if the thread aborts. If `main()` is not defined, or if it executes and then does a normal return, the main thread terminates normally and no error is raised.

Idle thread
: This thread executes when there is no other work for the system to do. If possible, the idle thread activates the board's power management support to save power; otherwise, the idle thread simply performs a "do nothing" loop. The idle thread remains in existence as long as the system is running and never terminates.

  The idle thread always uses the lowest configured thread priority.

The idle thread is an essential thread, which means a fatal system error is raised if the thread aborts.

Additional system threads may also be spawned, depending on the kernel and board configuration options specified by the application. For example, enabling the system workqueue spawns a system thread that services the work items submitted to it. (See *Workqueue Threads*.)

Implementation

Writing a main() function An application-supplied `main()` function begins executing once kernel initialization is complete. The kernel does not pass any arguments to the function, unless `CONFIG_BOOTARGS` is selected. In such case the kernel passes arguments to it and `main(int, char **)` can be used.

The following code outlines a trivial `main(void)` function. The function used by a real application can be as complex as needed.

```
int main(void)
{
    /* initialize a semaphore */
    ...

    /* register an ISR that gives the semaphore */
    ...

    /* monitor the semaphore forever */
    while (1) {
        /* wait for the semaphore to be given by the ISR */
        ...
        /* do whatever processing is now needed */
        ...
    }
}
```

Suggested Uses Use the main thread to perform thread-based processing in an application that only requires a single thread, rather than defining an additional application-specific thread.

Workqueue Threads

- *Work Item Lifecycle*
- *Delayable Work*
- *Triggered Work*
- *System Workqueue*
- *How to Use Workqueues*
- *Workqueue Best Practices*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

A *workqueue* is a kernel object that uses a dedicated thread to process work items in a first in, first out manner. Each work item is processed by calling the function specified by the work item. A

workqueue is typically used by an ISR or a high-priority thread to offload non-urgent processing to a lower-priority thread so it does not impact time-sensitive processing.

Any number of workqueues can be defined (limited only by available RAM). Each workqueue is referenced by its memory address.

A workqueue has the following key properties:

- A **queue** of work items that have been added, but not yet processed.
- A **thread** that processes the work items in the queue. The priority of the thread is configurable, allowing it to be either cooperative or preemptive as required.

Regardless of workqueue thread priority the workqueue thread will yield between each submitted work item, to prevent a cooperative workqueue from starving other threads.

A workqueue must be initialized before it can be used. This sets its queue to empty and spawns the workqueue's thread. The thread runs forever, but sleeps when no work items are available.

Work Item Lifecycle Any number of **work items** can be defined. Each work item is referenced by its memory address.

A work item is assigned a **handler function**, which is the function executed by the workqueue's thread when the work item is processed. This function accepts a single argument, which is the address of the work item itself. The work item also maintains information about its status.

A work item must be initialized before it can be used. This records the work item's handler function and marks it as not pending.

A work item may be **queued** (`K_WORK_QUEUED`) by submitting it to a workqueue by an ISR or a thread. Submitting a work item appends the work item to the workqueue's queue. Once the workqueue's thread has processed all of the preceding work items in its queue the thread will remove the next work item from the queue and invoke the work item's handler function. Depending on the scheduling priority of the workqueue's thread, and the work required by other items in the queue, a queued work item may be processed quickly or it may remain in the queue for an extended period of time.

A delayable work item may be **scheduled** (`K_WORK_DELAYED`) to a workqueue; see *Delayable Work*.

A work item will be **running** (`K_WORK_RUNNING`) when it is running on a work queue, and may also be **canceling** (`K_WORK_CANCELING`) if it started running before a thread has requested that it be cancelled.

A work item can be in multiple states; for example it can be:

- running on a queue;
- marked canceling (because a thread used `k_work_cancel_sync()` to wait until the work item completed);
- queued to run again on the same queue;
- scheduled to be submitted to a (possibly different) queue

all simultaneously. A work item that is in any of these states is **pending** (`k_work_is_pending()`) or **busy** (`k_work_busy_get()`).

A handler function can use any kernel API available to threads. However, operations that are potentially blocking (e.g. taking a semaphore) must be used with care, since the workqueue cannot process subsequent work items in its queue until the handler function finishes executing.

The single argument that is passed to a handler function can be ignored if it is not required. If the handler function requires additional information about the work it is to perform, the work item can be embedded in a larger data structure. The handler function can then use the argument value to compute the address of the enclosing data structure with `CONTAINER_OF`, and thereby obtain access to the additional information it needs.

A work item is typically initialized once and then submitted to a specific workqueue whenever work needs to be performed. If an ISR or a thread attempts to submit a work item that is already queued the work item is not affected; the work item remains in its current place in the workqueue's queue, and the work is only performed once.

A handler function is permitted to re-submit its work item argument to the workqueue, since the work item is no longer queued at that time. This allows the handler to execute work in stages, without unduly delaying the processing of other work items in the workqueue's queue.

Important

A pending work item *must not* be altered until the item has been processed by the workqueue thread. This means a work item must not be re-initialized while it is busy. Furthermore, any additional information the work item's handler function needs to perform its work must not be altered until the handler function has finished executing.

Delayable Work An ISR or a thread may need to schedule a work item that is to be processed only after a specified period of time, rather than immediately. This can be done by **scheduling** a **delayable work item** to be submitted to a workqueue at a future time.

A delayable work item contains a standard work item but adds fields that record when and where the item should be submitted.

A delayable work item is initialized and scheduled to a workqueue in a similar manner to a standard work item, although different kernel APIs are used. When the schedule request is made the kernel initiates a timeout mechanism that is triggered after the specified delay has elapsed. Once the timeout occurs the kernel submits the work item to the specified workqueue, where it remains queued until it is processed in the standard manner.

Note that work handler used for delayable still receives a pointer to the underlying non-delayable work structure, which is not publicly accessible from `k_work_delayable`. To get access to an object that contains the delayable work object use this idiom:

```
static void work_handler(struct k_work *work)
{
        struct k_work_delayable *dwork = k_work_delayable_from_work(work);
        struct work_context *ctx = CONTAINER_OF(dwork, struct work_context,
                                                timed_work);
        ...
```

Triggered Work The `k_work_poll_submit()` interface schedules a triggered work item in response to a **poll event** (see *Polling API*), that will call a user-defined function when a monitored resource becomes available or poll signal is raised, or a timeout occurs. In contrast to `k_poll()`, the triggered work does not require a dedicated thread waiting or actively polling for a poll event.

A triggered work item is a standard work item that has the following added properties:

- A pointer to an array of poll events that will trigger work item submissions to the workqueue
- A size of the array containing poll events.

A triggered work item is initialized and submitted to a workqueue in a similar manner to a standard work item, although dedicated kernel APIs are used. When a submit request is made, the kernel begins observing kernel objects specified by the poll events. Once at least one of the observed kernel object's changes state, the work item is submitted to the specified workqueue, where it remains queued until it is processed in the standard manner.

Important

The triggered work item as well as the referenced array of poll events have to be valid and cannot be modified for a complete triggered work item lifecycle, from submission to work item execution or cancellation.

An ISR or a thread may **cancel** a triggered work item it has submitted as long as it is still waiting for a poll event. In such case, the kernel stops waiting for attached poll events and the specified work is not executed. Otherwise the cancellation cannot be performed.

System Workqueue The kernel defines a workqueue known as the *system workqueue*, which is available to any application or kernel code that requires workqueue support. The system workqueue is optional, and only exists if the application makes use of it.

Important

Additional workqueues should only be defined when it is not possible to submit new work items to the system workqueue, since each new workqueue incurs a significant cost in memory footprint. A new workqueue can be justified if it is not possible for its work items to co-exist with existing system workqueue work items without an unacceptable impact; for example, if the new work items perform blocking operations that would delay other system workqueue processing to an unacceptable degree.

Also note: The system workqueue has the lowest cooperative priority by default. This means that draining the system workqueue takes precedence over *all preemptible threads*. Configuring the system workqueue's priority to be preemptible is risky, because subsystems and drivers may implicitly rely on work items being executed in a cooperative context. Therefore, a separate workqueue with lower priority may be appropriate for low-priority tasks.

How to Use Workqueues

Defining and Controlling a Workqueue A workqueue is defined using a variable of type `k_work_q`. The workqueue is initialized by defining the stack area used by its thread, initializing the `k_work_q`, either zeroing its memory or calling `k_work_queue_init()`, and then calling `k_work_queue_start()`. The stack area must be defined using `K_THREAD_STACK_DEFINE` to ensure it is properly set up in memory.

The following code defines and initializes a workqueue:

```
#define MY_STACK_SIZE 512
#define MY_PRIORITY 5

K_THREAD_STACK_DEFINE(my_stack_area, MY_STACK_SIZE);

struct k_work_q my_work_q;

k_work_queue_init(&my_work_q);

k_work_queue_start(&my_work_q, my_stack_area,
                   K_THREAD_STACK_SIZEOF(my_stack_area), MY_PRIORITY,
                   NULL);
```

In addition the queue identity and certain behavior related to thread rescheduling can be controlled by the optional final parameter; see `k_work_queue_start()` for details.

The following API can be used to interact with a workqueue:

- k_work_queue_drain() can be used to block the caller until the work queue has no items left. Work items resubmitted from the workqueue thread are accepted while a queue is draining, but work items from any other thread or ISR are rejected. The restriction on submitting more work can be extended past the completion of the drain operation in order to allow the blocking thread to perform additional work while the queue is "plugged". Note that draining a queue has no effect on scheduling or processing delayable items, but if the queue is plugged and the deadline expires the item will silently fail to be submitted.
- k_work_queue_unplug() removes any previous block on submission to the queue due to a previous drain operation.

Submitting a Work Item A work item is defined using a variable of type k_work. It must be initialized by calling k_work_init(), unless it is defined using K_WORK_DEFINE in which case initialization is performed at compile-time.

An initialized work item can be submitted to the system workqueue by calling k_work_submit(), or to a specified workqueue by calling k_work_submit_to_queue().

The following code demonstrates how an ISR can offload the printing of error messages to the system workqueue. Note that if the ISR attempts to resubmit the work item while it is still queued, the work item is left unchanged and the associated error message will not be printed.

```
struct device_info {
    struct k_work work;
    char name[16]
} my_device;

void my_isr(void *arg)
{
    ...
    if (error detected) {
        k_work_submit(&my_device.work);
    }
    ...
}

void print_error(struct k_work *item)
{
    struct device_info *the_device =
        CONTAINER_OF(item, struct device_info, work);
    printk("Got error on device %s\n", the_device->name);
}

/* initialize name info for a device */
strcpy(my_device.name, "FOO_dev");

/* initialize work item for printing device's error messages */
k_work_init(&my_device.work, print_error);

/* install my_isr() as interrupt handler for the device (not shown) */
...
```

The following API can be used to check the status of or synchronize with the work item:

- k_work_busy_get() returns a snapshot of flags indicating work item state. A zero value indicates the work is not scheduled, submitted, being executed, or otherwise still being referenced by the workqueue infrastructure.
- k_work_is_pending() is a helper that indicates true if and only if the work is scheduled, queued, or running.

- k_work_flush() may be invoked from threads to block until the work item has completed. It returns immediately if the work is not pending.
- k_work_cancel() attempts to prevent the work item from being executed. This may or may not be successful. This is safe to invoke from ISRs.
- k_work_cancel_sync() may be invoked from threads to block until the work completes; it will return immediately if the cancellation was successful or not necessary (the work wasn't submitted or running). This can be used after k_work_cancel() is invoked (from an ISR) to confirm completion of an ISR-initiated cancellation.

Scheduling a Delayable Work Item A delayable work item is defined using a variable of type k_work_delayable. It must be initialized by calling k_work_init_delayable().

For delayed work there are two common use cases, depending on whether a deadline should be extended if a new event occurs. An example is collecting data that comes in asynchronously, e.g. characters from a UART associated with a keyboard. There are two APIs that submit work after a delay:

- k_work_schedule() (or k_work_schedule_for_queue()) schedules work to be executed at a specific time or after a delay. Further attempts to schedule the same item with this API before the delay completes will not change the time at which the item will be submitted to its queue. Use this if the policy is to keep collecting data until a specified delay since the **first** unprocessed data was received;
- k_work_reschedule() (or k_work_reschedule_for_queue()) unconditionally sets the deadline for the work, replacing any previous incomplete delay and changing the destination queue if necessary. Use this if the policy is to keep collecting data until a specified delay since the **last** unprocessed data was received.

If the work item is not scheduled both APIs behave the same. If K_NO_WAIT is specified as the delay the behavior is as if the item was immediately submitted directly to the target queue, without waiting for a minimal timeout (unless k_work_schedule() is used and a previous delay has not completed).

Both also have variants that allow control of the queue used for submission.

The helper function k_work_delayable_from_work() can be used to get a pointer to the containing k_work_delayable from a pointer to k_work that is passed to a work handler function.

The following additional API can be used to check the status of or synchronize with the work item:

- k_work_delayable_busy_get() is the analog to k_work_busy_get() for delayable work.
- k_work_delayable_is_pending() is the analog to k_work_is_pending() for delayable work.
- k_work_flush_delayable() is the analog to k_work_flush() for delayable work.
- k_work_cancel_delayable() is the analog to k_work_cancel() for delayable work; similarly with k_work_cancel_delayable_sync().

Synchronizing with Work Items While the state of both regular and delayable work items can be determined from any context using k_work_busy_get() and k_work_delayable_busy_get() some use cases require synchronizing with work items after they've been submitted. k_work_flush(), k_work_cancel_sync(), and k_work_cancel_delayable_sync() can be invoked from thread context to wait until the requested state has been reached.

These APIs must be provided with a k_work_sync object that has no application-inspectable components but is needed to provide the synchronization objects. These objects should not be allocated on a stack if the code is expected to work on architectures with CONFIG_KERNEL_COHERENCE.

Workqueue Best Practices

Avoid Race Conditions Sometimes the data a work item must process is naturally thread-safe, for example when it's put into a k_queue by some thread and processed in the work thread. More often external synchronization is required to avoid data races: cases where the work thread might inspect or manipulate shared state that's being accessed by another thread or interrupt. Such state might be a flag indicating that work needs to be done, or a shared object that is filled by an ISR or thread and read by the work handler.

For simple flags *Atomic Services* may be sufficient. In other cases spin locks (k_spinlock) or thread-aware locks (k_sem, k_mutex , ...) may be used to ensure data races don't occur.

If the selected lock mechanism can *sleep* then allowing the work thread to sleep will starve other work queue items, which may need to make progress in order to get the lock released. Work handlers should try to take the lock with its no-wait path. For example:

```
static void work_handler(struct work *work)
{
        struct work_context *parent = CONTAINER_OF(work, struct work_context,
                                                   work_item);

        if (k_mutex_lock(&parent->lock, K_NO_WAIT) != 0) {
                /* NB: Submit will fail if the work item is being cancelled. */
                (void)k_work_submit(work);
                return;
        }

        /* do stuff under lock */
        k_mutex_unlock(&parent->lock);
        /* do stuff without lock */
}
```

Be aware that if the lock is held by a thread with a lower priority than the work queue the resubmission may starve the thread that would release the lock, causing the application to fail. Where the idiom above is required a delayable work item is preferred, and the work should be (re-)scheduled with a non-zero delay to allow the thread holding the lock to make progress.

Note that submitting from the work handler can fail if the work item had been cancelled. Generally this is acceptable, since the cancellation will complete once the handler finishes. If it is not, the code above must take other steps to notify the application that the work could not be performed.

Work items in isolation are self-locking, so you don't need to hold an external lock just to submit or schedule them. Even if you use external state protected by such a lock to prevent further resubmission, it's safe to do the resubmit as long as you're sure that eventually the item will take its lock and check that state to determine whether it should do anything. Where a delayable work item is being rescheduled in its handler due to inability to take the lock, some other self-locking state, such as an atomic flag set by the application/driver when the cancel is initiated, would be required to detect the cancellation and avoid the cancelled work item being submitted again after the deadline.

Check Return Values All work API functions return status of the underlying operation, and in many cases it is important to verify that the intended result was obtained.

- Submitting a work item (k_work_submit_to_queue()) can fail if the work is being cancelled or the queue is not accepting new items. If this happens the work will not be executed, which could cause a subsystem that is animated by work handler activity to become non-responsive.
- Asynchronous cancellation (k_work_cancel() or k_work_cancel_delayable()) can complete while the work item is still being run by a handler. Proceeding to manipulate state shared with the work handler will result in data races that can cause failures.

Many race conditions have been present in Zephyr code because the results of an operation were not checked.

There may be good reason to believe that a return value indicating that the operation did not complete as expected is not a problem. In those cases the code should clearly document this, by (1) casting the return value to `void` to indicate that the result is intentionally ignored, and (2) documenting what happens in the unexpected case. For example:

```
/* If this fails, the work handler will check pub->active and
 * exit without transmitting.
 */
(void)k_work_cancel_delayable(&pub->timer);
```

However in such a case the following code must still avoid data races, as it cannot guarantee that the work thread is not accessing work-related state.

Don't Optimize Prematurely The workqueue API is designed to be safe when invoked from multiple threads and interrupts. Attempts to externally inspect a work item's state and make decisions based on the result are likely to create new problems.

So when new work comes in, just submit it. Don't attempt to "optimize" by checking whether the work item is already submitted by inspecting snapshot state with `k_work_is_pending()` or `k_work_busy_get()`, or checking for a non-zero delay from `k_work_delayable_remaining_get()`. Those checks are fragile: a "busy" indication can be obsolete by the time the test is returned, and a "not-busy" indication can also be wrong if work is submitted from multiple contexts, or (for delayable work) if the deadline has completed but the work is still in queued or running state.

A general best practice is to always maintain in shared state some condition that can be checked by the handler to confirm whether there is work to be done. This way you can use the work handler as the standard cleanup path: rather than having to deal with cancellation and cleanup at points where items are submitted, you may be able to have everything done in the work handler itself.

A rare case where you could safely use `k_work_is_pending()` is as a check to avoid invoking `k_work_flush()` or `k_work_cancel_sync()`, if you are *certain* that nothing else might submit the work while you're checking (generally because you're holding a lock that prevents access to state used for submission).

Suggested Uses Use the system workqueue to defer complex interrupt-related processing from an ISR to a shared thread. This allows the interrupt-related processing to be done promptly without compromising the system's ability to respond to subsequent interrupts, and does not require the application to define and manage an additional thread to do the processing.

Configuration Options Related configuration options:

- `CONFIG_SYSTEM_WORKQUEUE_STACK_SIZE`
- `CONFIG_SYSTEM_WORKQUEUE_PRIORITY`
- `CONFIG_SYSTEM_WORKQUEUE_NO_YIELD`

Work Queue APIs

Operation without Threads

Thread support is not necessary in some applications:

- Bootloaders
- Simple event-driven applications

- Examples intended to demonstrate core functionality

Thread support can be disabled by setting CONFIG_MULTITHREADING to n. Since this configuration has a significant impact on Zephyr's functionality and testing of it has been limited, there are conditions on what can be expected to work in this configuration.

What Can be Expected to Work These core capabilities shall function correctly when CONFIG_MULTITHREADING is disabled:

- The *build system*
- The ability to boot the application to main()
- *Interrupt management*
- The system clock including k_uptime_get()
- Timers, i.e. k_timer()
- Non-sleeping delays e.g. k_busy_wait().
- Sleeping k_cpu_idle().
- Pre main() drivers and subsystems initialization e.g. SYS_INIT.
- *Memory Management*
- Specifically identified drivers in certain subsystems, listed below.

The expectations above affect selection of other features; for example CONFIG_SYS_CLOCK_EXISTS cannot be set to n.

What Cannot be Expected to Work Functionality that will not work when CONFIG_MULTITHREADING is disabled includes majority of the kernel API:

- *Threads*
- *Scheduling*
- *Workqueue Threads*
- *Polling API*
- *Semaphores*
- *Mutexes*
- *Condition Variables*
- *Data Passing*

Subsystem Behavior Without Thread Support The sections below list driver and functional subsystems that are expected to work to some degree when CONFIG_MULTITHREADING is disabled. Subsystems that are not listed here should not be expected to work.

Some existing drivers within the listed subsystems do not work when threading is disabled, but are within scope based on their subsystem, or may be sufficiently isolated that supporting them on a particular platform is low-impact. Enhancements to add support to existing capabilities that were not originally implemented to work with threads disabled will be considered.

Flash The *Flash* is expected to work for all SoC flash peripheral drivers. Bus-accessed devices like serial memories may not be supported.

List/table of supported drivers to go here

GPIO The *General-Purpose Input/Output (GPIO)* is expected to work for all SoC GPIO peripheral drivers. Bus-accessed devices like GPIO extenders may not be supported.

List/table of supported drivers to go here

UART A subset of the *Universal Asynchronous Receiver-Transmitter (UART)* is expected to work for all SoC UART peripheral drivers.

- Applications that select `CONFIG_UART_INTERRUPT_DRIVEN` may work, depending on driver implementation.
- Applications that select `CONFIG_UART_ASYNC_API` may work, depending on driver implementation.
- Applications that do not select either `CONFIG_UART_ASYNC_API` or `CONFIG_UART_INTERRUPT_DRIVEN` are expected to work.

List/table of supported drivers to go here, including which API options are supported

Interrupts

An *interrupt service routine* (ISR) is a function that executes asynchronously in response to a hardware or software interrupt. An ISR normally preempts the execution of the current thread, allowing the response to occur with very low latency. Thread execution resumes only once all ISR work has been completed.

- *Concepts*
  - *Multi-level Interrupt Handling*
  - *Preventing Interruptions*

  - *Defining a regular ISR*
  - *Defining a 'direct' ISR*
  - *RAM-based ISR Execution*
  - *Sharing an interrupt line*
  - *Dynamically disconnecting an ISR*
  - *Implementation Details*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of ISRs can be defined (limited only by available RAM), subject to the constraints imposed by underlying hardware.

An ISR has the following key properties:

- An **interrupt request (IRQ) signal** that triggers the ISR.
- A **priority level** associated with the IRQ.
- An **interrupt service routine** that is invoked to handle the interrupt.

- An **argument value** that is passed to that function.

An IDT (Interrupt Descriptor Table) or a vector table is used to associate a given interrupt source with a given ISR. Only a single ISR can be associated with a specific IRQ at any given time.

Multiple ISRs can utilize the same function to process interrupts, allowing a single function to service a device that generates multiple types of interrupts or to service multiple devices (usually of the same type). The argument value passed to an ISR's function allows the function to determine which interrupt has been signaled.

The kernel provides a default ISR for all unused IDT entries. This ISR generates a fatal system error if an unexpected interrupt is signaled.

The kernel supports **interrupt nesting**. This allows an ISR to be preempted in mid-execution if a higher priority interrupt is signaled. The lower priority ISR resumes execution once the higher priority ISR has completed its processing.

An ISR executes in the kernel's **interrupt context**. This context has its own dedicated stack area (or, on some architectures, stack areas). The size of the interrupt context stack must be capable of handling the execution of multiple concurrent ISRs if interrupt nesting support is enabled.

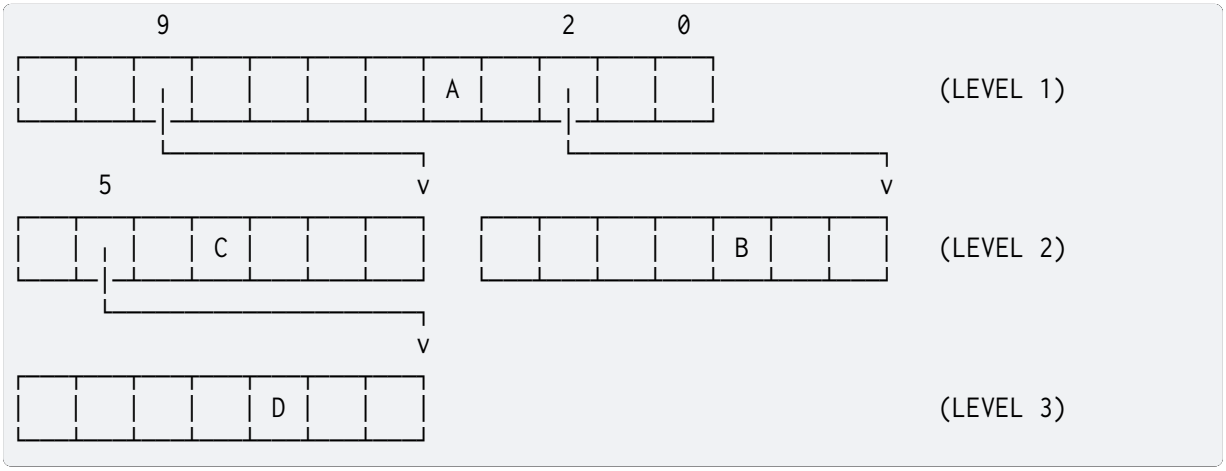
Important

Many kernel APIs can be used only by threads, and not by ISRs. In cases where a routine may be invoked by both threads and ISRs the kernel provides the `k_is_in_isr()` API to allow the routine to alter its behavior depending on whether it is executing as part of a thread or as part of an ISR.

Multi-level Interrupt Handling A hardware platform can support more interrupt lines than natively-provided through the use of one or more nested interrupt controllers. Sources of hardware interrupts are combined into one line that is then routed to the parent controller.

If nested interrupt controllers are supported, `CONFIG_MULTI_LEVEL_INTERRUPTS` should be enabled, and `CONFIG_2ND_LEVEL_INTERRUPTS` and `CONFIG_3RD_LEVEL_INTERRUPTS` configured as well, based on the hardware architecture.

A unique 32-bit interrupt number is assigned with information embedded in it to select and invoke the correct Interrupt Service Routine (ISR). Each interrupt level is given a byte within this 32-bit number, providing support for up to four interrupt levels using this arch, as illustrated and explained below:



There are three interrupt levels shown here.

- A cell represents an interrupt line and is numbered from 0 (right most).

- LEVEL 1 has 12 interrupt lines, with two lines (2 and 9) connected to nested controllers and one device 'A' on line 4.
- One of the LEVEL 2 controllers has interrupt line 5 connected to a LEVEL 3 nested controller and one device 'C' on line 3.
- The other LEVEL 2 controller has no nested controllers but has one device 'B' on line 2.
- The LEVEL 3 controller has one device 'D' on line 2.

Here's how unique interrupt numbers are generated for each hardware interrupt. Let's consider four interrupts shown above as A, B, C, and D:

```
A -> 0x00000004
B -> 0x00000302
C -> 0x00000409
D -> 0x00030609
```

Note

The bit positions for LEVEL 2 and onward are offset by 1, as 0 means that interrupt number is not present for that level. For our example, the LEVEL 3 controller has device D on line 2, connected to the LEVEL 2 controller's line 5, that is connected to the LEVEL 1 controller's line 9 (2 -> 5 -> 9). Because of the encoding offset for LEVEL 2 and onward, device D is given the number 0x00030609.

Preventing Interruptions In certain situations it may be necessary for the current thread to prevent ISRs from executing while it is performing time-sensitive or critical section operations.

A thread may temporarily prevent all IRQ handling in the system using an **IRQ lock**. This lock can be applied even when it is already in effect, so routines can use it without having to know if it is already in effect. The thread must unlock its IRQ lock the same number of times it was locked before interrupts can be once again processed by the kernel while the thread is running.

Important

A thread is not allowed to *sleep* while holding an IRQ lock; only *isr-ok* functions may be called.

Alternatively, a thread may temporarily **disable** a specified IRQ so its associated ISR does not execute when the IRQ is signaled. The IRQ must be subsequently **enabled** to permit the ISR to execute.

Important

Disabling an IRQ prevents *all* threads in the system from being preempted by the associated ISR, not just the thread that disabled the IRQ.

Zero Latency Interrupts Preventing interruptions by applying an IRQ lock may increase the observed interrupt latency. A high interrupt latency, however, may not be acceptable for certain low-latency use-cases.

The kernel addresses such use-cases by allowing interrupts with critical latency constraints to execute at a priority level that cannot be blocked by interrupt locking. These interrupts are defined as *zero-latency interrupts*. The support for zero-latency interrupts requires `CONFIG_ZERO_LATENCY_IRQS` to be enabled. Any interrupts configured as zero-latency must also be declared as *direct ISRs* (and must not use the `ISR_DIRECT_PM` in them), since regular ISRs interact with the kernel. In addition to that, the flag `IRQ_ZERO_LATENCY` must be passed to the

`IRQ_DIRECT_CONNECT` macro to configure the particular interrupt with zero latency. Declaring a zero-latency interrupt ISR to be both direct and dynamic is possible on some architectures, see *Defining a 'direct' ISR*.

Zero-latency interrupts are expected to be used to manage hardware events directly, and not to interoperate with the kernel code at all. They should treat all kernel APIs as undefined behavior (i.e. an application that uses the APIs inside a zero-latency interrupt context is responsible for directly verifying correct behavior). Zero-latency interrupts may not modify any data inspected by kernel APIs invoked from normal Zephyr contexts and shall not generate exceptions that need to be handled synchronously (e.g. kernel panic).

When system power management keeps interrupts locked across PM resume, a zero-latency interrupt is outside the locked-resume ordering and may be dispatched during PM suspend/resume logic, before PM resume bookkeeping and SoC/device hardware restore have completed. Such an ISR must be PM-wake-safe, or the interrupt source must be masked or disabled while the system state does not allow the ISR to execute. See *device power policy constraints* for one way to keep unsafe states out of policy selection while a device path that can produce a zero-latency interrupt is active.

Important

Zero-latency interrupts are supported on an architecture-specific basis. The feature is currently implemented in the ARM Cortex-M architecture variant.

Tip

To mitigate flash access latency, consider relocating ISRs and all related symbols to RAM.

Offloading ISR Work An ISR should execute quickly to ensure predictable system operation. If time consuming processing is required the ISR should offload some or all processing to a thread, thereby restoring the kernel's ability to respond to other interrupts.

The kernel supports several mechanisms for offloading interrupt-related processing to a thread.

- An ISR can signal a helper thread to do interrupt-related processing using a kernel object, such as a FIFO, LIFO, or semaphore.
- An ISR can instruct the system workqueue thread to execute a work item. (See *Workqueue Threads*.)

When an ISR offloads work to a thread, there is typically a single context switch to that thread when the ISR completes, allowing interrupt-related processing to continue almost immediately. However, depending on the priority of the thread handling the offload, it is possible that the currently executing cooperative thread or other higher-priority threads may execute before the thread handling the offload is scheduled.

Sharing interrupt lines In the case of some hardware platforms, the same interrupt lines may be used by different IPs. For example, interrupt 17 may be used by a DMA controller to signal that a data transfer has been completed or by a DAI controller to signal that the transfer FIFO has reached its watermark. To make this work, one would have to either employ some special logic or find a workaround (for example, using the shared_irq interrupt controller), which doesn't scale very well.

To solve this problem, one may use shared interrupts, which can be enabled using `CONFIG_SHARED_INTERRUPTS`. Whenever an attempt to register a second ISR/argument pair on the same interrupt line is made (using `IRQ_CONNECT` or `irq_connect_dynamic()`), the interrupt line will become shared, meaning the two ISR/argument pairs (previous one and the one that has just been registered) will be invoked each time the interrupt is triggered. The entities that make use

of an interrupt line in the shared interrupt context are known as clients. The maximum number of allowed clients for an interrupt is controlled by CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS.

Interrupt sharing is transparent to the user. As such, the user may register interrupts using IRQ_CONNECT and irq_connect_dynamic() as they normally would. The interrupt sharing is taken care of behind the scenes.

Enabling the shared interrupt support and dynamic interrupt support will allow users to dynamically disconnect ISRs using irq_disconnect_dynamic(). After an ISR is disconnected, whenever the interrupt line for which it was register gets triggered, the ISR will no longer get invoked.

Please note that enabling CONFIG_SHARED_INTERRUPTS will result in a non-negligible increase in the binary size. Use with caution.

Implementation

Defining a regular ISR An ISR is defined at runtime by calling IRQ_CONNECT. It must then be enabled by calling irq_enable().

> **Note**
>
> The unprefixed interrupt control APIs such as irq_enable() and irq_lock() are the legacy spelling. New code should use their namespaced equivalents, k_irq_enable(), k_irq_lock() and so on. The unprefixed names remain fully supported.

> **Important**
>
> IRQ_CONNECT() is not a C function and does some inline assembly magic behind the scenes. All its arguments must be known at build time. Drivers that have multiple instances may need to define per-instance config functions to configure each instance of the interrupt.

The following code defines and enables an ISR.

```
#define MY_DEV_IRQ  24       /* device uses IRQ 24 */
#define MY_DEV_PRIO  2       /* device uses interrupt priority 2 */
/* argument passed to my_isr(), in this case a pointer to the device */
#define MY_ISR_ARG  DEVICE_GET(my_device)
#define MY_IRQ_FLAGS 0       /* IRQ flags */

void my_isr(void *arg)
{
   ... /* ISR code */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG, MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Since the IRQ_CONNECT macro requires that all its parameters be known at build time, in some cases this may not be acceptable. It is also possible to install interrupts at runtime with irq_connect_dynamic(). It is used in exactly the same way as IRQ_CONNECT:

```
void my_isr_installer(void)
{
   ...
   irq_connect_dynamic(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_ISR_ARG,
                       MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
   ...
}
```

Dynamic interrupts require the CONFIG_DYNAMIC_INTERRUPTS option to be enabled. Removing or re-configuring a dynamic interrupt is currently unsupported.

Defining a 'direct' ISR Regular Zephyr interrupts introduce some overhead which may be unacceptable for some low-latency use-cases. Specifically:

- The argument to the ISR is retrieved and passed to the ISR
- If power management is enabled and the system was idle, all the hardware will be resumed from low-power state before the ISR is executed, which can be very time-consuming
- Although some architectures will do this in hardware, other architectures need to switch to the interrupt stack in code
- After the interrupt is serviced, the OS then performs some logic to potentially make a scheduling decision
- *Zero Latency Interrupts* must always be declared as direct ISRs, since regular ISRs interact with the kernel

Zephyr supports so-called 'direct' interrupts, which are installed via IRQ_DIRECT_CONNECT and whose handlers are declared using ISR_DIRECT_DECLARE. These direct interrupts have some special implementation requirements and a reduced feature set; see the definitions of IRQ_DIRECT_CONNECT and ISR_DIRECT_DECLARE for details.

Direct interrupts are only available on architectures selecting CONFIG_ARCH_HAS_DIRECT_INTERRUPTS. Using IRQ_DIRECT_CONNECT or ISR_DIRECT_DECLARE on any other architecture fails the build.

The following code demonstrates a direct ISR:

```
#define MY_DEV_IRQ  24       /* device uses IRQ 24 */
#define MY_DEV_PRIO  2       /* device uses interrupt priority 2 */
#define MY_IRQ_FLAGS 0       /* IRQ flags */

ISR_DIRECT_DECLARE(my_isr)
{
   do_stuff();
   /* PM done after servicing interrupt for best latency. This cannot be
   used for zero-latency IRQs because it accesses kernel data. */
   ISR_DIRECT_PM();
   /* Ask the kernel to check if scheduling decision should be made. If the
   ISR is for a zero-latency IRQ then the return value must always be 0. */
   return 1;
}

void my_isr_installer(void)
{
   ...
   IRQ_DIRECT_CONNECT(MY_DEV_IRQ, MY_DEV_PRIO, my_isr, MY_IRQ_FLAGS);
   irq_enable(MY_DEV_IRQ);
```

(continues on next page)

(continued from previous page)

```
    ...
}
```

Installation of dynamic direct interrupts is supported on an architecture-specific basis. The feature is currently implemented in the Arm Cortex-M architecture variant via the macro ARM_IRQ_DIRECT_DYNAMIC_CONNECT, which can be used to declare a direct and dynamic interrupt.

RAM-based ISR Execution For ultra-low latency, ISRs and vector tables can be relocated to RAM to eliminate flash access delays. That can be achieved by enabling the CONFIG_SRAM_VECTOR_TABLE and CONFIG_SRAM_SW_ISR_TABLE options which will result in vector tables being placed in RAM. Then, Zephyr *Code and Data Relocation* can be used to relocate the ISR code and all the related symbols to RAM as well.

Sharing an interrupt line The following code defines two ISRs using the same interrupt number.

```
#define MY_DEV_IRQ 24              /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2          /* device uses interrupt priority 2 */
/*  this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/*  this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0             /* IRQ flags */

void my_first_isr(void *arg)
{
    ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
    ... /* even more magic happens here */
}

void my_isr_installer(void)
{
    ...
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG,␣
↪MY_IRQ_FLAGS);
    IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG,␣
↪MY_IRQ_FLAGS);
    ...
}
```

The same restrictions regarding IRQ_CONNECT described in *Defining a regular ISR* are applicable here. If CONFIG_SHARED_INTERRUPTS is disabled, the above code will generate a build error. Otherwise, the above code will result in the two ISRs being invoked each time interrupt 24 is triggered.

If CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS is set to a value lower than 2 (current number of clients), a build error will be generated.

If dynamic interrupts are enabled, irq_connect_dynamic() will allow sharing interrupts during runtime. Exceeding the configured maximum number of allowed clients will result in a failed assertion.

Dynamically disconnecting an ISR The following code defines two ISRs using the same interrupt number. The second ISR is disconnected during runtime.

```
#define MY_DEV_IRQ 24              /* device uses INTID 24 */
#define MY_DEV_IRQ_PRIO 2          /* device uses interrupt priority 2 */
/*  this argument may be anything */
#define MY_FST_ISR_ARG INT_TO_POINTER(1)
/*  this argument may be anything */
#define MY_SND_ISR_ARG INT_TO_POINTER(2)
#define MY_IRQ_FLAGS 0             /* IRQ flags */

void my_first_isr(void *arg)
{
   ... /* some magic happens here */
}

void my_second_isr(void *arg)
{
   ... /* even more magic happens here */
}

void my_isr_installer(void)
{
   ...
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr, MY_FST_ISR_ARG,␣
↪MY_IRQ_FLAGS);
   IRQ_CONNECT(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_second_isr, MY_SND_ISR_ARG,␣
↪MY_IRQ_FLAGS);
   ...
}

void my_isr_uninstaller(void)
{
   ...
   irq_disconnect_dynamic(MY_DEV_IRQ, MY_DEV_IRQ_PRIO, my_first_isr,␣
↪MY_FST_ISR_ARG, MY_IRQ_FLAGS);
   ...
}
```

The `irq_disconnect_dynamic()` call will result in interrupt 24 becoming unshared, meaning the system will act as if the first `IRQ_CONNECT` call never happened. This behaviour is only allowed if `CONFIG_DYNAMIC_INTERRUPTS` is enabled, otherwise a linker error will be generated.

Implementation Details Interrupt tables are set up at build time using some special build tools. The details laid out here apply to all architectures except x86, which are covered in the *x86 Details* section below.

The invocation of `IRQ_CONNECT` will declare an instance of struct _isr_list which is placed in a special .intList section. This section is placed in compiled code on precompilation stages only. It is meant to be used by Zephyr script to generate interrupt tables and is removed from the final build. The script implements different parsers to process the data from .intList section and produce the required output.

The default parser generates C arrays filled with arguments and interrupt handlers in a form of addresses directly taken from .intList section entries. It works with all the architectures and compilers (with the exception mentioned above). The limitation of this parser is the fact that after the arrays are generated it is expected for the code not to relocate. Any relocation on this stage may lead to the situation where the entry in the interrupt array is no longer pointing to the function that was expected. It means that this parser, being more compatible, is limiting us

from using Link Time Optimization.

The local ISR declaration parser uses a different approach to construct the same arrays at the binary level. All the entries to the arrays are declared and defined locally, directly in the file where IRQ_CONNECT is used. They are placed in a section with a unique, synthesized name. The name of that section is then placed in the .intList section, which is used to generate a linker script fragment placing the entry at the right address. This parser is currently limited to the supported architectures and toolchains, but in return, it preserves the information about object relations for the linker, thus enabling Link Time Optimization.

Implementation using C arrays This is the default configuration available for all Zephyr supported architectures.

Any invocation of IRQ_CONNECT will declare an instance of struct _isr_list which is placed in a special .intList section:

```
struct _isr_list {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** ISR to call */
    void *func;
    /** Parameter for non-direct IRQs */
    void *param;
};
```

Zephyr is built in two phases; the first phase of the build produces ${ZEPHYR_PREBUILT_EXECUTABLE}.elf which contains all the entries in the .intList section preceded by a header:

```
struct {
    void *spurious_irq_handler;
    void *sw_irq_handler;
    uint32_t num_isrs;
    uint32_t num_vectors;
    struct _isr_list isrs[];  <- of size num_isrs
};
```

This data consisting of the header and instances of struct _isr_list inside ${ZEPHYR_PREBUILT_EXECUTABLE}.elf is then used by the gen_isr_tables.py script to generate a C file defining a vector table and software ISR table that are then compiled and linked into the final application.

The priority level of any interrupt is not encoded in these tables, instead IRQ_CONNECT also has a runtime component which programs the desired priority level of the interrupt to the interrupt controller. Some architectures do not support the notion of interrupt priority, in which case the priority argument is ignored.

Vector Table A vector table is generated when CONFIG_GEN_IRQ_VECTOR_TABLE is enabled. This data structure is used natively by the CPU and is simply an array of function pointers, where each element n corresponds to the IRQ handler for IRQ line n, and the function pointers are:

1. For 'direct' interrupts declared with IRQ_DIRECT_CONNECT, the handler function will be placed here.
2. For regular interrupts declared with IRQ_CONNECT, the address of the common software IRQ handler is placed here. This code does common kernel interrupt bookkeeping and looks up the ISR and parameter from the software ISR table.

3. For interrupt lines that are not configured at all, the address of the spurious IRQ handler will be placed here. The spurious IRQ handler causes a system fatal error if encountered.

Some architectures have a common entry point for all interrupts and do not support a vector table, in which case the CONFIG_GEN_IRQ_VECTOR_TABLE option should be disabled.

Some architectures may reserve some initial vectors for system exceptions and declare this in a table elsewhere, in which case CONFIG_GEN_IRQ_START_VECTOR needs to be set to properly offset the indices in the table.

SW ISR Table This is an array of struct _isr_table_entry:

```
struct _isr_table_entry {
    void *arg;
    void (*isr)(void *);
};
```

This is used by the common software IRQ handler to look up the ISR and its argument and execute it. The active IRQ line is looked up in an interrupt controller register and used to index this table.

Shared SW ISR Table This is an array of struct z_shared_isr_table_entry:

```
struct z_shared_isr_table_entry {
    struct _isr_table_entry clients[CONFIG_SHARED_IRQ_MAX_NUM_CLIENTS];
    size_t client_num;
};
```

This table keeps track of the registered clients for each of the interrupt lines. Whenever an interrupt line becomes shared, `z_shared_isr()` will replace the currently registered ISR in _sw_isr_table. This special ISR will iterate through the list of registered clients and invoke the ISRs.

Implementation using linker script This way of prepare and parse .isrList section to implement interrupt vectors arrays is called local ISR declaration. The name comes from the fact that all the entries to the arrays that would create interrupt vectors are created locally in place of invocation of `IRQ_CONNECT` macro. Then automatically generated linker scripts are used to place it in the right place in the memory.

This option requires enabling by the choose of `CONFIG_ISR_TABLES_LOCAL_DECLARATION`. If this configuration is supported by the used architecture and toolchaing the `CONFIG_ISR_TABLES_LOCAL_DECLARATION_SUPPORTED` is set. See details of this option for the information about currently supported configurations.

Any invocation of `IRQ_CONNECT` or `IRQ_DIRECT_CONNECT` will declare an instance of `struct _isr_list_sname` which is placed in a special .intList section:

```
struct _isr_list_sname {
    /** IRQ line number */
    int32_t irq;
    /** Flags for this IRQ, see ISR_FLAG_* definitions */
    int32_t flags;
    /** The section name */
    const char sname[];
};
```

Note that the section name is placed in flexible array member. It means that the size of the initialized structure will vary depending on the structure name length. The whole entry is used by the script during the build of the application and has all the information needed for proper interrupt placement.

Beside of the _isr_list_sname the IRQ_CONNECT macro generates an entry that would be the part of the interrupt array:

```
struct _isr_table_entry {
    const void *arg;
    void (*isr)(const void *);
};
```

This array is placed in a section with the name saved in _isr_list_sname structure.

The values created by IRQ_DIRECT_CONNECT macro depends on the architecture. It can be changed to variable that points to a interrupt handler:

```
static uintptr_t <unique name> = ((uintptr_t)func);
```

Or to actually naked function that implements a jump to the interrupt handler:

```
static void <unique name>(void)
{
    __asm(ARCH_IRQ_VECTOR_JUMP_CODE(func));
}
```

Similar like for IRQ_CONNECT, the created variable or function is placed in a section, saved in _isr_list_sname section.

Files generated by the script The interrupt tables generator script creates 3 files: `isr_tables.c`, `isr_tables_swi.ld`, and `isr_tables_vt.ld`.

The `isr_tables.c` will contain all the structures for interrupts, direct interrupts and shared interrupts (if enabled). This file implements only all the structures that are not implemented by the application, leaving a comment where the interrupt not implemented here can be found.

Then two linker files are used. The `isr_tables_vt.ld` file is included in place where the interrupt vectors are required to be placed in the selected architecture. The `isr_tables_swi.ld` file describes the placement of the software interrupt table elements. The separated file is required as it might be placed in writable or nonwritable section, depending on the current configuration.

x86 Details The x86 architecture has a special type of vector table called the Interrupt Descriptor Table (IDT) which must be laid out in a certain way per the x86 processor documentation. It is still fundamentally a vector table, and the *arch/x86/gen_idt.py* tool uses the .intList section to create it. However, on APIC-based systems the indexes in the vector table do not correspond to the IRQ line. The first 32 vectors are reserved for CPU exceptions, and all remaining vectors (up to index 255) correspond to the priority level, in groups of 16. In this scheme, interrupts of priority level 0 will be placed in vectors 32-47, level 1 48-63, and so forth. When the *arch/x86/gen_idt.py* tool is constructing the IDT, when it configures an interrupt it will look for a free vector in the appropriate range for the requested priority level and set the handler there.

On x86 when an interrupt or exception vector is executed by the CPU, there is no foolproof way to determine which vector was fired, so a software ISR table indexed by IRQ line is not used. Instead, the IRQ_CONNECT call creates a small assembly language function which calls the common interrupt code in `_interrupt_enter()` with the ISR and parameter as arguments. It is the address of this assembly interrupt stub which gets placed in the IDT. For interrupts declared with IRQ_DIRECT_CONNECT the parameterless ISR is placed directly in the IDT.

On systems where the position in the vector table corresponds to the interrupt's priority level, the interrupt controller needs to know at runtime what vector is associated with an IRQ line. *arch/x86/gen_idt.py* additionally creates an _irq_to_interrupt_vector array which maps an IRQ line to its configured vector in the IDT. This is used at runtime by IRQ_CONNECT to program the IRQ-to-vector association in the interrupt controller.

For dynamic interrupts, the build must generate some 4-byte dynamic interrupt stubs, one stub per dynamic interrupt in use. The number of stubs is controlled by the CONFIG_X86_DYNAMIC_IRQ_STUBS option. Each stub pushes an unique identifier which is then used to fetch the appropriate handler function and parameter out of a table populated when the dynamic interrupt was connected.

Going Beyond the Default Supported Number of Interrupts When generating interrupts in the multi-level configuration, 8-bits per level is the default mask used when determining which level a given interrupt code belongs to. This can become a problem when dealing with CPUs that support more than 255 interrupts per single aggregator. In this case it may be desirable to override these defaults and use a custom number of bits per level. Regardless of how many bits used for each level, the sum of the total bits used between all levels must sum to be less than or equal to 32-bits, fitting into a single 32-bit integer. To modify the bit total per level, override the default 8 in `Kconfig.multilevel` by setting CONFIG_1ST_LEVEL_INTERRUPT_BITS for the first level, CONFIG_2ND_LEVEL_INTERRUPT_BITS for the second level and CONFIG_3RD_LEVEL_INTERRUPT_BITS for the third level. These masks control the length of the bit masks and shift to apply when generating interrupt values, when checking the interrupts level and converting interrupts to a different level. The logic controlling this can be found in `irq_multilevel.h`

Suggested Uses Use a regular or direct ISR to perform interrupt processing that requires a very rapid response, and can be done quickly without blocking.

Note

Interrupt processing that is time consuming, or involves blocking, should be handed off to a thread. See *Offloading ISR Work* for a description of various techniques that can be used in an application.

Configuration Options Related configuration options:

- CONFIG_ISR_STACK_SIZE

Additional architecture-specific and device-specific configuration options also exist.

API Reference
Interrupt Service Routine APIs

Polling API

The polling API is used to wait concurrently for any one of multiple conditions to be fulfilled.

- *Concepts*
- *Implementation*
  - *Using k_poll()*
  - *Using k_poll_signal_raise()*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts The polling API's main function is `k_poll()`, which is very similar in concept to the POSIX `poll()` function, except that it operates on kernel objects rather than on file descriptors.

The polling API allows a single thread to wait concurrently for one or more conditions to be fulfilled without actively looking at each one individually.

There is a limited set of such conditions:

- a semaphore becomes available
- a kernel FIFO contains data ready to be retrieved
- a kernel LIFO contains data ready to be retrieved
- a kernel message queue contains data ready to be retrieved
- a kernel pipe contains data ready to be retrieved
- a poll signal is raised

A thread that wants to wait on multiple conditions must define an array of **poll events**, one for each condition.

All events in the array must be initialized before the array can be polled on.

Each event must specify which **type** of condition must be satisfied so that its state is changed to signal the requested condition has been met.

Each event must specify what **kernel object** it wants the condition to be satisfied for.

Each event must specify which **mode** of operation is used when the condition is satisfied.

Each event can optionally specify a **tag** to group multiple events together, at the user's discretion.

Apart from the kernel objects, there is also a **poll signal** pseudo-object type that be directly signaled.

The `k_poll()` function returns as soon as one of the conditions it is waiting for is fulfilled. It is possible for more than one to be fulfilled when `k_poll()` returns, if they were fulfilled before `k_poll()` was called, or due to the preemptive multi-threading nature of the kernel. The caller must look at the state of all the poll events in the array to figure out which ones were fulfilled and what actions to take.

Currently, there is only one mode of operation available: the object is not acquired. As an example, this means that when `k_poll()` returns and the poll event states that the semaphore is available, the caller of `k_poll()` must then invoke `k_sem_take()` to take ownership of the semaphore. If the semaphore is contested, there is no guarantee that it will be still available when `k_sem_take()` is called.

Implementation

Using k_poll() The main API is `k_poll()`, which operates on an array of poll events of type `k_poll_event`. Each entry in the array represents one event with a condition, which a call to `k_poll()` will wait for to be fulfilled.

Poll events can be initialized using either the runtime initializers `K_POLL_EVENT_INITIALIZER()` or `k_poll_event_init()`, or the static initializer `K_POLL_EVENT_STATIC_INITIALIZER()`. An object that matches the **type** specified must be passed to the initializers. The **mode** *must* be set to `K_POLL_MODE_NOTIFY_ONLY`. The state *must* be set to `K_POLL_STATE_NOT_READY` (the initializers take care of this). The user **tag** is optional and completely opaque to the API: it is there to help a user to group similar events together. Being optional, it is passed to the static initializer, but not the runtime ones for performance reasons. If using runtime initializers, the user must set it separately in the `k_poll_event` data structure. If an event in the array is to be ignored, most likely temporarily, its type can be set to `K_POLL_TYPE_IGNORE`.

```
struct k_poll_event events[4] = {
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_SEM_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_sem, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_FIFO_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_fifo, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_MSGQ_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_msgq, 0),
    K_POLL_EVENT_STATIC_INITIALIZER(K_POLL_TYPE_PIPE_DATA_AVAILABLE,
                                    K_POLL_MODE_NOTIFY_ONLY,
                                    &my_pipe, 0),
};
```

or at runtime

```
struct k_poll_event events[4];
void some_init(void)
{
    k_poll_event_init(&events[0],
                      K_POLL_TYPE_SEM_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_sem);

    k_poll_event_init(&events[1],
                      K_POLL_TYPE_FIFO_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_fifo);

    k_poll_event_init(&events[2],
                      K_POLL_TYPE_MSGQ_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_msgq);

    k_poll_event_init(&events[3],
                      K_POLL_TYPE_PIPE_DATA_AVAILABLE,
                      K_POLL_MODE_NOTIFY_ONLY,
                      &my_pipe);

    // tags are left uninitialized if unused
}
```

After the events are initialized, the array can be passed to `k_poll()`. A timeout can be specified to wait only for a specified amount of time, or the special values `K_NO_WAIT` and `K_FOREVER` to either not wait or wait until an event condition is satisfied and not sooner.

A list of pollers is offered on each semaphore or FIFO and as many events can wait in it as the app wants. Notice that the waiters will be served in first-come-first-serve order, not in priority order.

In case of success, `k_poll()` returns 0. If it times out, it returns -`EAGAIN`.

```
// assume there is no contention on this semaphore and FIFO
// -EADDRINUSE will not occur; the semaphore and/or data will be available

void do_stuff(void)
{
```

(continues on next page)

(continued from previous page)

```
    rc = k_poll(events, ARRAY_SIZE(events), K_MSEC(1000));
    if (rc == 0) {
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        } else if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        } else if (events[2].state == K_POLL_STATE_MSGQ_DATA_AVAILABLE) {
            ret = k_msgq_get(events[2].msgq, buf, K_NO_WAIT);
            // handle data
        } else if (events[3].state == K_POLL_STATE_PIPE_DATA_AVAILABLE) {
            bytes_read = k_pipe_read(events[3].pipe, buf, bytes_to_read,␣
↪K_NO_WAIT);
            // handle data
        }
    } else {
        // handle timeout
    }
}
```

When `k_poll()` is called in a loop, the events state must be reset to `K_POLL_STATE_NOT_READY` by the user.

```
void do_stuff(void)
{
    for(;;) {
        rc = k_poll(events, ARRAY_SIZE(events), K_FOREVER);
        if (events[0].state == K_POLL_STATE_SEM_AVAILABLE) {
            k_sem_take(events[0].sem, 0);
        }
        if (events[1].state == K_POLL_STATE_FIFO_DATA_AVAILABLE) {
            data = k_fifo_get(events[1].fifo, 0);
            // handle data
        }
        if (events[2].state == K_POLL_STATE_MSGQ_DATA_AVAILABLE) {
            ret = k_msgq_get(events[2].msgq, buf, K_NO_WAIT);
            // handle data
        }
        if (events[3].state == K_POLL_STATE_PIPE_DATA_AVAILABLE) {
            bytes_read = k_pipe_read(events[3].pipe, buf, bytes_to_read,␣
↪K_NO_WAIT);
            // handle data
        }
        events[0].state = K_POLL_STATE_NOT_READY;
        events[1].state = K_POLL_STATE_NOT_READY;
        events[2].state = K_POLL_STATE_NOT_READY;
        events[3].state = K_POLL_STATE_NOT_READY;
    }
}
```

Using k_poll_signal_raise() One of the types of events is `K_POLL_TYPE_SIGNAL`: this is a "direct" signal to a poll event. This can be seen as a lightweight binary semaphore only one thread can wait for.

A poll signal is a separate object of type `k_poll_signal` that must be attached to a k_poll_event, similar to a semaphore or FIFO. It must first be initialized either via `K_POLL_SIGNAL_INITIALIZER()` or `k_poll_signal_init()`.

```
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);
}
```

It is signaled via the `k_poll_signal_raise()` function. This function takes a user **result** parameter that is opaque to the API and can be used to pass extra information to the thread waiting on the event.

```
struct k_poll_signal signal;

// thread A
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
                                 K_POLL_MODE_NOTIFY_ONLY,
                                 &signal),
    };

    k_poll(events, 1, K_FOREVER);

    int signaled, result;

    k_poll_signal_check(&signal, &signaled, &result);

    if (signaled && (result == 0x1337)) {
        // A-OK!
    } else {
        // weird error
    }
}

// thread B
void signal_do_stuff(void)
{
    k_poll_signal_raise(&signal, 0x1337);
}
```

If the signal is to be polled in a loop, *both* its event state must be reset to `K_POLL_STATE_NOT_READY` *and* its `result` must be reset using `k_poll_signal_reset()` on each iteration if it has been signaled.

```
struct k_poll_signal signal;
void do_stuff(void)
{
    k_poll_signal_init(&signal);

    struct k_poll_event events[1] = {
        K_POLL_EVENT_INITIALIZER(K_POLL_TYPE_SIGNAL,
                                 K_POLL_MODE_NOTIFY_ONLY,
                                 &signal),
    };
```

(continues on next page)

(continued from previous page)

```
    for (;;) {
        k_poll(events, 1, K_FOREVER);

        int signaled, result;

        k_poll_signal_check(&signal, &signaled, &result);

        if (signaled && (result == 0x1337)) {
            // A-OK!
        } else {
            // weird error
        }

        k_poll_signal_reset(&signal);
        events[0].state = K_POLL_STATE_NOT_READY;
    }
}
```

Note that poll signals are not internally synchronized. A `k_poll()` call that is passed a signal will return after any code in the system calls `k_poll_signal_raise()`. But if the signal is being externally managed and reset via `k_poll_signal_init()`, it is possible that by the time the application checks, the event state may no longer be equal to `K_POLL_STATE_SIGNALED`, and a (naive) application will miss events. Best practice is always to reset the signal only from within the thread invoking the `k_poll()` loop, or else to use some other event type which tracks event counts: semaphores and FIFOs are more error-proof in this sense because they can't "miss" events, architecturally.

Suggested Uses Use `k_poll()` to consolidate multiple threads that would be pending on one object each, saving possibly large amounts of stack space.

Use a poll signal as a lightweight binary semaphore if only one thread pends on it.

Note

Because objects are only signaled if no other thread is waiting for them to become available and only one thread can poll on a specific object, polling is best used when objects are not subject of contention between multiple threads, basically when a single thread operates as a main "server" or "dispatcher" for multiple objects and is the only one trying to acquire these objects.

Semaphores

A *semaphore* is a kernel object that implements a traditional counting semaphore.

- *Concepts*

- *Implementation*
  - *Defining a Semaphore*
  - *Giving a Semaphore*
  - *Taking a Semaphore*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*
- *User Mode Semaphore API Reference*

Concepts Any number of semaphores can be defined (limited only by available RAM). Each semaphore is referenced by its memory address.

A semaphore has the following key properties:

- A **count** that indicates the number of times the semaphore can be taken. A count of zero indicates that the semaphore is unavailable.
- A **limit** that indicates the maximum value the semaphore's count can reach.

A semaphore must be initialized before it can be used. Its count must be set to a non-negative value that is less than or equal to its limit.

A semaphore may be **given** by a thread or an ISR. Giving the semaphore increments its count, unless the count is already equal to the limit.

A semaphore may be **taken** by a thread. Taking the semaphore decrements its count, unless the semaphore is unavailable (i.e. at zero). When a semaphore is unavailable, a thread may choose to wait for it to be given. Any number of threads may wait on an unavailable semaphore simultaneously. When the semaphore is given, it is taken by the highest priority thread that has waited longest.

Note

You may initialize a "full" semaphore (count equal to limit) to limit the number of threads able to execute the critical section at the same time. You may also initialize an empty semaphore (count equal to 0, with a limit greater than 0) to create a gate through which no waiting thread may pass until the semaphore is incremented. All standard use cases of the common semaphore are supported.

Note

The kernel does allow an ISR to take a semaphore, however the ISR must not attempt to wait if the semaphore is unavailable.

Implementation

Defining a Semaphore A semaphore is defined using a variable of type `k_sem`. It must then be initialized by calling `k_sem_init()`.

The following code defines a semaphore, then configures it as a binary semaphore by setting its count to 0 and its limit to 1.

```
struct k_sem my_sem;

k_sem_init(&my_sem, 0, 1);
```

Alternatively, a semaphore can be defined and initialized at compile time by calling K_SEM_DEFINE.

The following code has the same effect as the code segment above.

```
K_SEM_DEFINE(my_sem, 0, 1);
```

Giving a Semaphore A semaphore is given by calling k_sem_give().

The following code builds on the example above, and gives the semaphore to indicate that a unit of data is available for processing by a consumer thread.

```
void input_data_interrupt_handler(void *arg)
{
    /* notify thread that data is available */
    k_sem_give(&my_sem);

    ...
}
```

Taking a Semaphore A semaphore is taken by calling k_sem_take().

The following code builds on the example above, and waits up to 50 milliseconds for the semaphore to be given. A warning is issued if the semaphore is not obtained in time.

```
void consumer_thread(void)
{
    ...

    if (k_sem_take(&my_sem, K_MSEC(50)) != 0) {
        printk("Input data not available!");
    } else {
        /* fetch available data */
        ...
    }
    ...
}
```

Suggested Uses Use a semaphore to control access to a set of resources by multiple threads.

Use a semaphore to synchronize processing between producing and consuming threads or ISRs.

Configuration Options Related configuration options:

Mutexes

A *mutex* is a kernel object that implements a traditional reentrant mutex. A mutex allows multiple threads to safely share an associated hardware or software resource by ensuring mutually exclusive access to the resource.

- *Concepts*
  - *Reentrant Locking*
  - *Priority Inheritance*
- *Implementation*
  - *Defining a Mutex*
  - *Locking a Mutex*
  - *Unlocking a Mutex*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*
- *Futex API Reference*
- *User Mode Mutex API Reference*

Concepts Any number of mutexes can be defined (limited only by available RAM). Each mutex is referenced by its memory address.

A mutex has the following key properties:

- A **lock count** that indicates the number of times the mutex has been locked by the thread that has locked it. A count of zero indicates that the mutex is unlocked.
- An **owning thread** that identifies the thread that has locked the mutex, when it is locked.

A mutex must be initialized before it can be used. This sets its lock count to zero.

A thread that needs to use a shared resource must first gain exclusive rights to access it by **locking** the associated mutex. If the mutex is already locked by another thread, the requesting thread may choose to wait for the mutex to be unlocked.

After locking a mutex, the thread may safely use the associated resource for as long as needed; however, it is considered good practice to hold the lock for as short a time as possible to avoid negatively impacting other threads that want to use the resource. When the thread no longer needs the resource it must **unlock** the mutex to allow other threads to use the resource.

A mutex must not be freed, or have its memory reused, while it is locked or while threads are waiting on it. A mutex embedded in a dynamically allocated object must be unlocked before

that object is released; otherwise the owning thread is left tracking a mutex in memory that no longer belongs to it.

Any number of threads may wait on a locked mutex simultaneously. When the mutex becomes unlocked it is then locked by the highest-priority thread that has waited the longest.

> **Note**
>
> Mutex objects are *not* designed for use by ISRs.

Reentrant Locking A thread is permitted to lock a mutex it has already locked. This allows the thread to access the associated resource at a point in its execution when the mutex may or may not already be locked.

A mutex that is repeatedly locked by a thread must be unlocked an equal number of times before the mutex becomes fully unlocked so it can be claimed by another thread.

Priority Inheritance The thread that has locked a mutex is eligible for *priority inheritance*. This means the kernel will *temporarily* elevate the thread's priority if a higher priority thread begins waiting on the mutex. This allows the owning thread to complete its work and release the mutex more rapidly by executing at the same priority as the waiting thread. Once the mutex has been unlocked, the unlocking thread resets its priority to the level it had before locking that mutex.

> **Note**
>
> The `CONFIG_PRIORITY_CEILING` configuration option limits how high the kernel can raise a thread's priority due to priority inheritance. The default value of -128 permits unlimited. Setting this to a priority level that is at or lower than the priority of the idle thread disables it.

A thread's priority prior to any mutex-related boost is saved on the thread itself the first time it is raised, and each mutex it holds is tracked in a per-thread list. Each time a higher priority thread waits on a mutex, the kernel adjusts the owning thread's priority. When the owning thread releases a lock (or if the high priority waiting thread times out), the kernel rescans the thread's remaining held mutexes and recalculates its priority from the highest-priority waiter still pending on any of them, falling back to the thread's original priority if none remain. This gives correct results regardless of the order in which held mutexes are unlocked.

If the owner of a mutex is itself blocked waiting on another mutex, a priority boost is propagated along that ownership chain so that every thread blocking progress towards the waiter is raised in turn, up to an implementation-defined limit on the number of chain hops walked per lock attempt. Owners beyond that limit keep their pre-boost priority until a later lock attempt walks the chain again.

Implementation

Defining a Mutex A mutex is defined using a variable of type `k_mutex`. It must then be initialized by calling `k_mutex_init()`.

The following code defines and initializes a mutex.

```
struct k_mutex my_mutex;

k_mutex_init(&my_mutex);
```

Alternatively, a mutex can be defined and initialized at compile time by calling K_MUTEX_DEFINE.

The following code has the same effect as the code segment above.

```
K_MUTEX_DEFINE(my_mutex);
```

Locking a Mutex A mutex is locked by calling k_mutex_lock().

The following code builds on the example above, and waits indefinitely for the mutex to become available if it is already locked by another thread.

```
k_mutex_lock(&my_mutex, K_FOREVER);
```

The following code waits up to 100 milliseconds for the mutex to become available, and gives a warning if the mutex does not become available.

```
if (k_mutex_lock(&my_mutex, K_MSEC(100)) == 0) {
    /* mutex successfully locked */
} else {
    printf("Cannot lock XYZ display\n");
}
```

Unlocking a Mutex A mutex is unlocked by calling k_mutex_unlock().

The following code builds on the example above, and unlocks the mutex that was previously locked by the thread.

```
k_mutex_unlock(&my_mutex);
```

Suggested Uses Use a mutex to provide exclusive access to a resource, such as a physical device.

Configuration Options Related configuration options:

- CONFIG_PRIORITY_CEILING

API Reference
Mutex APIs

Related code samples

- Dining PhilosophersImplement a solution to the Dining Philosophers problem using Zephyr kernel services.

Futex API Reference k_futex is a lightweight mutual exclusion primitive designed to minimize kernel involvement. Uncontended operation relies only on atomic access to shared memory. k_futex are not kernel objects and do not use the kernel object permission management. They live in user memory and can be used by any thread which has read-write access to this memory.

FUTEX APIs

User Mode Mutex API Reference sys_mutex behaves almost exactly like k_mutex, with the added advantage that a sys_mutex instance can reside in user memory. When user mode isn't enabled, sys_mutex behaves like k_mutex.

User mode mutex APIs

Condition Variables

A *condition variable* is a synchronization primitive that enables threads to wait until a particular condition occurs.

- *Concepts*
- *Implementation*
  - *Defining a Condition Variable*
  - *Waiting on a Condition Variable*
  - *Signaling a Condition Variable*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of condition variables can be defined (limited only by available RAM). Each condition variable is referenced by its memory address.

To wait for a condition to become true, a thread can make use of a condition variable.

A condition variable is basically a queue of threads that threads can put themselves on when some state of execution (i.e., some condition) is not as desired (by waiting on the condition). The function `k_condvar_wait()` performs atomically the following steps;

1. Releases the last acquired mutex.
2. Puts the current thread in the condition variable queue.

Some other thread, when it changes said state, can then wake one (or more) of those waiting threads and thus allow them to continue by signaling on the condition using `k_condvar_signal()` or `k_condvar_broadcast()` then it:

1. Re-acquires the mutex previously released.
2. Returns from `k_condvar_wait()`.

Regardless of why the wait completes – whether the thread was signaled, the supplied timeout elapsed, or the wait was requested without blocking – `k_condvar_wait()` always returns with the associated mutex re-locked by the calling thread.

A condition variable must be initialized before it can be used.

Implementation

Defining a Condition Variable A condition variable is defined using a variable of type `k_condvar`. It must then be initialized by calling `k_condvar_init()`.

The following code defines a condition variable:

```
struct k_condvar my_condvar;

k_condvar_init(&my_condvar);
```

Alternatively, a condition variable can be defined and initialized at compile time by calling `K_CONDVAR_DEFINE`.

The following code has the same effect as the code segment above.

```
K_CONDVAR_DEFINE(my_condvar);
```

Waiting on a Condition Variable A thread can wait on a condition by calling `k_condvar_wait()`.

The following code waits on the condition variable.

```
K_MUTEX_DEFINE(mutex);
K_CONDVAR_DEFINE(condvar)

int main(void)
{
    k_mutex_lock(&mutex, K_FOREVER);

    /* block this thread until another thread signals cond. While
     * blocked, the mutex is released, then re-acquired before this
     * thread is woken up and the call returns.
     */
    k_condvar_wait(&condvar, &mutex, K_FOREVER);
    ...
    k_mutex_unlock(&mutex);
}
```

Signaling a Condition Variable A condition variable is signaled on by calling `k_condvar_signal()` for one thread or by calling `k_condvar_broadcast()` for multiple threads.

The following code builds on the example above.

```
void worker_thread(void)
{
    k_mutex_lock(&mutex, K_FOREVER);

    /*
     * Do some work and fulfill the condition
     */
    ...
    ...
    k_condvar_signal(&condvar);
    k_mutex_unlock(&mutex);
}
```

Suggested Uses Use condition variables with a mutex to signal changing states (conditions) from one thread to another thread. Condition variables are not the condition itself and they are not events. The condition is contained in the surrounding programming logic.

Mutexes alone are not designed for use as a notification/synchronization mechanism. They are meant to provide mutually exclusive access to a shared resource only.

Configuration Options Related configuration options:

Events

An *event object* is a kernel object that implements traditional events.

- *Concepts*
- *Implementation*
  - *Defining an Event Object*
  - *Setting Events*
  - *Posting Events*
  - *Waiting for Events (without removal)*
  - *Waiting for Events (with removal)*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of event objects can be defined (limited only by available RAM). Each event object is referenced by its memory address. One or more threads may wait on an event object until the desired set of events has been delivered to the event object. When new events are delivered to the event object, all threads whose wait conditions have been satisfied become ready simultaneously.

An event object has the following key properties:

- A 32-bit value that tracks which events have been delivered to it.

An event object must be initialized before it can be used.

Events may be **delivered** by a thread or an ISR. When delivering events, the events may either overwrite the existing set of events or add to them in a bitwise fashion. When overwriting the existing set of events, this is referred to as setting. When adding to them in a bitwise fashion, this is referred to as posting. Both posting and setting events have the potential to fulfill match conditions of multiple threads waiting on the event object. All threads whose match conditions have been met are made active at the same time.

Threads may wait on one or more events. They may either wait for all of the requested events, or for any of them. Furthermore, threads making a wait request have the option of resetting the current set of events tracked by the event object prior to waiting. Care must be taken with this option when multiple threads wait on the same event object.

Note

The kernel does allow an ISR to query an event object, however the ISR must not attempt to wait for the events.

Implementation

Defining an Event Object An event object is defined using a variable of type `k_event`. It must then be initialized by calling `k_event_init()`.

The following code defines an event object.

```
struct k_event my_event;

k_event_init(&my_event);
```

Alternatively, an event object can be defined and initialized at compile time by calling `K_EVENT_DEFINE`.

The following code has the same effect as the code segment above.

```
K_EVENT_DEFINE(my_event);
```

Setting Events Events in an event object are set by calling `k_event_set()`.

The following code builds on the example above, and sets the events tracked by the event object to 0x001.

```
void input_available_interrupt_handler(void *arg)
{
    /* notify threads that data is available */

    k_event_set(&my_event, 0x001);

    ...
}
```

Posting Events Events are posted to an event object by calling `k_event_post()`.

The following code builds on the example above, and posts a set of events to the event object.

```
void input_available_interrupt_handler(void *arg)
{
    ...

    /* notify threads that more data is available */

    k_event_post(&my_event, 0x120);

    ...
}
```

Waiting for Events (without removal) Threads wait for events by calling `k_event_wait()`.

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
```

(continues on next page)

(continued from previous page)

```
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events before continuing using `k_event_wait_all()`.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_all(&my_event, 0x121, false, K_MSEC(50));
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
        ...
    }
    ...
}
```

Waiting for Events (with removal) Threads wait for events (with atomic removal upon receipt) by calling `k_event_wait_safe()`.

The following code builds on the example above, and waits up to 50 milliseconds for any of the specified events to be posted. A warning is issued if none of the events are posted in time.

If events are received on time, then they will not be present in the event object until the next time that the events are set or posted.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_safe(&my_event, 0xFFF, false, K_MSEC(50));
    if (events == 0) {
        printk("No input devices are available!");
    } else {
        /* Access the desired input device(s) */
        ...
    }
    ...
}
```

Alternatively, the consumer thread may desire to wait for all the events (with atomic removal upon receipt) before continuing using `k_event_wait_all_safe()`.

If all events are received on time, then they will not be present in the event object until the next time that the events are set or posted.

```
void consumer_thread(void)
{
    uint32_t  events;

    events = k_event_wait_all_safe(&my_event, 0x121, false, K_MSEC(50));
```

(continues on next page)

(continued from previous page)

```
    if (events == 0) {
        printk("At least one input device is not available!");
    } else {
        /* Access the desired input devices */
        ...
    }
    ...
}
```

Suggested Uses Use events to indicate that a set of conditions have occurred.

Use events to pass small amounts of data to multiple threads at once.

Spinlocks

- *Usage*
  - *Acquiring without spinning*
  - *Rules*
- *Spinlocks on uniprocessor systems*
- *Spinlock validation*
- *Fair spinlocks*
- *Suggested uses*
- *API reference*

A spinlock is the lowest-level mutual-exclusion primitive in Zephyr. It guards a brief critical section so that only one execution context can access a shared resource at a time. A context that finds the lock already held "spins", busy waiting until the lock becomes available, rather than blocking and yielding the CPU. This is why spinlocks are only appropriate for short critical sections.

Acquiring a spinlock also masks interrupts on the local CPU for as long as the lock is held. This is what makes a spinlock safe to share between threads and interrupt handlers: while a context holds the lock, no ISR on the same CPU can preempt it and no other CPU can take the same lock, so neither can observe or corrupt the protected data mid-update. For these reasons, `k_spinlock` is the primary synchronization primitive used within the Zephyr kernel itself, protecting access to its core data structures.

Application code may use it directly as well, but it is generally recommended to use a higher-level synchronization primitive such as a `k_mutex` or `k_sem` instead.

Usage Declare a `k_spinlock` for each independent resource you need to protect. Acquire it with `k_spin_lock()`, which returns a `k_spinlock_key_t` that must be passed back to `k_spin_unlock()` to release the lock:

```
static struct k_spinlock lock;

void update_shared_state(void)
{
        k_spinlock_key_t key = k_spin_lock(&lock);

        /* critical section: exclusive access */

        k_spin_unlock(&lock, key);
}
```

The K_SPINLOCK helper acquires the lock for the duration of the enclosed block and releases it automatically on exiting the block.

```
K_SPINLOCK(&lock) {
        /* critical section: exclusive access */
}
```

The block must either run to its end or be left with K_SPINLOCK_BREAK. Leaving it with a plain break, goto or return skips the release and leaks the lock:

```
K_SPINLOCK(&lock) {
        if (nothing_to_do) {
                K_SPINLOCK_BREAK;
        }

        /* critical section: exclusive access */
}
```

Acquiring without spinning k_spin_trylock() makes a single attempt to take the lock and reports failure instead of waiting, which is useful when the caller has other work to do or must not stall. On success it stores the key, which is released exactly as for k_spin_lock():

```
k_spinlock_key_t key;

if (k_spin_trylock(&lock, &key) == 0) {
        /* critical section: exclusive access */
        k_spin_unlock(&lock, key);
} else {
        /* lock is held elsewhere, do something else */
}
```

Rules Follow these rules when using a spinlock:

- Keep the critical section as short as possible. Interrupts are masked on the local CPU while the lock is held, and other CPUs may be spinning on it.
- Never perform a blocking or sleeping operation while holding a spinlock.
- Do not acquire a spinlock recursively. A context that already holds a lock must not try to take it again, or it will deadlock. Nesting **distinct** spinlocks is allowed, but must follow a consistent lock ordering to avoid deadlock.

Spinlocks on uniprocessor systems In a kernel built with CONFIG_SMP disabled, a spinlock does not actually spin. With only one CPU there is nothing to contend with, so k_spin_lock() reduces to masking interrupts on the local CPU. This prevents both ISRs and context switches from observing the protected data mid-update, which is all that is needed for mutual exclusion on a uniprocessor.

Spinlock validation A validation layer, enabled with `CONFIG_SPIN_VALIDATE`, is available to detect various misuses of spinlocks. It can detect the following:

- Recursive acquisition of a spinlock
- Release of a spinlock that is not held by the current context
- Out-of-order release of spinlocks (an outer lock released while an inner lock is still held)
- Context switching while a spinlock is held, or while interrupts are masked by a nested `irq_lock()`

On a uniprocessor system, only the recursive acquisition check is meaningful. The other misuses cannot occur, since there is no contention and interrupts are masked while the lock is held.

Fair spinlocks The default spinlock implementation is built on a single `atomic_t` variable and does not guarantee fairness between contending CPUs: It is possible for one CPU to repeatedly win the contention, thus starving the others. Where this matters, enabling `CONFIG_TICKET_SPINLOCKS` switches to a ticket-based implementation that grants a contended lock to requesting CPUs in FIFO order at the cost of a slightly larger lock object.

Suggested uses Use a spinlock to protect a short critical section that is shared between threads and interrupt handlers, or between CPUs on an SMP system.

Prefer another primitive when it fits better:

- `k_mutex` for a critical section that may be long, may block, or may sleep. Only threads can take a mutex.
- `k_sem` for signalling between contexts, and for counting access to a pool of resources.
- *atomic services* when the shared state is a single word that can be updated with one atomic operation, in which case no lock is needed.

Spinlock APIs

Symmetric Multiprocessing

On multiprocessor architectures, Zephyr supports the use of multiple physical CPUs running Zephyr application code. This support is "symmetric" in the sense that no specific CPU is treated specially by default. Any processor is capable of running any Zephyr thread, with access to all standard Zephyr APIs supported.

No special application code needs to be written to take advantage of this feature. If there are two Zephyr application threads runnable on a supported dual processor device, they will both run simultaneously.

SMP configuration is controlled under the `CONFIG_SMP` kconfig variable. This must be set to "y" to enable SMP features, otherwise a uniprocessor kernel will be built. In general the platform default will have enabled this anywhere it's supported. When enabled, the number of physical CPUs available is visible at build time as `CONFIG_MP_MAX_NUM_CPUS`. Likewise, the default for this will be the number of available CPUs on the platform and it is not expected that typical apps will change it. But it is legal and supported to set this to a smaller (but obviously not larger) number for special purposes (e.g. for testing, or to reserve a physical CPU for running non-Zephyr code).

Synchronization At the application level, core Zephyr IPC and synchronization primitives all behave identically under an SMP kernel. For example semaphores used to implement blocking mutual exclusion continue to be a proper application choice.

At the lowest level, however, Zephyr code has often used the `irq_lock()`/`irq_unlock()` primitives to implement fine grained critical sections using interrupt masking. These APIs continue to

work via an emulation layer (see below), but the masking technique does not: the fact that your CPU will not be interrupted while you are in your critical section says nothing about whether a different CPU will be running simultaneously and be inspecting or modifying the same data!

Spinlocks SMP systems provide a more constrained `k_spin_lock()` primitive that masks interrupts locally, like `irq_lock()`, while also atomically guarding a shared lock variable so that only one CPU enters the critical section at a time. Unlike the legacy IRQ locks, spinlocks are separable and must not be acquired recursively. See *Spinlocks* for a full description, including ticket spinlocks and the API reference.

Legacy irq_lock() emulation For the benefit of applications written to the uniprocessor locking API, `irq_lock()` and `irq_unlock()` continue to work compatibly on SMP systems with identical semantics to their legacy versions. They are implemented as a single global spinlock, with a nesting count and the ability to be atomically reacquired on context switch into locked threads. The kernel will ensure that only one thread across all CPUs can hold the lock at any time, that it is released on context switch, and that it is re-acquired when necessary to restore the lock state when a thread is switched in. Other CPUs will spin waiting for the release to happen.

The overhead involved in this process has measurable performance impact, however. Unlike uniprocessor apps, SMP apps using `irq_lock()` are not simply invoking a very short (often ~1 instruction) interrupt masking operation. That, and the fact that the IRQ lock is global, means that code expecting to be run in an SMP context should be using the spinlock API wherever possible.

Memory Coherence Some multiprocessor architectures are *cache-incoherent*: the per-CPU caches are not automatically kept consistent with each other, so data written by one CPU may not be visible to another until it is flushed from the cache. On such systems, shared kernel data structures must reside in memory that all CPUs observe consistently.

When `CONFIG_KERNEL_COHERENCE` is enabled, the kernel places all shared data into multiprocessor-coherent (generally uncached) memory. Thread stacks remain cached, as does application memory explicitly declared with `__incoherent`. This mode is intended only for SMP kernels running on cache-incoherent architectures, and it carries an implicit API contract: any memory passed to the kernel is assumed to be cache-coherent, so kernel data structures must not be created in uncached regions.

CPU Mask It is often desirable for real time applications to deliberately partition work across physical CPUs instead of relying solely on the kernel scheduler to decide on which threads to execute. Zephyr provides an API, controlled by the `CONFIG_SCHED_CPU_MASK` kconfig variable, which can associate a specific set of CPUs with each thread, indicating on which CPUs it can run.

By default, new threads can run on any CPU. Calling `k_thread_cpu_mask_disable()` with a particular CPU ID will prevent that thread from running on that CPU in the future. Likewise `k_thread_cpu_mask_enable()` will re-enable execution. There are also `k_thread_cpu_mask_clear()` and `k_thread_cpu_mask_enable_all()` APIs available for convenience. For obvious reasons, these APIs are illegal if called on a runnable thread. The thread must be blocked or suspended, otherwise an `-EINVAL` will be returned.

CPU mask filtering is supported with all three scheduler backends. The performance impact differs by backend:

- `CONFIG_SCHED_SIMPLE` — O(N) linear scan of the run queue; every context switch walks the full list looking for the first eligible thread.
- `CONFIG_SCHED_SCALABLE` — O(N) in-order walk of the red/black tree; priority ordering is preserved but the full tree may be traversed when many threads are masked off.
- `CONFIG_SCHED_MULTIQ` — scans priority buckets from highest to lowest and walks the per-bucket list; worst case is O(P·N) where P is the number of occupied priority levels.

For workloads that use CONFIG_SCHED_CPU_MASK_PIN_ONLY, each CPU maintains its own independent run queue, so the scheduler needs only examine that queue with no mask filtering overhead.

Note that k_thread_cpu_mask_clear(), k_thread_cpu_mask_enable_all(), and k_thread_cpu_mask_disable() are not permitted in CONFIG_SCHED_CPU_MASK_PIN_ONLY mode because they can produce a mask that is not exactly one bit, which violates the invariant that every thread is pinned to precisely one CPU.

SMP Boot Process A Zephyr SMP kernel begins boot identically to a uniprocessor kernel. Auxiliary CPUs begin in a disabled state in the architecture layer. All standard kernel initialization, including device initialization, happens on a single CPU before other CPUs are brought online.

Just before entering the application main() function, the kernel calls z_smp_init() to launch the SMP initialization process. This enumerates over the configured CPUs, calling into the architecture layer using arch_cpu_start() for each one. This function is passed a memory region to use as a stack on the foreign CPU (in practice it uses the area that will become that CPU's interrupt stack), the address of a local smp_init_top() callback function to run on that CPU, and a pointer to a "start flag" address which will be used as an atomic signal.

The local SMP initialization (smp_init_top()) on each CPU is then invoked by the architecture layer. Note that interrupts are still masked at this point. This routine is responsible for calling smp_timer_init() to set up any needed stat in the timer driver. On many architectures the timer is a per-CPU device and needs to be configured specially on auxiliary CPUs. Then it waits (spinning) for the atomic "start flag" to be released in the main thread, to guarantee that all SMP initialization is complete before any Zephyr application code runs, and finally calls z_swap() to transfer control to the appropriate runnable thread via the standard scheduler API.

By default the kernel brings up every available CPU during this start-up sequence. A CPU whose devicetree node carries the zephyr,deferred-start flag is skipped and left disabled so that architecture, SoC, board, or application code can start it later at run time; deferral is per CPU, so a system may bring up some secondary CPUs at boot and leave others to be started on demand. A deferred CPU is started with k_smp_cpu_start(), which performs full per-CPU initialization; k_smp_cpu_resume() is the counterpart used to bring a previously stopped CPU back online without repeating one-time initialization.

Interprocessor Interrupts When running in multiprocessor environments, it is occasionally the case that state modified on the local CPU needs to be synchronously handled on a different processor.

One example is the Zephyr k_thread_abort() API, which cannot return until the thread that had been aborted is no longer runnable. If it is currently running on another CPU, that becomes difficult to implement.

Another is low power idle. It is a firm requirement on many devices that system idle be implemented using a low-power mode with as many interrupts (including periodic timer interrupts) disabled or deferred as is possible. If a CPU is in such a state, and on another CPU a thread becomes runnable, the idle CPU has no way to "wake up" to handle the newly-runnable load.

So where possible, Zephyr SMP architectures should implement an interprocessor interrupt. The current framework is very simple: the architecture provides at least a arch_sched_broadcast_ipi() call, which when invoked will flag an interrupt on all CPUs (except the current one, though that is allowed behavior). If the architecture supports directed IPIs (see CONFIG_ARCH_HAS_DIRECTED_IPIS), then the architecture also provides a arch_sched_directed_ipi() call, which when invoked will flag an interrupt on the specified CPUs. When an interrupt is flagged on the CPUs, the z_sched_ipi() function implemented in the scheduler will get invoked on those CPUs. The expectation is that these APIs will evolve over time to encompass more functionality (e.g. cross-CPU calls), and that the scheduler-specific calls here will be implemented in terms of a more general framework.

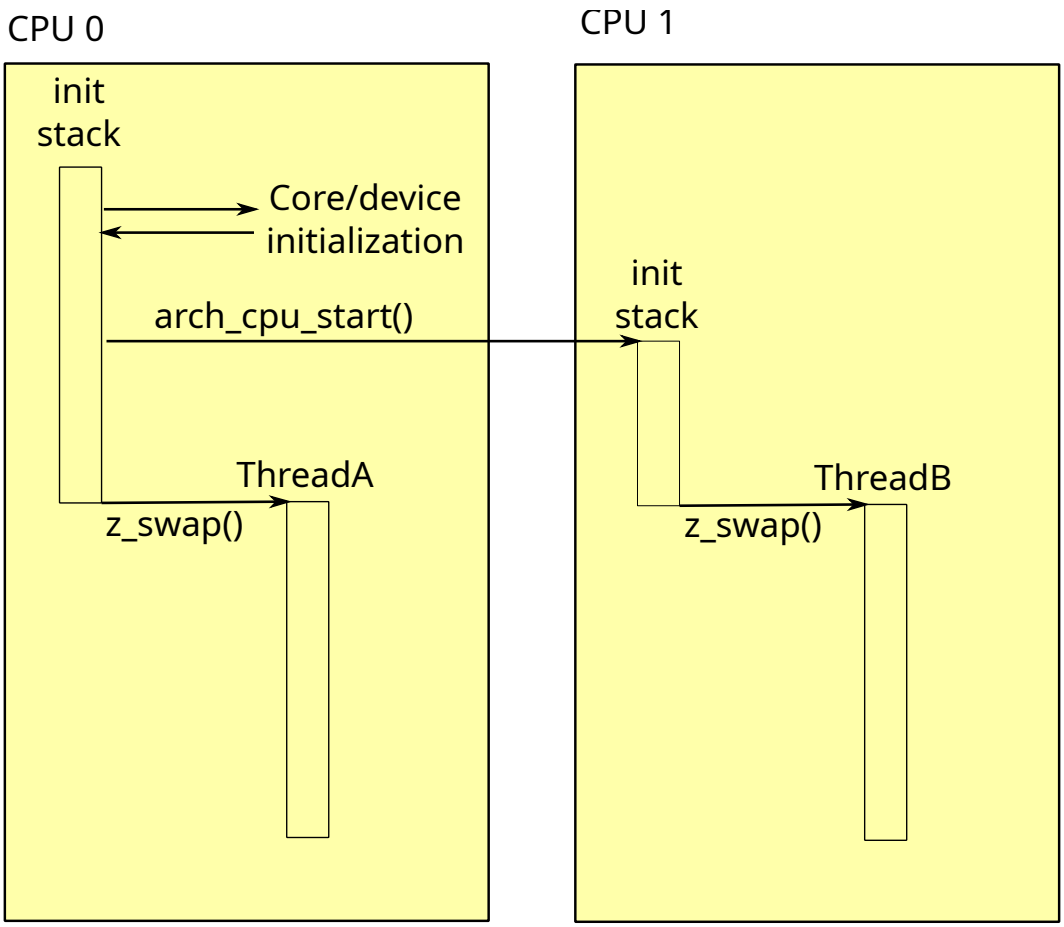

Fig. 1: Example SMP initialization process, showing a configuration with two CPUs and two app threads which begin operating simultaneously.

When directed IPIs are available, the scheduler signals only those CPUs that actually need to reschedule when a thread becomes ready, rather than broadcasting to every other CPU. This avoids disturbing CPUs whose currently running thread does not need to be preempted, reducing the overall interrupt load.

Note that not all SMP architectures will have a usable IPI mechanism (either missing, or just undocumented/unimplemented). In those cases Zephyr provides fallback behavior that is correct, but perhaps suboptimal.

Using this, `k_thread_abort()` becomes only slightly more complicated in SMP: for the case where a thread is actually running on another CPU (we can detect this atomically inside the scheduler), we broadcast an IPI and spin, waiting for the thread to either become "DEAD" or for it to re-enter the queue (in which case we terminate it the same way we would have in uniprocessor mode). Note that the "aborted" check happens on any interrupt exit, so there is no special handling needed in the IPI per se. This allows us to implement a reasonable fallback when IPI is not available: we can simply spin, waiting until the foreign CPU receives any interrupt, though this may be a much longer time!

Likewise idle wakeups are trivially implementable with an empty IPI handler. If a thread is added to an empty run queue (i.e. there may have been idle CPUs), we broadcast an IPI. A foreign CPU will then be able to see the new thread when exiting from the interrupt and will switch to it if available.

Without an IPI, however, a low power idle that requires an interrupt will not work to synchronously run new threads. The workaround in that case is more invasive: Zephyr will **not** enter the system idle handler and will instead spin in its idle loop, testing the scheduler state at high frequency (not spinning on it though, as that would involve severe lock contention) for new threads. The expectation is that power constrained SMP applications are always going to provide an IPI, and this code will only be used for testing purposes or on systems without power consumption requirements.

IPI Cascades The kernel can not control the order in which IPIs are processed by the CPUs in the system. In general, this is not an issue and a single set of IPIs is sufficient to trigger a reschedule on the N CPUs that results with them scheduling the highest N priority ready threads to execute. When CPU masking is used, there may be more than one valid set of threads (not to be confused with an optimal set of threads) that can be scheduled on the N CPUs and a single set of IPIs may be insufficient to result in any of these valid sets.

Note

When CPU masking is not in play, the optimal set of threads is the same as the valid set of threads. However when CPU masking is in play, there may be more than one valid set–one of which may be optimal.

To better illustrate the distinction, consider a 2-CPU system with ready threads T1 and T2 at priorities 1 and 2 respectively. Let T2 be pinned to CPU0 and T1 not be pinned. If CPU0 is executing T2 and CPU1 executing T1, then this set is is both valid and optimal. However, if CPU0 is executing T1 and CPU1 is idling, then this too would be valid though not optimal.

In those cases where a single set of IPIs is not sufficient to generate a valid set, the resulting set of executing threads are expected to be close to a valid set, and subsequent IPIs can generally be expected to correct the situation soon. However, for cases where neither the approximation nor the delay are acceptable, enabling `CONFIG_SCHED_IPI_CASCADE` will allow the kernel to generate cascading IPIs until the kernel has selected a valid set of ready threads for the CPUs.

There are three types of costs/penalties associated with the IPI cascades–and for these reasons they are disabled by default. The first is a cost incurred by the CPU producing the IPI when a new thread preempts the old thread as checks must be done to compare the old thread against the threads executing on the other CPUs. The second is a cost incurred by the CPUs receiving the

IPIs as they must be processed. The third is the apparent sputtering of a thread as it "winks in" and then "winks out" due to cascades stemming from the aforementioned first cost.

IPI Work Items The kernel allows developers to execute functions on other CPUs at ISR level using one or more IPI work items. After IPI work items have been added to the specified CPUs' work queues using `k_ipi_work_add()`, the targeted CPUs will process them after receiving an IPI. Signaling an IPI is done by calling `k_ipi_work_signal()`. Waiting for an IPI work item to be completed by the targeted CPUs is done by calling `k_ipi_work_wait()`. Only a single waiter is permitted at a time.

> **Note**
>
> IPI work items will only be added to the IPI work queues of other CPUs. If adding IPI work items at thread level, the developer must ensure that the current thread does not change CPUs until after signaling the IPIs.

Sample Use The following code outlines how to use IPI work items to update status information across a set of CPUs as a result of one CPU handling an ISR.

```
struct k_ipi_work my_work;

void remote_cpu_action(struct k_ipi_work *arg)
{
    ...
}

void my_isr(void)
{
    /*
     * Wait for previous use of <my_work> to complete.
     * It assumes that <my_work> was initialized elsewhere.
     */

    uint32_t cpu_mask = <bitmask identifying CPUs to update>;

    while (k_ipi_work_wait(&my_work, K_NO_WAIT) == -EAGAIN) {
    }

    /* Add and signal the new work */

    k_ipi_work_add(&my_work, cpu_mask, remote_cpu_action);

    k_ipi_work_signal();
}
```

SMP Kernel Internals In general, Zephyr kernel code is SMP-agnostic and, like application code, will work correctly regardless of the number of CPUs available. But in a few areas there are notable changes in structure or behavior.

Per-CPU data Many elements of the core kernel data need to be implemented for each CPU in SMP mode. For example, the `_current` thread pointer obviously needs to reflect what is running locally, there are many threads running concurrently. Likewise a kernel-provided interrupt stack needs to be created and assigned for each physical CPU, as does the interrupt nesting count used to detect ISR state.

These fields are now moved into a separate struct _cpu instance within the _kernel struct, which has a cpus[] array indexed by ID. Compatibility fields are provided for legacy uniprocessor code trying to access the fields of cpus[0] using the older syntax and assembly offsets.

Note that an important requirement on the architecture layer is that the pointer to this CPU struct be available rapidly when in kernel context. The expectation is that arch_curr_cpu() will be implemented using a CPU-provided register or addressing mode that can store this value across arbitrary context switches or interrupts and make it available to any kernel-mode code.

Similarly, where on a uniprocessor system Zephyr could simply create a global "idle thread" at the lowest priority, in SMP we may need one for each CPU. This makes the internal predicate test for "_is_idle()" in the scheduler, which is a hot path performance environment, more complicated than simply testing the thread pointer for equality with a known static variable. In SMP mode, idle threads are distinguished by a separate field in the thread struct.

Switch-based context switching The traditional Zephyr context switch primitive has been z_swap(). Unfortunately, this function takes no argument specifying a thread to switch to. The expectation has always been that the scheduler has already made its preemption decision when its state was last modified and cached the resulting "next thread" pointer in a location where architecture context switch primitives can find it via a simple struct offset. That technique will not work in SMP, because the other CPU may have modified scheduler state since the current CPU last exited the scheduler (for example: it might already be running that cached thread!).

Instead, the SMP "switch to" decision needs to be made synchronously with the swap call, and as we don't want per-architecture assembly code to be handling scheduler internal state, Zephyr requires a somewhat lower-level context switch primitives for SMP systems: arch_switch() is always called with interrupts masked, and takes exactly two arguments. The first is an opaque (architecture defined) handle to the context to which it should switch, and the second is a pointer to such a handle into which it should store the handle resulting from the thread that is being switched out. The kernel then implements a portable z_swap() implementation on top of this primitive which includes the relevant scheduler logic in a location where the architecture doesn't need to understand it.

Similarly, on interrupt exit, switch-based architectures are expected to call z_get_next_switch_handle() to retrieve the next thread to run from the scheduler. The argument to z_get_next_switch_handle() is either the interrupted thread's "handle" reflecting the same opaque type used by arch_switch(), or NULL if that thread cannot be released to the scheduler just yet. The choice between a handle value or NULL depends on the way CPU interrupt mode is implemented.

Architectures with a large CPU register file would typically preserve only the caller-saved registers on the current thread's stack when interrupted in order to minimize interrupt latency, and preserve the callee-saved registers only when arch_switch() is called to minimize context switching latency. Such architectures must use NULL as the argument to z_get_next_switch_handle() to determine if there is a new thread to schedule, and follow through with their own arch_switch() or derivative if so, or directly leave interrupt mode otherwise. In the former case it is up to that switch code to store the handle resulting from the thread that is being switched out in that thread's "switch_handle" field after its context has fully been saved.

Architectures whose entry in interrupt mode already preserves the entire thread state may pass that thread's handle directly to z_get_next_switch_handle() and be done in one step.

Note that while SMP requires CONFIG_USE_SWITCH, the reverse is not true. A uniprocessor architecture built with CONFIG_SMP set to No might still decide to implement its context switching using arch_switch().

Thread Queue Ordering When a thread is preempted by another thread of higher priority in an SMP system, it is moved to the back of the queue for its priority level. In contrast, on UP systems, a preempted thread does not move to the back of its priority queue; it simply waits to regain the CPU, preserving its original ordering relative to other threads of the same priority.

3.1.2 Data Passing

These pages cover kernel objects which can be used to pass data between threads and ISRs.

The following table summarizes their high-level features.

Object	Bidirectional?	Data structure	Data item size	Data Alignment	ISRs can receive?	ISRs can send?	Overrun handling
FIFO	No	Queue	Arbitrary[1]	4 B[2]	Yes[3]	Yes	N/A
LIFO	No	Queue	Arbitrary[1]	4 B[2]	Yes[3]	Yes	N/A
Stack	No	Array	Word	Word	Yes[3]	Yes	Undefined behavior
Message queue	No	Ring buffer	Arbitrary[6]	Power of two	Yes[3]	Yes	Pend thread or return -errno
Mailbox	Yes	Queue	Arbitrary[1]	Arbitrary	No	No	N/A
Pipe	No	Ring buffer[4]	Arbitrary	Arbitrary	Yes[5]	Yes[5]	Pend thread or return -errno

Queues

A Queue in Zephyr is a kernel object that implements a traditional queue, allowing threads and ISRs to add and remove data items of any size. The queue is similar to a FIFO and serves as the underlying implementation for both *k_fifo* and *k_lifo*. For more information on usage see *k_fifo*.

Cancelling a Wait A thread that is blocked waiting to retrieve an item from a queue can be released without an item by calling `k_queue_cancel_wait()` from another thread or an ISR. The first thread pending on the queue returns from its `k_queue_get()` call with a `NULL` value, exactly as if its timeout had expired. If the queue is instead being waited on through `k_poll()`, that call returns `-EINTR` with the poll event in the cancelled state.

This mechanism is also available to the queue-based primitives through `k_fifo_cancel_wait` and `k_lifo_cancel_wait`.

Queue APIs

FIFOs

A *FIFO* is a kernel object that implements a traditional first in, first out (FIFO) queue, allowing threads and ISRs to add and remove data items of any size.

[1] Callers allocate space for queue overhead in the data elements themselves.
[2] Objects added with `k_fifo_alloc_put()` and `k_lifo_alloc_put()` do not have alignment constraints, but use temporary memory from the calling thread's resource pool.
[3] ISRs can receive only when passing K_NO_WAIT as the timeout argument.
[6] Data item size must be a multiple of the data alignment.
[4] Optional.
[5] ISRs can send and/or receive only when passing K_NO_WAIT as the timeout argument.

- *Concepts*

  - *Defining a FIFO*
  - *Writing to a FIFO*
  - *Reading from a FIFO*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of FIFOs can be defined (limited only by available RAM). Each FIFO is referenced by its memory address.

A FIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A FIFO must be initialized before it can be used. This sets its queue to empty.

FIFO data items must be aligned as required for a pointer, as the kernel reserves the first pointer-sized field of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_fifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

Note

FIFO data items are restricted to single active instance across all FIFO data queues. Any attempt to re-add a FIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a FIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the FIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a FIFO by a thread. If the FIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty FIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a FIFO, however the ISR must not attempt to wait if the FIFO is empty.

If desired, **multiple data items** can be added to a FIFO in a single operation if they are chained together into a singly-linked list. This capability can be useful if multiple writers are adding sets of related data items to the FIFO, as it ensures the data items in each set are not interleaved with other data items. Adding multiple data items to a FIFO is also more efficient than adding them

one at a time, and can be used to guarantee that anyone who removes the first data item in a set will be able to remove the remaining data items without waiting.

Implementation

Defining a FIFO A FIFO is defined using a variable of type `k_fifo`. It must then be initialized by calling `k_fifo_init()`.

The following code defines and initializes an empty FIFO.

```
struct k_fifo my_fifo;

k_fifo_init(&my_fifo);
```

Alternatively, an empty FIFO can be defined and initialized at compile time by calling `K_FIFO_DEFINE`.

The following code has the same effect as the code segment above.

```
K_FIFO_DEFINE(my_fifo);
```

Writing to a FIFO A data item is added to a FIFO by calling `k_fifo_put()`.

The following code builds on the example above, and uses the FIFO to send data to one or more consumer threads.

```
struct data_item_t {
    void *fifo_reserved;   /* 1st word reserved for use by FIFO */
    ...
};

struct data_item_t tx_data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_fifo_put(&my_fifo, &tx_data);

        ...
    }
}
```

Additionally, a singly-linked list of data items can be added to a FIFO by calling `k_fifo_put_list()` or `k_fifo_put_slist()`.

Finally, a data item can be added to a FIFO with `k_fifo_alloc_put()`. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a FIFO A data item is removed from a FIFO by calling `k_fifo_get()`.

The following code builds on the example above, and uses the FIFO to obtain data items from a producer thread, which are then processed in some manner.

```
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t  *rx_data;

    while (1) {
        rx_data = k_fifo_get(&my_fifo, K_FOREVER);

        /* process FIFO data item */
        ...
    }
}
```

Suggested Uses Use a FIFO to asynchronously transfer data items of arbitrary size in a "first in, first out" manner.

LIFOs

A *LIFO* is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove data items of any size.

- *Concepts*
- *Implementation*
  - *Defining a LIFO*
  - *Writing to a LIFO*
  - *Reading from a LIFO*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of LIFOs can be defined (limited only by available RAM). Each LIFO is referenced by its memory address.

A LIFO has the following key properties:

- A **queue** of data items that have been added but not yet removed. The queue is implemented as a simple linked list.

A LIFO must be initialized before it can be used. This sets its queue to empty.

LIFO data items must be aligned as required for a pointer, as the kernel reserves the first pointer-sized field of an item for use as a pointer to the next data item in the queue. Consequently, a data item that holds N bytes of application data requires N+4 (or N+8) bytes of memory. There are no alignment or reserved space requirements for data items if they are added with `k_lifo_alloc_put()`, instead additional memory is temporarily allocated from the calling thread's resource pool.

Note

LIFO data items are restricted to single active instance across all LIFO data queues. Any attempt to re-add a LIFO data item to a queue before it has been removed from the queue to which it was previously added will result in undefined behavior.

A data item may be **added** to a LIFO by a thread or an ISR. The item is given directly to a waiting thread, if one exists; otherwise the item is added to the LIFO's queue. There is no limit to the number of items that may be queued.

A data item may be **removed** from a LIFO by a thread. If the LIFO's queue is empty a thread may choose to wait for a data item to be given. Any number of threads may wait on an empty LIFO simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a LIFO, however the ISR must not attempt to wait if the LIFO is empty.

Implementation

Defining a LIFO A LIFO is defined using a variable of type `k_lifo`. It must then be initialized by calling `k_lifo_init()`.

The following defines and initializes an empty LIFO.

```
struct k_lifo my_lifo;

k_lifo_init(&my_lifo);
```

Alternatively, an empty LIFO can be defined and initialized at compile time by calling `K_LIFO_DEFINE`.

The following code has the same effect as the code segment above.

```
K_LIFO_DEFINE(my_lifo);
```

Writing to a LIFO A data item is added to a LIFO by calling `k_lifo_put()`.

The following code builds on the example above, and uses the LIFO to send data to one or more consumer threads.

```
struct data_item_t {
    void *LIFO_reserved;   /* 1st word reserved for use by LIFO */
    ...
};
```

(continues on next page)

(continued from previous page)

```
struct data_item_t tx data;

void producer_thread(int unused1, int unused2, int unused3)
{
    while (1) {
        /* create data item to send */
        tx_data = ...

        /* send data to consumers */
        k_lifo_put(&my_lifo, &tx_data);

        ...
    }
}
```

A data item can be added to a LIFO with `k_lifo_alloc_put()`. With this API, there is no need to reserve space for the kernel's use in the data item, instead additional memory will be allocated from the calling thread's resource pool until the item is read.

Reading from a LIFO A data item is removed from a LIFO by calling `k_lifo_get()`.

The following code builds on the example above, and uses the LIFO to obtain data items from a producer thread, which are then processed in some manner.

```
void consumer_thread(int unused1, int unused2, int unused3)
{
    struct data_item_t  *rx_data;

    while (1) {
        rx_data = k_lifo_get(&my_lifo, K_FOREVER);

        /* process LIFO data item */
        ...
    }
}
```

Suggested Uses Use a LIFO to asynchronously transfer data items of arbitrary size in a "last in, first out" manner.

Configuration Options Related configuration options:

- None.

Stacks

A *stack* is a kernel object that implements a traditional last in, first out (LIFO) queue, allowing threads and ISRs to add and remove a limited number of integer data values.

- *Concepts*
- *Implementation*
  - *Defining a Stack*
  - *Pushing to a Stack*
  - *Popping from a Stack*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of stacks can be defined (limited only by available RAM). Each stack is referenced by its memory address.

A stack has the following key properties:

- A **queue** of integer data values that have been added but not yet removed. The queue is implemented using an array of stack_data_t values and must be aligned on a native word boundary. The stack_data_t type corresponds to the native word size i.e. 32 bits or 64 bits depending on the CPU architecture and compilation mode.
- A **maximum quantity** of data values that can be queued in the array.

A stack must be initialized before it can be used. This sets its queue to empty.

A data value can be **added** to a stack by a thread or an ISR. The value is given directly to a waiting thread, if one exists; otherwise the value is added to the LIFO's queue.

Note

If `CONFIG_NO_RUNTIME_CHECKS` is enabled, the kernel will *not* detect and prevent attempts to add a data value to a stack that has already reached its maximum quantity of queued values. Adding a data value to a stack that is already full will result in array overflow, and lead to unpredictable behavior.

A data value may be **removed** from a stack by a thread. If the stack's queue is empty a thread may choose to wait for it to be given. Any number of threads may wait on an empty stack simultaneously. When a data item is added, it is given to the highest priority thread that has waited longest.

Note

The kernel does allow an ISR to remove an item from a stack, however the ISR must not attempt to wait if the stack is empty.

Implementation

Defining a Stack A stack is defined using a variable of type `k_stack`. It must then be initialized by calling `k_stack_init()` or `k_stack_alloc_init()`. In the latter case, a buffer is not provided and it is instead allocated from the calling thread's resource pool.

The following code defines and initializes an empty stack capable of holding up to ten word-sized data values.

```
#define MAX_ITEMS 10

stack_data_t my_stack_array[MAX_ITEMS];
struct k_stack my_stack;

k_stack_init(&my_stack, my_stack_array, MAX_ITEMS);
```

Alternatively, a stack can be defined and initialized at compile time by calling `K_STACK_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the stack and its array of data values.

```
K_STACK_DEFINE(my_stack, MAX_ITEMS);
```

Pushing to a Stack A data item is added to a stack by calling `k_stack_push()`.

The following code builds on the example above, and shows how a thread can create a pool of data structures by saving their memory addresses in a stack.

```
/* define array of data structures */
struct my_buffer_type {
    int field1;
    ...
    };
struct my_buffer_type my_buffers[MAX_ITEMS];

/* save address of each data structure in a stack */
for (int i = 0; i < MAX_ITEMS; i++) {
    k_stack_push(&my_stack, (stack_data_t)&my_buffers[i]);
}
```

Popping from a Stack A data item is taken from a stack by calling `k_stack_pop()`.

The following code builds on the example above, and shows how a thread can dynamically allocate an unused data structure. When the data structure is no longer required, the thread must push its address back on the stack to allow the data structure to be reused.

```
struct my_buffer_type *new_buffer;

k_stack_pop(&buffer_stack, (stack_data_t *)&new_buffer, K_FOREVER);
new_buffer->field1 = ...
```

Suggested Uses Use a stack to store and retrieve integer data values in a "last in, first out" manner, when the maximum number of stored items is known.

Message Queues

A *message queue* is a kernel object that implements a simple message queue, allowing threads and ISRs to asynchronously send and receive fixed-size data items.

- *Concepts*
- *Implementation*
  - *Defining a Message Queue*
  - *Writing to a Message Queue*
  - *Reading from a Message Queue*
  - *Peeking into a Message Queue*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of message queues can be defined (limited only by available RAM). Each message queue is referenced by its memory address.

A message queue has the following key properties:

- A **ring buffer** of data items that have been sent but not yet received.
- A **data item size**, measured in bytes.
- A **maximum quantity** of data items that can be queued in the ring buffer.

A message queue must be initialized before it can be used. This sets its ring buffer to empty.

A data item can be **sent** to a message queue by a thread or an ISR. The data item pointed at by the sending thread is copied to a waiting thread, if one exists; otherwise the item is copied to the message queue's ring buffer, if space is available. In either case, the size of the data area being sent *must* equal the message queue's data item size.

If a thread attempts to send a data item when the ring buffer is full, the sending thread may choose to wait for space to become available. Any number of sending threads may wait simultaneously when the ring buffer is full; when space becomes available it is given to the highest priority sending thread that has waited the longest.

A data item can be **received** from a message queue by a thread. The data item is copied to the area specified by the receiving thread; the size of the receiving area *must* equal the message queue's data item size.

If a thread attempts to receive a data item when the ring buffer is empty, the receiving thread may choose to wait for a data item to be sent. Any number of receiving threads may wait simultaneously when the ring buffer is empty; when a data item becomes available it is given to the highest priority receiving thread that has waited the longest.

A thread can also **peek** at the message on the head of a message queue without removing it from the queue. The data item is copied to the area specified by the receiving thread; the size of the receiving area *must* equal the message queue's data item size.

Note

The kernel does allow an ISR to receive an item from a message queue, however the ISR must not attempt to wait if the message queue is empty.

Note

Alignment of the message queue's ring buffer is not necessary. The underlying implementation uses `memcpy()` (which is alignment-agnostic) and does not expose any internal pointers.

Implementation

Defining a Message Queue A message queue is defined using a variable of type `k_msgq`. It must then be initialized by calling `k_msgq_init()`.

The following code defines and initializes an empty message queue that is capable of holding 10 items, each of which is 12 bytes long.

```
struct data_item_type {
    uint32_t field1;
    uint32_t field2;
    uint32_t field3;
};

char my_msgq_buffer[10 * sizeof(struct data_item_type)];
struct k_msgq my_msgq;

k_msgq_init(&my_msgq, my_msgq_buffer, sizeof(struct data_item_type), 10);
```

Alternatively, a message queue can be defined and initialized at compile time by calling one of the following macros:

- `K_MSGQ_DEFINE` – Defines a public message queue.
- `K_MSGQ_DEFINE_STATIC` – Defines a private (static scope) message queue.
- `K_MSGQ_DEFINE_TYPE` – Defines a public message queue for given item type.
- `K_MSGQ_DEFINE_STATIC_TYPE` – Defines a private message queue for given item type.

The following code has the same effect as the code segment above. Observe that the macro defines both the message queue and its buffer.

```
K_MSGQ_DEFINE(my_msgq, sizeof(struct data_item_type), 10, 1);
```

The `K_MSGQ_DEFINE_TYPE` shorthand can be used if the queue item type is known at compile time. This macro configures the queue item size and alignment automatically:

```
K_MSGQ_DEFINE_TYPE(my_msgq, struct data_item_type, 10);
```

Writing to a Message Queue A data item is added to a message queue by calling `k_msgq_put()`.

The following code builds on the example above, and uses the message queue to pass data items from a producing thread to one or more consuming threads. If the message queue fills up because the consumers can't keep up, the producing thread throws away all existing data so the newer data can be saved. Note that this api will trigger reschedule.

```
void producer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* create data item to send (e.g. measurement, timestamp, ...) */
        data = ...

        /* send data to consumers */
        while (k_msgq_put(&my_msgq, &data, K_NO_WAIT) != 0) {
            /* message queue is full: purge old data & try again */
            k_msgq_purge(&my_msgq);
        }

        /* data item was successfully added to message queue */
    }
}
```

Reading from a Message Queue A data item is taken from a message queue by calling `k_msgq_get()`.

The following code builds on the example above, and uses the message queue to process data items generated by one or more producing threads. Note that the return value of `k_msgq_get()` should be tested as `-ENOMSG` can be returned due to `k_msgq_purge()`.

```
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* get a data item */
        k_msgq_get(&my_msgq, &data, K_FOREVER);

        /* process data item */
        ...
    }
}
```

Peeking into a Message Queue A data item is read from a message queue by calling `k_msgq_peek()`.

The following code peeks into the message queue to read the data item at the head of the queue that is generated by one or more producing threads.

```
void consumer_thread(void)
{
    struct data_item_type data;

    while (1) {
        /* read a data item by peeking into the queue */
        k_msgq_peek(&my_msgq, &data);
```

(continues on next page)

(continued from previous page)

```
        /* process data item */
        ...
    }
}
```

Suggested Uses Use a message queue to transfer small data items between threads in an asynchronous manner.

Note

A message queue can be used to transfer large data items, if desired. However, this can increase interrupt latency as interrupts are locked while a data item is written or read. The time to write or read a data item increases linearly with its size since the item is copied in its entirety to or from the buffer in memory. For this reason, it is usually preferable to transfer large data items by exchanging a pointer to the data item, rather than the data item itself.

A synchronous transfer can be achieved by using the kernel's mailbox object type.

Configuration Options Related configuration options:

- None.

Mailboxes

A *mailbox* is a kernel object that provides enhanced message queue capabilities that go beyond the capabilities of a message queue object. A mailbox allows threads to send and receive messages of any size synchronously or asynchronously.

- *Concepts*
  - *Message Format*
  - *Message Lifecycle*
  - *Thread Compatibility*
  - *Message Flow Control*
- *Implementation*
  - *Defining a Mailbox*
  - *Message Descriptors*
  - *Sending a Message*
  - *Receiving a Message*

- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of mailboxes can be defined (limited only by available RAM). Each mailbox is referenced by its memory address.

A mailbox has the following key properties:

- A **send queue** of messages that have been sent but not yet received.
- A **receive queue** of threads that are waiting to receive a message.

A mailbox must be initialized before it can be used. This sets both of its queues to empty.

A mailbox allows threads, but not ISRs, to exchange messages. A thread that sends a message is known as the **sending thread**, while a thread that receives the message is known as the **receiving thread**. Each message may be received by only one thread (i.e. point-to-multipoint and broadcast messaging is not supported).

Messages exchanged using a mailbox are handled non-anonymously, allowing both threads participating in an exchange to know (and even specify) the identity of the other thread.

Message Format A **message descriptor** is a data structure that specifies where a message's data is located, and how the message is to be handled by the mailbox. Both the sending thread and the receiving thread supply a message descriptor when accessing a mailbox. The mailbox uses the message descriptors to perform a message exchange between compatible sending and receiving threads. The mailbox also updates certain message descriptor fields during the exchange, allowing both threads to know what has occurred.

A mailbox message contains zero or more bytes of **message data**. The size and format of the message data is application-defined, and can vary from one message to the next.

A **message buffer** is an area of memory provided by the thread that sends or receives the message data. An array or structure variable can often be used for this purpose.

A message that has neither form of message data is called an **empty message**.

Note

A message whose message buffer exists, but contains zero bytes of actual data, is *not* an empty message.

Message Lifecycle The life cycle of a message is straightforward. A message is created when it is given to a mailbox by the sending thread. The message is then owned by the mailbox until it is given to a receiving thread. The receiving thread may retrieve the message data when it receives the message from the mailbox, or it may perform data retrieval during a second, subsequent mailbox operation. Only when data retrieval has occurred is the message deleted by the mailbox.

Thread Compatibility A sending thread can specify the address of the thread to which the message is sent, or send it to any thread by specifying `K_ANY`. Likewise, a receiving thread can specify the address of the thread from which it wishes to receive a message, or it can receive a message from any thread by specifying `K_ANY`. A message is exchanged only when the requirements of both the sending thread and receiving thread are satisfied; such threads are said to be **compatible**.

For example, if thread A sends a message to thread B (and only thread B) it will be received by thread B if thread B tries to receive a message from thread A or if thread B tries to receive from any thread. The exchange will not occur if thread B tries to receive a message from thread C. The message can never be received by thread C, even if it tries to receive a message from thread A (or from any thread).

Message Flow Control Mailbox messages can be exchanged **synchronously** or **asynchronously**. In a synchronous exchange, the sending thread blocks until the message has been fully processed by the receiving thread. In an asynchronous exchange, the sending thread does not wait until the message has been received by another thread before continuing; this allows the sending thread to do other work (such as gather data that will be used in the next message) *before* the message is given to a receiving thread and fully processed. The technique used for a given message exchange is determined by the sending thread.

The synchronous exchange technique provides an implicit form of flow control, preventing a sending thread from generating messages faster than they can be consumed by receiving threads. The asynchronous exchange technique provides an explicit form of flow control, which allows a sending thread to determine if a previously sent message still exists before sending a subsequent message.

Implementation

Defining a Mailbox A mailbox is defined using a variable of type `k_mbox`. It must then be initialized by calling `k_mbox_init()`.

The following code defines and initializes an empty mailbox.

```
struct k_mbox my_mailbox;

k_mbox_init(&my_mailbox);
```

Alternatively, a mailbox can be defined and initialized at compile time by calling `K_MBOX_DEFINE`.

The following code has the same effect as the code segment above.

```
K_MBOX_DEFINE(my_mailbox);
```

Message Descriptors A message descriptor is a structure of type `k_mbox_msg`. Only the fields listed below should be used; any other fields are for internal mailbox use only.

info
: A 32-bit value that is exchanged by the message sender and receiver, and whose meaning is defined by the application. This exchange is bi-directional, allowing the sender to pass a value to the receiver during any message exchange, and allowing the receiver to pass a value to the sender during a synchronous message exchange.

size
: The message data size, in bytes. Set it to zero when sending an empty message, or when sending a message buffer with no actual data. When receiving a message, set it to the maximum amount of data desired, or to zero if the message data is not wanted. The mailbox updates this field with the actual number of data bytes exchanged once the message is received.

tx_data
: A pointer to the sending thread's message buffer. Set it to `NULL` when sending an empty message. Leave this field uninitialized when receiving a message.

tx_target_thread
: The address of the desired receiving thread. Set it to `K_ANY` to allow any thread to receive

the message. Leave this field uninitialized when receiving a message. The mailbox updates this field with the actual receiver's address once the message is received.

rx_source_thread
The address of the desired sending thread. Set it to `K_ANY` to receive a message sent by any thread. Leave this field uninitialized when sending a message. The mailbox updates this field with the actual sender's address when the message is put into the mailbox.

Sending a Message A thread sends a message by first creating its message data, if any.

Next, the sending thread creates a message descriptor that characterizes the message to be sent, as described in the previous section.

Finally, the sending thread calls a mailbox send API to initiate the message exchange. The message is immediately given to a compatible receiving thread, if one is currently waiting. Otherwise, the message is added to the mailbox's send queue.

Any number of messages may exist simultaneously on a send queue. The messages in the send queue are sorted according to the priority of the sending thread. Messages of equal priority are sorted so that the oldest message can be received first.

For a synchronous send operation, the operation normally completes when a receiving thread has both received the message and retrieved the message data. If the message is not received before the waiting period specified by the sending thread is reached, the message is removed from the mailbox's send queue and the send operation fails. When a send operation completes successfully the sending thread can examine the message descriptor to determine which thread received the message, how much data was exchanged, and the application-defined info value supplied by the receiving thread.

Note

A synchronous send operation may block the sending thread indefinitely, even when the thread specifies a maximum waiting period. The waiting period only limits how long the mailbox waits before the message is received by another thread. Once a message is received there is *no* limit to the time the receiving thread may take to retrieve the message data and unblock the sending thread.

For an asynchronous send operation, the operation always completes immediately. This allows the sending thread to continue processing regardless of whether the message is given to a receiving thread immediately or added to the send queue. The sending thread may optionally specify a semaphore that the mailbox gives when the message is deleted by the mailbox, for example, when the message has been received and its data retrieved by a receiving thread. The use of a semaphore allows the sending thread to easily implement a flow control mechanism that ensures that the mailbox holds no more than an application-specified number of messages from a sending thread (or set of sending threads) at any point in time.

Note

A thread that sends a message asynchronously has no way to determine which thread received the message, how much data was exchanged, or the application-defined info value supplied by the receiving thread.

Sending an Empty Message This code uses a mailbox to synchronously pass 4 byte random values to any consuming thread that wants one. The message "info" field is large enough to carry the information being exchanged, so the data portion of the message isn't used.

```
void producer_thread(void)
{
    struct k_mbox_msg send_msg;

    while (1) {

        /* generate random value to send */
        uint32_t random_value = sys_rand32_get();

        /* prepare to send empty message */
        send_msg.info = random_value;
        send_msg.size = 0;
        send_msg.tx_data = NULL;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);
    }
}
```

Sending Data Using a Message Buffer This code uses a mailbox to synchronously pass variable-sized requests from a producing thread to any consuming thread that wants it. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```
void producer_thread(void)
{
    char buffer[100];
    int buffer_bytes_used;

    struct k_mbox_msg send_msg;

    while (1) {

        /* generate data to send */
        ...
        buffer_bytes_used = ... ;
        memcpy(buffer, source, buffer_bytes_used);

        /* prepare to send message */
        send_msg.info = buffer_bytes_used;
        send_msg.size = buffer_bytes_used;
        send_msg.tx_data = buffer;
        send_msg.tx_target_thread = K_ANY;

        /* send message and wait until a consumer receives it */
        k_mbox_put(&my_mailbox, &send_msg, K_FOREVER);

        /* info, size, and tx_target_thread fields have been updated */

        /* verify that message data was fully received */
        if (send_msg.size < buffer_bytes_used) {
            printf("some message data dropped during transfer!");
            printf("receiver only had room for %d bytes", send_msg.info);
        }
    }
```

(continues on next page)

(continued from previous page)

```
}
```

Receiving a Message A thread receives a message by first creating a message descriptor that characterizes the message it wants to receive. It then calls one of the mailbox receive APIs. The mailbox searches its send queue and takes the message from the first compatible thread it finds. If no compatible thread exists, the receiving thread may choose to wait for one. If no compatible thread appears before the waiting period specified by the receiving thread is reached, the receive operation fails. Once a receive operation completes successfully the receiving thread can examine the message descriptor to determine which thread sent the message, how much data was exchanged, and the application-defined info value supplied by the sending thread.

Any number of receiving threads may wait simultaneously on a mailboxes' receive queue. The threads are sorted according to their priority; threads of equal priority are sorted so that the one that started waiting first can receive a message first.

Note

Receiving threads do not always receive messages in a first in, first out (FIFO) order, due to the thread compatibility constraints specified by the message descriptors. For example, if thread A waits to receive a message only from thread X and then thread B waits to receive a message from thread Y, an incoming message from thread Y to any thread will be given to thread B and thread A will continue to wait.

The receiving thread controls both the quantity of data it retrieves from an incoming message and where the data ends up. The thread may choose to take all of the data in the message, to take only the initial part of the data, or to take no data at all. Similarly, the thread may choose to have the data copied into a message buffer of its choice.

The following sections outline various approaches a receiving thread may use when retrieving message data.

Retrieving Data at Receive Time The most straightforward way for a thread to retrieve message data is to specify a message buffer when the message is received. The thread indicates both the location of the message buffer (which must not be `NULL`) and its size.

The mailbox copies the message's data to the message buffer as part of the receive operation. If the message buffer is not big enough to contain all of the message's data, any uncopied data is lost. If the message is not big enough to fill all of the buffer with data, the unused portion of the message buffer is left unchanged. In all cases the mailbox updates the receiving thread's message descriptor to indicate how many data bytes were copied (if any).

The immediate data retrieval technique is best suited for small messages where the maximum size of a message is known in advance.

The following code uses a mailbox to process variable-sized requests from any producing thread, using the immediate data retrieval technique. The message "info" field is used to exchange information about the maximum size message buffer that each thread can handle.

```
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[100];

    int i;
    int total;
```

(continues on next page)

(continued from previous page)

```
    while (1) {
        /* prepare to receive message */
        recv_msg.info = 100;
        recv_msg.size = 100;
        recv_msg.rx_source_thread = K_ANY;

        /* get a data item, waiting as long as needed */
        k_mbox_get(&my_mailbox, &recv_msg, buffer, K_FOREVER);

        /* info, size, and rx_source_thread fields have been updated */

        /* verify that message data was fully received */
        if (recv_msg.info != recv_msg.size) {
            printf("some message data dropped during transfer!");
            printf("sender tried to send %d bytes", recv_msg.info);
        }

        /* compute sum of all message bytes (from 0 to 100 of them) */
        total = 0;
        for (i = 0; i < recv_msg.size; i++) {
            total += buffer[i];
        }
    }
}
```

Retrieving Data Later Using a Message Buffer A receiving thread may choose to defer message data retrieval at the time the message is received, so that it can retrieve the data into a message buffer at a later time. The thread does this by specifying a message buffer location of `NULL` and a size indicating the maximum amount of data it is willing to retrieve later.

The mailbox does not copy any message data as part of the receive operation. However, the mailbox still updates the receiving thread's message descriptor to indicate how many data bytes are available for retrieval.

The receiving thread must then respond as follows:

- If the message descriptor size is zero, then either the sender's message contained no data or the receiving thread did not want to receive any data. The receiving thread does not need to take any further action, since the mailbox has already completed data retrieval and deleted the message.
- If the message descriptor size is non-zero and the receiving thread still wants to retrieve the data, the thread must call `k_mbox_data_get()` and supply a message buffer large enough to hold the data. The mailbox copies the data into the message buffer and deletes the message.
- If the message descriptor size is non-zero and the receiving thread does *not* want to retrieve the data, the thread must call `k_mbox_data_get()` and specify a message buffer of `NULL`. The mailbox deletes the message without copying the data.

The subsequent data retrieval technique is suitable for applications where immediate retrieval of message data is undesirable. For example, it can be used when memory limitations make it impractical for the receiving thread to always supply a message buffer capable of holding the largest possible incoming message.

The following code uses a mailbox's deferred data retrieval mechanism to get message data from a producing thread only if the message meets certain criteria, thereby eliminating unneeded data copying. The message "info" field supplied by the sender is used to classify the message.

```
void consumer_thread(void)
{
    struct k_mbox_msg recv_msg;
    char buffer[10000];

    while (1) {
        /* prepare to receive message */
        recv_msg.size = 10000;
        recv_msg.rx_source_thread = K_ANY;

        /* get message, but not its data */
        k_mbox_get(&my_mailbox, &recv_msg, NULL, K_FOREVER);

        /* get message data for only certain types of messages */
        if (is_message_type_ok(recv_msg.info)) {
            /* retrieve message data and delete the message */
            k_mbox_data_get(&recv_msg, buffer);

            /* process data in "buffer" */
            ...
        } else {
            /* ignore message data and delete the message */
            k_mbox_data_get(&recv_msg, NULL);
        }
    }
}
```

Suggested Uses Use a mailbox to transfer data items between threads whenever the capabilities of a message queue are insufficient.

Pipes

A *pipe* is a kernel object that allows a thread to send a byte stream to another thread. Pipes enable efficient inter-thread communication and can be used to synchronously transfer chunks of data in whole or in part.

- *Concepts*
- *Implementation*
  - *Writing to a Pipe*
  - *Reading from a Pipe*
  - *Resetting a Pipe*
- *Suggested Uses*
- *API Reference*

Concepts Any number of pipes can be defined, limited only by available RAM. Each pipe is referenced by its memory address.

A pipe has the following key property:

- A **size** that indicates the capacity of the pipe's ring buffer. Note that a size of zero defines a pipe with no ring buffer.

A pipe must be initialized before it can be used. When initialized, the pipe is empty.

Threads interact with the pipe as follows:

- **Writing**: Data is synchronously written, either in whole or in part, to a pipe by a thread. Accepted data is either copied directly to the waiting reader(s) or to the pipe's ring buffer. If the ring buffer is full or simply absent, the operation blocks until sufficient space becomes available or the specified timeout expires.
- **Reading**: Data is synchronously read, either in whole or in part, from a pipe by a thread. Accepted data is either copied from the pipe's ring buffer or directly from the waiting sender(s). If the ring buffer is empty or simply absent, the operation blocks until data becomes available or the specified timeout expires.
- **Resetting**: A thread can reset a pipe, which resets its internal state and ends all pending read and write operations with an error code.

Pipes are well-suited for scenarios like producer-consumer patterns or streaming data between threads.

Implementation A pipe is defined using a variable of type `k_pipe` and a byte buffer. The pipe must then be initialized by calling `k_pipe_init()`.

The following code defines and initializes an empty pipe with a ring buffer capable of holding 100 bytes, aligned to a 4-byte boundary:

```
uint8_t __aligned(4) my_ring_buffer[100];
struct k_pipe my_pipe;

k_pipe_init(&my_pipe, my_ring_buffer, sizeof(my_ring_buffer));
```

Alternatively, a pipe can be defined and initialized at compile time using the `K_PIPE_DEFINE` macro, which defines both the pipe and its ring buffer:

```
K_PIPE_DEFINE(my_pipe, 100, 4);
```

This has the same effect as the code above.

When no ring buffer is used, the buffer pointer argument should be NULL and the size argument should be 0.

Writing to a Pipe Data is added to a pipe by calling `k_pipe_write()`.

The following example demonstrates using a pipe to send data from a producer thread to one or more consumer threads. If the pipe's ring buffer fills up, the producer thread waits for a specified amount of time.

```
struct message_header {
    size_t num_data_bytes; /* Example field */
    ...
};

void producer_thread(void)
{
    int rc;
```

(continues on next page)

(continued from previous page)

```
    uint8_t *data;
    size_t total_size;
    size_t bytes_written;

    while (1) {
        /* Craft message to send in the pipe */
        make_message(data, &total_size);
        bytes_written = 0;

        /* Write data to the pipe, handling partial writes */
        while (bytes_written < total_size) {
            rc = k_pipe_write(&my_pipe, &data[bytes_written], total_size -␣
↪bytes_written, K_NO_WAIT);

            if (rc < 0) {
                /* Error occurred */
                ...
                break;
            } else {
                /* Partial or full write succeeded; adjust for next iteration */
                bytes_written += rc;
            }
        }

        /* Reset bytes_written for the next message */
        bytes_written = 0;
        ...
    }
}
```

Reading from a Pipe Data is retrieved from the pipe by calling `k_pipe_read()`.

The following example builds on the producer thread example above. It shows a consumer thread that processes data generated by the producer.

```
struct message_header {
    size_t num_data_bytes; /* Example field */
    ...
};

void consumer_thread(void)
{
    int rc;
    uint8_t buffer[128];
    size_t bytes_read = 0;
    struct message_header *header = (struct message_header *)buffer;

    while (1) {
        /* Step 1: Read the message header */
        bytes_read = 0;
   read_header:
        while (bytes_read < sizeof(*header)) {
            rc = k_pipe_read(&my_pipe, &buffer[bytes_read], sizeof(*header) -␣
↪bytes_read, &bytes_read, K_NO_WAIT);

            if (rc < 0) {
```

(continues on next page)

(continued from previous page)

```
                /* Error occurred */
                ...
                goto read_header;
            }

            /* Adjust for partial reads */
            bytes_read += rc;
        }

        /* Step 2: Read the message body */
        bytes_read = 0;
        while (bytes_read < header->num_data_bytes) {
            rc = k_pipe_read(&my_pipe, &buffer[sizeof(*header) + bytes_read],␣
↪header->num_data_bytes - bytes_read, K_NO_WAIT);

            if (rc < 0) {
                /* Error occurred */
                ...
                goto read_header;
            }

            /* Adjust for partial reads */
            bytes_read += rc;
        }
        /* Successfully received the complete message */
    }
}
```

Resetting a Pipe The pipe can be reset by calling `k_pipe_reset()`. Resetting a pipe resets its internal state and ends all pending operations with an error code.

The following example demonstrates resetting a pipe in response to a critical error:

```
void monitor_thread(void)
{
    while (1) {
        ...
        /* Critical error detected: reset the entire pipe to reset it. */
        k_pipe_reset(&my_pipe);
        ...
    }
}
```

Suggested Uses Pipes are useful for sending streams of data between threads. Typical applications include:

- Implementing producer-consumer patterns.
- Streaming logs or packets between threads.
- Handling variable-length message passing in real-time systems.

Pipe APIs

3.1.3 Memory Management

See *Memory Management*.

3.1.4 Timing

These pages cover timing related services.

Kernel Timing

Zephyr provides a robust and scalable timing framework to enable reporting and tracking of timed events from hardware timing sources of arbitrary precision.

Time Units Kernel time is tracked in several units which are used for different purposes.

Real time values, typically specified in milliseconds or microseconds, are the default presentation of time to application code. They have the advantages of being universally portable and pervasively understood, though they may not match the precision of the underlying hardware perfectly.

The kernel presents a "cycle" count via the `k_cycle_get_32()` and `k_cycle_get_64()` APIs. The intent is that this counter represents the fastest cycle counter that the operating system is able to present to the user (for example, a CPU cycle counter) and that the read operation is very fast. The expectation is that very sensitive application code might use this in a polling manner to achieve maximal precision. The frequency of this counter is available from `sys_clock_hw_cycles_per_sec()`. On most platforms this is a runtime constant that evaluates to `CONFIG_SYS_CLOCK_HW_CYCLES_PER_SEC` and is fixed for the lifetime of the system. On platforms where the system timer frequency is not fixed, `sys_clock_hw_cycles_per_sec()` returns a runtime value and application code must not assume a single immutable frequency.

Runtime System Timer Frequency Some platforms need the system timer frequency to be available at runtime, either because the timer driver discovers the clock rate from hardware or because the timer clock rate can change after boot.

Platforms that can change the active system timer frequency at runtime must enable `CONFIG_SYSTEM_CLOCK_HW_CYCLES_PER_SEC_RUNTIME_UPDATE` and:

- Call `z_sys_clock_hw_cycles_per_sec_update()` after applying the clock change.
- If the system timer driver caches derived constants (e.g. cycles-per-tick) or needs to reprogram hardware when the clock changes, provide a timer-driver override of `z_sys_clock_hw_cycles_per_sec_update()`.

The default implementation of `z_sys_clock_hw_cycles_per_sec_update()` only updates the stored frequency value.

> **Note**
>
> `CONFIG_SYSTEM_CLOCK_HW_CYCLES_PER_SEC_RUNTIME_UPDATE` tracks the system timer frequency as a single **global** value. It is not compatible with per-CPU frequency scaling configurations where different CPUs could observe different system timer frequencies.
>
> When enabled, `sys_clock_hw_cycles_per_sec()` and time unit conversions follow the current runtime value.

For asynchronous timekeeping, the kernel defines a "ticks" concept. A "tick" is the internal count in which the kernel does all its internal uptime and timeout bookkeeping. Interrupts are expected to be delivered on tick boundaries to the extent practical, and no fractional ticks are tracked. The choice of tick rate is configurable via `CONFIG_SYS_CLOCK_TICKS_PER_SEC`. Defaults

on most hardware platforms (ones that support setting arbitrary interrupt timeouts) are expected to be in the range of 10 kHz, with software emulation platforms and legacy drivers using a more traditional 100 Hz value.

Conversion Zephyr provides an extensively enumerated conversion library with rounding control for all time units. Any unit of "ms" (milliseconds), "us" (microseconds), "tick", or "cyc" can be converted to any other. Control of rounding is provided, and each conversion is available in "floor" (round down to nearest output unit), "ceil" (round up) and "near" (round to nearest). Finally the output precision can be specified as either 32 or 64 bits.

For example: `k_ms_to_ticks_ceil32()` will convert a millisecond input value to the next higher number of ticks, returning a result truncated to 32 bits of precision; and `k_cyc_to_us_floor64()` will convert a measured cycle count to an elapsed number of microseconds in a full 64 bits of precision. See the reference documentation for the full enumeration of conversion routines.

On most platforms, where the various counter rates are integral multiples of each other and where the output fits within a single word, these conversions expand to a 2-4 operation sequence, requiring full precision only where actually required and requested.

Uptime The kernel tracks a system uptime count on behalf of the application. This is available at all times via `k_uptime_get()`, which provides an uptime value in milliseconds since system boot. This is expected to be the utility used by most portable application code.

The internal tracking, however, is as a 64 bit integer count of ticks. Apps with precise timing requirements (that are willing to do their own conversions to portable real time units) may access this with `k_uptime_ticks()`.

`k_uptime_delta()` can be used to get the time elapsed between a reference and the current time. The referenced time will be updated to the current uptime, to easily calculate the next elapsed time.

Timeouts The Zephyr kernel provides many APIs with a "timeout" parameter. Conceptually, this indicates the time at which an event will occur. For example:

- Kernel blocking operations like `k_sem_take()` or `k_queue_get()` may provide a timeout after which the routine will return with an error code if no data is available.
- Kernel `k_timer` objects must specify delays for their duration and period.
- The kernel `k_work_delayable` API provides a timeout parameter indicating when a work queue item will be added to the system queue.

All these values are specified using a `k_timeout_t` value. This is an opaque struct type that must be initialized using one of a family of kernel timeout macros. The most common, `K_MSEC`, defines a time in milliseconds after the current time.

What is meant by "current time" for relative timeouts depends on the context:

- When scheduling a relative timeout from within a timeout callback (e.g. from within the expiry function passed to `k_timer_init()` or the work handler passed to `k_work_init_delayable()`), "current time" is the exact time at which the currently firing timeout was originally scheduled even if the "real time" will already have advanced. This is to ensure that timers scheduled from within another timer's callback will always be calculated with a precise offset to the firing timer. It is thereby possible to fire at regular intervals without introducing systematic clock drift over time.
- When scheduling a timeout from application context, "current time" means the value returned by `k_uptime_ticks()` at the time at which the kernel receives the timeout value.

Other options for timeout initialization follow the unit conventions described above: `K_NSEC()`, `K_USEC`, `K_TICKS` and `K_CYC()` specify timeout values that will expire after specified numbers of nanoseconds, microseconds, ticks and cycles, respectively.

Precision of k_timeout_t values is configurable, with the default being 32 bits. Large uptime counts in non-tick units will experience complicated rollover semantics, so it is expected that timing-sensitive applications with long uptimes will be configured to use a 64 bit timeout type.

Finally, it is possible to specify timeouts as absolute times since system boot. A timeout initialized with K_TIMEOUT_ABS_MS indicates a timeout that will expire after the system uptime reaches the specified value. There are likewise nanosecond, microsecond, cycles and ticks variants of this API.

Timing Internals

Timeout Queue All Zephyr k_timeout_t events specified using the API above are managed in a single, global queue of events. The action to take on an event is specified as a callback function pointer provided by the subsystem requesting the event, along with a _timeout tracking struct that is expected to be embedded within subsystem-defined data structures (for example: a wait_q struct, or a k_tid_t thread struct).

Note that all variant units passed via a k_timeout_t are converted to ticks once on insertion into the queue. There are no multiple-conversion steps internal to the kernel, so precision is guaranteed at the tick level no matter how many events exist or how long a timeout might be.

The data structure that holds the queue is selected at build time through the CONFIG_TIMEOUT_BACKEND choice. Only the front end is shared between backends (the announce path, the SMP re-entry handling, and the relative versus absolute timeout rules); each backend supplies the queue itself, so an integrator can match the data structure to the workload without touching the common code.

The default, CONFIG_TIMEOUT_BACKEND_DLIST, stores events in a doubly linked list sorted by expiry, each holding a delta count in ticks from its predecessor. Insertion is O(N) in the number of pending timeouts: inexpensive for the handful a typical system has pending, but it scales poorly when many are outstanding. The four alternative backends, all currently experimental, trade extra memory or behaviour for faster insertion at scale:

- CONFIG_TIMEOUT_BACKEND_MINHEAP keeps the events in a binary min-heap keyed on absolute expiry, making insertion and removal O(log N). It requires 64-bit ticks (CONFIG_TIMEOUT_64BIT) and a fixed-capacity heap (CONFIG_TIMEOUT_HEAP_MAX_ENTRIES, whose overflow is fatal), and it does not preserve the firing order of timeouts that expire on the same tick.
- CONFIG_TIMEOUT_BACKEND_WHEEL is a hierarchical timer wheel with O(1) insertion and removal for the near future and a sorted overflow list beyond. It has the largest per-event and static footprint, does not preserve same-tick firing order, and wakes a tickless-idle CPU periodically because its next-timeout estimate is bounded by the wheel period (a power cost the other backends avoid).
- CONFIG_TIMEOUT_BACKEND_BUCKET is a single-level bucketed delta list, a simpler relative of the wheel. It gives O(1) insertion within a tunable near-future window (CONFIG_TIMEOUT_BUCKET_LISTS) and falls back to a sorted overflow list beyond it. It also requires 64-bit ticks, but unlike the wheel it preserves same-tick firing order and adds no idle-wakeup cost.
- CONFIG_TIMEOUT_BACKEND_SKIPLIST is a Pugh skip list keyed on absolute expiry. Expected insertion and removal are O(log N) with no capacity limit, and same-tick firing order is FIFO. It requires 64-bit ticks. Each event stores CONFIG_TIMEOUT_SKIPLIST_MAX_LEVEL forward pointers, so per-event RAM is higher than the delta list or min-heap.

The non-default backends target systems that hold many concurrent timeouts, especially ones clustered in the near future. For most applications the delta list remains the appropriate default.

Timer Drivers Kernel timing at the tick level is driven by a timer driver. That interface and the locking it runs under are described in *System Timer Drivers*.

Time Slicing An auxiliary job of the timing subsystem is to provide tick counters to the scheduler that allow implementation of time slicing of threads. A thread time-slice cannot be a timeout value, as it does not reflect a global expiration but instead a per-CPU value that needs to be tracked independently on each CPU in an SMP context.

Because there may be no other hardware available to drive timeslicing, Zephyr multiplexes the existing timer driver. This means that the value passed to `sys_clock_set_timeout()` may be clamped to a smaller value than the current next timeout when a time sliced thread is currently scheduled.

Subsystems that keep millisecond APIs In general, code like this will port just like applications code will. Millisecond values from the user may be treated any way the subsystem likes, and then converted into kernel timeouts using `K_MSEC()` at the point where they are presented to the kernel.

Obviously this comes at the cost of not being able to use new features, like the higher precision timeout constructors or absolute timeouts. But for many subsystems with simple needs, this may be acceptable.

One complexity is `K_FOREVER`. Subsystems that might have been able to accept this value to their millisecond API in the past no longer can, because it is no longer an integral type. Such code will need to use a different, integer-valued token to represent "forever". `K_NO_WAIT` has the same typesafety concern too, of course, but as it is (and has always been) simply a numerical zero, it has a natural porting path.

Subsystems using `k_timeout_t` Ideally, code that takes a "timeout" parameter specifying a time to wait should be using the kernel native abstraction where possible. But `k_timeout_t` is opaque, and needs to be converted before it can be inspected by an application.

Some conversions are simple. Code that needs to test for `K_FOREVER` can simply use the `K_TIMEOUT_EQ()` macro to test the opaque struct for equality and take special action.

The more complicated case is when the subsystem needs to take a timeout and loop, waiting for it to finish while doing some processing that may require multiple blocking operations on underlying kernel code. For example, consider this design:

```
void my_wait_for_event(struct my_subsys *obj, int32_t timeout_in_ms)
{
    while (true) {
        uint32_t start = k_uptime_get_32();

        if (is_event_complete(obj)) {
            return;
        }

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout_in_ms);

        /* Subtract elapsed time */
        timeout_in_ms -= (k_uptime_get_32() - start);
    }
}
```

This code requires that the timeout value be inspected, which is no longer possible. For situations like this, the new API provides the internal `sys_timepoint_calc()` and `sys_timepoint_timeout()` routines that converts an arbitrary timeout to and from a timepoint value based on an uptime tick at which it will expire. So such a loop might look like:

```
void my_wait_for_event(struct my_subsys *obj, k_timeout_t timeout)
{
    /* Compute the end time from the timeout */
    k_timepoint_t end = sys_timepoint_calc(timeout);

    do {
        if (is_event_complete(obj)) {
            return;
        }

        /* Update timeout with remaining time */
        timeout = sys_timepoint_timeout(end);

        /* Wait for notification of state change */
        k_sem_take(obj->sem, timeout);
    } while (!K_TIMEOUT_EQ(timeout, K_NO_WAIT));
}
```

Note that `sys_timepoint_calc()` accepts special values `K_FOREVER` and `K_NO_WAIT`, and works identically for absolute timeouts as well as conventional ones. Conversely, `sys_timepoint_timeout()` may return `K_FOREVER` or `K_NO_WAIT` if those were used to create the timepoint, the later also being returned if the timepoint is now in the past. For simple cases, `sys_timepoint_expired()` can be used as well.

But some care is still required for subsystems that use those. Note that delta timeouts need to be interpreted relative to a "current time", and obviously that time is the time of the call to `sys_timepoint_calc()`. But the user expects that the time is the time they passed the timeout to you. Care must be taken to call this function just once, as synchronously as possible to the timeout creation in user code. It should not be used on a "stored" timeout value, and should never be called iteratively in a loop.

API Reference

System Clock APIs

Timers

A *timer* is a kernel object that measures the passage of time using the kernel's system clock. When a timer's specified time limit is reached it can perform an application-defined action, or it can simply record the expiration and wait for the application to read its status.

- *Concepts*
- *Timer Observers*
- *Implementation*
  - *Defining a Timer*
  - *Using a Timer Expiry Function*
  - *Reading Timer Status*
  - *Using Timer Status Synchronization*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of timers can be defined (limited only by available RAM). Each timer is referenced by its memory address.

A timer has the following key properties:

- A **duration** specifying the time interval before the timer expires for the first time. This is a `k_timeout_t` value that may be initialized via different units.
- A **period** specifying the time interval between all timer expirations after the first one, also a `k_timeout_t`. It must be non-negative. A period of `K_NO_WAIT` (i.e. zero) or `K_FOREVER` means that the timer is a one-shot timer that stops after a single expiration. (For example then, if a timer is started with a duration of 200 and a period of 75, it will first expire after 200 ms and then every 75 ms after that.)
- An **expiry function** that is executed each time the timer expires. The function is executed by the system clock interrupt handler. If no expiry function is required a `NULL` function can be specified.
- A **stop function** that is executed if the timer is stopped prematurely while running. The function is executed by the thread that stops the timer. If no stop function is required a `NULL` function can be specified.
- A **status** value that indicates how many times the timer has expired since the status value was last read.

A timer must be initialized before it can be used. This specifies its expiry function and stop function values, sets the timer's status to zero, and puts the timer into the **stopped** state.

A timer is **started** by specifying a duration and a period. The timer's status is reset to zero, and then the timer enters the **running** state and begins counting down towards expiry.

Note

The timer's duration is a **minimum** delay relative to the time the timer was started. The timer's period is a **minimum** delay relative to the last time the timer "should" have expired. This means that a periodic timer will not drift relative to the system timer, and that its periodic delay can be shorter or longer than the specified period.

To ensure a minimum delay until the timer expires, restart the timer from within the **expiry function** or after the timer expired.

The variability of the delays stem from system variables like interrupt handling delays and execution time of preceding timer handlers.

When a running timer expires its status is incremented and the timer executes its expiry function, if one exists; If a thread is waiting on the timer, it is unblocked. If the timer's period is zero the timer enters the stopped state; otherwise, the timer restarts with a new duration equal to the delta between the time the timer "should" have expired and its period.

A running timer can be stopped in mid-countdown, if desired. The timer's status is left unchanged, then the timer enters the stopped state and executes its stop function, if one exists. If a thread is waiting on the timer, it is unblocked. Attempting to stop a non-running timer is permitted, but has no effect on the timer since it is already stopped.

A running timer can be restarted in mid-countdown, if desired. The timer's status is reset to zero, then the timer begins counting down using the new duration and period values specified by the caller. If a thread is waiting on the timer, it continues waiting.

A timer's status can be read directly at any time to determine how many times the timer has expired since its status was last read. Reading a timer's status resets its value to zero. The amount of time remaining before the timer expires can also be read; a value of zero indicates that the timer is stopped.

A thread may read a timer's status indirectly by **synchronizing** with the timer. This blocks the thread until the timer's status is non-zero (indicating that it has expired at least once) or the timer is stopped; if the timer status is already non-zero or the timer is already stopped the thread continues without waiting. The synchronization operation returns the timer's status and resets it to zero.

> **Note**
>
> Only a single user should examine the status of any given timer, since reading the status (directly or indirectly) changes its value. Similarly, only a single thread at a time should synchronize with a given timer. ISRs are not permitted to synchronize with timers, since ISRs are not allowed to block.

Timer Observers When `CONFIG_TIMER_OBSERVER` is enabled, code can register *timer observers* that are notified of timer lifecycle events across all timers in the system. An observer is a set of optional callbacks invoked when a timer is initialized, started, stopped, or expires. This allows external modules – for example tracing, profiling, or power-management code – to react to timer activity without modifying kernel internals or the individual timers.

An observer is defined statically with `K_TIMER_OBSERVER_DEFINE`, which takes pointers to the `on_init`, `on_start`, `on_stop`, and `on_expiry` callbacks; any callback that is not needed may be passed as `NULL`. Because the expiry callback runs in interrupt context, it must be kept short and non-blocking.

Implementation

Defining a Timer A timer is defined using a variable of type `k_timer`. It must then be initialized by calling `k_timer_init()`.

The following code defines and initializes a timer.

```
struct k_timer my_timer;
extern void my_expiry_function(struct k_timer *timer_id);

k_timer_init(&my_timer, my_expiry_function, NULL);
```

Alternatively, a timer can be defined and initialized at compile time by calling `K_TIMER_DEFINE`.

The following code has the same effect as the code segment above.

```
K_TIMER_DEFINE(my_timer, my_expiry_function, NULL);
```

Using a Timer Expiry Function The following code uses a timer to perform a non-trivial action on a periodic basis. Since the required work cannot be done at the interrupt level, the timer's expiry function submits a work item to the *system workqueue*, whose thread performs the work.

```
void my_work_handler(struct k_work *work)
{
    /* do the processing that needs to be done periodically */
    ...
}

K_WORK_DEFINE(my_work, my_work_handler);

void my_timer_handler(struct k_timer *dummy)
{
```

(continues on next page)

(continued from previous page)

```
    k_work_submit(&my_work);
}

K_TIMER_DEFINE(my_timer, my_timer_handler, NULL);

...

/* start a periodic timer that expires once every second */
k_timer_start(&my_timer, K_SECONDS(1), K_SECONDS(1));
```

Reading Timer Status The following code reads a timer's status directly to determine if the timer has expired or not.

```
K_TIMER_DEFINE(my_status_timer, NULL, NULL);

...

/* start a one-shot timer that expires after 200 ms */
k_timer_start(&my_status_timer, K_MSEC(200), K_NO_WAIT);

/* do work */
...

/* check timer status */
if (k_timer_status_get(&my_status_timer) > 0) {
    /* timer has expired */
} else if (k_timer_remaining_get(&my_status_timer) == 0) {
    /* timer was stopped (by someone else) before expiring */
} else {
    /* timer is still running */
}
```

Using Timer Status Synchronization The following code performs timer status synchronization to allow a thread to do useful work while ensuring that a pair of protocol operations are separated by the specified time interval.

```
K_TIMER_DEFINE(my_sync_timer, NULL, NULL);

...

/* do first protocol operation */
...

/* start a one-shot timer that expires after 500 ms */
k_timer_start(&my_sync_timer, K_MSEC(500), K_NO_WAIT);

/* do other work */
...

/* ensure timer has expired (waiting for expiry, if necessary) */
k_timer_status_sync(&my_sync_timer);

/* do second protocol operation */
...
```

Note

If the thread had no other work to do it could simply sleep between the two protocol operations, without using a timer.

Suggested Uses Use a timer to initiate an asynchronous operation after a specified amount of time.

Use a timer to determine whether or not a specified amount of time has elapsed. In particular, timers should be used when higher precision and/or unit control is required than that afforded by the simpler `k_sleep()` and `k_usleep()` calls.

Use a timer to perform other work while carrying out operations involving time limits.

Note

If a thread needs to measure the time required to perform an operation it can read the *system clock or the hardware clock* directly, rather than using a timer.

Timer APIs

System Timer Drivers

This page describes the interface between the kernel's tick accounting and the driver for the hardware that produces those ticks. The kernel side of that accounting, and everything an application sees, is described in *Kernel Timing*.

Timer Drivers Kernel timing at the tick level is driven by a timer driver with a comparatively simple API.

- The driver is expected to be able to "announce" new ticks to the kernel via the `sys_clock_announce()` call, which passes an integer number of ticks that have elapsed since the last announce call (or system boot). These calls can occur at any time, but the driver is expected to attempt to ensure (to the extent practical given interrupt latency interactions) that they occur near tick boundaries (i.e. not "halfway through" a tick), and most importantly that they be correct over time and subject to minimal skew vs. other counters and real world time.
- The driver is expected to provide a `sys_clock_set_timeout()` call to the kernel which indicates how many ticks may elapse before the kernel must receive an announce call to trigger registered timeouts. It is legal to announce new ticks before that moment (though they must be correct) but delay after that will cause events to be missed. Note that the timeout value passed here is in a delta from current time, but that does not absolve the driver of the requirement to provide ticks at a steady rate over time. Naive implementations of this function are subject to bugs where the fractional tick gets "reset" incorrectly and causes clock skew.
- The driver is expected to provide a `sys_clock_elapsed()` call which provides a current indication of how many ticks have elapsed (as compared to a real world clock) since the last call to `sys_clock_announce()`, which the kernel needs to test newly arriving timeouts for expiration.

- The driver may optionally provide a `sys_clock_no_timeout()` call. The kernel invokes it in place of `sys_clock_set_timeout()` when no timeout is pending, that is when the timeout queue is empty, and `CONFIG_SYSTEM_CLOCK_SLOPPY_IDLE` is enabled.

  No tick announcement is forthcoming and the system does not care about precise uptime keeping, so the driver may do something to save resources. Normal operation resumes at the next `sys_clock_set_timeout()`; unlike `sys_clock_disable()`, this is not a teardown.

  The timer *counter* must not be stopped. `sys_clock_cycle_get_32()` and `sys_clock_cycle_get_64()` must keep counting up as if the call had never happened.

  > **Note**
  >
  > The CPU keeps running with an empty timeout queue, for instance because the ready queue still holds threads, or because an interrupt fires. Those threads and ISRs may call `k_cycle_get_32()` or `k_busy_wait()`. That limits what an implementation may do: masking the timer interrupt is safe, gating the timer's clock most likely is not. Exactly what is safe is hardware specific.

  The hook is optional. Without it, `sys_clock_set_timeout()` is asked for the longest wait it can express, `UINT32_MAX` ticks. That is numerically what `K_TICKS_FOREVER` was here, the long-standing "no deadline" signal, so a driver that has not been converted keeps working.

- The driver may optionally provide a `sys_clock_idle_enter()` call, which the power-management path uses in place of `sys_clock_set_timeout()` when the CPU is about to enter low-power idle. It receives the number of ticks until the next expected wakeup, or `SYS_CLOCK_IDLE_FOREVER` when there is none and the uptime accounting may drift.

  A driver that hands off to a low-power wakeup timer, or otherwise reconfigures itself for sleep, does so here. Told `SYS_CLOCK_IDLE_FOREVER` it may also stop its time base, which `sys_clock_no_timeout()` does not allow, because the CPU is on its way out and `sys_clock_idle_exit()` is guaranteed to run on the way back in. Only the calling CPU goes idle, so a driver whose time base is shared between CPUs must ensure only the last CPU going idle stops the clock.

  The hook is optional. Without it, `sys_clock_set_timeout()` is called with its deprecated `idle` argument set to `true`, so a driver still keying its low-power handling on that argument keeps working.

The last three entry points divide the four states a system can be in:

	nothing pending	something pending
running	`sys_clock_no_timeout()`	`sys_clock_set_timeout(ticks)`
idle	`sys_clock_idle_enter(SYS_CLOCK_IDLE_I`	`sys_clock_idle_enter(ticks)`

Without `CONFIG_SYSTEM_CLOCK_SLOPPY_IDLE` the left column never arises: the kernel keeps a synthetic deadline armed so the uptime stays exact, and a driver only ever sees the right one.

Timer Driver Locking The kernel exposes a unified timer lock via `sys_clock_lock()` and `sys_clock_unlock()`. This lock protects both the kernel's internal tick accounting (`curr_tick`, the timeout queue) and any driver-private state that must be consistent with it (e.g. a hardware cycle counter baseline).

Timer drivers that maintain internal state should acquire this lock at the start of their ISR, update their hardware state, then pass the lock key to `sys_clock_announce_locked()` which consumes it. This ensures that the driver's cycle counter baseline and the kernel's `curr_tick` are always updated under the same lock, eliminating race conditions that can arise on SMP systems (or, less commonly, on UP systems where higher-priority ISRs need consistent realtime references) when two separate locks are used.

The driver-provided callbacks `sys_clock_set_timeout()` and `sys_clock_elapsed()` are always invoked by the kernel with this lock already held.

For backward compatibility, `sys_clock_announce()` remains available and acquires the lock internally. New and migrated drivers should prefer the `sys_clock_lock()` / `sys_clock_announce_locked()` pattern.

Note that a natural implementation of this API results in a "tickless" kernel, which receives and processes timer interrupts only for registered events, relying on programmable hardware counters to provide irregular interrupts. But a traditional, "ticked" or "dumb" counter driver can be trivially implemented also:

- The driver can receive interrupts at a regular rate corresponding to the OS tick rate, calling `sys_clock_announce()` with an argument of one each time.
- The driver can ignore calls to `sys_clock_set_timeout()`, as every tick will be announced regardless of timeout status.
- The driver can return zero for every call to `sys_clock_elapsed()` as no more than one tick can be detected as having elapsed (because otherwise an interrupt would have been received).

SMP Details In general, the timer API described above does not change when run in a multiprocessor context. The kernel will internally synchronize all access appropriately, and ensure that all critical sections are small and minimal. But some notes are important to detail:

- Zephyr is agnostic about which CPU services timer interrupts. It is not illegal (though probably undesirable in some circumstances) to have every timer interrupt handled on a single processor. Existing SMP architectures implement symmetric timer drivers.
- The `sys_clock_announce()` call is expected to be globally synchronized at the driver level. The kernel does not do any per-CPU tracking, and expects that if two timer interrupts fire near simultaneously, that only one will provide the current tick count to the timing subsystem. The other may legally provide a tick count of zero if no ticks have elapsed. It should not "skip" the announce call because of timeslicing requirements (see the time slicing notes in *Kernel Timing*).
- Some SMP hardware uses a single, global timer device, others use a per-CPU counter. The complexity here (for example: ensuring counter synchronization between CPUs) is expected to be managed by the driver, not the kernel.
- The next timeout value passed back to the driver via `sys_clock_set_timeout()` is done identically for every CPU. So by default, every CPU will see simultaneous timer interrupts for every event, even though by definition only one of them should see a non-zero ticks argument to `sys_clock_announce()`. This is probably a correct default for timing sensitive applications (because it minimizes the chance that an errant ISR or interrupt lock will delay a timeout), but may be a performance problem in some cases. The current design expects that any such optimization is the responsibility of the timer driver.

Generic Tickless Core The work described above, the cycle-to-tick conversion, the announce baseline, the tick-aligned deadline computation and the counter wrap and range handling, is nearly the same in every tickless driver, and the hand-rolled variations are a recurring source of timer bugs. drivers/timer/system_timer_generic.h carries that logic once.

It is an implementation header, not a declaration header: including it *defines* `sys_clock_set_timeout()`, `sys_clock_elapsed()` and `sys_clock_cycle_get_32()` / `sys_clock_cycle_get_64()`. Any number of drivers can be built on it; each includes it once, after providing the macros and primitives below. A build compiles a single system timer driver, so those definitions land once. The driver then works in cycles only; the core owns the tick domain.

The core emits both cycle getters, the 64-bit one whatever the counter's width: the announce baseline is 64-bit, and the linker drops the getter where nothing calls it.

Whether a driver also selects CONFIG_TIMER_HAS_64BIT_CYCLE_COUNTER stays its own call. That option says a 64-bit read is cheap, or at least no dearer than a 32-bit one, so nothing is gained by preferring the narrower getter. With TIMER_CORE_COUNTER_NONATOMIC both go through the clock lock and that holds; with an atomic counter narrower than 64 bits only the 64-bit getter takes the lock, and the 32-bit one stays a lock-free read.

Two primitives are required: timer_driver_cycle_get(), which reads the hardware cycle counter, and one arming function, timer_driver_set_compare() or timer_driver_set_reload() depending on the backend. The driver's ISR acknowledges the hardware then calls timer_core_announce(), its init connects the IRQ then calls timer_core_init(), and on SMP its smp_timer_init() calls timer_core_smp_prime().

Backend selection Exactly one of these states what the hardware is:

TIMER_CORE_BACKEND_COMPARE_ORDERED
: Absolute comparator, ordered match: the interrupt fires once the counter has reached or passed the programmed value, so a deadline already in the past fires at once. The usable range is half the counter width.

TIMER_CORE_BACKEND_COMPARE_EXACT
: Absolute comparator, equality match: a value written after the counter has passed it is missed for a whole counter period. The core writes the comparator through a verify loop, so the driver needs no minimum-delay floor of its own.

TIMER_CORE_BACKEND_RELOAD
: Relative delay: down-counters and compare-match-reset periodics. Assumed to auto-reload, so a ticked kernel free-runs from the value set at init.

Optional macros Each is defined only when the default, given below, does not fit:

TIMER_CORE_CYCLES_PER_SEC
: Counter rate, in Hz. Defaults to the kernel system clock rate. Set it when the counter is prescaled or runs at a fixed rate of its own. The core derives TIMER_CORE_CYC_PER_TICK from it, which a driver may read for its own hardware setup, typically the one-tick period it programs at init, but never defines itself.

TIMER_CORE_CYCLES_PER_SEC_RUNTIME
: The rate above is a variable, not a build-time constant, because it is read from the clock controller or computed at init. The core then precomputes the cycles per tick once instead of relying on the division folding. The variable must hold its final value before timer_core_init() is called.

TIMER_CORE_COUNTER_WIDTH
: Width, in bits, up to 64, of the count timer_driver_cycle_get() returns. Defaults to the native register width. A counter of another width states its own, and must: a genuine 64-bit counter on a 32-bit CPU would otherwise inherit a 32-bit mask and lose any span past 2^32 cycles. The core masks every delta to this width, so a narrow counter is read raw and the driver never has to widen the count in software.

TIMER_CORE_COUNTER_NONMONOTONIC
: The counter may momentarily read behind a value already observed, as a global timer does under QEMU SMP. The core treats a backwards read as no elapse rather than a huge jump.

TIMER_CORE_COUNTER_NONATOMIC
: timer_driver_cycle_get() is not a single atomic read but a value synthesized from state the ISR also touches. The core then reads it under the clock lock.

TIMER_CORE_HAVE_CYCLE_GET_32, TIMER_CORE_HAVE_CYCLE_GET_64
: The driver defines that entry point itself and the core does not. For a counter that needs scaling. timer_core_cycle_get(), available after the include, gives the full-width count in the counter's own domain to scale from.

The 32-bit one is required of a driver that sets `TIMER_CORE_CYCLES_PER_SEC`, a counter running at a rate of its own being one the kernel cannot read raw. The core then emits no 64-bit getter either, that being in the domain the driver just declared foreign. Supply one as well to have it.

`TIMER_CORE_ALARM_MAX_CYCLES`
: Largest value the arming primitive can express, nothing more. Defaults to the whole span of `TIMER_CORE_COUNTER_WIDTH`, the alarm and the counter usually being one piece of hardware. Set it where the arming range is decided by something else: a compare or reload register narrower than the counter, or a separate device.

  It states hardware capacity, so it carries no safety margin. The core derives its own from `TIMER_CORE_COUNTER_WIDTH`: it arms no further ahead of the last announce than half the counter's span, a quarter with `TIMER_CORE_COUNTER_NONMONOTONIC`, so a late announce still yields a delta the masking can resolve. Whichever of the two binds first wins.

`TIMER_CORE_ALARM_MIN_CYCLES`
: Reload floor, in cycles, `TIMER_CORE_BACKEND_RELOAD` only. Defaults to 1.

`TIMER_CORE_ALARM_LEAD_CYCLES`
: Cycles a compare must be ahead of the counter for the match to be caught, `TIMER_CORE_BACKEND_COMPARE_EXACT` only. Defaults to 1, a comparator written while the counter is still below it firing. Raise it for hardware that has to carry the write into the counter's clock domain first and misses a match programmed closer than that.

New tickless drivers should build on this header rather than reimplement the tick accounting. The header documents each macro and primitive in full.

3.1.5 Other

These pages cover other kernel services.

Atomic Services

An *atomic variable* is one that can be read and modified by threads and ISRs in an uninterruptible manner. It is a 32-bit variable on 32-bit machines and a 64-bit variable on 64-bit machines.

- *Concepts*
- *Implementation*
  - *Defining an Atomic Variable*
  - *Manipulating an Atomic Variable*
  - *Manipulating an Array of Atomic Variables*
  - *Memory Ordering*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts Any number of atomic variables can be defined (limited only by available RAM).

Using the kernel's atomic APIs to manipulate an atomic variable guarantees that the desired operation occurs correctly, even if higher priority contexts also manipulate the same variable.

The kernel also supports the atomic manipulation of a single bit in an array of atomic variables.

Implementation

Defining an Atomic Variable An atomic variable is defined using a variable of type `atomic_t`.

By default an atomic variable is initialized to zero. However, it can be given a different value using `ATOMIC_INIT`:

```
atomic_t flags = ATOMIC_INIT(0xFF);
```

Manipulating an Atomic Variable An atomic variable is manipulated using the APIs listed at the end of this section.

The following code shows how an atomic variable can be used to keep track of the number of times a function has been invoked. Since the count is incremented atomically, there is no risk that it will become corrupted in mid-increment if a thread calling the function is interrupted if by a higher priority context that also calls the routine.

```
atomic_t call_count;

int call_counting_routine(void)
{
    /* increment invocation counter */
    atomic_inc(&call_count);

    /* do rest of routine's processing */
    ...
}
```

Manipulating an Array of Atomic Variables An array of 32-bit atomic variables can be defined in the conventional manner. However, you can also define an N-bit array of atomic variables using `ATOMIC_DEFINE`.

A single bit in array of atomic variables can be manipulated using the APIs listed at the end of this section that end with `_bit()`.

The following code shows how a set of 200 flag bits can be implemented using an array of atomic variables.

```
#define NUM_FLAG_BITS 200

ATOMIC_DEFINE(flag_bits, NUM_FLAG_BITS);

/* set specified flag bit & return its previous value */
int set_flag_bit(int bit_position)
{
    return (int)atomic_set_bit(flag_bits, bit_position);
}
```

Memory Ordering For consistency and correctness, all Zephyr atomic APIs are expected to include a full memory barrier (in the sense of e.g. “serializing” instructions on x86, “DMB” on ARM, or a “sequentially consistent” operation as defined by the C++ memory model) where needed by hardware to guarantee a reliable picture across contexts. Any architecture-specific implementations are responsible for ensuring this behavior.

Suggested Uses Use an atomic variable to implement critical section processing that only requires the manipulation of a single 32-bit value.

Use multiple atomic variables to implement critical section processing on a set of flag bits in a bit array longer than 32 bits.

Note

Using atomic variables is typically far more efficient than using other techniques to implement critical sections such as using a mutex or locking interrupts.

Configuration Options Related configuration options:

- `CONFIG_ATOMIC_OPERATIONS_ARCH`
- `CONFIG_ATOMIC_OPERATIONS_C`

Important

All atomic services APIs can be used by both threads and ISRs.

API Reference
Atomic Services APIs

Floating Point Services

The kernel allows threads to use floating point registers on board configurations that support these registers.

Note

Floating point services are currently available only for boards based on ARM Cortex-M SoCs supporting the Floating Point Extension, the Intel x86 architecture, the SPARC architecture and ARCv2 SoCs supporting the Floating Point Extension. The services provided are architecture specific.

The kernel does not support the use of floating point registers by ISRs.

- *Concepts*
  - *No FP registers mode*
  - *Unshared FP registers mode*
  - *Shared FP registers mode*
- *Implementation*
  - *Performing Floating Point Arithmetic*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts The kernel can be configured to provide only the floating point services required by an application. Three modes of operation are supported, which are described below. In addition, the kernel's support for the SSE registers can be included or omitted, as desired.

A thread's participation in floating point context preservation can also be managed at run time. `k_float_enable()` enables preservation for a thread and accepts options – such as `K_FP_REGS` and `K_SSE_REGS` – that select which register sets are preserved, while `k_float_disable()` turns preservation off again. On targets that do not implement floating point context management these routines return `-ENOTSUP`, and they return `-EINVAL` if the request is otherwise invalid and cannot be performed.

No FP registers mode This mode is used when the application has no threads that use floating point registers. It is the kernel's default floating point services mode.

If a thread uses any floating point register, the kernel generates a fatal error condition and aborts the thread.

Unshared FP registers mode This mode is used when the application has only a single thread that uses floating point registers.

On x86 platforms, the kernel initializes the floating point registers so they can be used by any thread (initialization in skipped on ARM Cortex-M platforms and ARCv2 platforms). The floating point registers are left unchanged whenever a context switch occurs.

> **Note**
>
> The behavior is undefined, if two or more threads attempt to use the floating point registers, as the kernel does not attempt to detect (or prevent) multiple threads from using these registers.

Shared FP registers mode This mode is used when the application has two or more threads that use floating point registers. Depending upon the underlying CPU architecture, the kernel supports one or more of the following thread sub-classes:

- non-user: A thread that cannot use any floating point registers
- FPU user: A thread that can use the standard floating point registers
- SSE user: A thread that can use both the standard floating point registers and SSE registers

The kernel initializes and enables access to the floating point registers, so they can be used by any thread, then saves and restores these registers during context switches to ensure the computations performed by each FPU user or SSE user are not impacted by the computations performed by the other users.

> **Note**
>
> The Shared FP registers mode is the default Floating Point Services mode in ARM Cortex-M.

ARM Cortex-M architecture (with the Floating Point Extension) On the ARM Cortex-M architecture with the Floating Point Extension, the kernel treats *all* threads as FPU users when shared FP registers mode is enabled. This means that any thread is allowed to access the floating point registers. The ARM kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them.

Pretag a thread that intends to use the FP registers by using one of the techniques listed below.

- A statically-created ARM thread can be pretagged by passing the K_FP_REGS option to K_THREAD_DEFINE.
- A dynamically-created ARM thread can be pretagged by passing the K_FP_REGS option to k_thread_create().

Pretagging a thread with the K_FP_REGS option instructs the MPU-based stack protection mechanism to properly configure the size of the thread's guard region to always guarantee stack overflow detection, and enable lazy stacking for the given thread upon thread creation.

During thread context switching the ARM kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers.

Each thread that intends to use the floating point registers must provide an extra 72 bytes of stack space where the callee-saved FP context can be saved.

Lazy Stacking is currently enabled in Zephyr applications on ARM Cortex-M architecture, minimizing interrupt latency, when the floating point context is active.

When the MPU-based stack protection mechanism is not enabled, lazy stacking is always active in the Zephyr application. When the MPU-based stack protection is enabled, the following rules apply with respect to lazy stacking:

- Lazy stacking is activated by default on threads that are pretagged with K_FP_REGS
- Lazy stacking is activated dynamically on threads that are not pretagged with K_FP_REGS, as soon as the kernel detects that they are using the floating point registers.

If an ARM thread does not require use of the floating point registers any more, it can call k_float_disable(). This instructs the kernel not to save or restore its FP context during thread context switching.

Note

The Shared FP registers mode is the default Floating Point Services mode on ARM64. The compiler is free to optimize code using FP/SIMD registers, and library functions such as memcpy are known to make use of them.

ARM64 architecture On the ARM64 (Aarch64) architecture the kernel treats each thread as a FPU user on a case-by-case basis. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don't have a persistent register context, there are no provision for saving an ISR's FPU context either, hence the IRQ disabling.

Each thread object becomes 512 bytes larger when Shared FP registers mode is enabled.

ARCv2 architecture On the ARCv2 architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques.

- A statically-created ARC thread can be tagged by passing the K_FP_REGS option to K_THREAD_DEFINE.

- A dynamically-created ARC thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

If an ARC thread does not require use of the floating point registers any more, it can call `k_float_disable()`. This instructs the kernel not to save or restore its FP context during thread context switching.

During thread context switching the ARC kernel saves the *callee-saved* floating point registers, if the switched-out thread has been using them. Additionally, the *caller-saved* floating point registers are saved on the thread's stack. If the switched-in thread has been using the floating point registers, the kernel restores the *callee-saved* FP registers of the switched-in thread and the *caller-saved* FP context is restored from the thread's stack. Thus, the kernel does not save or restore the FP context of threads that are not using the FP registers. An extra 16 bytes (single floating point hardware) or 32 bytes (double floating point hardware) of stack space is required to load and store floating point registers.

RISC-V architecture On the RISC-V architecture the kernel treats each thread as an FPU user on a case-by-case basis with the FPU access allocated on demand. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the FPU registers are *not* saved when switching from an FPU user to a non-user thread (or an FPU user that doesn't touch the FPU during its scheduling slot), and then back to the original FPU user.

FPU register usage by ISRs is supported although not recommended. When an ISR uses floating point or SIMD registers, then the access is trapped, the current FPU user context is saved in the thread object and the ISR is resumed with interrupts disabled so to prevent another IRQ from interrupting the ISR and potentially requesting FPU usage. Because ISR don't have a persistent register context, there are no provision for saving an ISR's FPU context either, hence the IRQ disabling.

As an optimization, the FPU context is preemptively restored upon scheduling back an "active FPU user" thread that had its FPU context saved away due to FPU usage by another thread. Active FPU users are so designated when they make the FPU state "dirty" during their most recent scheduling slot before being scheduled out. So if a thread doesn't modify the FPU state within its scheduling slot and another thread claims the FPU for itself afterwards then that first thread will be subjected to the on-demand regime and won't have its FPU context restored until it attempts to access it again. But if that thread does modify the FPU before being scheduled out then it is likely to continue using it when scheduled back in and preemptively restoring its FPU context saves on the exception trap overhead that would occur otherwise.

Each thread object becomes 136 bytes (single-precision floating point hardware) or 264 bytes (double-precision floating point hardware) larger when Shared FP registers mode is enabled.

SPARC architecture On the SPARC architecture, the kernel treats each thread as a non-user or FPU user and the thread must be tagged by one of the following techniques:

- A statically-created thread can be tagged by passing the `K_FP_REGS` option to `K_THREAD_DEFINE`.
- A dynamically-created thread can be tagged by passing the `K_FP_REGS` to `k_thread_create()`.

During thread context switch at exit from interrupt handler, the SPARC kernel saves *all* floating point registers, if the FPU was enabled in the switched-out thread. Floating point registers are saved on the thread's stack. Floating point registers are restored when a thread context is restored iff they were saved at the context save. Saving and restoring of the floating point registers is synchronous and thus not lazy. The FPU is always disabled when an ISR is called (independent of `CONFIG_FPU_SHARING`).

Floating point disabling with `k_float_disable()` is not implemented.

When CONFIG_FPU_SHARING is used, then 136 bytes of stack space is required for each FPU user thread to load and store floating point registers. No extra stack is required if CONFIG_FPU_SHARING is not used.

x86 architecture On the x86 architecture the kernel treats each thread as a non-user, FPU user or SSE user on a case-by-case basis. A "lazy save" algorithm is used during context switching which updates the floating point registers only when it is absolutely necessary. For example, the registers are *not* saved when switching from an FPU user to a non-user thread, and then back to the original FPU user. The following table indicates the amount of additional stack space a thread must provide so the registers can be saved properly.

Thread type	FP register use	Extra stack space required
cooperative	any	0 bytes
preemptive	none	0 bytes
preemptive	FPU	108 bytes
preemptive	SSE	464 bytes

The x86 kernel automatically detects that a given thread is using the floating point registers the first time the thread accesses them. The thread is tagged as an SSE user if the kernel has been configured to support the SSE registers, or as an FPU user if the SSE registers are not supported. If this would result in a thread that is an FPU user being tagged as an SSE user, or if the application wants to avoid the exception handling overhead involved in auto-tagging threads, it is possible to pretag a thread using one of the techniques listed below.

- A statically-created x86 thread can be pretagged by passing the K_FP_REGS or K_SSE_REGS option to K_THREAD_DEFINE.
- A dynamically-created x86 thread can be pretagged by passing the K_FP_REGS or K_SSE_REGS option to k_thread_create().
- An already-created x86 thread can pretag itself once it has started by passing the K_FP_REGS or K_SSE_REGS option to k_float_enable().

If an x86 thread uses the floating point registers infrequently it can call k_float_disable() to remove its tagging as an FPU user or SSE user. This eliminates the need for the kernel to take steps to preserve the contents of the floating point registers during context switches when there is no need to do so. When the thread again needs to use the floating point registers it can re-tag itself as an FPU user or SSE user by calling k_float_enable().

Implementation

Performing Floating Point Arithmetic No special coding is required for a thread to use floating point arithmetic if the kernel is properly configured.

The following code shows how a routine can use floating point arithmetic to avoid overflow issues when computing the average of a series of integer values.

```
int average(int *values, int num_values)
{
    double sum;
    int i;

    sum = 0.0;

    for (i = 0; i < num_values; i++) {
        sum += *values;
        values++;
```

(continues on next page)

(continued from previous page)

```
    }

    return (int)((sum / num_values) + 0.5);
}
```

Suggested Uses Use the kernel floating point services when an application needs to perform floating point operations.

Configuration Options To configure unshared FP registers mode, enable the `CONFIG_FPU` configuration option and leave the `CONFIG_FPU_SHARING` configuration option disabled.

To configure shared FP registers mode, enable both the `CONFIG_FPU` configuration option and the `CONFIG_FPU_SHARING` configuration option. Also, ensure that any thread that uses the floating point registers has sufficient added stack space for saving floating point register values during context switches, as described above.

For x86, use the `CONFIG_X86_SSE` configuration option to enable support for SSEx instructions.

Assertions

Zephyr provides several assertion facilities for catching programming errors:

- **Runtime assertions** check a condition while the code is running and, if it fails, induce a *fatal error*. The recommended API is the module-aware `ZASSERT()` macro; the older `__ASSERT()` macro is now a thin compatibility layer on top of it and is deprecated.
- **Build assertions** (`BUILD_ASSERT()`) are evaluated entirely at compile-time and always checked.

> **Note**
>
> The runtime `ZASSERT()` macro documented here is unrelated to the lowercase `zassert_*` macros (`zassert_true()`, `zassert_equal()`, ...) provided by the *Ztest* framework. The `zassert_*` macros report test failures, the `ZASSERT()` macro raises a fatal error when a programming error is detected.

Runtime Assertions

ZASSERT() The module-aware assertion API is declared in include/zephyr/sys/zassert.h. Each source file opts into an assertion *module* whose level is a compile-time constant. Because the level is known at compile time, the compiler can optimize the footprint of the assertion code based on the associated assertion level of the module the assert belongs to.

Assertion Levels Every module resolves to one of four levels:

- ZASSERT_LEVEL_OFF – assertions are compiled out entirely.
- ZASSERT_LEVEL_TERSE – assertions are checked; on failure only a fixed ASSERTION FAIL banner is reported. The location, condition, message and arguments are not compiled in.
- ZASSERT_LEVEL_NORMAL – assertions are checked; on failure only the location is reported (ASSERTION FAIL @ file:line). The condition, message and arguments are not compiled in.
- ZASSERT_LEVEL_VERBOSE – assertions are checked; on failure the stringified condition, location and optional message are reported.

CONFIG_ASSERT is the master switch. When it is disabled, every module is forced to ZASSERT_LEVEL_OFF and all ZASSERT() / ZASSERT_MODULE() usage compiles to nothing, regardless of any module's configured level.

note

ZASSERTS footprint reduction relies on compiler optimizations to prune unused conditions, arguments, and string literals at compile time. Lower optimization levels may prevent dead-code elimination, leaving assertion artifacts in the binary despite a low module assertion setting.

Selecting a Module Place ZASSERT_MODULE once at file scope, before any use of ZASSERT in the translation unit:

```
#include <zephyr/sys/zassert.h>

ZASSERT_MODULE(MYMODULE);
```

The module name is an UPPERCASE identifier. Its default level is taken from the Kconfig symbol CONFIG_ASSERT_MODULE_<module>_LEVEL (here CONFIG_ASSERT_MODULE_MYMODULE_LEVEL). A file may override the module default by passing an explicit level as a second argument, for example ZASSERT_MODULE(MYMODULE, ZASSERT_LEVEL_VERBOSE).

Once a module is selected, use ZASSERT like a conditional check with an optional printf()-like message:

```
ZASSERT(x == 3, "x was %d, expected 3", x);
```

If the condition is false and the module's level is at least ZASSERT_LEVEL_TERSE, a fatal error is raised. The location is only compiled in and printed at ZASSERT_LEVEL_NORMAL or above, and the condition, message and its arguments are only compiled in and printed at ZASSERT_LEVEL_VERBOSE.

For headers and inline functions, avoid ZASSERT_MODULE() at file scope, as the selection would leak into every file that includes the header. Use one of the following instead.

Place ZASSERT_MODULE inside the function body. The selection is then block-scoped and does not escape to the includer, and plain ZASSERT works within that function:

```
static inline void f(void *ptr)
{
        ZASSERT_MODULE(MYMODULE);

        ZASSERT(ptr != NULL, "ptr must not be NULL");
}
```

For an assertion with a fixed level, use ZASSERT_TERSE, ZASSERT_NORMAL or ZASSERT_VERBOSE. These forms select the level at the call site and declare nothing in scope:

```
ZASSERT_TERSE(ptr != NULL);
ZASSERT_NORMAL(ptr != NULL);
ZASSERT_VERBOSE(ptr != NULL, "ptr must not be NULL");
```

The ZASSERT_LEVEL_TERSE, ZASSERT_LEVEL_NORMAL and ZASSERT_LEVEL_VERBOSE defines configure module assertion levels, while ZASSERT_TERSE(), ZASSERT_NORMAL() and ZASSERT_VERBOSE() perform fixed-level assertions.

Note

A few rules apply to ZASSERT() and its file-scope module:

- ZASSERT_MODULE() must appear before the first ZASSERT() in the translation unit, and only one module may be selected per file.
- Using ZASSERT() with no module in scope is a compile error. Select a module first, or use the fixed-level ZASSERT_TERSE(), ZASSERT_NORMAL() or ZASSERT_VERBOSE() form.
- CONFIG_ASSERT remains the master switch: when it is disabled the module level is forced to ZASSERT_LEVEL_OFF regardless of the configured level.

Defining a Module's Kconfig Level The CONFIG_ASSERT_MODULE_<module>_LEVEL symbol is generated from the template subsys/debug/zassert/Kconfig.template.assert. Source it from a Kconfig file, setting the module name and a human-readable description first:

```
module = MYMODULE
module-str = the MYMODULE assert module
source "subsys/debug/zassert/Kconfig.template.assert"
```

This produces a user-facing Off / Terse / Normal / Verbose choice and the derived, non-assignable integer symbol CONFIG_ASSERT_MODULE_MYMODULE_LEVEL consumed by ZASSERT_MODULE(MYMODULE). The choice defaults to Verbose and stays overridable from prj.conf.

Example The assert sample demonstrates enabling verbose assertions for a single file while the master assertion switch is enabled. A condensed version:

```
#include <zephyr/kernel.h>
#include <zephyr/sys/zassert.h>

ZASSERT_MODULE(MYMODULE);

int main(void)
{
        int x = 2;

        ZASSERT(x == 3, "x was %d, expected 3", x);

        return 0;
}
```

With CONFIG_ASSERT_MODULE_MYMODULE_LEVEL_VERBOSE=y the failing check produces:

```
ASSERTION FAIL [x == 3] @ .../src/main.c:...
x was 2, expected 3
```

Customizing the Failure Behavior The entire assertion cold path is consolidated into a small set of weak, overridable functions declared in include/zephyr/sys/zassert.h and implemented in subsys/debug/zassert/zassert.c:

- `zassert_fail()` reports a failed assertion (location, and when a message is present the message and its arguments) and then invokes `zassert_post_action()`. Overriding it is the single surface for capturing or redirecting the whole assertion output.
- `zassert_post_action()` takes the terminal action. The default implementation invokes `k_oops()` if the failing thread was running in user mode, and `k_panic()` otherwise.
- `zassert_vprint()` is the single primitive through which all assertion text flows. Override it to capture or redirect every assertion message from one place. `zassert_print()` is a variadic convenience wrapper around it, used by the legacy `__ASSERT_PRINT()` compatibility shims.

When `CONFIG_ASSERT_TEST` is enabled, the post action handler is allowed to return (rather than abort) so that tests can validate assertion behavior by installing a custom hook.

Build Assertions Zephyr provides a macro for performing build-time assertion checks. It is evaluated completely at compile-time and always checked.

BUILD_ASSERT() This has the same semantics as C's `_Static_assert` or C++'s `static_assert`. If the evaluation fails, a build error will be generated by the compiler. If the compiler supports it, the provided message will be printed to provide further context.

Unlike `__ASSERT()`, the message must be a static string or string concatenation of static strings. The macro does not support formatting or variable arguments.

For example, suppose this check fails:

```
BUILD_ASSERT(FOO == 2000, "Invalid value of FOO, expected 2000, got "␣
↪STRINGIFY(FOO));
```

With GCC, the output resembles:

```
    tests/kernel/fatal/src/main.c: In function 'test_main':
    include/zephyr/toolchain/gcc.h:28:37: error: static assertion failed:
"Invalid value of FOO, expected 2000, got 1000"
     #define BUILD_ASSERT(EXPR, MSG) _Static_assert(EXPR, "" MSG)
                                     ^~~~~~~~~~~~~~
    tests/kernel/fatal/src/main.c:370:2: note: in expansion of macro 'BUILD_ASSERT
↪'
      BUILD_ASSERT(FOO == 2000,
      ^~~~~~~~~~~~~~~~
```

Legacy __ASSERT() The `__ASSERT()` family, declared in include/zephyr/sys/__assert.h, predates `ZASSERT()` and is now a compatibility shim using the built-in `DEFAULT` assertion module. New code should prefer `ZASSERT()` with a dedicated module.

Note

`__ASSERT()` and the `CONFIG_ASSERT*` Kconfig options are deprecated. They continue to work through the `DEFAULT` module, but the underlying assert API may change in future releases.

The `DEFAULT` module is enabled by `CONFIG_ASSERT`. Its level is controlled by `CONFIG_ASSERT_MODULE_DEFAULT_LEVEL`, configured through the `Off` / `Terse` / `Normal` / `Verbose` choice (`CONFIG_ASSERT_MODULE_DEFAULT_LEVEL_OFF` / `CONFIG_ASSERT_MODULE_DEFAULT_LEVEL_TERSE` / `CONFIG_ASSERT_MODULE_DEFAULT_LEVEL_NORMAL`

/ CONFIG_ASSERT_MODULE_DEFAULT_LEVEL_VERBOSE). Assertions are enabled by default when running Zephyr test cases, as configured by the CONFIG_TEST option.

The deprecated legacy symbols are still honored and derive the DEFAULT module level: CONFIG_ASSERT_VERBOSE maps to Verbose, CONFIG_ASSERT_NO_COND_INFO, CONFIG_ASSERT_NO_MSG_INFO and CONFIG_ASSERT_NO_FILE_INFO map to Terse, and a CONFIG_ASSERT_LEVEL == 0 leaves it Off. When none of these are set, the DEFAULT module choice falls through to its own CONFIG_ASSERT_MODULE_DEFAULT_LEVEL_VERBOSE default, preserving the legacy behavior of verbose assertions as the default. To disable all assertions regardless of how the level was configured, set CONFIG_ASSERT=n.

API Reference

Module based assert handling

Fatal Errors

Software Errors Triggered in Source Code Zephyr provides several methods for inducing fatal error conditions through either build-time checks, conditionally compiled assertions, or deliberately invoked panic or oops conditions.

Failed runtime assertions (ZASSERT() and the legacy __ASSERT()) induce a fatal error. See *Assertions* for details on the assertion APIs and how their failure behavior is configured.

Kernel Oops A kernel oops is a software triggered fatal error invoked by k_oops(). This should be used to indicate an unrecoverable condition in application logic.

The fatal error reason code generated will be K_ERR_KERNEL_OOPS.

Kernel Panic A kernel error is a software triggered fatal error invoked by k_panic(). This should be used to indicate that the Zephyr kernel is in an unrecoverable state. Implementations of k_sys_fatal_error_handler() should not return if the kernel encounters a panic condition, as the entire system needs to be reset.

Threads running in user mode are not permitted to invoke k_panic(), and doing so will generate a kernel oops instead. Otherwise, the fatal error reason code generated will be K_ERR_KERNEL_PANIC.

Exceptions

Spurious Interrupts If the CPU receives a hardware interrupt on an interrupt line that has not had a handler installed with IRQ_CONNECT() or irq_connect_dynamic(), then the kernel will generate a fatal error with the reason code K_ERR_SPURIOUS_IRQ().

Stack Overflows In the event that a thread pushes more data onto its execution stack than its stack buffer provides, the kernel may be able to detect this situation and generate a fatal error with a reason code of K_ERR_STACK_CHK_FAIL.

If a thread is running in user mode, then stack overflows are always caught, as the thread will simply not have permission to write to adjacent memory addresses outside of the stack buffer. Because this is enforced by the memory protection hardware, there is no risk of data corruption to memory that the thread would not otherwise be able to write to.

If a thread is running in supervisor mode, or if CONFIG_USERSPACE is not enabled, depending on configuration stack overflows may or may not be caught. CONFIG_HW_STACK_PROTECTION is supported on some architectures and will catch stack overflows in supervisor mode, including when handling a system call on behalf of a user thread. Typically this is implemented via dedicated CPU features, or read-only MMU/MPU guard regions placed immediately adjacent to the stack buffer. Stack overflows caught in this way can detect the overflow, but cannot guarantee against

data corruption and should be treated as a very serious condition impacting the health of the entire system.

If a platform lacks memory management hardware support, CONFIG_STACK_SENTINEL is a software-only stack overflow detection feature which periodically checks if a sentinel value at the end of the stack buffer has been corrupted. It does not require hardware support, but provides no protection against data corruption. Since the checks are typically done at interrupt exit, the overflow may be detected a nontrivial amount of time after the stack actually overflowed.

Finally, Zephyr supports GCC compiler stack canaries via CONFIG_STACK_CANARIES. If enabled, the compiler will insert a canary value randomly generated at boot into function stack frames, checking that the canary has not been overwritten at function exit. If the check fails, the compiler invokes `__stack_chk_fail()`, whose Zephyr implementation invokes a fatal stack overflow error. An error in this case does not indicate that the entire stack buffer has overflowed, but instead that the current function stack frame has been corrupted. See the compiler documentation for more details.

By default a single canary value, generated at boot, is shared by all threads. When CONFIG_STACK_CANARIES_TLS is enabled, the canary is instead stored in *thread-local storage* so that each thread has its own value, making the canary location and value harder to predict at the cost of additional per-thread setup.

As a complementary hardening measure, CONFIG_STACK_POINTER_RANDOM applies a randomized offset to each thread's initial stack pointer when the thread is created. This is a limited form of address space layout randomization that makes the location of any given stack frame nondeterministic, hindering some classes of security attack, at the cost of consuming up to the configured number of bytes from each thread's stack region.

Other Exceptions Any other type of unhandled CPU exception will generate an error code of K_ERR_CPU_EXCEPTION.

Fatal Error Handling The policy for what to do when encountering a fatal error is determined by the implementation of the `k_sys_fatal_error_handler()` function. This function has a default implementation with weak linkage that calls `LOG_PANIC()` to dump all pending logging messages and then unconditionally halts the system with `k_fatal_halt()`.

Applications are free to implement their own error handling policy by overriding the implementation of `k_sys_fatal_error_handler()`. If the implementation returns, the faulting thread will be aborted and the system will otherwise continue to function. See the documentation for this function for additional details and constraints.

Fatal error APIs

Thread Local Storage (TLS)

Thread Local Storage (TLS) allows variables to be allocated on a per-thread basis. These variables are stored in the thread stack which means every thread has its own copy of these variables.

Zephyr currently requires toolchain support for TLS.

Configuration To enable thread local storage in Zephyr, CONFIG_THREAD_LOCAL_STORAGE needs to be enabled. Note that this option may not be available if the architecture or the SoC does not have the hidden option CONFIG_ARCH_HAS_THREAD_LOCAL_STORAGE enabled, which means the architecture or the SoC does not have the necessary code to support thread local storage and/or the toolchain does not support TLS.

CONFIG_ERRNO_IN_TLS can be enabled together with CONFIG_ERRNO to let the variable `errno` be a thread local variable. This allows user threads to access the value of `errno` without making a system call.

Declaring and Using Thread Local Variables The macro `Z_THREAD_LOCAL` can be used to declare thread local variables.

For example, to declare a thread local variable in header files:

```
extern Z_THREAD_LOCAL int i;
```

And to declare the actual variable in source files:

```
Z_THREAD_LOCAL int i;
```

Keyword `static` can also be used to limit the variable within a source file:

```
static Z_THREAD_LOCAL int j;
```

Using the thread local variable is the same as using other variable, for example:

```
void testing(void) {
    i = 10;
}
```

3.2 Device Driver Model

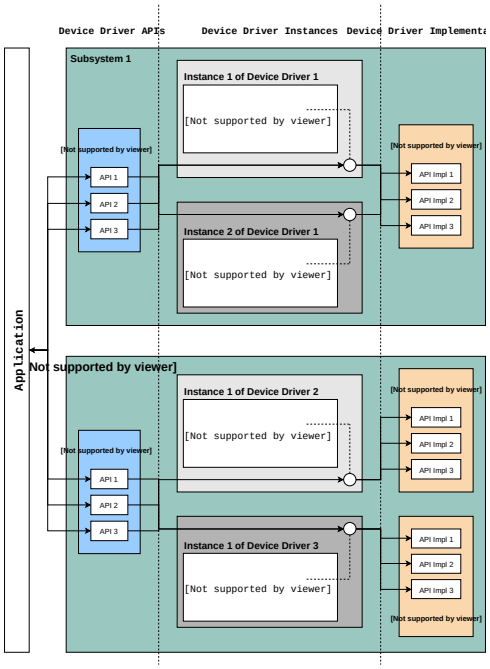
3.2.1 Introduction

The Zephyr kernel supports a variety of device drivers. Whether a driver is available depends on the board and the driver.

The Zephyr device model provides a consistent device model for configuring the drivers that are part of a system. The device model is responsible for initializing all the drivers configured into the system.

Each type of driver (e.g. UART, SPI, I2C) is supported by a generic type API.

In this model the driver fills in the pointer to the structure containing the function pointers to its API functions during driver initialization. These structures are placed into the RAM section in initialization level order.



3.2.2 Standard Drivers

Device drivers which are present on all supported board configurations are listed below.

- **Interrupt controller**: This device driver is used by the kernel's interrupt management subsystem.
- **Timer**: This device driver is used by the kernel's system clock and hardware clock subsystem.
- **Serial communication**: This device driver is used by the kernel's system console subsystem.
- **Entropy**: This device driver provides a source of entropy numbers for the random number generator subsystem.

> **Important**
>
> Use the *random API functions* for random values. *Entropy functions* should not be directly used as a random number generator source as some hardware implementations are designed to be an entropy seed source for random number generators and will not provide cryptographically secure random number streams.

3.2.3 Synchronous Calls

Zephyr provides a set of device drivers for multiple boards. Each driver should support an interrupt-based implementation, rather than polling, unless the specific hardware does not provide any interrupt.

High-level calls accessed through device-specific APIs, such as `i2c.h` or `spi.h`, are usually intended as synchronous. Thus, these calls should be blocking.

3.2.4 Driver APIs

The following APIs for device drivers are provided by `device.h`. The APIs are intended for use in device drivers only and should not be used in applications.

`DEVICE_DEFINE()`
: Create device object and related data structures including setting it up for boot-time initialization.

`DEVICE_NAME_GET()`
: Converts a device identifier to the global identifier for a device object.

`DEVICE_GET()`
: Obtain a pointer to a device object by name.

`DEVICE_DECLARE()`
: Declare a device object. Use this when you need a forward reference to a device that has not yet been defined.

`DEVICE_API()`
: Wrap a driver API declaration to assign it to its respective linker section. Use of this macro is mandatory for any driver implementing an upstream driver class, as `DEVICE_API_GET` and `DEVICE_API_IS` rely on API instances being placed in their class linker section to validate the device's API class at runtime.

3.2.5 Driver Data Structures

The device initialization macros populate some data structures at build time which are split into read-only and runtime-mutable parts. At a high level we have:

```
struct device {
      const char *name;
      const void *config;
      const void *api;
      void * const data;
};
```

The `config` member is for read-only configuration data set at build time. For example, base memory mapped IO addresses, IRQ line numbers, or other fixed physical characteristics of the device. This is the `config` pointer passed to `DEVICE_DEFINE()` and related macros.

The `data` struct is kept in RAM, and is used by the driver for per-instance runtime housekeeping. For example, it may contain reference counts, semaphores, scratch buffers, etc.

The `api` struct maps generic subsystem APIs to the device-specific implementations in the driver. It is typically read-only and populated at build time. The next section describes this in more detail.

3.2.6 Subsystems and API Structures

Most drivers will be implementing a device-independent subsystem API. Applications can simply program to that generic API, and application code is not specific to any particular driver implementation.

Driver API instances must be declared with `DEVICE_API()` so that they are assigned to their respective API linker section. This is required for `DEVICE_API_GET` and `DEVICE_API_IS` to validate at runtime that a device's API belongs to the expected class.

A subsystem API definition typically looks like this:

```
typedef int (*subsystem_do_this_t)(const struct device *dev, int foo, int bar);
typedef void (*subsystem_do_that_t)(const struct device *dev, void *baz);

__subsystem struct subsystem_driver_api {
      subsystem_do_this_t do_this;
      subsystem_do_that_t do_that;
};

static inline int subsystem_do_this(const struct device *dev, int foo, int bar)
{
      return DEVICE_API_GET(subsystem, dev)->do_this(dev, foo, bar);
}

static inline void subsystem_do_that(const struct device *dev, void *baz)
{
      DEVICE_API_GET(subsystem, dev)->do_that(dev, baz);
}
```

A driver implementing a particular subsystem will define the real implementation of these APIs, and populate an instance of subsystem_driver_api structure using the `DEVICE_API()` wrapper:

```
static int my_driver_do_this(const struct device *dev, int foo, int bar)
{
      ...
}

static void my_driver_do_that(const struct device *dev, void *baz)
{
      ...
```

(continues on next page)

(continued from previous page)

```
}

static DEVICE_API(subsystem, my_driver_api_funcs) = {
	.do_this = my_driver_do_this,
	.do_that = my_driver_do_that,
};
```

The driver would then pass `my_driver_api_funcs` as the `api` argument to `DEVICE_DEFINE()`.

> **Note**
>
> Since pointers to the API functions are referenced in the `api` struct, they will always be included in the binary even if unused; `gc-sections` linker option will always see at least one reference to them. Providing for link-time size optimizations with driver APIs in most cases requires that the optional feature be controlled by a Kconfig option.

3.2.7 API Class Inheritance

A subsystem API can extend another subsystem API, forming a parent-child relationship. This allows a device implementing the child API to also be recognized as implementing the parent API. For example, an I3C controller extends the I2C API, so it can be used wherever an I2C device is expected.

To define a child API, embed the parent API struct as the **first member** of the child struct and declare the relationship with `DEVICE_API_EXTENDS`:

```
__subsystem struct child_driver_api {
	struct subsystem_driver_api parent_api;
	child_do_extra_t do_extra;
};

DEVICE_API_EXTENDS(child, subsystem, parent_api);
```

A driver implementing the child API populates both the parent and child methods:

```
static DEVICE_API(child, my_child_api) = {
	.parent_api = {
		.do_this = my_child_do_this,
		.do_that = my_child_do_that,
	},
	.do_extra = my_child_do_extra,
};
```

With this in place, `DEVICE_API_IS` returns true for both the child and parent classes, and `DEVICE_API_GET` can retrieve the API as either type:

```
/* Both return true for a child device */
DEVICE_API_IS(subsystem, dev);
DEVICE_API_IS(child, dev);

/* Access through parent API */
DEVICE_API_GET(subsystem, dev)->do_this(dev, foo, bar);
```

Multi-level inheritance is supported (e.g. grandchild extends child extends parent). Sibling relationships also work correctly: two different child APIs extending the same parent are distinguished by `DEVICE_API_IS`.

3.2.8 Device-Specific API Extensions

Some devices can be cast as an instance of a driver subsystem such as GPIO, but provide additional functionality that cannot be exposed through the standard API. These devices combine subsystem operations with device-specific APIs, described in a device-specific header.

A device-specific API definition typically looks like this:

```
#include <zephyr/drivers/subsystem.h>

/* When extensions need not be invoked from user mode threads */
int specific_do_that(const struct device *dev, int foo);

/* When extensions must be invokable from user mode threads */
__syscall int specific_from_user(const struct device *dev, int bar);

/* Only needed when extensions include syscalls */
#include <zephyr/syscalls/specific.h>
```

A driver implementing extensions to the subsystem will define the real implementation of both the subsystem API and the specific APIs:

```
static int generic_do_this(const struct device *dev, void *arg)
{
   ...
}

static struct generic_api api {
   ...
   .do_this = generic_do_this,
   ...
};

/* supervisor-only API is globally visible */
int specific_do_that(const struct device *dev, int foo)
{
   ...
}

/* syscall API passes through a translation */
int z_impl_specific_from_user(const struct device *dev, int bar)
{
   ...
}

#ifdef CONFIG_USERSPACE

#include <zephyr/internal/syscall_handler.h>

int z_vrfy_specific_from_user(const struct device *dev, int bar)
{
    K_OOPS(K_SYSCALL_SPECIFIC_DRIVER(dev, K_OBJ_DRIVER_GENERIC, &api));
    return z_impl_specific_do_that(dev, bar)
}

#include <zephyr/syscalls/specific_from_user_mrsh.c>

#endif /* CONFIG_USERSPACE */
```

Applications use the device through both the subsystem and specific APIs.

3.2.9 Single Driver, Multiple Instances

Some drivers may be instantiated multiple times in a given system. For example there can be multiple GPIO banks, or multiple UARTS. Each instance of the driver will have a different `config` struct and `data` struct.

Configuring interrupts for multiple drivers instances is a special case. If each instance needs to configure a different interrupt line, this can be accomplished through the use of per-instance configuration functions, since the parameters to `IRQ_CONNECT()` need to be resolvable at build time.

For example, let's say we need to configure two instances of `my_driver`, each with a different interrupt line. In `drivers/subsystem/subsystem_my_driver.h`:

```
typedef void (*my_driver_config_irq_t)(const struct device *dev);

struct my_driver_config {
	DEVICE_MMIO_ROM;
	my_driver_config_irq_t config_func;
};
```

In the implementation of the common init function:

```
void my_driver_isr(const struct device *dev)
{
	/* Handle interrupt */
	...
}

int my_driver_init(const struct device *dev)
{
	const struct my_driver_config *config = dev->config;

	DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);

	/* Do other initialization stuff */
	...

	config->config_func(dev);

	return 0;
}
```

Then when the particular instance is declared:

```
#if CONFIG_MY_DRIVER_0

DEVICE_DECLARE(my_driver_0);

static void my_driver_config_irq_0(const struct device *dev)
{
	IRQ_CONNECT(MY_DRIVER_0_IRQ, MY_DRIVER_0_PRI, my_driver_isr,
		    DEVICE_GET(my_driver_0), MY_DRIVER_0_FLAGS);
}

const static struct my_driver_config my_driver_config_0 = {
	DEVICE_MMIO_ROM_INIT(DT_DRV_INST(0)),
	.config_func = my_driver_config_irq_0
}
```

(continues on next page)

(continued from previous page)

```
static struct my_data_0;

DEVICE_DEFINE(my_driver_0, MY_DRIVER_0_NAME, my_driver_init,
              NULL, &my_data_0, &my_driver_config_0,
              POST_KERNEL, MY_DRIVER_0_PRIORITY, &my_api_funcs);

#endif /* CONFIG_MY_DRIVER_0 */
```

Note the use of `DEVICE_DECLARE()` to avoid a circular dependency on providing the IRQ handler argument and the definition of the device itself.

3.2.10 Initialization Levels

Drivers may depend on other drivers being initialized first, or require the use of kernel services. `DEVICE_DEFINE()` and related APIs allow the user to specify at what time during the boot sequence the init function will be executed. Any driver will specify one of three initialization levels:

PRE_KERNEL_1
: Used for devices that have no dependencies, such as those that rely solely on hardware present in the processor/SOC. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. The interrupt subsystem will be configured however so it's OK to set up interrupts. Init functions at this level run on the interrupt stack.

PRE_KERNEL_2
: Used for devices that rely on the initialization of devices initialized as part of the `PRE_KERNEL_1` level. These devices cannot use any kernel services during configuration, since the kernel services are not yet available. Init functions at this level run on the interrupt stack.

POST_KERNEL
: Used for devices that require kernel services during configuration. Init functions at this level run in context of the kernel main task.

Within each initialization level you may specify a priority level, relative to other devices in the same initialization level. The priority level is specified as an integer value in the range 0 to 999; lower values indicate earlier initialization. The priority level must be a decimal integer literal without leading zeroes or sign (e.g. 32), or an equivalent symbolic name (e.g. `\#define MY_INIT_PRIO 32`); symbolic expressions are *not* permitted (e.g. `CONFIG_KERNEL_INIT_PRIORITY_DEFAULT + 5`).

Drivers and other system utilities can determine whether startup is still in pre-kernel states by using the `k_is_pre_kernel()` function.

3.2.11 Deferred initialization

Initialization of devices can also be deferred to a later time. In this case, the device is not automatically initialized by Zephyr at boot time. Instead, the device is initialized when the application calls `device_init()`. To defer a device driver initialization, add the property `zephyr,deferred-init` to the associated device node in the DTS file. For example:

```
/ {
        a-driver@40000000 {
                reg = <0x40000000 0x1000>;
                zephyr,deferred-init;
        };
};
```

3.2.12 System Drivers

In some cases you may just need to run a function at boot. For such cases, the SYS_INIT can be used. This macro does not take any config or runtime data structures and there isn't a way to later get a device pointer by name. The same device policies for initialization level and priority apply.

3.2.13 Inspecting the initialization sequence

Device drivers declared with DEVICE_DEFINE (or any variations of it) and SYS_INIT are processed at boot time and the corresponding initialization functions are called sequentially according to their specified level and priority.

Sometimes it's useful to inspect the final sequence of initialization function call as produced by the linker. To do that, use the `initlevels` CMake target, for example `west build -t initlevels`.

3.2.14 Error handling

In general, it's best to use `__ASSERT()` macros instead of propagating return values unless the failure is expected to occur during the normal course of operation (such as a storage device full). Bad parameters, programming errors, consistency checks, pathological/unrecoverable failures, etc., should be handled by assertions.

When it is appropriate to return error conditions for the caller to check, 0 should be returned on success and a POSIX `errno.h` code returned on failure. See https://github.com/zephyrproject-rtos/zephyr/wiki/Naming-Conventions#return-codes for details about this.

3.2.15 Memory Mapping

On some systems, the linear address of peripheral memory-mapped I/O (MMIO) regions cannot be known at build time:

- The I/O ranges must be probed at runtime from the bus, such as with PCI express
- A memory management unit (MMU) is active, and the physical address of the MMIO range must be mapped into the page tables at some virtual memory location determined by the kernel.

These systems must maintain storage for the MMIO range within RAM and establish the mapping within the driver's init function. Other systems do not care about this and can use MMIO physical addresses directly from DTS and do not need any RAM-based storage for it.

For drivers that may need to deal with this situation, a set of APIs under the DEVICE_MMIO scope are defined, along with a mapping function `device_map()`.

Device Model Drivers with one MMIO region

The simplest case is for drivers which need to maintain one MMIO region. These drivers will need to use the `DEVICE_MMIO_ROM` and `DEVICE_MMIO_RAM` macros in the definitions for their `config_info` and `driver_data` structures, with initialization of the `config_info` from DTS using `DEVICE_MMIO_ROM_INIT`. A call to `DEVICE_MMIO_MAP()` is made within the init function:

```
struct my_driver_config {
   DEVICE_MMIO_ROM; /* Must be first */
   ...
}

struct my_driver_dev_data {
   DEVICE_MMIO_RAM; /* Must be first */
   ...
```

(continues on next page)

(continued from previous page)

```
}

const static struct my_driver_config my_driver_config_0 = {
   DEVICE_MMIO_ROM_INIT(DT_DRV_INST(...)),
   ...
}

int my_driver_init(const struct device *dev)
{
   ...
   DEVICE_MMIO_MAP(dev, K_MEM_CACHE_NONE);
   ...
}

int my_driver_some_function(const struct device *dev)
{
   ...
   /* Write some data to the MMIO region */
   sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev));
   ...
}
```

The particular expansion of these macros depends on configuration. On a device with no MMU or PCI-e, `DEVICE_MMIO_MAP` and `DEVICE_MMIO_RAM` expand to nothing.

Device Model Drivers with multiple MMIO regions

Some drivers may have multiple MMIO regions. In addition, some drivers may already be implementing a form of inheritance which requires some other data to be placed first in the `config_info` and `driver_data` structures.

This can be managed with the `DEVICE_MMIO_NAMED` variant macros. These require that `DEV_CFG()` and `DEV_DATA()` macros be defined to obtain a properly typed pointer to the driver's config_info or dev_data structs. For example:

```
struct my_driver_config {
   ...
     DEVICE_MMIO_NAMED_ROM(corge);
     DEVICE_MMIO_NAMED_ROM(grault);
   ...
}

struct my_driver_dev_data {
        ...
     DEVICE_MMIO_NAMED_RAM(corge);
     DEVICE_MMIO_NAMED_RAM(grault);
     ...
}

#define DEV_CFG(_dev) \
   ((const struct my_driver_config *)((_dev)->config))

#define DEV_DATA(_dev) \
   ((struct my_driver_dev_data *)((_dev)->data))

const static struct my_driver_config my_driver_config_0 = {
   ...
```

(continues on next page)

(continued from previous page)

```
   DEVICE_MMIO_NAMED_ROM_INIT(corge, DT_DRV_INST(...)),
   DEVICE_MMIO_NAMED_ROM_INIT(grault, DT_DRV_INST(...)),
   ...
}

int my_driver_init(const struct device *dev)
{
   ...
   DEVICE_MMIO_NAMED_MAP(dev, corge, K_MEM_CACHE_NONE);
   DEVICE_MMIO_NAMED_MAP(dev, grault, K_MEM_CACHE_NONE);
   ...
}

int my_driver_some_function(const struct device *dev)
{
   ...
   /* Write some data to the MMIO regions */
   sys_write32(0xDEADBEEF, DEVICE_MMIO_GET(dev, grault));
   sys_write32(0xF0CCAC1A, DEVICE_MMIO_GET(dev, corge));
   ...
}
```

Device Model Drivers with multiple MMIO regions in the same DT node

Some drivers may have multiple MMIO regions defined into the same DT device node using the `reg-names` property to differentiate them, for example:

```
/dts-v1/;

/ {
        a-driver@40000000 {
                reg = <0x40000000 0x1000>,
                      <0x40001000 0x1000>;
                reg-names = "corge", "grault";
        };
};
```

This can be managed as seen in the previous section but this time using the `DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME` macro instead. So the only difference would be in the driver config struct:

```
const static struct my_driver_config my_driver_config_0 = {
   ...
   DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(corge, DT_DRV_INST(...)),
   DEVICE_MMIO_NAMED_ROM_INIT_BY_NAME(grault, DT_DRV_INST(...)),
   ...
}
```

Drivers that do not use Zephyr Device Model

Some drivers or driver-like code may not use Zephyr's device model, and alternative storage must be arranged for the MMIO data. An example of this are timer drivers, or interrupt controller code.

This can be managed with the `DEVICE_MMIO_TOPLEVEL` set of macros, for example:

```
DEVICE_MMIO_TOPLEVEL_STATIC(my_regs, DT_DRV_INST(..));

void some_init_code(...)
{
   ...
   DEVICE_MMIO_TOPLEVEL_MAP(my_regs, K_MEM_CACHE_NONE);
   ...
}

void some_function(...)
   ...
   sys_write32(DEVICE_MMIO_TOPLEVEL_GET(my_regs), 0xDEADBEEF);
   ...
}
```

Drivers that do not use DTS

Some drivers may not obtain the MMIO physical address from DTS, such as is the case with PCI-E. In this case the `device_map()` function may be used directly:

```
void some_init_code(...)
{
   ...
   struct pcie_bar mbar;
   bool bar_found = pcie_get_mbar(bdf, index, &mbar);

   device_map(DEVICE_MMIO_RAM_PTR(dev), mbar.phys_addr, mbar.size,␣
↪K_MEM_CACHE_NONE);
   ...
}
```

For these cases, DEVICE_MMIO_ROM directives may be omitted.

3.2.16 API Reference

Device Model

3.3 User Mode

Zephyr offers the capability to run threads at a reduced privilege level which we call user mode. The current implementation is designed for devices with MPU hardware.

For details on creating threads that run in user mode, please see *Lifecycle*.

3.3.1 Overview

Threat Model

User mode threads are considered to be untrusted by Zephyr and are therefore isolated from other user mode threads and from the kernel. A flawed or malicious user mode thread cannot leak or modify the private data/resources of another thread or the kernel, and cannot interfere with or control another user mode thread or the kernel.

Example use-cases of Zephyr's user mode features:

- The kernel can protect against many unintentional programming errors which could otherwise silently or spectacularly corrupt the system.

- The kernel can sandbox complex data parsers such as interpreters, network protocols, and filesystems such that malicious third-party code or data cannot compromise the kernel or other threads.
- The kernel can support the notion of multiple logical "applications", each with their own group of threads and private data structures, which are isolated from each other if one crashes or is otherwise compromised.

Design Goals For threads running in a non-privileged CPU state (hereafter referred to as 'user mode') we aim to protect against the following:

- We prevent access to memory not specifically granted, or incorrect access to memory that has an incompatible policy, such as attempting to write to a read-only area.
  - Access to thread stack buffers will be controlled with a policy which partially depends on the underlying memory protection hardware.
    - A user thread will by default have read/write access to its own stack buffer.
    - A user thread will never by default have access to user thread stacks that are not members of the same memory domain.
    - A user thread will never by default have access to thread stacks owned by a supervisor thread, or thread stacks used to handle system call privilege elevations, interrupts, or CPU exceptions.
    - A user thread may have read/write access to the stacks of other user threads in the same memory domain, depending on hardware.
      - On MPU systems, threads may only access their own stack buffer.
      - On MMU systems, threads may access any user thread stack in the same memory domain. Portable code should not assume this.
  - By default, program text and read-only data are accessible to all threads on read-only basis, kernel-wide. This policy may be adjusted.
  - User threads by default are not granted default access to any memory except what is noted above.
- We prevent use of device drivers or kernel objects not specifically granted, with the permission granularity on a per object or per driver instance basis.
- We validate kernel or driver API calls with incorrect parameters that would otherwise cause a crash or corruption of data structures private to the kernel. This includes:
  - Using the wrong kernel object type.
  - Using parameters outside of proper bounds or with nonsensical values.
  - Passing memory buffers that the calling thread does not have sufficient access to read or write, depending on the semantics of the API.
  - Use of kernel objects that are not in a proper initialization state.
- We ensure the detection and safe handling of user mode stack overflows.
- We prevent invoking system calls to functions excluded by the kernel configuration.
- We prevent disabling of or tampering with kernel-defined and hardware-enforced memory protections.
- We prevent re-entry from user to supervisor mode except through the kernel-defined system calls and interrupt handlers.
- We prevent the introduction of new executable code by user mode threads, except to the extent to which this is supported by kernel system calls.

We are specifically not protecting against the following attacks:

- The kernel itself, and any threads that are executing in supervisor mode, are assumed to be trusted.
- The toolchain and any supplemental programs used by the build system are assumed to be trusted.
- The kernel build is assumed to be trusted. There is considerable build-time logic for creating the tables of valid kernel objects, defining system calls, and configuring interrupts. The .elf binary files that are worked with during this process are all assumed to be trusted code.
- We can't protect against mistakes made in memory domain configuration done in kernel mode that exposes private kernel data structures to a user thread. RAM for kernel objects should always be configured as supervisor-only.
- It is possible to make top-level declarations of user mode threads and assign them permissions to kernel objects. In general, all C and header files that are part of the kernel build producing zephyr.elf are assumed to be trusted.
- We do not protect against denial of service attacks through thread CPU starvation. Zephyr has no thread priority aging and a user thread of a particular priority can starve all threads of lower priority, and also other threads of the same priority if time-slicing is not enabled.
- There are build-time defined limits on how many threads can be active simultaneously, after which creation of new user threads will fail.
- Stack overflows for threads running in supervisor mode may be caught, but the integrity of the system cannot be guaranteed.

High-level Policy Details

Broadly speaking, we accomplish these thread-level memory protection goals through the following mechanisms:

- Any user thread will only have access to a subset of memory: typically its stack, program text, read-only data, and any partitions configured in the *Memory Protection Design* it belongs to. Access to any other RAM must be done on the thread's behalf through system calls, or specifically granted by a supervisor thread using the memory domain APIs. Newly created threads inherit the memory domain configuration of the parent. Threads may communicate with each other by having shared membership of the same memory domains, or via kernel objects such as semaphores and pipes.
- User threads cannot directly access memory belonging to kernel objects. Although pointers to kernel objects are used to reference them, actual manipulation of kernel objects is done through system call interfaces. Device drivers and threads stacks are also considered kernel objects. This ensures that any data inside a kernel object that is private to the kernel cannot be tampered with.
- User threads by default have no permission to access any kernel object or driver other than their own thread object. Such access must be granted by another thread that is either in supervisor mode or has permission on both the receiving thread object and the kernel object being granted access to. The creation of new threads has an option to automatically inherit permissions of all kernel objects granted to the parent, except the parent thread itself.
- For performance and footprint reasons Zephyr normally does little or no parameter error checking for kernel object or device driver APIs. Access from user mode through system calls involves an extra layer of handler functions, which are expected to rigorously validate access permissions and type of the object, check the validity of other parameters through bounds checking or other means, and verify proper read/write access to any memory buffers involved.
- Thread stacks are defined in such a way that exceeding the specified stack space will generate a hardware fault. The way this is done specifically varies per architecture.

Constraints

All kernel objects, thread stacks, and device driver instances must be defined at build time if they are to be used from user mode. Dynamic use-cases for kernel objects will need to go through pre-defined pools of available objects.

There are some constraints if additional application binary data is loaded for execution after the kernel starts:

- Loaded object code will not be able to define any kernel objects that will be recognized by the kernel. This code will instead need to use APIs for requesting kernel objects from pools.
- Similarly, since the loaded object code will not be part of the kernel build process, this code will not be able to install interrupt handlers, instantiate device drivers, or define system calls, regardless of what mode it runs in.
- Loaded object code that does not come from a verified source should always be entered with the CPU already in user mode.

3.3.2 Memory Protection Design

Zephyr's memory protection design is geared towards microcontrollers with MPU (Memory Protection Unit) hardware. We do support some architectures, such as x86, which have a paged MMU (Memory Management Unit), but in that case the MMU is used like an MPU with an identity page table.

All of the discussion below will be using MPU terminology; systems with MMUs can be considered to have an MPU with an unlimited number of programmable regions.

There are a few different levels on how memory access is configured when Zephyr memory protection features are enabled, which we will describe here:

Boot Time Memory Configuration

This is the configuration of the MPU after the kernel has started up. It should contain the following:

- Any configuration of memory regions which need to have special caching or write-back policies for basic hardware and driver function. Note that most MPUs have the concept of a default memory access policy map, which can be enabled as a "background" mapping for any area of memory that doesn't have an MPU region configuring it. It is strongly recommended to use this to maximize the number of available MPU regions for the end user. On ARMv7-M/ARMv8-M this is called the System Address Map, other CPUs may have similar capabilities. See *Memory Attributes* for information on how to annotate the system map in the device tree.
- A read-only, executable region or regions for program text and ro-data, that is accessible to user mode. This could be further sub-divided into a read-only region for ro-data, and a read-only, executable region for text, but this will require an additional MPU region. This is required so that threads running in user mode can read ro-data and fetch instructions.
- Depending on configuration, user-accessible read-write regions to support extra features like GCOV, HEP, etc.

Assuming there is a background map which allows supervisor mode to access any memory it needs, and regions are defined which grant user mode access to text/ro-data, this is sufficient for the boot time configuration.

Hardware Stack Overflow

`CONFIG_HW_STACK_PROTECTION` is an optional feature which detects stack buffer overflows when the system is running in supervisor mode. This catches issues when the entire stack buffer has

overflowed, and not individual stack frames, use compiler-assisted CONFIG_STACK_CANARIES for that.

Like any crash in supervisor mode, no guarantees can be made about the overall health of the system after a supervisor mode stack overflow, and any instances of this should be treated as a serious error. However it's still very useful to know when these overflows happen, as without robust detection logic the system will either crash in mysterious ways or behave in an undefined manner when the stack buffer overflows.

Some systems implement this feature by creating at runtime a 'guard' MPU region which is set to be read-only and is at either the beginning or immediately preceding the supervisor mode stack buffer. If the stack overflows an exception will be generated.

This feature is optional and is not required to catch stack overflows in user mode; disabling this may free 1-2 MPU regions depending on the MPU design.

Other systems may have dedicated CPU support for catching stack overflows and no extra MPU regions will be required.

Thread Stack

Any thread running in user mode will need access to its own stack buffer. On context switch into a user mode thread, a dedicated MPU region or MMU page table entries will be programmed with the bounds of the stack buffer. A thread exceeding its stack buffer will start pushing data onto memory it doesn't have access to and a memory access violation exception will be generated.

Note that user threads have access to the stacks of other user threads in the same memory domain. This is the minimum required for architectures to support memory domains. Architecture can further restrict access to stacks so each user thread only has access to its own stack if such architecture advertises this capability via CONFIG_ARCH_MEM_DOMAIN_SUPPORTS_ISOLATED_STACKS. This behavior is enabled by default if supported and can be selectively disabled via CONFIG_MEM_DOMAIN_ISOLATED_STACKS if architecture supports both operating modes. However, some architectures may decide to enable this all the time, and thus this option cannot be disabled. Regardless of these kconfigs, user threads cannot access the stacks of other user threads outside of their memory domains.

Thread Resource Pools

A small subset of kernel APIs, invoked as system calls, require heap memory allocations. This memory is used only by the kernel and is not accessible directly by user mode. In order to use these system calls, invoking threads must assign themselves to a resource pool, which is a k_heap object. Memory is drawn from a thread's resource pool using z_thread_malloc() and freed with k_free().

The APIs which use resource pools are as follows, with any alternatives noted for users who do not want heap allocations within their application:

- k_stack_alloc_init() sets up a k_stack with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare k_stacks that are automatically initialized at boot with K_STACK_DEFINE(), or to initialize the k_stack in supervisor mode with k_stack_init().
- k_msgq_alloc_init() sets up a k_msgq object with its storage buffer allocated out of a resource pool instead of a buffer provided by the user. An alternative is to declare a k_msgq that is automatically initialized at boot with K_MSGQ_DEFINE(), or to initialize the k_msgq in supervisor mode with k_msgq_init().
- k_poll() when invoked from user mode, needs to make a kernel-side copy of the provided events array while waiting for an event. This copy is freed when k_poll() returns for any reason.

- `k_queue_alloc_prepend()` and `k_queue_alloc_append()` allocate a container structure to place the data in, since the internal bookkeeping information that defines the queue cannot be placed in the memory provided by the user.
- `k_object_alloc()` allows for entire kernel objects to be dynamically allocated at runtime and a usable pointer to them returned to the caller.

The relevant API is `k_thread_heap_assign()` which assigns a k_heap to draw these allocations from for the target thread.

If the system heap is enabled, then the system heap may be used with `k_thread_system_pool_assign()`, but it is preferable for different logical applications running on the system to have their own pools.

Memory Domains

The kernel ensures that any user thread will have access to its own stack buffer, plus program text and read-only data. The memory domain APIs are the way to grant access to additional blocks of memory to a user thread.

Conceptually, a memory domain is a collection of some number of memory partitions. The maximum number of memory partitions in a domain is limited by the number of available MPU regions. This is why it is important to minimize the number of boot-time MPU regions.

Memory domains are *not* intended to control access to memory from supervisor mode. In some cases this may be unavoidable; for example some architectures do not allow for the definition of regions which are read-only to user mode but read-write to supervisor mode. A great deal of care must be taken when working with such regions to not unintentionally cause the kernel to crash when accessing such a region. Any attempt to use memory domain APIs to control supervisor mode access is at best undefined behavior; supervisor mode access policy is only intended to be controlled by boot-time memory regions.

Memory domain APIs are only available to supervisor mode. The only control user mode has over memory domains is that any user thread's child threads will automatically become members of the parent's domain.

All threads are members of a memory domain, including supervisor threads (even though this has no implications on their memory access). There is a default domain `k_mem_domain_default` which will be assigned to threads if they have not been specifically assigned to a domain, or inherited a memory domain membership from their parent thread. The main thread starts as a member of the default domain.

Memory Partitions Each memory partition consists of a memory address, a size, and access attributes. It is intended that memory partitions are used to control access to system memory. Defining memory partitions are subject to the following constraints:

- The partition must represent a memory region that can be programmed by the underlying memory management hardware, and needs to conform to any underlying hardware constraints. For example, many MPU-based systems require that partitions be sized to some power of two, and aligned to their own size. For MMU-based systems, the partition must be aligned to a page and the size some multiple of the page size.
- Partitions within the same memory domain may not overlap each other. There is no notion of precedence among partitions within a memory domain. Partitions within a memory domain are assumed to have a higher precedence than any boot-time memory regions, however whether a memory domain partition can overlap a boot-time memory region is architecture specific.
- The same partition may be specified in multiple memory domains. For example there may be a shared memory area that multiple domains grant access to.
- Care must be taken in determining what memory to expose in a partition. It is not appropriate to provide direct user mode access to any memory containing private kernel data.

- Memory domain partitions are intended to control access to system RAM. Configuration of memory partitions which do not correspond to RAM may not be supported by the architecture; this is true for MMU-based systems.

There are two ways to define memory partitions: either manually or automatically.

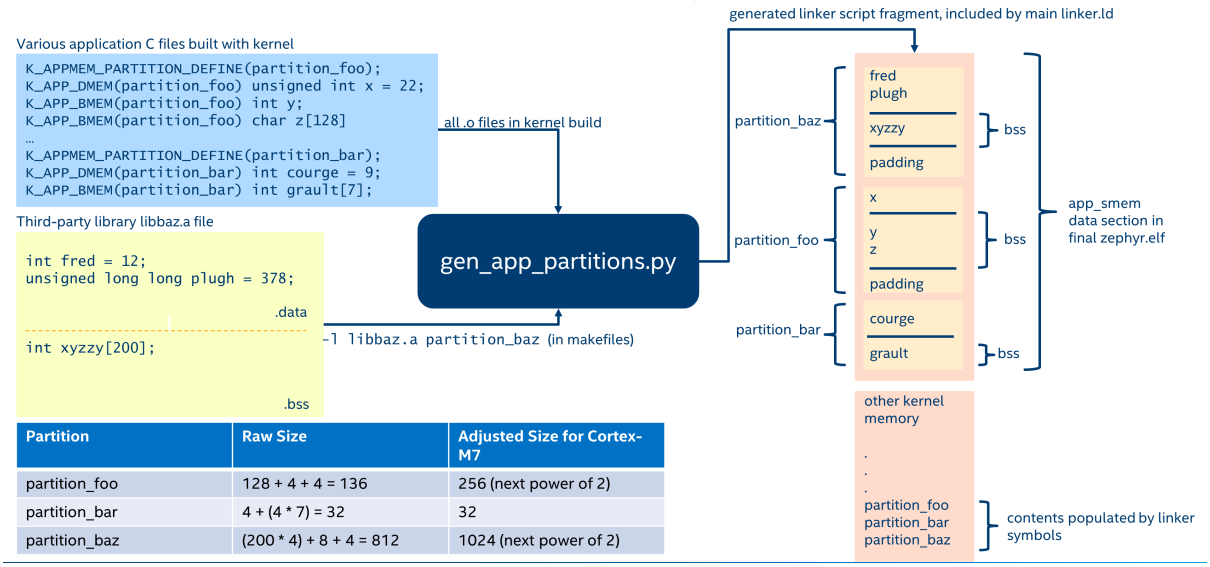
Manual Memory Partitions The following code declares a global array `buf`, and then declares a read-write partition for it which may be added to a domain:

```
uint8_t __aligned(32) buf[32];

K_MEM_PARTITION_DEFINE(my_partition, buf, sizeof(buf),
                       K_MEM_PARTITION_P_RW_U_RW);
```

This does not scale particularly well when we are trying to contain multiple objects spread out across several C files into a single partition.

Automatic Memory Partitions Automatic memory partitions are created by the build system. All globals which need to be placed inside a partition are tagged with their destination partition. The build system will then coalesce all of these into a single contiguous block of memory, zero any BSS variables at boot, and define a memory partition of appropriate base address and size which contains all the tagged data.



Partition	Raw Size	Adjusted Size for Cortex-M7
partition_foo	128 + 4 + 4 = 136	256 (next power of 2)
partition_bar	4 + (4 * 7) = 32	32
partition_baz	(200 * 4) + 8 + 4 = 812	1024 (next power of 2)

Fig. 2: Automatic Memory Domain build flow

Automatic memory partitions are only configured as read-write regions. They are defined with `K_APPMEM_PARTITION_DEFINE()`. Global variables are then routed to this partition using `K_APP_DMEM()` for initialized data and `K_APP_BMEM()` for BSS.

```
#include <zephyr/app_memory/app_memdomain.h>

/* Declare a k_mem_partition "my_partition" that is read-write to
 * user mode. Note that we do not specify a base address or size.
 */
K_APPMEM_PARTITION_DEFINE(my_partition);

/* The global variable var1 will be inside the bounds of my_partition
 * and be initialized with 37 at boot.
 */
```

(continues on next page)

(continued from previous page)

```
K_APP_DMEM(my_partition) int var1 = 37;

/* The global variable var2 will be inside the bounds of my_partition
 * and be zeroed at boot size K_APP_BMEM() was used, indicating a BSS
 * variable.
 */
K_APP_BMEM(my_partition) int var2;
```

The build system will ensure that the base address of `my_partition` will be properly aligned, and the total size of the region conforms to the memory management hardware requirements, adding padding if necessary.

If multiple partitions are being created, a variadic preprocessor macro can be used as provided in `app_macro_support.h`:

```
FOR_EACH(K_APPMEM_PARTITION_DEFINE, part0, part1, part2);
```

Automatic Partitions for Static Library Globals The build-time logic for setting up automatic memory partitions is in `scripts/build/gen_app_partitions.py`. If a static library is linked into Zephyr, it is possible to route all the globals in that library to a specific memory partition with the `--library` argument.

For example, if the Newlib C library is enabled, the Newlib globals all need to be placed in `z_libc_partition`. The invocation of the script in the top-level `CMakeLists.txt` adds the following:

```
gen_app_partitions.py ... --library libc.a z_libc_partition ..
```

For pre-compiled libraries there is no support for expressing this in the project-level configuration or build files; the toplevel `CMakeLists.txt` must be edited.

For Zephyr libraries created using `zephyr_library` or `zephyr_library_named` the `zephyr_library_app_memory` function can be used to specify the memory partition where all globals in the library should be placed.

Pre-defined Memory Partitions There are a few memory partitions which are pre-defined by the system:

- `z_malloc_partition` - This partition contains the system-wide pool of memory used by libc malloc(). Due to possible starvation issues, it is not recommended to draw heap memory from a global pool, instead it is better to define various sys_heap objects and assign them to specific memory domains.
- `z_libc_partition` - Contains globals required by the C library and runtime. Required when using either the Minimal C library or the Newlib C Library. Required when `CONFIG_STACK_CANARIES` is enabled.

Library-specific partitions are listed in include/zephyr/app_memory/partitions.h. For example, to use the MBEDTLS library from user mode, the `k_mbedtls_partition` must be added to the domain.

Memory Domain Usage

Create a Memory Domain A memory domain is defined using a variable of type `k_mem_domain`. It must then be initialized by calling `k_mem_domain_init()`.

The following code defines and initializes an empty memory domain.

```
struct k_mem_domain app0_domain;

k_mem_domain_init(&app0_domain, 0, NULL);
```

Add Memory Partitions into a Memory Domain There are two ways to add memory partitions into a memory domain.

This first code sample shows how to add memory partitions while creating a memory domain.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

struct k_mem_partition *app0_parts[] = {
    app0_part0,
    app0_part1
};

k_mem_domain_init(&app0_domain, ARRAY_SIZE(app0_parts), app0_parts);
```

This second code sample shows how to add memory partitions into an initialized memory domain one by one.

```
/* the start address of the MPU region needs to align with its size */
uint8_t __aligned(32) app0_buf[32];
uint8_t __aligned(32) app1_buf[32];

K_MEM_PARTITION_DEFINE(app0_part0, app0_buf, sizeof(app0_buf),
                       K_MEM_PARTITION_P_RW_U_RW);

K_MEM_PARTITION_DEFINE(app0_part1, app1_buf, sizeof(app1_buf),
                       K_MEM_PARTITION_P_RW_U_RO);

k_mem_domain_add_partition(&app0_domain, &app0_part0);
k_mem_domain_add_partition(&app0_domain, &app0_part1);
```

Note

The maximum number of memory partitions is limited by the maximum number of MPU regions or the maximum number of MMU tables.

Memory Domain Assignment Any thread may join a memory domain, and any memory domain may have multiple threads assigned to it. Threads are assigned to memory domains with an API call:

```
k_mem_domain_add_thread(&app0_domain, app_thread_id);
```

If the thread was already a member of some other domain (including the default domain), it will be removed from it in favor of the new one.

In addition, if a thread is a member of a memory domain, and it creates a child thread, that thread will belong to the domain as well.

Remove a Memory Partition from a Memory Domain The following code shows how to remove a memory partition from a memory domain.

```
k_mem_domain_remove_partition(&app0_domain, &app0_part1);
```

The k_mem_domain_remove_partition() API finds the memory partition that matches the given parameter and removes that partition from the memory domain.

Available Partition Attributes When defining a partition, we need to set access permission attributes to the partition. Since the access control of memory partitions relies on either an MPU or MMU, the available partition attributes would be architecture dependent.

The complete list of available partition attributes for a specific architecture is found in the architecture-specific include file `include/zephyr/arch/<arch name>/arch.h`, (for example, include/zephyr/arch/arm/arch.h.) Some examples of partition attributes are:

```
/* Denote partition is privileged read/write, unprivileged read/write */
K_MEM_PARTITION_P_RW_U_RW
/* Denote partition is privileged read/write, unprivileged read-only */
K_MEM_PARTITION_P_RW_U_RO
```

In almost all cases `K_MEM_PARTITION_P_RW_U_RW` is the right choice.

API Reference

The following memory domain APIs are provided by include/zephyr/kernel.h:

Memory domain APIs

3.3.3 Kernel Objects

A kernel object can be one of three classes of data:

- A core kernel object, such as a semaphore, thread, pipe, etc.
- A thread stack, which is an array of `z_thread_stack_element` and declared with `K_THREAD_STACK_DEFINE()`
- A device driver instance (const struct device) that belongs to one of a defined set of subsystems

The set of known kernel objects and driver subsystems is defined in include/zephyr/sys/kobject.h as `k_objects`.

Kernel objects are completely opaque to user threads. User threads work with addresses to kernel objects when making API calls, but may never dereference these addresses, doing so will cause a memory protection fault. All kernel objects must be placed in memory that is not accessible by user threads.

Since user threads may not directly manipulate kernel objects, all use of them must go through system calls. In order to perform a system call on a kernel object, checks are performed by system call handler functions that the kernel object address is valid and that the calling thread has sufficient permissions to work with it.

Permission on an object also has the semantics of a reference to an object. This is significant for certain object APIs which do temporary allocations, or objects which themselves have been allocated from a runtime memory pool.

If an object loses all references, two events may happen:

- If the object has an associated cleanup function, the cleanup function may be called to release any runtime-allocated buffers the object was using.
- If the object itself was dynamically allocated, the memory for the object will be freed.

Object Placement

Kernel objects that are only used by supervisor threads have no restrictions and can be located anywhere in the binary, or even declared on stacks. However, to prevent accidental or intentional corruption by user threads, they must not be located in any memory that user threads have direct access to.

In order for a static kernel object to be usable by a user thread via system call APIs, several conditions must be met on how the kernel object is declared:

- The object must be declared as a top-level global at build time, such that it appears in the ELF symbol table. It is permitted to declare kernel objects with static scope. The post-build script *scripts/build/gen_kobject_list.py* scans the generated ELF file to find kernel objects and places their memory addresses in a special table of kernel object metadata. Kernel objects may be members of arrays or embedded within other data structures.
- Kernel objects must be located in memory reserved for the kernel. They must not be located in any memory partitions that are user-accessible.
- Any memory reserved for a kernel object must be used exclusively for that object. Kernel objects may not be members of a union data type.

Kernel objects that are found but do not meet the above conditions will not be included in the generated table that is used to validate kernel object pointers passed in from user mode.

The debug output of the *scripts/build/gen_kobject_list.py* script may be useful when debugging why some object was unexpectedly not being tracked. This information will be printed if the script is run with the `--verbose` flag, or if the build system is invoked with verbose output.

Dynamic Objects

Kernel objects may also be allocated at runtime if `CONFIG_DYNAMIC_OBJECTS` is enabled. In this case, the `k_object_alloc()` API may be used to instantiate an object from the calling thread's resource pool. Such allocations may be freed in two ways:

- Supervisor threads may call `k_object_free()` to force a dynamic object to be released.
- If an object's references drop to zero (which happens when no threads have permissions on it) the object will be automatically freed. User threads may drop their own permission on an object with `k_object_release()`, and their permissions are automatically cleared when a thread terminates. Supervisor threads may additionally revoke references for another thread using `k_object_access_revoke()`.

Because permissions are also used for reference counting, it is important for supervisor threads to acquire permissions on objects they are using even though the access control aspects of the permission system are not enforced.

Implementation Details The *scripts/build/gen_kobject_list.py* script is a post-build step which finds all the valid kernel object instances in the binary. It accomplishes this by parsing the DWARF debug information present in the generated ELF file for the kernel.

Any instances of structs or arrays corresponding to kernel objects that meet the object placement criteria will have their memory addresses placed in a special perfect hash table of kernel objects

generated by the 'gperf' tool. When a system call is made and the kernel is presented with a memory address of what may or may not be a valid kernel object, the address can be validated with a constant-time lookup in this table.

Drivers are a special case. All drivers are instances of `device`, but it is important to know what subsystem a driver belongs to so that incorrect operations, such as calling a UART API on a sensor driver object, can be prevented. When a device struct is found, its API pointer is examined to determine what subsystem the driver belongs to.

The table itself maps kernel object memory addresses to instances of `z_object`, which has all the metadata for that object. This includes:

- A bitfield indicating permissions on that object. All threads have a numerical ID assigned to them at build time, used to index the permission bitfield for an object to see if that thread has permission on it. The size of this bitfield is controlled by the `CONFIG_MAX_THREAD_BYTES` option and the build system will generate an error if this value is too low.
- A type field indicating what kind of object this is, which is some instance of `k_objects`.
- A set of flags for that object. This is currently used to track initialization state and whether an object is public or not.
- An extra data field. The semantics of this field vary by object type, see the definition of `z_object_data`.

Dynamic objects allocated at runtime are tracked in a runtime red/black tree which is used in parallel to the gperf table when validating object pointers.

Supervisor Thread Access Permission

Supervisor threads can access any kernel object. However, permissions for supervisor threads are still tracked for two reasons:

- If a supervisor thread calls `k_thread_user_mode_enter()`, the thread will then run in user mode with any permissions it had been granted (in many cases, by itself) when it was a supervisor thread.
- If a supervisor thread creates a user thread with the `K_INHERIT_PERMS` option, the child thread will be granted the same permissions as the parent thread, except the parent thread object.

User Thread Access Permission

By default, when a user thread is created, it will only have access permissions on its own thread object. Other kernel objects by default are not usable. Access to them needs to be explicitly or implicitly granted. There are several ways to do this.

- If a thread is created with the `K_INHERIT_PERMS`, that thread will inherit all the permissions of the parent thread, except the parent thread object.
- A thread that has permission on an object, or is running in supervisor mode, may grant permission on that object to another thread via the `k_object_access_grant()` API. The convenience pseudo-function `k_thread_access_grant()` may also be used, which accepts an arbitrary number of pointers to kernel objects and calls `k_object_access_grant()` on each of them. The thread being granted permission, or the object whose access is being granted, do not need to be in an initialized state. If the caller is from user mode, the caller must have permissions on both the kernel object and the target thread object.
- Supervisor threads may declare a particular kernel object to be a public object, usable by all current and future threads with the `k_object_access_all_grant()` API. You must assume that any untrusted or exploited code will then be able to access the object. Use this API with caution!

- If a thread was declared statically with K_THREAD_DEFINE(), then the K_THREAD_ACCESS_GRANT() may be used to grant that thread access to a set of kernel objects at boot time.

Once a thread has been granted access to an object, such access may be removed with the k_object_access_revoke() API. This API is not available to user threads, however user threads may use k_object_release() to relinquish their own permissions on an object.

Supervisor threads may use k_object_access_revoke_others() to revoke access from all threads except the caller. This is useful to reset the permissions of an object in cases where access was previously given to an untrusted user thread, which may have in turn given it to others. This API also reverts a public access state which may have been set previously via k_object_access_all_grant().

API calls from supervisor mode to set permissions on kernel objects that are not being tracked by the kernel will be no-ops. Doing the same from user mode will result in a fatal error for the calling thread.

Objects allocated with k_object_alloc() implicitly grant permission on the allocated object to the calling thread.

Initialization State

Most operations on kernel objects will fail if the object is considered to be in an uninitialized state. The appropriate init function for the object must be performed first.

Some objects will be implicitly initialized at boot:

- Kernel objects that were declared with static initialization macros (such as K_SEM_DEFINE for semaphores) will be in an initialized state at build time.
- Device driver objects are considered initialized after their init function is run by the kernel early in the boot process.

If a kernel object is initialized with a private static initializer, the object must have k_object_init() called on it at some point by a supervisor thread, otherwise the kernel will consider the object uninitialized if accessed by a user thread. This is very uncommon, typically only for kernel objects that are embedded within some larger struct and initialized statically.

```
struct foo {
    struct k_sem sem;
    ...
};

struct foo my_foo = {
    .sem = Z_SEM_INITIALIZER(my_foo.sem, 0, 1),
    ...
};

...
k_object_init(&my_foo.sem);
...
```

Creating New Kernel Object Types

When implementing new kernel features or driver subsystems, it may be necessary to define some new kernel object types. There are different steps needed for creating core kernel objects and new driver subsystems.

Creating New Core Kernel Objects

- In scripts/build/gen_kobject_list.py, add the name of the struct to the kobjects list.

Instances of the new struct should now be tracked.

Creating New Driver Subsystem Kernel Objects All driver instances are `device`. They are differentiated by what API struct they are set to.

- In `scripts/build/gen_kobject_list.py`, add the name of the API struct for the new subsystem to the `subsystems` list.

Driver instances of the new subsystem should now be tracked.

API Reference

User Mode APIs

3.3.4 System Calls

User threads run with a reduced set of privileges than supervisor threads: certain CPU instructions may not be used, and they have access to only a limited part of the memory map. System calls (may) allow user threads to perform operations not directly available to them.

When defining system calls, it is very important to ensure that access to the API's private data is done exclusively through system call interfaces. Private kernel data should never be made available to user mode threads directly. For example, the `k_queue` APIs were intentionally not made available as they store bookkeeping information about the queue directly in the queue buffers which are visible from user mode.

APIs that allow the user to register callback functions that run in supervisor mode should never be exposed as system calls. Reserve these for supervisor-mode access only.

This section describes how to declare new system calls and discusses a few implementation details relevant to them.

Components

All system calls have the following components:

- A **C prototype** prefixed with `__syscall` for the API. It will be declared in some header under `include/` or in another `SYSCALL_INCLUDE_DIRS` directory. This prototype is never implemented manually, instead it gets created by the *scripts/build/gen_syscalls.py* script. What gets generated is an inline function which either calls the implementation function directly (if called from supervisor mode) or goes through privilege elevation and validation steps (if called from user mode).
- An **implementation function**, which is the real implementation of the system call. The implementation function may assume that all parameters passed in have been validated if it was invoked from user mode.
- A **verification function**, which wraps the implementation function and does validation of all the arguments passed in.
- An **unmarshalling function**, which is an automatically generated handler that must be included by user source code.

C Prototype

The C prototype represents how the API is invoked from either user or supervisor mode. For example, to initialize a semaphore:

```
__syscall void k_sem_init(struct k_sem *sem, unsigned int initial_count,
                          unsigned int limit);
```

The `__syscall` attribute is very special. To the C compiler, it simply expands to 'static inline'. However to the post-build *scripts/build/parse_syscalls.py* script, it indicates that this API is a system call. The *scripts/build/parse_syscalls.py* script does some parsing of the function prototype, to determine the data types of its return value and arguments, and has some limitations:

- Array arguments must be passed in as pointers, not arrays. For example, `int foo[]` or `int foo[12]` is not allowed, but should instead be expressed as `int *foo`.
- Function pointers horribly confuse the limited parser. The workaround is to typedef them first, and then express in the argument list in terms of that typedef.
- `__syscall` must be the first thing in the prototype.

The preprocessor is intentionally not used when determining the set of system calls to generate. However, any generated system calls that don't actually have a verification function defined (because the related feature is not enabled in the kernel configuration) will instead point to a special verification for unimplemented system calls. Data type definitions for APIs should not have conditional visibility to the compiler.

Any header file that declares system calls must include a special generated header at the very bottom of the header file. This header follows the naming convention `syscalls/<name of header file>`. For example, at the bottom of include/zephyr/drivers/sensor.h:

```
#include <zephyr/syscalls/sensor.h>
```

C prototype functions must be declared in one of the directories listed in the CMake variable `SYSCALL_INCLUDE_DIRS`. This list always contains `APPLICATION_SOURCE_DIR` when `CONFIG_APPLICATION_DEFINED_SYSCALL` is set, or `${ZEPHYR_BASE}/subsys/testsuite/ztest/include` when `CONFIG_ZTEST` is set. Additional paths can be added to the list through the CMake command line or in CMake code that is run before `find_package(Zephyr ...)` is run. `${ZEPHYR_BASE}/include` is always scanned for potential syscall prototypes.

Note that not all syscalls will be included in the final binaries. CMake functions `zephyr_syscall_header` and `zephyr_syscall_header_ifdef` are used to specify which header files contain syscall prototypes where those syscalls must be present in the final binaries. Note that header files inside directories listed in CMake variable `SYSCALL_INCLUDE_DIRS` will always have their syscalls present in final binaries. To force all syscalls to be included in the final binaries, turn on `CONFIG_EMIT_ALL_SYSCALLS`.

Invocation Context Source code that uses system call APIs can be made more efficient if it is known that all the code inside a particular C file runs exclusively in user mode, or exclusively in supervisor mode. The system will look for the definition of macros `__ZEPHYR_SUPERVISOR__` or `__ZEPHYR_USER__`, typically these will be added to the compiler flags in the build system for the related files.

- If `CONFIG_USERSPACE` is not enabled, all APIs just directly call the implementation function.
- Otherwise, the default case is to make a runtime check to see if the processor is currently running in user mode, and either make the system call or directly call the implementation function as appropriate.
- If `__ZEPHYR_SUPERVISOR__` is defined, then it is assumed that all the code runs in supervisor mode and all APIs just directly call the implementation function. If the code was actually running in user mode, there will be a CPU exception as soon as it tries to do something it isn't allowed to do.

- If `__ZEPHYR_USER__` is defined, then it is assumed that all the code runs in user mode and system calls are unconditionally made.

Implementation Details Declaring an API with `__syscall` causes some code to be generated in C and header files by the *scripts/build/gen_syscalls.py* script, all of which can be found in the project out directory under `include/generated/`:

- The system call is added to the enumerated type of system call IDs, which is expressed in `include/generated/zephyr/syscall_list.h`. It is the name of the API in uppercase, prefixed with `K_SYSCALL_`.
- An entry for the system call is created in the dispatch table `_k_syscall_table`, expressed in `include/generated/zephyr/syscall_dispatch.c`
  - This table only contains syscalls where their corresponding prototypes are declared in header files when `CONFIG_EMIT_ALL_SYSCALLS` is enabled:
    * Indicated by CMake functions `zephyr_syscall_header` and `zephyr_syscall_header_ifdef`, or
    * Under directories specified in CMake variable `SYSCALL_INCLUDE_DIRS`.
- A weak verification function is declared, which is just an alias of the 'unimplemented system call' verifier. This is necessary since the real verification function may or may not be built depending on the kernel configuration. For example, if a user thread makes a sensor subsystem API call, but the sensor subsystem is not enabled, the weak verifier will be invoked instead.
- An unmarshalling function is defined in `include/generated/zephyr/syscalls/<name>_mrsh.c`

The body of the API is created in the generated system header. Using the example of `k_sem_init()`, this API is declared in include/zephyr/kernel.h. At the bottom of include/zephyr/kernel.h is:

```
#include <zephyr/syscalls/kernel.h>
```

Inside this header is the body of `k_sem_init()`:

```
static inline void k_sem_init(struct k_sem * sem, unsigned int initial_count,␣
↪unsigned int limit)
{
#ifdef CONFIG_USERSPACE
        if (z_syscall_trap()) {
                arch_syscall_invoke3(*(uintptr_t *)&sem, *(uintptr_t␣
↪*)&initial_count, *(uintptr_t *)&limit, K_SYSCALL_K_SEM_INIT);
                return;
        }
        compiler_barrier();
#endif
        z_impl_k_sem_init(sem, initial_count, limit);
}
```

This generates an inline function that takes three arguments with void return value. Depending on context it will either directly call the implementation function or go through a system call elevation. A prototype for the implementation function is also automatically generated.

The final layer is the invocation of the system call itself. All architectures implementing system calls must implement the seven inline functions `_arch_syscall_invoke0()` through `_arch_syscall_invoke6()`. These functions marshal arguments into designated CPU registers and perform the necessary privilege elevation. Parameters of API inline function, before being passed as arguments to system call, are C casted to `uintptr_t` which matches size of register. Exception to above is passing 64-bit parameters on 32-bit systems, in which case 64-bit parameters

are split into lower and higher part and passed as two consecutive arguments. There is always a `uintptr_t` type return value, which may be neglected if not needed.

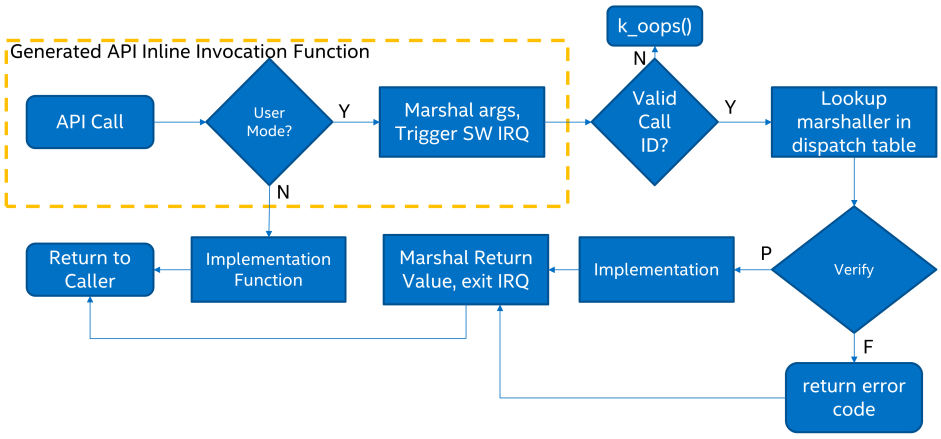

Fig. 3: System Call execution flow

Some system calls may have more than six arguments, but number of arguments passed via registers is limited to six for all architectures. Additional arguments will need to be passed in an array in the source memory space, which needs to be treated as untrusted memory in the verification function. This code (packing, unpacking and validation) is generated automatically as needed in the stub above and in the unmarshalling function.

System calls return `uintptr_t` type value that is C casted, by wrapper, to a return type of API prototype declaration. This means that 64-bit value may not be directly returned, from a system call to its wrapper, on 32-bit systems. To solve the problem the automatically generated wrapper function defines 64-bit intermediate variable, which is considered **untrusted** buffer, on its stack and passes pointer to that variable to the system call, as a final argument. Upon return from the system call the value written to that buffer will be returned by the wrapper function. The problem does not exist on 64-bit systems which are able to return 64-bit values directly.

Implementation Function

The implementation function is what actually does the work for the API. Zephyr normally does little to no error checking of arguments, or does this kind of checking with assertions. When writing the implementation function, validation of any parameters is optional and should be done with assertions.

All implementation functions must follow the naming convention, which is the name of the API prefixed with `z_impl_`. Implementation functions may be declared in the same header as the API as a static inline function or declared in some C file. There is no prototype needed for implementation functions, these are automatically generated.

Verification Function

The verification function runs on the kernel side when a user thread makes a system call. When the user thread makes a software interrupt to elevate to supervisor mode, the common system call entry point uses the system call ID provided by the user to look up the appropriate unmarshalling function for that system call and jump into it. This in turn calls the verification function.

Verification and unmarshalling functions only run when system call APIs are invoked from user mode. If an API is invoked from supervisor mode, the implementation is simply called and there is no software trap.

The purpose of the verification function is to validate all the arguments passed in. This includes:

- Any kernel object pointers provided. For example, the semaphore APIs must ensure that the semaphore object passed in is a valid semaphore and that the calling thread has permission on it.
- Any memory buffers passed in from user mode. Checks must be made that the calling thread has read or write permissions on the provided buffer.
- Any other arguments that have a limited range of valid values.

Verification functions involve a great deal of boilerplate code which has been made simpler by some macros in include/zephyr/internal/syscall_handler.h. Verification functions should be declared using these macros.

Argument Validation Several macros exist to validate arguments:

- `K_SYSCALL_OBJ()` Checks a memory address to assert that it is a valid kernel object of the expected type, that the calling thread has permissions on it, and that the object is initialized.
- `K_SYSCALL_OBJ_INIT()` is the same as `K_SYSCALL_OBJ()`, except that the provided object may be uninitialized. This is useful for verifiers of object init functions.
- `K_SYSCALL_OBJ_NEVER_INIT()` is the same as `K_SYSCALL_OBJ()`, except that the provided object must be uninitialized. This is not used very often, currently only for `k_thread_create()`.
- `K_SYSCALL_MEMORY_READ()` validates a memory buffer of a particular size. The calling thread must have read permissions on the entire buffer.
- `K_SYSCALL_MEMORY_WRITE()` is the same as `K_SYSCALL_MEMORY_READ()` but the calling thread must additionally have write permissions.
- `K_SYSCALL_MEMORY_ARRAY_READ()` validates an array whose total size is expressed as separate arguments for the number of elements and the element size. This macro correctly accounts for multiplication overflow when computing the total size. The calling thread must have read permissions on the total size.
- `K_SYSCALL_MEMORY_ARRAY_WRITE()` is the same as `K_SYSCALL_MEMORY_ARRAY_READ()` but the calling thread must additionally have write permissions.
- `K_SYSCALL_VERIFY_MSG()` does a runtime check of some boolean expression which must evaluate to true otherwise the check will fail. A variant `K_SYSCALL_VERIFY` exists which does not take a message parameter, instead printing the expression tested if it fails. The latter should only be used for the most obvious of tests.
- `K_SYSCALL_DRIVER_OP()` checks at runtime if a driver instance is capable of performing a particular operation. While this macro can be used by itself, it's mostly a building block for macros that are automatically generated for every driver subsystem. For instance, to validate the GPIO driver, one could use the `K_SYSCALL_DRIVER_GPIO()` macro.
- `K_SYSCALL_SPECIFIC_DRIVER()` is a runtime check to verify that a provided pointer is a valid instance of a specific device driver, that the calling thread has permissions on it, and that the driver has been initialized. It does this by checking the API structure pointer that is stored within the driver instance and ensuring that it matches the provided value, which should be the address of the specific driver's API structure.

If any check fails, the macros will return a nonzero value. The macro `K_OOPS()` can be used to induce a kernel oops which will kill the calling thread. This is done instead of returning some error condition to keep the APIs the same when calling from supervisor mode.

Verifier Definition All system calls are dispatched to a verifier function with a prefixed `z_vrfy_` name based on the system call. They have exactly the same return type and argument types as the wrapped system call. Their job is to execute the system call (generally by calling the implementation function) after having validated all arguments.

The verifier is itself invoked by an automatically generated unmarshaller function which takes care of unpacking the register arguments from the architecture layer and casting them to the correct type. This is defined in a header file that must be included from user code, generally somewhere after the definition of the verifier in a translation unit (so that it can be inlined).

For example:

```
static int z_vrfy_k_sem_take(struct k_sem *sem, int32_t timeout)
{
    K_OOPS(K_SYSCALL_OBJ(sem, K_OBJ_SEM));
    return z_impl_k_sem_take(sem, timeout);
}
#include <zephyr/syscalls/k_sem_take_mrsh.c>
```

Verification Memory Access Policies Parameters passed to system calls by reference require special handling, because the value of these parameters can be changed at any time by any user thread that has access to the memory that parameter points to. If the kernel makes any logical decisions based on the contents of this memory, this can open up the kernel to attacks even if checking is done. This is a class of exploits known as TOCTOU (Time Of Check to Time Of Use).

The proper procedure to mitigate these attacks is to make a copies in the verification function, and only perform parameter checks on the copies, which user threads will never have access to. The implementation functions get passed the copy and not the original data sent by the user. The `k_usermode_to_copy()` and `k_usermode_from_copy()` APIs exist for this purpose.

C strings passed from user mode need similar care, since their length is not known in advance and the terminating `NUL` must be located without reading past memory the caller can access. The `k_usermode_string_copy()` and `k_usermode_string_alloc_copy()` helpers safely validate and copy a user-supplied string into kernel-controlled memory before it is used by the implementation function.

There is one exception in place, with respect to large data buffers which are only used to provide a memory area that is either only written to, or whose contents are never used for any validation or control flow. Further discussion of this later in this section.

As a first example, consider a parameter which is used as an output parameter for some integral value:

```
int z_vrfy_some_syscall(int *out_param)
{
    int local_out_param;
    int ret;

    ret = z_impl_some_syscall(&local_out_param);
    K_OOPS(k_usermode_to_copy(out_param, &local_out_param, sizeof(*out_param)));
    return ret;
}
```

Here we have allocated `local_out_param` on the stack, passed its address to the implementation function, and then used `k_usermode_to_copy()` to fill in the memory passed in by the caller.

It might be tempting to do something more concise:

```
int z_vrfy_some_syscall(int *out_param)
{
    K_OOPS(K_SYSCALL_MEMORY_WRITE(out_param, sizeof(*out_param)));
    return z_impl_some_syscall(out_param);
}
```

However, this is unsafe if the implementation ever does any reads to this memory as part of its logic. For example, it could be used to store some counter value, and this could be meddled with

by user threads that have access to its memory. It is by far safest for small integral values to do the copying as shown in the first example.

Some parameters may be input/output. For instance, it's not uncommon to see APIs which pass in a pointer to some `size_t` which is a maximum allowable size, which is then updated by the implementation to reflect the actual number of bytes processed. This too should use a stack copy:

```
int z_vrfy_in_out_syscall(size_t *size_ptr)
{
    size_t size;
    int ret;

    K_OOPS(k_usermode_from_copy(&size, size_ptr, sizeof(size));
    ret = z_impl_in_out_syscall(&size);
    K_OOPS(k_usermode_to_copy(size_ptr, &size, sizeof(size)));
    return ret;
}
```

Many system calls pass in structures or even linked data structures. All should be copied. Typically this is done by allocating copies on the stack:

```
struct bar {
    ...
};

struct foo {
    ...
    struct bar *bar_left;
    struct bar *bar_right;
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar bar_right_copy;
    struct bar bar_left_copy;

    K_OOPS(k_usermode_from_copy(&foo_copy, foo, sizeof(*foo)));
    K_OOPS(k_usermode_from_copy(&bar_right_copy, foo_copy.bar_right,
                                sizeof(struct bar)));
    foo_copy.bar_right = &bar_right_copy;
    K_OOPS(k_usermode_from_copy(&bar_left_copy, foo_copy.bar_left,
                                sizeof(struct bar)));
    foo_copy.bar_left = &bar_left_copy;

    return z_impl_must_alloc(&foo_copy);
}
```

In some cases the amount of data isn't known at compile time or may be too large to allocate on the stack. In this scenario, it may be necessary to draw memory from the caller's resource pool via `z_thread_malloc()`. This should always be considered last resort. Functional safety programming guidelines heavily discourage usage of heap and the fact that a resource pool is used must be clearly documented. Any issues with allocation must be reported, to a caller, with returning the `-ENOMEM` . The `K_OOPS()` should never be used to verify if resource allocation has been successful.

```
struct bar {
    ...
```

(continues on next page)

(continued from previous page)

```
};

struct foo {
    size_t count;
    struct bar *bar_list; /* array of struct bar of size count */
};

int z_vrfy_must_alloc(struct foo *foo)
{
    int ret;
    struct foo foo_copy;
    struct bar *bar_list_copy;
    size_t bar_list_bytes;

    /* Safely copy foo into foo_copy */
    K_OOPS(k_usermode_from_copy(&foo_copy, foo, sizeof(*foo)));

    /* Bounds check the count member, in the copy we made */
    if (foo_copy.count > 32) {
        return -EINVAL;
    }

    /* Allocate RAM for the bar_list, replace the pointer in
     * foo_copy */
    bar_list_bytes = foo_copy.count * sizeof(struct_bar);
    bar_list_copy = z_thread_malloc(bar_list_bytes);
    if (bar_list_copy == NULL) {
        return -ENOMEM;
    }
    K_OOPS(k_usermode_from_copy(bar_list_copy, foo_copy.bar_list,
                                bar_list_bytes));
    foo_copy.bar_list = bar_list_copy;

    ret = z_impl_must_alloc(&foo_copy);

    /* All done with the memory, free it and return */
    k_free(foo_copy.bar_list_copy);
    return ret;
}
```

Finally, we must consider large data buffers. These represent areas of user memory which either have data copied out of, or copied into. It is permitted to pass these pointers to the implementation function directly. The caller's access to the buffer still must be validated with K_SYSCALL_MEMORY APIs. The following constraints need to be met:

- If the buffer is used by the implementation function to write data, such as data captured from some MMIO region, the implementation function must only write this data, and never read it.
- If the buffer is used by the implementation function to read data, such as a block of memory to write to some hardware destination, this data must be read without any processing. No conditional logic can be implemented due to the data buffer's contents. If such logic is required a copy must be made.
- The buffer must only be used synchronously with the call. The implementation must not ever save the buffer address and use it asynchronously, such as when an interrupt fires.

```
int z_vrfy_get_data_from_kernel(void *buf, size_t size)
{
    K_OOPS(K_SYSCALL_MEMORY_WRITE(buf, size));
    return z_impl_get_data_from_kernel(buf, size);
}
```

Verification Return Value Policies When verifying system calls, it's important to note which kinds of verification failures should propagate a return value to the caller, and which should simply invoke `K_OOPS()` which kills the calling thread. The current conventions are as follows:

1. For system calls that are defined but not compiled, invocations of these missing system calls are routed to `handler_no_syscall()` which invokes `K_OOPS()`.
2. Any invalid access to memory found by the set of `K_SYSCALL_MEMORY` APIs, `k_usermode_from_copy()`, `k_usermode_to_copy()` should trigger a `K_OOPS`. This happens when the caller doesn't have appropriate permissions on the memory buffer or some size calculation overflowed.
3. Most system calls take kernel object pointers as an argument, checked either with one of the `K_SYSCALL_OBJ` functions, `K_SYSCALL_DRIVER_nnnnn`, or manually using `k_object_validate()`. These can fail for a variety of reasons: missing driver API, bad kernel object pointer, wrong kernel object type, or improper initialization state. These issues should always invoke `K_OOPS()`.
4. Any error resulting from a failed memory heap allocation, often from invoking `z_thread_malloc()`, should propagate `-ENOMEM` to the caller.
5. General parameter checks should be done in the implementation function, in most cases using `CHECKIF()`.
    - The behavior of `CHECKIF()` depends on the kernel configuration, but if user mode is enabled, `CONFIG_RUNTIME_ERROR_CHECKS` is enforced, which guarantees that these checks will be made and a return value propagated.
6. It is totally forbidden for any kind of kernel mode callback function to be registered from user mode. APIs which simply install callbacks shall not be exposed as system calls. Some driver subsystem APIs may take optional function callback pointers. User mode verification functions for these APIs must enforce that these are NULL and should invoke `K_OOPS()` if not.
7. Some parameter checks are enforced only from user mode. These should be checked in the verification function and propagate a return value to the caller if possible.

There are some known exceptions to these policies currently in Zephyr:

- `k_thread_join()` and `k_thread_abort()` are no-ops if the thread object isn't initialized. This is because for threads, the initialization bit pulls double-duty to indicate whether a thread is running, cleared upon exit. See #23030.
- `k_thread_create()` invokes `K_OOPS()` for parameter checks, due to a great deal of existing code ignoring the return value. This will also be addressed by #23030.
- `k_thread_abort()` invokes `K_OOPS()` if an essential thread is aborted, as the function has no return value.
- Various system calls related to logging invoke `K_OOPS()` when bad parameters are passed in as they do not propagate errors.

- _arch_syscall_invoke5()
- _arch_syscall_invoke6()

3.3.5 MPU Stack Objects

Thread Stack Creation

Thread stacks are declared statically with K_THREAD_STACK_DEFINE().

For architectures which utilize memory protection unit (MPU) hardware, stacks are physically contiguous allocations. This contiguous allocation has implications for the placement of stacks in memory, as well as the implementation of other features such as stack protection and userspace. The implications for placement are directly attributed to the alignment requirements for MPU regions. This is discussed in the memory placement section below.

Stack Guards

Stack protection mechanisms require hardware support that can restrict access to memory. Memory protection units can provide this kind of support. The MPU provides a fixed number of regions. Each region contains information about the start, end, size, and access attributes to be enforced on that particular region.

Stack guards are implemented by using a single MPU region and setting the attributes for that region to not allow write access. If invalid accesses occur, a fault ensues. The stack guard is defined at the bottom (the lowest address) of the stack.

Memory Placement

During stack creation, a set of constraints are enforced on the allocation of memory. These constraints include determining the alignment of the stack and the correct sizing of the stack. During linking of the binary, these constraints are used to place the stacks properly.

The main source of the memory constraints is the MPU design for the SoC. The MPU design may require specific constraints on the region definition. These can include alignment of beginning and end addresses, sizes of allocations, or even interactions between overlapping regions.

Some MPUs require that each region be aligned to a power of two. These SoCs will have `CONFIG_MPU_REQUIRES_POWER_OF_TWO_ALIGNMENT` defined. This means that a 1500 byte stack should be aligned to a 2kB boundary and the stack size should also be adjusted to 2kB to ensure that nothing else is placed in the remainder of the region. SoCs which include the unmodified ARM v7m MPU will have these constraints.

Some ARM MPUs use start and end addresses to define MPU regions and both the start and end addresses require 32 byte alignment. An example of this kind of MPU is found in the NXP FRDM K64F.

MPUs may have a region priority mechanisms that use the highest priority region that covers the memory access to determine the enforcement policy. Others may logically OR regions to determine enforcement policy.

Size and alignment constraints may result in stack allocations being larger than the requested size. Region priority mechanisms may result in some added complexity when implementing stack guards.

3.3.6 MPU Backed Userspace

The MPU backed userspace implementation requires the creation of a secondary set of stacks. These stacks exist in a 1:1 relationship with each thread stack defined in the system. The privileged stacks are created as a part of the build process.

A post-build script *scripts/build/gen_kobject_list.py* scans the generated ELF file and finds all of the thread stack objects. A set of privileged stacks, a lookup table, and a set of helper functions are created and added to the image.

During the process of dropping a thread to user mode, the privileged stack information is filled in and later used by the swap and system call infrastructure to configure the MPU regions properly for the thread stack and guard (if applicable).

During system calls, the user mode thread's access to the system call and the passed-in parameters are all validated. The user mode thread is then elevated to privileged mode, the stack is switched to use the privileged stack, and the call is made to the specified kernel API. On return from the kernel API, the thread is set back to user mode and the stack is restored to the user stack.

3.4 Memory Management

The following contains various topics regarding memory management.

3.4.1 Memory Heaps

Zephyr provides a collection of utilities that allow threads to dynamically allocate memory.

Synchronized Heap Allocator

Creating a Heap The simplest way to define a heap is statically, with the `K_HEAP_DEFINE` macro. This creates a static `k_heap` variable with a given name that manages a memory region of the specified size.

Heaps can also be created to manage arbitrary regions of application-controlled memory using k_heap_init().

Allocating Memory Memory can be allocated from a heap using k_heap_alloc(), passing it the address of the heap object and the number of bytes desired. This functions similarly to standard C malloc(), returning a NULL pointer on an allocation failure.

The heap supports blocking operation, allowing threads to go to sleep until memory is available. The final argument is a k_timeout_t timeout value indicating how long the thread may sleep before returning, or else one of the constant timeout values K_NO_WAIT or K_FOREVER.

When a block with a specific alignment is required, k_heap_aligned_alloc() allocates a block whose start address is a multiple of a caller-supplied power-of-two alignment. k_heap_calloc() allocates and zero-initializes an array.

The size of an existing allocation can be changed with k_heap_realloc(), which returns a block of the requested size while preserving the contents up to the smaller of the old and new sizes. As with the standard C realloc(), the returned pointer may differ from the original.

Releasing Memory Memory allocated with k_heap_alloc() must be released using k_heap_free(). Similar to standard C free(), the pointer provided must be either a NULL value or a pointer previously returned by k_heap_alloc() for the same heap. Freeing a NULL value is defined to have no effect.

Enumerating Heaps All heaps defined statically with K_HEAP_DEFINE are placed in a dedicated linker section, which allows them to be enumerated at run time. k_heap_array_get() returns the address of the array of statically defined heaps and the number of entries it contains. This is primarily useful for instrumentation and diagnostics that need to inspect every heap in the system.

Low Level Heap Allocator

The underlying implementation of the k_heap abstraction is provided a data structure named sys_heap. This implements exactly the same allocation semantics, but provides no kernel synchronization tools. It is available for applications that want to manage their own blocks of memory in contexts (for example, userspace) where synchronization is unavailable or more complicated. Unlike k_heap, all calls to any sys_heap functions on a single heap must be serialized by the caller. Simultaneous use from separate threads is disallowed.

Implementation Internally, the sys_heap memory block is partitioned into "chunks" of 8 bytes. All allocations are made out of a contiguous region of chunks. The first chunk of every allocation or unused block is prefixed by a chunk header that stores the length of the chunk, the length of the next lower ("left") chunk in physical memory, a bit indicating whether the chunk is in use, and chunk-indexed link pointers to the previous and next chunk in a "free list" to which unused chunks are added.

The heap code takes reasonable care to avoid fragmentation. Free block lists are stored in "buckets" by their size, each bucket storing blocks within one power of two (i.e. a bucket for blocks of 3-4 chunks, another for 5-8, 9-16, etc...) this allows new allocations to be made from the smallest/most-fragmented blocks available. Also, as allocations are freed and added to the heap, they are automatically combined with adjacent free blocks to prevent fragmentation.

All metadata is stored at the beginning of the contiguous block of heap memory, including the variable-length list of bucket list heads (which depend on heap size). The only external memory required is the sys_heap structure itself.

The sys_heap functions are unsynchronized. Care must be taken by any users to prevent concurrent access. Only one context may be inside one of the API functions at a time.

The heap code takes care to present high performance and reliable latency. All sys_heap API functions are guaranteed to complete within constant time. On typical architectures, they will all complete within 1-200 cycles. One complexity is that the search of the minimum bucket size for an allocation (the set of free blocks that "might fit") has a compile-time upper bound of iterations to prevent unbounded list searches, at the expense of some fragmentation resistance. This CONFIG_SYS_HEAP_ALLOC_LOOPS value may be chosen by the user at build time, and defaults to a value of 3.

Multi-Heap Wrapper Utility

The sys_heap utility requires that all managed memory be in a single contiguous block. It is common for complicated microcontroller applications to have more complicated memory setups that they still want to manage dynamically as a "heap". For example, the memory might exist as separate discontiguous regions, different areas may have different cache, performance or power behavior, peripheral devices may only be able to perform DMA to certain regions, etc...

For those situations, Zephyr provides a sys_multi_heap utility. Effectively this is a simple wrapper around a set of one or more sys_heap objects. It should be initialized after its child heaps via sys_multi_heap_init(), after which each heap can be added to the managed set via sys_multi_heap_add_heap(). No destruction utility is provided; just as for sys_heap, applications that want to destroy a multi heap should simply ensure all allocated blocks are freed (or at least will never be used again) and repurpose the underlying memory for another usage.

It has a single pair of allocation entry points, sys_multi_heap_alloc() and sys_multi_heap_aligned_alloc(). These behave identically to the sys_heap functions with similar names, except that they also accept an opaque "configuration" parameter. This pointer is uninspected by the multi heap code itself; instead it is passed to a callback function provided at initialization time. This application-provided callback is responsible for doing the underlying allocation from one of the managed heaps, and may use the configuration parameter in any way it likes to make that decision.

For modifying the size of an allocated buffer (whether shrinking or enlarging it), you can use the sys_multi_heap_realloc() and sys_multi_heap_aligned_realloc() APIs. If the buffer cannot be enlarged on the heap where it currently resides, any of the eligible heaps specified by the configuration parameter may be used.

When unused, a multi heap may be freed via sys_multi_heap_free(). The application does not need to pass a configuration parameter. Memory allocated from any of the managed sys_heap objects may be freed with in the same way.

System Heap

The *system heap* is a predefined memory allocator that allows threads to dynamically allocate memory from a common memory region in a malloc()-like manner.

Only a single system heap is defined. Unlike other heaps or memory pools, the system heap cannot be directly referenced using its memory address.

The size of the system heap is configurable to arbitrary sizes, subject to space availability.

A thread can dynamically allocate a chunk of heap memory by calling k_malloc(). The address of the allocated chunk is guaranteed to be aligned on a multiple of pointer sizes. If a suitable chunk of heap memory cannot be found NULL is returned.

When the thread is finished with a chunk of heap memory it can release the chunk back to the system heap by calling k_free().

Defining the Heap Memory Pool The size of the heap memory pool is specified using the CONFIG_HEAP_MEM_POOL_SIZE configuration option.

By default, the heap memory pool size is zero bytes. This value instructs the kernel not to define the heap memory pool object. The maximum size is limited by the amount of available memory in the system. The project build will fail in the link stage if the size specified can not be supported.

In addition, each subsystem (board, driver, library, etc) can set a custom requirement by defining a Kconfig option with the prefix `HEAP_MEM_POOL_ADD_SIZE_` (this value is in bytes). If multiple subsystems specify custom values, the sum of these will be used as the minimum requirement. If the application tries to set a value that's less than the minimum value, this will be ignored and the minimum value will be used instead.

To force a smaller than minimum value to be used, the application may enable the `CONFIG_HEAP_MEM_POOL_IGNORE_MIN` option. This can be useful when optimizing the heap size and the minimum requirement can be more accurately determined for a specific application.

Allocating Memory A chunk of heap memory is allocated by calling `k_malloc()`.

The following code allocates a 200 byte chunk of heap memory, then fills it with zeros. A warning is issued if a suitable chunk is not obtained.

```
char *mem_ptr;

mem_ptr = k_malloc(200);
if (mem_ptr != NULL)) {
    memset(mem_ptr, 0, 200);
    ...
} else {
    printf("Memory not allocated");
}
```

Releasing Memory A chunk of heap memory is released by calling `k_free()`.

The following code allocates a 75 byte chunk of memory, then releases it once it is no longer needed.

```
char *mem_ptr;

mem_ptr = k_malloc(75);
... /* use memory block */
k_free(mem_ptr);
```

Suggested Uses Use the heap memory pool to dynamically allocate memory in a `malloc()`-like manner.

3.4.2 Shared Multi Heap

The shared multi-heap memory pool manager uses the multi-heap allocator to manage a set of reserved memory regions with different capabilities / attributes (cacheable, non-cacheable, etc...).

All the different regions can be added at run-time to the shared multi-heap pool providing an opaque "attribute" value (an integer or enum value) that can be used by drivers or applications to request memory with certain capabilities.

This framework is commonly used as follow:

1. At boot time some platform code initialize the shared multi-heap framework using `shared_multi_heap_pool_init()` and add the memory regions to the pool with `shared_multi_heap_add()`, possibly gathering the needed information for the regions from the DT.
2. Each memory region encoded in a `shared_multi_heap_region` structure. This structure is also carrying an opaque and user-defined integer value that is used to define the region capabilities (for example: cacheability, cpu affinity, etc...)

```
// Init the shared multi-heap pool
shared_multi_heap_pool_init()

// Fill the struct with the data for cacheable memory
struct shared_multi_heap_region cacheable_r0 = {
     .addr = addr_r0,
     .size = size_r0,
     .attr = SMH_REG_ATTR_CACHEABLE,
};

// Add the region to the pool
shared_multi_heap_add(&cacheable_r0, NULL);

// Add another cacheable region
struct shared_multi_heap_region cacheable_r1 = {
     .addr = addr_r1,
     .size = size_r1,
     .attr = SMH_REG_ATTR_CACHEABLE,
};

shared_multi_heap_add(&cacheable_r1, NULL);

// Add a non-cacheable region
struct shared_multi_heap_region non_cacheable_r2 = {
     .addr = addr_r2,
     .size = size_r2,
     .attr = SMH_REG_ATTR_NON_CACHEABLE,
};

shared_multi_heap_add(&non_cacheable_r2, NULL);
```

3. When a driver or application needs some dynamic memory with a certain capability, it can use `shared_multi_heap_alloc()` (or the aligned version) to request the memory by using the opaque parameter to select the correct set of attributes for the needed memory. The framework will take care of selecting the correct heap (thus memory region) to carve memory from, based on the opaque parameter and the runtime state of the heaps (available memory, heap state, etc...)

```
// Allocate 4K from cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_CACHEABLE, 0x1000);

// Allocate 4K from non-cacheable memory
shared_multi_heap_alloc(SMH_REG_ATTR_NON_CACHEABLE, 0x1000);
```

Adding new attributes

The API does not enforce any attributes, but at least it defines the two most common ones: `SMH_REG_ATTR_CACHEABLE` and `SMH_REG_ATTR_NON_CACHEABLE`.

Shared multi-heap interface

3.4.3 Memory Slabs

A *memory slab* is a kernel object that allows memory blocks to be dynamically allocated from a designated memory region. All memory blocks in a memory slab have a single fixed size, allowing them to be allocated and released efficiently and avoiding memory fragmentation concerns.

- *Concepts*
  - *Internal Operation*
- *Implementation*
  - *Defining a Memory Slab*
  - *Allocating a Memory Block*
  - *Releasing a Memory Block*
  - *Querying Slab Usage*
- *Suggested Uses*
- *Configuration Options*
- *API Reference*

Concepts

Any number of memory slabs can be defined (limited only by available RAM). Each memory slab is referenced by its memory address.

A memory slab has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least 4N bytes long on 32-bit platforms and at least 8N bytes long on 64-bit platforms, where N is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the memory for the memory slab's blocks. It must be at least "block size" times "number of blocks" bytes long.

The memory slab's buffer must be aligned to an N-byte boundary, where N is a power of 2. N must be at least 4 on 32-bit platforms and at least 8 on 64-bit platforms. To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

A memory slab must be initialized before it can be used. This marks all of its blocks as unused.

A thread that needs to use a memory block simply allocates it from a memory slab. When the thread finishes with a memory block, it must release the block back to the memory slab so the block can be reused.

If all the blocks are currently in use, a thread can optionally wait for one to become available. Any number of threads may wait on an empty memory slab simultaneously; when a memory block becomes available, it is given to the highest-priority thread that has waited the longest.

More than one memory slab can be defined, if needed. This allows for a memory slab with smaller blocks and others with larger-sized blocks. Alternatively, a memory pool object may be used.

Internal Operation A memory slab's buffer is an array of fixed-size blocks, with no wasted space between the blocks.

The memory slab keeps track of unallocated blocks using a linked list. 32-bit platforms use the first 4 bytes of each unused block to provide the necessary linkage, while 64-bit platforms use the first 8 bytes of each unused block.

Implementation

Defining a Memory Slab A memory slab is defined using a variable of type `k_mem_slab`. It must then be initialized by calling `k_mem_slab_init()`.

The following code defines and initializes a memory slab that has 6 blocks that are 400 bytes long, each of which is aligned to an 8-byte boundary.

```
struct k_mem_slab my_slab;
char __aligned(8) my_slab_buffer[6 * 400];

k_mem_slab_init(&my_slab, my_slab_buffer, 400, 6);
```

Alternatively, a memory slab can be defined and initialized at compile time by calling `K_MEM_SLAB_DEFINE`.

The following code has the same effect as the code segment above. Observe that the macro defines both the memory slab and its buffer.

```
K_MEM_SLAB_DEFINE(my_slab, 400, 6, 8);
```

Similarly, you can define a memory slab in private scope:

```
K_MEM_SLAB_DEFINE_STATIC(my_slab, 400, 6, 8);
```

Allocating a Memory Block A memory block is allocated by calling `k_mem_slab_alloc()`.

The following code builds on the example above, and waits up to 100 milliseconds for a memory block to become available, then fills it with zeroes. A warning is printed if a suitable block is not obtained.

```
char *block_ptr;

if (k_mem_slab_alloc(&my_slab, (void **)&block_ptr, K_MSEC(100)) == 0) {
    memset(block_ptr, 0, 400);
    ...
} else {
    printf("Memory allocation time-out");
}
```

Releasing a Memory Block A memory block is released by calling `k_mem_slab_free()`.

The following code builds on the example above, and allocates a memory block, then releases it once it is no longer needed.

```
char *block_ptr;

k_mem_slab_alloc(&my_slab, (void **)&block_ptr, K_FOREVER);
... /* use memory block pointed at by block_ptr */
k_mem_slab_free(&my_slab, (void *)block_ptr);
```

Querying Slab Usage The current utilization of a memory slab can be queried at run time. `k_mem_slab_num_used_get()` returns the number of blocks currently allocated, and `k_mem_slab_num_free_get()` returns the number of blocks still available. When `CONFIG_MEM_SLAB_TRACE_MAX_UTILIZATION` is enabled, `k_mem_slab_max_used_get()` reports the peak number of blocks that have been allocated simultaneously, and `k_mem_slab_runtime_stats_get()` returns these figures together in a `sys_memory_stats` structure.

Suggested Uses

Use a memory slab to allocate and free memory in fixed-size blocks.

Use memory slab blocks when sending large amounts of data from one thread to another, to avoid unnecessary copying of the data.

Configuration Options

Related configuration options:

Memory Slab APIs

3.4.4 Memory Blocks Allocator

The Memory Blocks Allocator allows memory blocks to be dynamically allocated from a designated memory region, where:

- All memory blocks have a single fixed size.
- Multiple blocks can be allocated or freed at the same time.
- A group of blocks allocated together may not be contiguous. This is useful for operations such as scatter-gather DMA transfers.
- Bookkeeping of allocated blocks is done outside of the associated buffer (unlike memory slab). This allows the buffer to reside in memory regions where these can be powered down to conserve energy.

  - *Internal Operation*
- *Memory Blocks Allocator*
- *Multi Memory Blocks Allocator Group*

- *Usage*
  - *Defining a Memory Blocks Allocator*
  - *Allocating Memory Blocks*
  - *Releasing a Memory Block*
  - *Using Multi Memory Blocks Allocator Group*
- *API Reference*

Concepts

Any number of Memory Blocks Allocator can be defined (limited only by available RAM). Each allocator is referenced by its memory address.

A memory blocks allocator has the following key properties:

- The **block size** of each block, measured in bytes. It must be at least 4N bytes long, where N is greater than 0.
- The **number of blocks** available for allocation. It must be greater than zero.
- A **buffer** that provides the backing store from which the memory blocks allocator will allocate blocks. It must be at least "block size" times "number of blocks" bytes long.
- A **blocks bitmap** to keep track of which block has been allocated.

The buffer must be aligned to an N-byte boundary, where N is a power of 2 larger than 2 (i.e. 4, 8, 16, ...). To ensure that all memory blocks in the buffer are similarly aligned to this boundary, the block size must also be a multiple of N.

Due to the use of internal bookkeeping structures and their creation, each memory blocks allocator must be declared and defined at compile time.

Internal Operation Each buffer associated with an allocator is an array of fixed-size blocks, with no wasted space between the blocks.

The memory blocks allocator keeps track of unallocated blocks using a bitmap.

Memory Blocks Allocator

Internally, the memory blocks allocator uses a bitmap to keep track of which blocks have been allocated. Each allocator, utilizing the `sys_bitarray` interface, gets memory blocks one by one from the backing buffer up to the requested number of blocks. All the metadata about an allocator is stored outside of the backing buffer. This allows the memory region of the backing buffer to be powered down to conserve energy, as the allocator code never touches the content of the buffer.

Multi Memory Blocks Allocator Group

The Multi Memory Blocks Allocator Group utility functions are used to conveniently manage a group of allocators. A custom function may be written to choose which allocator managed by this group should be used for block allocation.

An allocator group should be initialized at runtime via `sys_multi_mem_blocks_init()`. Each allocator can then be added via `sys_multi_mem_blocks_add_allocator()`.

To allocate memory blocks from group, `sys_multi_mem_blocks_alloc()` is called with an opaque "configuration" parameter. This parameter is passed directly to the allocator choice function so that an appropriate allocator can be chosen. After an allocator is chosen, memory blocks are allocated via `sys_mem_blocks_alloc()`.

Allocated memory blocks can be freed via sys_multi_mem_blocks_free(). The caller does not need to pass a configuration parameter. The allocator code matches the passed in memory addresses to find the correct allocator and then memory blocks are freed via sys_mem_blocks_free().

Usage

Defining a Memory Blocks Allocator A memory blocks allocator is defined using a variable of type sys_mem_blocks_t. It needs to be defined and initialized at compile time by calling SYS_MEM_BLOCKS_DEFINE.

The following code defines and initializes a memory blocks allocator which has 4 blocks that are 64 bytes long, each of which is aligned to a 4-byte boundary:

```
SYS_MEM_BLOCKS_DEFINE(allocator, 64, 4, 4);
```

Similarly, you can define a memory blocks allocator in private scope:

```
SYS_MEM_BLOCKS_DEFINE_STATIC(static_allocator, 64, 4, 4);
```

A pre-defined buffer can also be provided to the allocator where the buffer can be placed separately. Note that the buffer **must** have its alignment specified when it is defined.

```
uint8_t __aligned(4) backing_buffer[64 * 4];
SYS_MEM_BLOCKS_DEFINE_WITH_EXT_BUF(allocator, 64, 4, backing_buffer);
```

Allocating Memory Blocks Memory blocks can be allocated by calling sys_mem_blocks_alloc().

```
int ret;
uintptr_t blocks[2];

ret = sys_mem_blocks_alloc(allocator, 2, blocks);
```

If `ret == 0`, the array `blocks` will contain an array of memory addresses pointing to the allocated blocks.

Releasing a Memory Block Memory blocks are released by calling sys_mem_blocks_free().

The following code builds on the example above which allocates 2 memory blocks, then releases them once they are no longer needed.

```
int ret;
uintptr_t blocks[2];

ret = sys_mem_blocks_alloc(allocator, 2, blocks);
... /* perform some operations on the allocated memory blocks */
ret = sys_mem_blocks_free(allocator, 2, blocks);
```

Using Multi Memory Blocks Allocator Group The following code demonstrates how to initialize an allocator group:

```
sys_mem_blocks_t *choice_fn(struct sys_multi_mem_blocks *group, void *cfg)
{
    ... /* choose which allocator in the group to use based on cfg */
}
```

(continues on next page)

(continued from previous page)

```
SYS_MEM_BLOCKS_DEFINE(allocator0, 64, 4, 4);
SYS_MEM_BLOCKS_DEFINE(allocator1, 64, 4, 4);

static sys_multi_mem_blocks_t alloc_group;

sys_multi_mem_blocks_init(&alloc_group, choice_fn);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator0);
sys_multi_mem_blocks_add_allocator(&alloc_group, &allocator1);
```

To allocate and free memory blocks from the group:

```
int ret;
uintptr_t blocks[1];
size_t blk_size;

ret = sys_multi_mem_blocks_alloc(&alloc_group, UINT_TO_POINTER(0),
                                 1, blocks, &blk_size);

ret = sys_multi_mem_blocks_free(&alloc_group, 1, blocks);
```

Memory Blocks APIs

3.4.5 Demand Paging

Demand paging provides a mechanism where data is only brought into physical memory as required by current execution context. The physical memory is conceptually divided in page-sized page frames as regions to hold data.

The Zephyr kernel image itself is always resident in physical memory and is never a candidate for eviction. Demand paging applies only to:

- anonymous memory mappings created at runtime via `k_mem_map()`, and
- memory placed in explicit on-demand linker sections via the `__ondemand_func` / `__ondemand_rodata` attributes when `CONFIG_LINKER_USE_ONDEMAND_SECTION` is enabled.

This is the same model used by every major operating system: the dispatch path for an exception or interrupt is never on a pageable page, so a fault during fault-handling is impossible by construction. Code or data added to an `__ondemand_*` section is the contributor's explicit opt-in to make that region pageable, and carries the responsibility of ensuring it is not reached from the page-fault handler's own execution path.

Note

Earlier versions of Zephyr also supported a selective-pinning scheme based on `__pinned_*` linker attributes that kept only the tagged subset of the kernel image resident and demand-paged the rest. That model was found to be both unsafe and/or very invasive: a CPU exception dispatch could target a thread's privileged stack on an evictable page, escalating to a double fault on x86 or a nested abort on ARM64 if that page had been evicted; and the contract that every byte on the fault-handler-reachable surface (scheduler, drivers, libc, locking primitives) be exhaustively tagged was impractical to establish once and unmaintainable thereafter. The `__pinned_*` attribute family, the corresponding Kconfig options (`LINKER_USE_PINNED_SECTION` / `LINKER_GENERIC_SECTIONS_PRESENT_AT_BOOT`) and the `K_*_PINNED_STACK_*` stack macros were removed in Zephyr 4.4. See GitHub #108773 for the full analysis.

- When the processor tries to access data and the data page exists in one of the page frames, the execution continues without any interruptions.
- When the processor tries to access the data page that does not exist in any page frames, a page fault occurs. The paging code then brings in the corresponding data page from backing store into physical memory if there is a free page frame. If there is no more free page frames, the eviction algorithm is invoked to select a data page to be paged out, thus freeing up a page frame for new data to be paged in. If this data page has been modified after it is first paged in, the data will be written back into the backing store. If no modifications is done or after written back into backing store, the data page is now considered paged out and the corresponding page frame is now free. The paging code then invokes the backing store to page in the data page corresponding to the location of the requested data. The backing store copies that data page into the free page frame. Now the data page is in physical memory and execution can continue.

There are functions where paging in and out can be invoked manually using `k_mem_page_in()` and `k_mem_page_out()`. `k_mem_page_in()` can be used to page in data pages in anticipation that they are required in the near future. This is used to minimize number of page faults as these data pages are already in physical memory, and thus minimizing latency. `k_mem_page_out()` can be used to page out data pages where they are not going to be accessed for a considerable amount of time. This frees up page frames so that the next page in can be executed faster as the paging code does not need to invoke the eviction algorithm.

A data region can also be **pinned** in physical memory using `k_mem_pin()`. This pages the region in if necessary and marks its page frames so that the eviction algorithm will never select them, guaranteeing that the region remains resident and that accesses to it never fault. This is a stronger form of `k_mem_page_in()` and is appropriate for latency- or safety-critical data that must always be available. A pinned region is later released with `k_mem_unpin()`, which marks the page frames as evictable again; unpinning does not itself evict the region, so it may be followed by `k_mem_page_out()` if immediate eviction is desired.

Terminology

Data Page
A data page is a page-sized region of data. It may exist in a page frame, or be paged out to some backing store. Its location can always be looked up in the CPU's page tables (or equivalent) by virtual address. The data type will always be `void *` or in some cases `uint8_t *` when doing pointer arithmetic.

Page Frame
A page frame is a page-sized physical memory region in RAM. It is a container where a data page may be placed. It is always referred to by physical address. Zephyr has a convention of using `uintptr_t` for physical addresses. For every page frame, a `struct k_mem_page_frame` is instantiated to store metadata. Flags for each page frame:

- `K_MEM_PAGE_FRAME_FREE` indicates a page frame is unused and on the list of free page frames. When this flag is set, none of the other flags are meaningful and they must not be modified.
- `K_MEM_PAGE_FRAME_PINNED` indicates a page frame is pinned in memory and should never be paged out.
- `K_MEM_PAGE_FRAME_RESERVED` indicates a physical page reserved by hardware and should not be used at all.
- `K_MEM_PAGE_FRAME_MAPPED` is set when a physical page is mapped to virtual memory address.
- `K_MEM_PAGE_FRAME_BUSY` indicates a page frame is currently involved in a page-in/out operation.
- `K_MEM_PAGE_FRAME_BACKED` indicates a page frame has a clean copy in the backing store.

K_MEM_SCRATCH_PAGE
: The virtual address of a special page provided to the backing store to: * Copy a data page from k_MEM_SCRATCH_PAGE to the specified location; or, * Copy a data page from the provided location to K_MEM_SCRATCH_PAGE. This is used as an intermediate page for page in/out operations. This scratch needs to be mapped read/write for backing store code to access. However the data page itself may only be mapped as read-only in virtual address space. If this page is provided as-is to backing store, the data page must be re-mapped as read/write which has security implications as the data page is no longer read-only to other parts of the application.

Paging Statistics

Paging statistics can be obtained via various function calls when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is enabled:

- Overall statistics via k_mem_paging_stats_get()
- Per-thread statistics via k_mem_paging_thread_stats_get() if CONFIG_DEMAND_PAGING_THREAD_STATS is enabled
- Execution time histogram can be obtained when CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM is enabled, and CONFIG_DEMAND_PAGING_TIMING_HISTOGRAM_NUM_BINS is defined. Note that the timing is highly dependent on the architecture, SoC or board. It is highly recommended that k_mem_paging_eviction_histogram_bounds[] and k_mem_paging_backing_store_histogram_bounds[] be defined for a particular application.
  - Execution time histogram of eviction algorithm via k_mem_paging_histogram_eviction_get()
  - Execution time histogram of backing store doing page-in via k_mem_paging_histogram_backing_store_page_in_get()
  - Execution time histogram of backing store doing page-out via k_mem_paging_histogram_backing_store_page_out_get()

Eviction Algorithm

The eviction algorithm is used to determine which data page and its corresponding page frame can be paged out to free up a page frame for the next page in operation. There are four functions which are called from the kernel paging code:

- k_mem_paging_eviction_init() is called to initialize the eviction algorithm. This is called at POST_KERNEL.
- k_mem_paging_eviction_add() is called each time a data page becomes eligible for future eviction.
- k_mem_paging_eviction_remove() is called when a data page is no longer eligible for eviction. This may happen if the given data page becomes pinned, gets unmapped or is about to be evicted.
- k_mem_paging_eviction_select() is called to select a data page to evict. A function argument dirty is written to signal the caller whether the selected data page has been modified since it is first paged in. If the dirty bit is returned as set, the paging code signals to the backing store to write the data page back into storage (thus updating its content). The function returns a pointer to the page frame corresponding to the selected data page.

There is one additional function which is called by the architecture's memory management code to flag data pages when they trigger an access fault: k_mem_paging_eviction_accessed(). This is used by the LRU algorithm to requeue "used" pages.

Two eviction algorithms are currently available:

- An NRU (Not-Recently-Used) eviction algorithm has been implemented as a sample. This is a very simple algorithm which ranks data pages on whether they have been accessed and modified. The selection is based on this ranking.
- An LRU (Least-Recently-Used) eviction algorithm is also available. It is based on a sorted queue of data pages. The LRU code is more complex compared to the NRU code but also considerably more efficient. This is recommended for production use.

To implement a new eviction algorithm, `k_mem_paging_eviction_init()` and `k_mem_paging_eviction_select()` must be implemented. If `CONFIG_EVICTION_TRACKING` is enabled for an algorithm, these additional functions must also be implemented, `k_mem_paging_eviction_add()`, `k_mem_paging_eviction_remove()`, `k_mem_paging_eviction_accessed()`.

Backing Store

Backing store is responsible for paging in/out data page between their corresponding page frames and storage. These are the functions which must be implemented:

- `k_mem_paging_backing_store_init()` is called to initialized the backing store at `POST_KERNEL`.
- `k_mem_paging_backing_store_location_get()` is called to reserve a backing store location so a data page can be paged out. This `location` token is passed to `k_mem_paging_backing_store_page_out()` to perform actual page out operation.
- `k_mem_paging_backing_store_location_free()` is called to free a backing store location (the `location` token) which can then be used for subsequent page out operation.
- `k_mem_paging_backing_store_location_query()` is called to obtain the `location` token corresponding to storage content to be virtually mapped and paged-in on demand. Most useful with `CONFIG_DEMAND_MAPPING`.
- `k_mem_paging_backing_store_page_in()` copies a data page from the backing store location associated with the provided `location` token to the page pointed by `K_MEM_SCRATCH_PAGE`.
- `k_mem_paging_backing_store_page_out()` copies a data page from `K_MEM_SCRATCH_PAGE` to the backing store location associated with the provided `location` token.
- `k_mem_paging_backing_store_page_finalize()` is invoked after `k_mem_paging_backing_store_page_in()` so that the page frame struct may be updated for internal accounting. This can be a no-op.

To implement a new backing store, the functions mentioned above must be implemented. `k_mem_paging_backing_store_page_finalize()` can be an empty function if so desired.

3.4.6 Virtual Memory

Virtual memory (VM) in Zephyr provides developers with the ability to fine tune access to memory. To utilize virtual memory, the platform must support Memory Management Unit (MMU) and it must be enabled in the build. Due to the target of Zephyr mainly being embedded systems, virtual memory support in Zephyr differs a bit from that in traditional operating systems:

Mapping of Kernel Image
: Default is to do 1:1 mapping for the kernel image (including code and data) between physical and virtual memory address spaces, if demand paging is not enabled. Deviation from this requires careful manipulation of linker script.

Secondary Storage
: Basic virtual memory support does not utilize secondary storage to extend usable memory. The maximum usable memory is the same as the physical memory.

  - *Demand Paging* enables utilizing secondary storage as a backing store for virtual memory, thus allowing larger usable memory than the available physical memory. Note that demand paging needs to be explicitly enabled.
  - Although the virtual memory space can be larger than physical memory space, without enabling demand paging, all virtually mapped memory must be backed by physical memory.

Kconfigs

Required These are the Kconfigs that need to be enabled or defined for kernel to support virtual memory.

- `CONFIG_MMU`: must be enabled for virtual memory support in kernel.
- `CONFIG_MMU_PAGE_SIZE`: size of a memory page. Default is 4KB.
- `CONFIG_KERNEL_VM_BASE`: base address of virtual address space.
- `CONFIG_KERNEL_VM_SIZE`: size of virtual address space. Default is 8MB.
- `CONFIG_KERNEL_VM_OFFSET`: kernel image starts at this offset from `CONFIG_KERNEL_VM_BASE`.

Optional

- `CONFIG_KERNEL_DIRECT_MAP`: permits 1:1 mappings between virtual and physical addresses, instead of kernel choosing addresses within the virtual address space. This is useful for mapping device MMIO regions for more precise access control.

Memory Map Overview

This is an overview of the memory map of the virtual memory address space. Note that the `Z_*` macros, which are used in code, may have different meanings depending on architecture and Kconfigs, which will be explained below.

```
+--------------+ <- K_MEM_VIRT_RAM_START
| Undefined VM | <- architecture specific reserved area
+--------------+ <- K_MEM_KERNEL_VIRT_START
| Mapping for  |
| main kernel  |
| image        |
|              |
|              |
+--------------+ <- K_MEM_VM_FREE_START
|              |
| Unused,      |
```

(continues on next page)

(continued from previous page)

```
| Available VM |
|              |
|..............| <- grows downward as more mappings are made
| Mapping      |
+--------------+
| Mapping      |
+--------------+
| ...          |
+--------------+
| Mapping      |
+--------------+ <- memory mappings start here
| Reserved     | <- special purpose virtual page(s) of size K_MEM_VM_RESERVED
+--------------+ <- K_MEM_VIRT_RAM_END
```

- `K_MEM_VIRT_RAM_START` is the beginning of the virtual memory address space. This needs to be page aligned. Currently, it is the same as `CONFIG_KERNEL_VM_BASE`.
- `K_MEM_VIRT_RAM_SIZE` is the size of the virtual memory address space. This needs to be page aligned. Currently, it is the same as `CONFIG_KERNEL_VM_SIZE`.
- `K_MEM_VIRT_RAM_END` is simply (`K_MEM_VIRT_RAM_START` + `K_MEM_VIRT_RAM_SIZE`).
- `K_MEM_KERNEL_VIRT_START` is the same as `z_mapped_start` specified in the linker script. This is the virtual address of the beginning of the kernel image at boot time.
- `K_MEM_KERNEL_VIRT_END` is the same as `z_mapped_end` specified in the linker script. This is the virtual address of the end of the kernel image at boot time.
- `K_MEM_VM_FREE_START` is the beginning of the virtual address space where addresses can be allocated for memory mapping. This depends on whether `CONFIG_ARCH_MAPS_ALL_RAM` is enabled.
  - If it is enabled, which means all physical memory are mapped in virtual memory address space, and it is the same as (`DT_CHOSEN_SRAM_ADDR` + `DT_CHOSEN_SRAM_SIZE`).
  - If it is disabled, `K_MEM_VM_FREE_START` is the same `K_MEM_KERNEL_VIRT_END` which is the end of the kernel image.
- `K_MEM_VM_RESERVED` is an area reserved to support kernel functions. For example, some addresses are reserved to support demand paging.

Virtual Memory Mappings

Setting up Mappings at Boot In general, most supported architectures set up the memory mappings at boot as following:

- `.text` section is read-only and executable. It is accessible in both kernel and user modes.
- `.rodata` section is read-only and non-executable. It is accessible in both kernel and user modes.
- Other kernel sections, such as `.data`, `.bss` and `.noinit`, are read-write and non-executable. They are only accessible in kernel mode.
  - Stacks for user mode threads are automatically granted read-write access to their corresponding user mode threads during thread creation.
  - Global variables, by default, are not accessible to user mode threads. Refer to *Memory Domains and Partitions* on how to use global variables in user mode threads, and on how to share data between user mode threads.

Caching modes for these mappings are architecture specific. They can be none, write-back, or write-through.

Note that SoCs have their own additional mappings required to boot where these mappings are defined under their own SoC configurations. These mappings usually include device MMIO regions needed to setup the hardware.

Mapping Anonymous Memory The unused physical memory can be mapped in virtual address space on demand. This is conceptually similar to memory allocation from heap, but these mappings must be aligned on page size and have finer access control.

- `k_mem_map()` can be used to map unused physical memory:
  - The requested size must be multiple of page size.
  - The address returned is inside the virtual address space between `K_MEM_VM_FREE_START` and `K_MEM_VIRT_RAM_END`.
  - The mapped region is not guaranteed to be physically contiguous in memory.
  - Guard pages immediately before and after the mapped virtual region are automatically allocated to catch access issue due to buffer underrun or overrun.
- The mapped region can be unmapped (i.e. freed) via `k_mem_unmap()`:
  - Caution must be exercised to give the pass the same region size to both `k_mem_map()` and `k_mem_unmap()`. The unmapping function does not check if it is a valid mapped region before unmapping.

API Reference

Kernel Memory Management

3.5 Data Structures

Zephyr provides a library of common general purpose data structures used within the kernel, but useful by application code in general. These include list and balanced tree structures for storing ordered data, and a ring buffer for managing "byte stream" data in a clean way.

Note that in general, the collections are implemented as "intrusive" data structures. The "node" data is the only struct used by the library code, and it does not store a pointer or other metadata to indicate what user data is "owned" by that node. Instead, the expectation is that the node will be itself embedded within a user-defined struct. Macros are provided to retrieve a user struct address from the embedded node pointer in a clean way. The purpose behind this design is to allow the collections to be used in contexts where dynamic allocation is disallowed (i.e. there is no need to allocate node objects because the memory is provided by the user).

Note also that these libraries are generally unsynchronized; access to them is not threadsafe by default. These are data structures, not synchronization primitives. The expectation is that any locking needed will be provided by the user. Some of the provided data structures are thread safe in specific usage scenarios (see *Single Producer Single Consumer Lock Free Queue* and *Multi Producer Single Consumer Lock Free Queue*).

3.5.1 Single-linked List

Zephyr provides a `sys_slist_t` type for storing simple singly-linked list data (i.e. data where each list element stores a pointer to the next element, but not the previous one). This supports constant-time access to the first (head) and last (tail) elements of the list, insertion before the head and after the tail of the list and constant time removal of the head. Removal of subsequent nodes requires access to the "previous" pointer and thus can only be performed in linear time by searching the list.

The sys_slist_t struct may be instantiated by the user in any accessible memory. It should be initialized with either sys_slist_init() or by static assignment from SYS_SLIST_STATIC_INIT before use. Its interior fields are opaque and should not be accessed by user code.

The end nodes of a list may be retrieved with sys_slist_peek_head() and sys_slist_peek_tail(), which will return NULL if the list is empty, otherwise a pointer to a sys_snode_t struct.

The sys_snode_t struct represents the data to be inserted. In general, it is expected to be allocated/controlled by the user, usually embedded within a struct which is to be added to the list. The container struct pointer may be retrieved from a list node using SYS_SLIST_CONTAINER, passing it the struct name of the containing struct and the field name of the node. Internally, the sys_snode_t struct contains only a next pointer, which may be accessed with sys_slist_peek_next().

Lists may be modified by adding a single node at the head or tail with sys_slist_prepend() and sys_slist_append(). They may also have a node added to an interior point with sys_slist_insert(), which inserts a new node after an existing one. Similarly sys_slist_remove() will remove a node given a pointer to its predecessor. These operations are all constant time.

Convenience routines exist for more complicated modifications to a list. sys_slist_merge_slist() will append an entire list to an existing one. sys_slist_append_list() will append a bounded subset of an existing list in constant time. And sys_slist_find_and_remove() will search a list (in linear time) for a given node and remove it if present.

Finally the slist implementation provides a set of "for each" macros that allows for iterating over a list in a natural way without needing to manually traverse the next pointers. SYS_SLIST_FOR_EACH_NODE will enumerate every node in a list given a local variable to store the node pointer. SYS_SLIST_FOR_EACH_NODE_SAFE behaves similarly, but has a more complicated implementation that requires an extra scratch variable for storage and allows the user to delete the iterated node during the iteration. Each of those macros also exists in a "container" variant (SYS_SLIST_FOR_EACH_CONTAINER and SYS_SLIST_FOR_EACH_CONTAINER_SAFE) which assigns a local variable of a type that matches the user's container struct and not the node struct, performing the required offsets internally. And SYS_SLIST_ITERATE_FROM_NODE exists to allow for enumerating a node and all its successors only, without inspecting the earlier part of the list.

Single-linked List Internals

The slist code is designed to be minimal and conventional. Internally, a sys_slist_t struct is nothing more than a pair of "head" and "tail" pointer fields. And a sys_snode_t stores only a single "next" pointer.

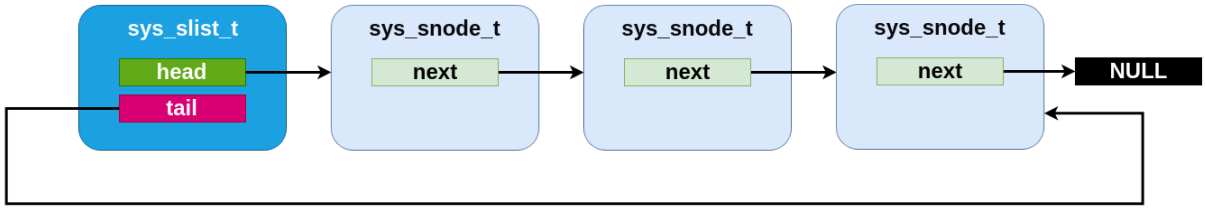

Fig. 4: An slist containing three elements.

The specific implementation of the list code, however, is done with an internal "Z_GENLIST" template API which allows for extracting those fields from arbitrary structures and emits an arbitrarily named set of functions. This allows for implementing more complicated single-linked list variants using the same basic primitives. The genlist implementer is responsible for a custom implementation of the primitive operations only: an "init" step for each struct, and a "get" and "set" primitives for each of head, tail and next pointers on their relevant structs. These inline functions are passed as parameters to the genlist macro expansion.

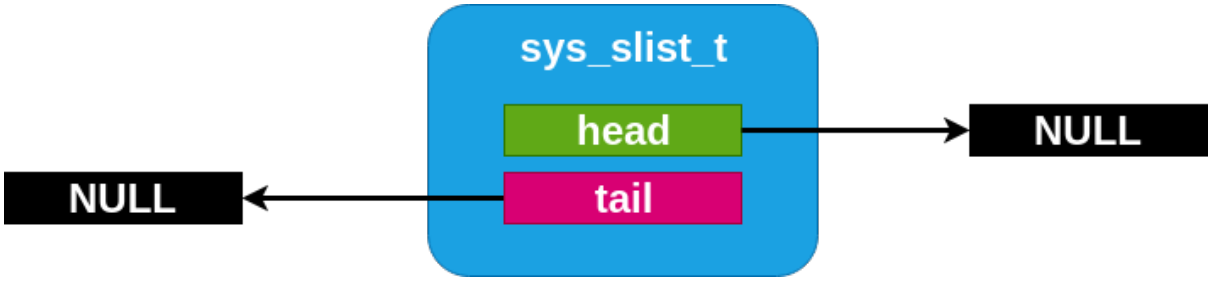

Fig. 5: An empty slist

Only one such variant, sflist, exists in Zephyr at the moment.

Flagged List

The `sys_sflist_t` is implemented using the described genlist template API. With the exception of symbol naming ("sflist" instead of "slist") and the additional API described next, it operates in all ways identically to the slist API.

It adds the ability to associate exactly two bits of user defined "flags" with each list node. These can be accessed and modified with `sys_sfnode_flags_get()` and `sys_sfnode_flags_set()`. Internally, the flags are stored unioned with the bottom bits of the next pointer and incur no SRAM storage overhead when compared with the simpler slist code.

Single-linked List API Reference

Single-linked list

Flagged List API Reference

Flagged Single-linked list

3.5.2 Double-linked List

Similar to the single-linked list in many respects, Zephyr includes a double-linked implementation. This provides the same algorithmic behavior for all the existing slist operations, but also allows for constant-time removal and insertion (at all points: before or after the head, tail or any internal node). To do this, the list stores two pointers per node, and thus has somewhat higher runtime code and memory space needs.

A `sys_dlist_t` struct may be instantiated by the user in any accessible memory. It must be initialized with `sys_dlist_init()` or `SYS_DLIST_STATIC_INIT` before use. The `sys_dnode_t` struct is expected to be provided by the user for any nodes added to the list (typically embedded within the struct to be tracked, as described above). It must be initialized in zeroed/bss memory or with `sys_dnode_init()` before use.

Primitive operations may retrieve the head/tail of a list and the next/prev pointers of a node with `sys_dlist_peek_head()`, `sys_dlist_peek_tail()`, `sys_dlist_peek_next()` and `sys_dlist_peek_prev()`. These can all return NULL where appropriate (i.e. for empty lists, or nodes at the endpoints of the list).

A dlist can be modified in constant time by removing a node with `sys_dlist_remove()`, by adding a node to the head or tail of a list with `sys_dlist_prepend()` and `sys_dlist_append()`, or by inserting a node before an existing node with `sys_dlist_insert()`.

As for slist, each node in a dlist can be processed in a natural code block style using `SYS_DLIST_FOR_EACH_NODE`. This macro also exists in a "FROM_NODE" form which allows for iterating from a known starting point, a "SAFE" variant that allows for removing the node being

inspected within the code block, a “CONTAINER” style that provides the pointer to a containing struct instead of the raw node, and a “CONTAINER_SAFE” variant that provides both properties.

Convenience utilities provided by dlist include `sys_dlist_insert_at()`, which inserts a node that linearly searches through a list to find the right insertion point, which is provided by the user as a C callback function pointer, and `sys_dnode_is_linked()`, which will affirmatively return whether or not a node is currently linked into a dlist or not (via an implementation that has zero overhead vs. the normal list processing).

Double-linked List Internals

Internally, the dlist implementation is minimal: the `sys_dlist_t` struct contains “head” and “tail” pointer fields, the `sys_dnode_t` contains “prev” and “next” pointers, and no other data is stored. But in practice the two structs are internally identical, and the list struct is inserted as a node into the list itself. This allows for a very clean symmetry of operations:

- An empty list has backpointers to itself in the list struct, which can be trivially detected.
- The head and tail of the list can be detected by comparing the prev/next pointers of a node vs. the list struct address.
- An insertion or deletion never needs to check for the special case of inserting at the head or tail. There are never any NULL pointers within the list to be avoided. Exactly the same operations are run, without tests or branches, for all list modification primitives.

Effectively, a dlist of N nodes can be thought of as a “ring” of “N+1” nodes, where one node represents the list tracking struct.

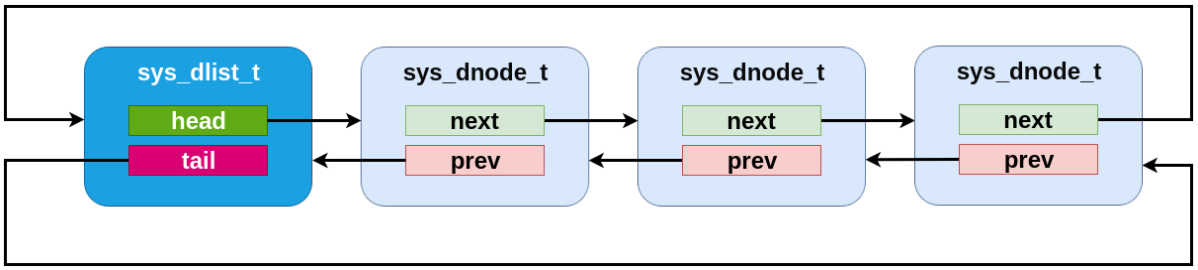

Fig. 6: A dlist containing three elements. Note that the list struct appears as a fourth “element” in the list.

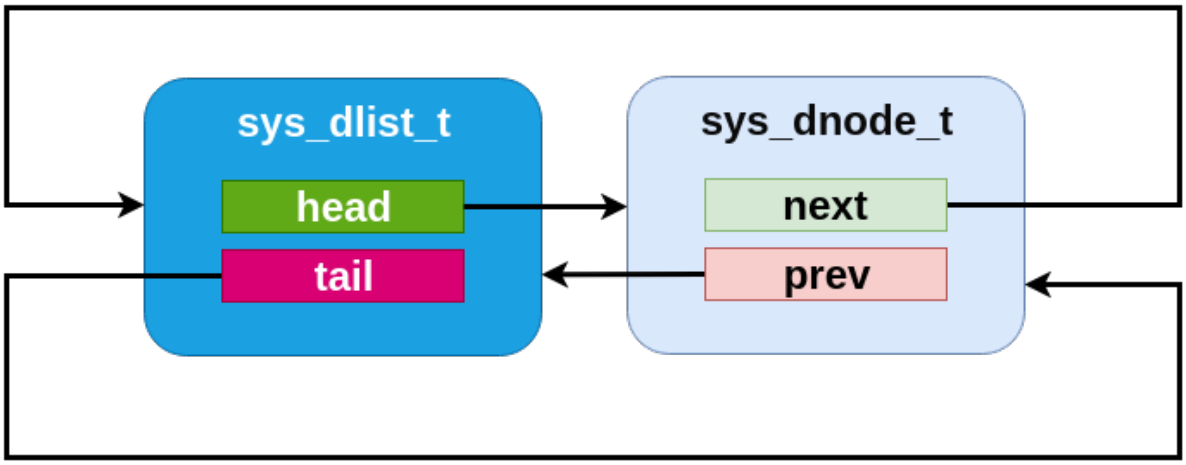

Fig. 7: An dlist containing just one element.

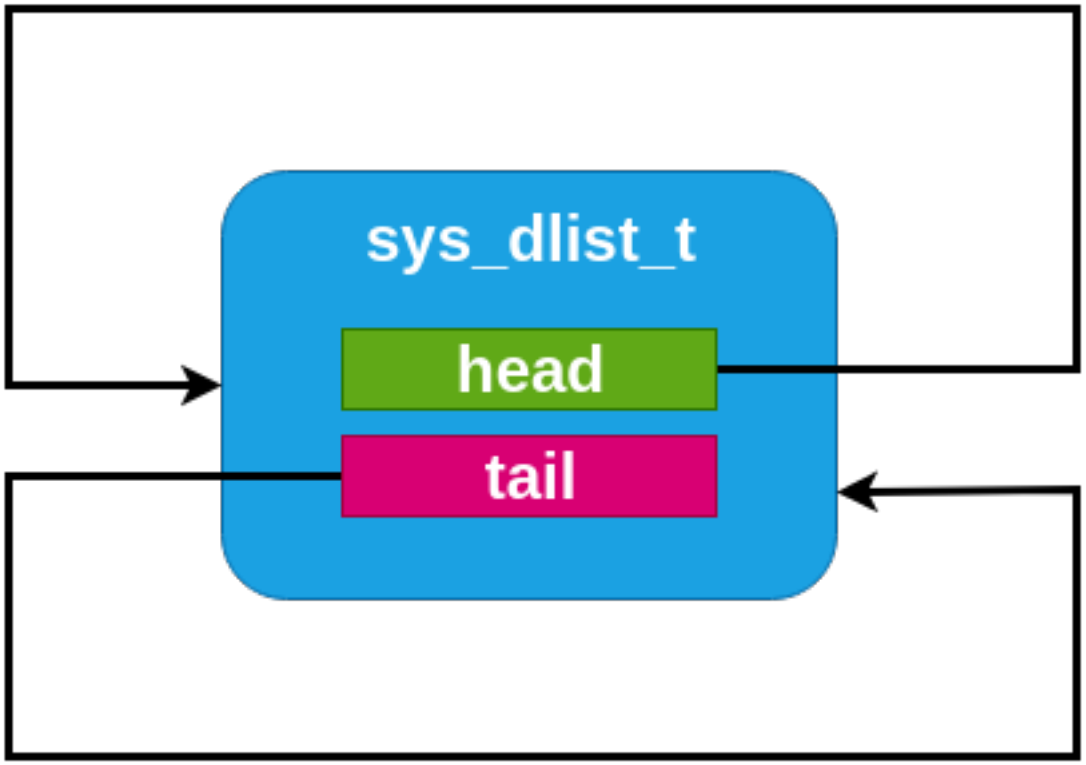

Fig. 8: An empty dlist.

3.5.3 Multi Producer Single Consumer Packet Buffer

A *Multi Producer Single Consumer Packet Buffer (MPSC_PBUF)* is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that consumes the data. However, it is possible that another context may interfere to flush the data and never come back (panic case). Packet is produced in two steps: first requested amount of data is allocated, producer fills the data and commits it. Consuming a packet is also performed in two steps: consumer claims the packet, gets pointer to it and length and later on packet is freed. This approach reduces memory copying.

A *MPSC Packet Buffer* has the following key properties:

- Allocate, commit scheme used for packet producing.
- Claim, free scheme used for packet consuming.
- Allocator ensures that contiguous memory of requested length is allocated.
- Following policies can be applied when requested space cannot be allocated:
  - **Overwrite** - oldest entries are dropped until requested amount of memory can be allocated. For each dropped packet user callback is called.
  - **No overwrite** - When requested amount of space cannot be allocated, allocation fails.
- Dedicated, optimized API for storing short packets.
- Allocation with timeout.

Internals

Each packet in the buffer contains MPSC_PBUF specific header which is used for internal management. Header consists of 2 bit flags. In order to optimize memory usage, header can be added on top of the user header using MPSC_PBUF_HDR and remaining bits in the first word can be application specific. Header consists of following flags:

- valid - bit set to one when packet contains valid user packet
- busy - bit set when packet is being consumed (claimed but not free)

Header state:

valid	busy	description
0	0	space is free
1	0	valid packet
1	1	claimed valid packet
0	1	internal skip packet

Packet buffer space contains free space, valid user packets and internal skip packets. Internal skip packets indicates padding, e.g. at the end of the buffer.

Allocation Using pairs for read and write indexes, available space is determined. If space can be allocated, temporary write index is moved and pointer to a space within buffer is returned. Packet header is reset. If allocation required wrapping of the write index, a skip packet is added to the end of buffer. If space cannot be allocated and overwrite is disabled then NULL pointer is returned or context blocks if allocation was with timeout.

Allocation with overwrite If overwrite is enabled, oldest packets are dropped until requested amount of space can be allocated. When packets are dropped busy flag is checked in the header to ensure that currently consumed packet is not overwritten. In that case, skip packet is added before busy packet and packets following the busy packet are dropped. When busy packet is being freed, such situation is detected and packet is converted to skip packet to avoid double processing.

Usage

Packet header definition Packet header details can be found in include/zephyr/sys/mpsc_packet.h. API functions can be found in include/zephyr/sys/mpsc_pbuf.h. Headers are split to avoid include spam when declaring the packet.

User header structure must start with internal header:

```
#include <zephyr/sys/mpsc_packet.h>

struct foo_header {
        MPSC_PBUF_HDR;
        uint32_t length: 32 - MPSC_PBUF_HDR_BITS;
};
```

Packet buffer configuration Configuration structure contains buffer details, configuration flags and callbacks. Following callbacks are used by the packet buffer:

- Drop notification - callback called whenever a packet is dropped due to overwrite.
- Get packet length - callback to determine packet length

Packet producing Standard, two step method:

```
foo_packet *packet = mpsc_pbuf_alloc(buffer, len, K_NO_WAIT);

fill_data(packet);

mpsc_pbuf_commit(buffer, packet);
```

Performance optimized storing of small packets:

- 32 bit word packet
- 32 bit word with pointer packet

Note that since packets are written by value, they should already contain `valid` bit set in the header.

```
mpsc_pbuf_put_word(buffer, data);
mpsc_pbuf_put_word_ext(buffer, data, ptr);
```

Packet consuming Two step method:

```
foo_packet *packet = mpsc_pbuf_claim(buffer);

process(packet);

mpsc_pbuf_free(buffer, packet);
```

3.5.4 Single Producer Single Consumer Packet Buffer

A *Single Producer Single Consumer Packet Buffer (SPSC_PBUF)* is a circular buffer, whose contents are stored in first-in-first-out order. Variable size packets are stored in the buffer. Packet buffer works under assumption that there is a single context that produces packets and a single context that consumes the data.

Implementation is focused on performance and memory footprint.

Packets are added to the buffer using `spsc_pbuf_write()` which copies a data into the buffer. If the buffer is full error is returned.

Packets are copied out of the buffer using `spsc_pbuf_read()`.

3.5.5 Balanced Red/Black Tree

For circumstances where sorted containers may become large at runtime, a list becomes problematic due to algorithmic costs of searching it. For these situations, Zephyr provides a balanced tree implementation which has runtimes on search and removal operations bounded at O(log2(N)) for a tree of size N. This is implemented using a conventional red/black tree as described by multiple academic sources.

The `rbtree` tracking struct for a rbtree may be initialized anywhere in user accessible memory. It should contain only zero bits before first use. No specific initialization API is needed or required.

Unlike a list, where position is explicit, the ordering of nodes within an rbtree must be provided as a predicate function by the user. A function of type `rb_lessthan_t()` should be assigned to the `lessthan_fn` field of the `rbtree` struct before any tree operations are attempted. This function should, as its name suggests, return a boolean True value if the first node argument is “less than” the second in the ordering desired by the tree. Note that “equal” is not allowed, nodes within a tree must have a single fixed order for the algorithm to work correctly.

As with the slist and dlist containers, nodes within an rbtree are represented as a `rbnode` structure which exists in user-managed memory, typically embedded within the data structure being

tracked in the tree. Unlike the list code, the data within an rbnode is entirely opaque. It is not possible for the user to extract the binary tree topology and "manually" traverse the tree as it is for a list.

Nodes can be inserted into a tree with `rb_insert()` and removed with `rb_remove()`. Access to the "first" and "last" nodes within a tree (in the sense of the order defined by the comparison function) is provided by `rb_get_min()` and `rb_get_max()`. There is also a predicate, `rb_contains()`, which returns a boolean True if the provided node pointer exists as an element within the tree. As described above, all of these routines are guaranteed to have at most log time complexity in the size of the tree.

There are two mechanisms provided for enumerating all elements in an rbtree. The first, `rb_walk()`, is a simple callback implementation where the caller specifies a C function pointer and an untyped argument to be passed to it, and the tree code calls that function for each node in order. This has the advantage of a very simple implementation, at the cost of a somewhat more cumbersome API for the user (not unlike ISO C's `bsearch()` routine). It is a recursive implementation, however, and is thus not always available in environments that forbid the use of unbounded stack techniques like recursion.

There is also a `RB_FOR_EACH` iterator provided, which, like the similar APIs for the lists, works to iterate over a list in a more natural way, using a nested code block instead of a callback. It is also nonrecursive, though it requires log-sized space on the stack by default (however, this can be configured to use a fixed/maximally size buffer instead where needed to avoid the dynamic allocation). As with the lists, this is also available in a `RB_FOR_EACH_CONTAINER` variant which enumerates using a pointer to a container field and not the raw node pointer.

Tree Internals

As described, the Zephyr rbtree implementation is a conventional red/black tree as described pervasively in academic sources. Low level details about the algorithm are out of scope for this document, as they match existing conventions. This discussion will be limited to details notable or specific to the Zephyr implementation.

The core invariant guaranteed by the tree is that the path from the root of the tree to any leaf is no more than twice as long as the path to any other leaf. This is achieved by associating one bit of "color" with each node, either red or black, and enforcing a rule that no red child can be a child of another red child (i.e. that the number of black nodes on any path to the root must be the same, and that no more than that number of "extra" red nodes may be present). This rule is enforced by a set of rotation rules used to "fix" trees following modification.

These rotations are conceptually implemented on top of a primitive that "swaps" the position of one node with another in the list. Typical implementations effect this by simply swapping the nodes internal "data" pointers, but because the Zephyr `rbnode` is intrusive, that cannot work. Zephyr must include somewhat more elaborate code to handle the edge cases (for example, one swapped node can be the root, or the two may already be parent/child).

The `rbnode` struct for a Zephyr rbtree contains only two pointers, representing the "left", and "right" children of a node within the binary tree. Traversal of a tree for rebalancing following modification, however, routinely requires the ability to iterate "upwards" from a node as well. It is very common for red/black trees in the industry to store a third "parent" pointer for this purpose. Zephyr avoids this requirement by building a "stack" of node pointers locally as it traverses downward through the tree and updating it appropriately as modifications are made. So a Zephyr rbtree can be implemented with no more runtime storage overhead than a dlist.

These properties, of a balanced tree data structure that works with only two pointers of data per node and that works without any need for a memory allocation API, are quite rare in the industry and are somewhat unique to Zephyr.

Red/Black Tree API Reference

Balanced Red/Black Tree

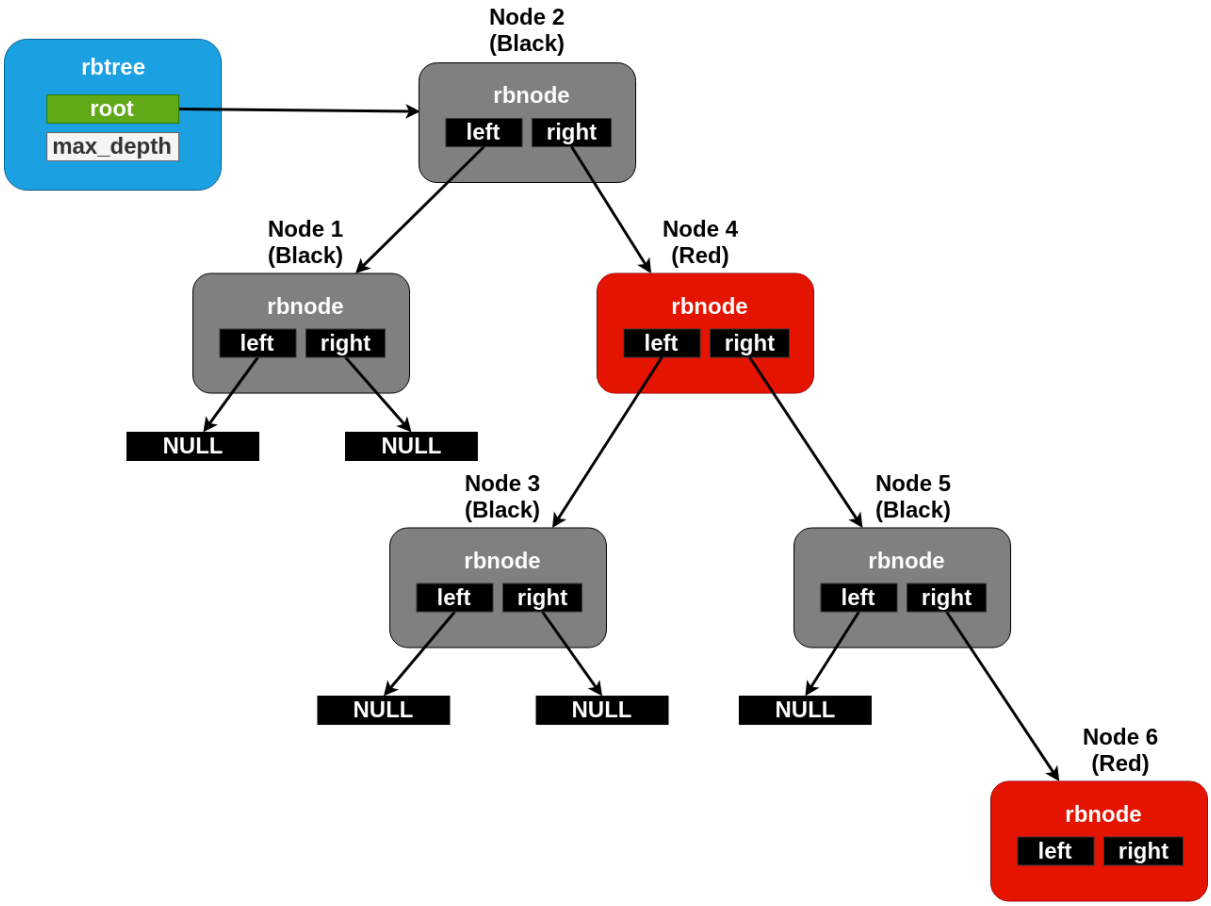

Fig. 9: A maximally unbalanced rbtree with a black height of two. No more nodes can be added underneath the rightmost node without rebalancing.

3.5.6 Ring Buffers

A *ring buffer* is a circular buffer, whose contents are stored in first-in-first-out order.

For circumstances where an application needs to implement asynchronous "streaming" copying of data, Zephyr provides a `struct ring_buf` abstraction to manage copies of such data in and out of a shared buffer of memory.

- *Concepts*
  - *Instantiation and Usage*
  - *Concurrency*
  - *Internal Operation*
- *Implementation*
  - *Defining a Ring Buffer*
  - *Enqueuing Data*
  - *Retrieving Data*
- *Configuration Options*
- *API Reference*

Concepts

Any number of ring buffers can be defined (limited only by available RAM). Each ring buffer is referenced by its memory address.

A ring buffer has the following key properties:

- A **data buffer** of bytes. The data buffer contains the raw bytes that have been added to the ring buffer but not yet removed.
- A **data buffer size**, measured in bytes. This governs the maximum amount of data the ring buffer can hold.

A ring buffer must be initialized before it can be used. This sets its data buffer to empty.

A `struct ring_buf` may be placed anywhere in user-accessible memory, and must be initialized with `ring_buf_init()` before use. This must be provided a region of user-controlled memory for use as the buffer itself. Note carefully that the units of the size of the buffer passed change (either bytes or words) depending on how the ring buffer will be used later. Macros for combining these steps in a single static declaration exist for convenience. `RING_BUF_DECLARE` will declare and statically initialize a ring buffer with a specified byte count, where

"Bytes" data may be copied into the ring buffer using `ring_buf_put()`, passing a data pointer and byte count. These bytes will be copied into the buffer in order, as many as will fit in the allocated buffer. The total number of bytes copied (which may be fewer than provided) will be returned. Likewise `ring_buf_get()` will copy bytes out of the ring buffer in the order that they were written, into a user-provided buffer, returning the number of bytes that were transferred.

To avoid multiply-copied-data situations, a zero-copy "pointer" API exists. `ring_buf_put_ptr()` returns a pointer to memory internal to the ring buffer that can be used to receive bytes, along with the size of the contiguous internal region available for writing (which may be smaller than the total free space if the region wraps). The user can then write data directly into that region (e.g. via DMA) without assembling all the bytes in a single region first. When complete, `ring_buf_commit()` is used to signal the buffer that the transfer is complete, passing the number of bytes actually transferred. At this point a new transfer can be initiated. Similarly, `ring_buf_get_ptr()` returns a pointer to internal ring buffer data from which the user can read

without making a verbatim copy, and ring_buf_consume() signals the buffer with how many bytes have been consumed and allows for a new transfer to begin.

The legacy ring_buf_put_claim() / ring_buf_put_finish() and ring_buf_get_claim() / ring_buf_get_finish() APIs provide similar functionality but reserve the claimed region until finished, which incurs additional code size and runtime cost. These APIs are deprecated and will be removed in a future release; new code should use the _ptr / _commit / _consume variants described above.

The user can manage the capacity of a ring buffer without modifying it using either ring_buf_space_get() which returns the number of free bytes, or by testing the ring_buf_is_empty() predicate.

Finally, a ring_buf_reset() call exists to immediately empty a ring buffer, discarding the tracking of any bytes already written to the buffer. It does not modify the memory contents of the buffer itself, however.

Instantiation and Usage A ring buffer instance is declared using RING_BUF_DECLARE() and accessed using: ring_buf_put_ptr(), ring_buf_commit(), ring_buf_get_ptr(), ring_buf_consume(), ring_buf_put() and ring_buf_get().

Data can be copied into the ring buffer (see ring_buf_put()) or ring buffer memory can be used directly by the user. In the latter case, the operation is split into three stages:

1. Accessing the ring buffers internal buffer (ring_buf_put_ptr()) to get a pointer to the next location where data can be written, and the amount of contiguous space available at that location.
2. writing the data by the user (e.g. buffer written by DMA).
3. indicating the amount of data written to the provided buffer (ring_buf_commit()). The amount committed can be less than or equal to the amount provided by ring_buf_put_ptr().

Data can be retrieved from a ring buffer through copying (see ring_buf_get()) or accessed directly by address. In the latter case, the operation is split into three stages:

1. Accessing the ring buffers internal buffer (see ring_buf_get_ptr()) to get a pointer to the next location where data can be read, and the amount of contiguous data available at that location.
2. Processing data
3. Signal to the ring buffer that the data has been consumed (see ring_buf_consume()). The amount consumed can be less than or equal to the amount provided by ring_buf_get_ptr().

Concurrency The ring buffer APIs do not provide any internal concurrency control. Depending on usage (particularly with respect to number of concurrent readers/writers) applications may need to protect the ring buffer with mutexes and/or use semaphores to notify consumers that there is data to read.

A single producer and a single consumer running in separate execution contexts (for example two threads, or one thread and one ISR) may use the same ring buffer concurrently without additional locking. The producer side only updates the put indices and the consumer side only updates the get indices, so the two sides never write the same fields. This holds for both the copying APIs (ring_buf_put() / ring_buf_get()) and the zero-copy "claim" APIs (ring_buf_put_claim() / ring_buf_put_finish() and ring_buf_get_claim() / ring_buf_get_finish()).

When the producer and consumer run on different CPUs (SMP), the application must still ensure that data writes are visible before the index update that publishes them. In practice this happens for free when the producer and consumer use a kernel synchronization primitive to coordinate (for example a k_sem signaled by the producer and waited on by the consumer), since those primitives include the necessary memory barriers.

Any use case with more than one concurrent producer, or more than one concurrent consumer, must serialize those accesses externally (for example with a mutex or by disabling preemption).

Internal Operation Data streamed through a ring buffer is always written to the next byte within the buffer, wrapping around to the first element after reaching the end, thus the "ring" structure. Internally, the `struct ring_buf` contains its own buffer pointer and its size, and also a set of "head" and "tail" indices representing where the next read and write operations may occur.

This boundary is invisible to the user using the normal put/get APIs, but becomes a barrier to the "claim" API, because obviously no contiguous region can be returned that crosses the end of the buffer. This can be surprising to application code, and produce performance artifacts when transfers need to happen close to the end of the buffer, as the number of calls to claim/finish needs to double for such transfers.

Implementation

Defining a Ring Buffer A ring buffer is defined using a variable of type `ring_buf`. It must then be initialized by calling `ring_buf_init()`.

A ring buffer can be defined and initialized at compile time using the macros at file scope. The macro defines the ring buffer itself and its data buffer.

The following code defines a ring buffer:

```
#define MY_RING_BUF_BYTES 93
RING_BUF_DECLARE(my_ring_buf, MY_RING_BUF_BYTES);
```

Enqueuing Data Bytes are copied to a ring buffer by calling `ring_buf_put()`.

```
uint8_t my_data[MY_RING_BUF_BYTES];
uint32_t ret;

ret = ring_buf_put(&ring_buf, my_data, MY_RING_BUF_BYTES);
if (ret != MY_RING_BUF_BYTES) {
    /* not enough room, partial copy. */
    ...
}
```

Data can be added to a ring buffer by directly accessing the ring buffer's memory. For example:

```
uint32_t size;
uint32_t rx_size;
uint8_t *data;

/* Get pointer to writable area within the ring buffer memory. */
size = ring_buf_put_ptr(&ring_buf, &data, 0);

/* Work directly on a ring buffer memory. */
rx_size = uart_rx(data, size);

/* Indicate amount of valid data. rx_size must be equal or less than size. */
ring_buf_commit(&ring_buf, rx_size);
```

Retrieving Data Data bytes are copied out from a ring buffer by calling `ring_buf_get()`. For example:

```
uint8_t my_data[MY_DATA_BYTES];
size_t  ret;

ret = ring_buf_get(&ring_buf, my_data, sizeof(my_data));
if (ret != sizeof(my_data)) {
    /* Fewer bytes copied. */
} else {
    /* Requested amount of bytes retrieved. */
    ...
}
```

Data can be retrieved from a ring buffer by direct operations on the ring buffer's memory. For example:

```
uint32_t size;
uint32_t proc_size;
uint8_t *data;

/* Get pointer to readable data within the ring buffer memory. */
size = ring_buf_get_ptr(&ring_buf, &data, 0);

/* Work directly on a ring buffer memory. */
proc_size = process(data, size);

/* Indicate amount of data that has been consumed. proc_size must be equal
 * or less than size.
 */
ring_buf_consume(&ring_buf, proc_size);
```

Configuration Options

Related configuration options:

- CONFIG_RING_BUFFER: Restore the deprecated legacy ring buffer APIs (the claim/finish and fixed-size item APIs). The ring buffer itself is header-only and always available, so this option is not required for normal use.
- CONFIG_RING_BUFFER_LARGE: Increase the maximum buffer size from 32KB to 1GB.

API Reference

The following ring buffer APIs are provided by include/zephyr/sys/ring_buffer.h:

3.5.9 Min-Heap Data Structure

- *Heap Structure*
- *Use Cases*
- *Value and reference variants*
- *Samples*
- *API Reference*
  - *Value heap*
  - *Reference heap*

The Min-Heap implementation provides an efficient data structure for managing a dynamically changing list of elements while maintaining the ability to quickly extract the minimum value. It's a tree-based data structure that satisfies the heap property and supports common operations such as insertion, removal and popping the minimum element from the Min-Heap

This section explains the motivation behind the implementation, its internal structure, API usage, and example scenarios for embedded systems and real-time environments.

Heap Structure

The heap is maintained as a complete binary tree stored in an array. Each node satisfies the **min-heap** property:

- The value of each node is less than or equal to the values of its children.

This property ensures that the **minimum element is always at the root** (index 0).

```
Index:      0   1   2   3   4   5   6
Values:    [1,  3,  5,  8,  9, 10, 12]

               1
             /   \
           3       5
         / \     / \
        8   9  10  12
```

For any node at index `i`, its children are at indices:

- Left child: $2 * i + 1$
- Right child: $2 * i + 2$

Its parent is at index:

- Parent: $(i - 1)/2$

Use Cases

MinHeap is well suited for:

- Implementing priority queues
- Sorting data incrementally

- Resource arbitration (e.g., lowest-cost resource selection)
- Scheduling in cooperative multitasking systems
- Managing timeouts and delay queues
- Priority-based sensor or data sampling

In RTOS environments like Zephyr, this heap can be used in kernel-level or application-level modules where minimal latency to obtain the highest priority resource is needed.

Value and reference variants

Two variants are provided, differing only in how elements are stored:

- `min_heap` (described above) stores elements **by value** in a contiguous buffer. An arbitrary element is removed by content (search) or by index. This suits priority queues of small values looked up by content.
- `min_heap_ref` stores **references** to caller-owned nodes, each embedding a `min_heap_handle`. Insertion is zero-copy, and a specific node is removed in $O(\log n)$ using the handle the caller already holds, with no search. This suits long-lived objects removed by identity rather than by content, such as kernel timeouts.

The two are complementary: the value heap cannot remove by identity in better than $O(n)$, while the reference heap is a poor fit for value-with-search use. `min_heap_ref` is header-only and requires no Kconfig.

Samples

min-heap sample demos the API usage of Min-Heap implementation in Zephyr RTOS.

3.5.10 sys_ringq Data Structure

- *Overview*
  - *Concurrency*
- *Instantiation & Usage*
- *API Reference*

Overview

A ring queue (or circular buffer) is a data structure that uses a single, fixed-size buffer as if it were connected end-to-end. This structure is particularly useful for buffering items in a ordered manner.

The ringq is used whenever you need to decouple producers and consumers of discrete data sizes without worrying about partial reads or variable-length payloads. This differentiation separates it from the *ring_buffer* data structure, which is a streaming data structure of bytes.

Concurrency The sys_ringq api do not provide any concurrency control. Depending on usage, applications should protect the sys_ringq structure with appropriate synchronization mechanisms (e.g., mutexes, semaphores) to ensure thread safety when accessed from multiple threads.

Instantiation & Usage

A `sys_ringq` can be declared either using the `SYS_RINGQ_DEFINE(name, item_size, item_capacity)` macro or in runtime using the `sys_ringq_init(struct sys_ringq *ringq, uint8_t *data, size_t data_size, size_t item_size);` function.

```
SYS_RINGQ_DEFINE(my_ringq, item_size, item_capacity);
/* equivalent to */

static struct sys_ringq my_ringq;
static uint8_t buffer[item_size * item_capacity];
void init_fn (void) {
   sys_ringq_init(&my_ringq, buffer, sizeof(buffer), item_size);
   ....
}
```

Once the `sys_ringq` is initialized, items can be added to the ringq using the `sys_ringq_put()` function and removed using the `sys_ringq_get()` function. The ringq maintains the order of the items and ensures proper boundary checking of the underlying data buffer.

```
struct my_item item_to_add = { ... };
struct my_item item_removed;

/* Add an item to the queue */
if (sys_ringq_put(&my_ringq, &item_to_add) == 0) {
    // Item added successfully
} else {
    // ringq is full
}

/* Remove an item from the queue */
if (sys_ringq_get(&my_ringq, &item_removed) == 0) {
    // Item removed successfully
} else {
    // ringq is empty
}
```

In addition to the standard data operations (sys_ringq_put() and sys_ringq_get()), the sys_ringq API provides a set of utility functions for managing and inspecting the data structures state.

- sys_ringq_capacity() – Returns the total capacity of the sys_ringq in terms of the number of items it can hold.
- sys_ringq_empty() – Returns true if the sys_ringq contains no items.
- sys_ringq_full() – Returns true if the sys_ringq cannot accept more items.
- sys_ringq_space() – Returns the number of free slots remaining.
- sys_ringq_size() – Returns the number of items currently stored.
- sys_ringq_reset() – Resets the sys_ringq to an empty state.

Ring queue

3.6 Executing Time Functions

The timing functions can be used to obtain execution time of a section of code to aid in analysis and optimization.

Please note that the timing functions may use a different timer than the default kernel timer, where the timer being used is specified by architecture, SoC or board configuration.

3.6.1 Configuration

To allow using the timing functions, `CONFIG_TIMING_FUNCTIONS` needs to be enabled.

3.6.2 Usage

To gather timing information:

1. Call `timing_init()` to initialize the timer.
2. Call `timing_start()` to signal the start of gathering of timing information. This usually starts the timer.
3. Call `timing_counter_get()` to mark the start of code execution.
4. Call `timing_counter_get()` to mark the end of code execution.
5. Call `timing_cycles_get()` to get the number of timer cycles between start and end of code execution.
6. Call `timing_cycles_to_ns()` with total number of cycles to convert number of cycles to nanoseconds.
7. Repeat from step 3 to gather timing information for other blocks of code.
8. Call `timing_stop()` to signal the end of gathering of timing information. This usually stops the timer.

Example

This shows an example on how to use the timing functions:

```
#include <zephyr/timing/timing.h>

void gather_timing(void)
{
    timing_t start_time, end_time;
    uint64_t total_cycles;
    uint64_t total_ns;

    timing_init();
    timing_start();

    start_time = timing_counter_get();

    code_execution_to_be_measured();

    end_time = timing_counter_get();

    total_cycles = timing_cycles_get(&start_time, &end_time);
    total_ns = timing_cycles_to_ns(total_cycles);

    timing_stop();
}
```

3.7 Object Cores

Object cores are a kernel debugging tool that can be used to both identify and perform operations on registered objects.

- *Object Core Concepts*
- *Object Core Statistics Concepts*
- *Implementation*
  - *Defining a New Object Type*
  - *Initializing a New Object Core*
  - *Walking a List of Object Cores*
  - *Object Core Statistics Querying*
- *Configuration Options*
- *API Reference*

3.7.1 Object Core Concepts

Each instance of an object embeds an object core field named `obj_core`. An object core links the object to its object type, and each object type lets debugging tools enumerate the objects of that type. Object types are linked together via a singly linked list. Together, this allows debugging tools to traverse all the objects in the system.

An object type enumerates its objects from two places:

- Its permanent objects, which are statically defined instances such as those created with `K_SEM_DEFINE`. They are walked in place from their iterable section and are never registered at run time.
- A bounded registry of the objects initialized at run time, for instance a semaphore in a driver's data structure initialized with `k_sem_init()`. The registry only references the objects; it never stores anything inside them.

Because of that, an object may be initialized in any storage, initialized again in place, or discarded without any object core call: the registry cannot be corrupted by an object that no longer exists. Some rules follow from this model:

- An object located in the running thread's stack or in the interrupt stack is not registered: its life ends with the stack frame. The object type counts such objects in its `skipped` field. Other stacks are not recognized, such as the privileged stack a user thread's system calls run on or an exception stack specific to an architecture; an object there is registered and stays reported until its storage is reused.
- When the registry is full, further objects are not registered and the object type counts them in its `dropped` field. The registry size is set with `CONFIG_OBJ_CORE_MAX_DYNAMIC_OBJECTS`.

- An object that was discarded without being unregistered stays reported until its storage is reused: the walk recognizes the reused storage by the missing type tag and drops the entry. The kernel unregisters objects itself when it releases them: on thread abort, in `k_object_free()`, `k_timer_cleanup()`, `k_msgq_cleanup()` and `k_stack_cleanup()`, and, with `CONFIG_OBJ_CORE_EVICT_ON_FREE`, when memory is returned to a heap, a memory slab or a memory blocks allocator. Code that ends an object's life in another way may call `k_obj_core_unlink()` so that the object stops being reported at once; the type tag check is only a backstop, and it reads the object's former storage, which must still be mapped.
- Once a type's `dropped` count is not zero, objects exist that no walk reports, so an inventory is complete only while it is zero.

Object cores have been integrated into the following kernel objects:

- *Condition Variables*
- *Events*
- *FIFOs* and *LIFOs*
- *Mailboxes*
- *Memory Slabs*
- *Message Queues*
- *Mutexes*
- *Pipes*
- *Queues*
- *Semaphores*
- *Threads*
- *Timers*
- *System Memory Blocks*

Developers are free to integrate them if desired into other objects within their projects. The object_cores sample shows the facility step by step and the object_monitor sample uses it to watch the objects of a running application.

3.7.2 Object Core Statistics Concepts

A variety of kernel objects allow for the gathering and reporting of statistics. Object cores provide a uniform means to retrieve that information via object core statistics. When enabled, the object type contains a pointer to a statistics descriptor that defines the various operations that have been enabled for interfacing with the object's statistics. Additionally, the object core contains a pointer to the "raw" statistical information associated with that object. Raw data is the raw, unmanipulated data associated with the statistics. Queried data may be "raw", but it may also have been manipulated in some way by calculation (such as determining an average).

The following table indicates both what objects have been integrated into the object core statistics as well as the structures used for both "raw" and "queried" data.

Object	Raw Data Type	Query Data Type
struct mem_slab	struct mem_slab_info	struct sys_memory_stats
struct sys_mem_blocks	struct sys_mem_blocks_info	struct sys_memory_stats
struct k_thread	struct k_cycle_stats	struct k_thread_runtime_stats
struct _cpu	struct k_cycle_stats	struct k_thread_runtime_stats
struct z_kernel	struct k_cycle_stats[num CPUs]	struct k_thread_runtime_stats

3.7.3 Implementation

Defining a New Object Type

An object type is a global variable of type `k_obj_type`. When the object struct has statically defined instances in an iterable section, the type is defined at build time with `K_OBJ_TYPE_DEFINE` and those instances become its permanent objects. The following code shows how a new object type can be defined for use with object cores and object core statistics.

```
/* Unique object type ID */

#define K_OBJ_TYPE_MY_NEW_TYPE  K_OBJ_TYPE_ID_GEN("UNIQ")

struct my_obj_type_raw_info {
    ...
};

struct my_obj_type_query_stats {
    ...
};

struct my_new_obj {
    ...
    struct k_obj_core obj_core;
    struct my_obj_type_raw_info  info;
};

struct k_obj_core_stats_desc my_obj_type_stats_desc = {
    .raw_size = sizeof(struct my_obj_type_raw_stats),
    .query_size = sizeof(struct my_obj_type_query_stats),
    .raw = my_obj_type_stats_raw,
    .query = my_obj_type_stats_query,
    .reset = my_obj_type_stats_reset,
    .disable = NULL,    /* Stats gathering is always on */
    .enable = NULL,     /* Stats gathering is always on */
};

K_OBJ_TYPE_DEFINE_STATS(my_obj_type, my_new_obj, K_OBJ_TYPE_MY_NEW_TYPE,
                        &my_obj_type_stats_desc, info);
```

A type whose objects are not in an iterable section is initialized at run time instead, before any of its objects. A permanent array of objects can be registered as the type's range so that its objects need no registry entry.

```
struct k_obj_type  my_obj_type;
struct my_new_obj  my_objects[8];

void my_obj_type_init(void)
{
    z_obj_type_init(&my_obj_type, K_OBJ_TYPE_MY_NEW_TYPE,
                    offsetof(struct my_new_obj, obj_core));
    k_obj_type_init_range(&my_obj_type, my_objects,
                          &my_objects[ARRAY_SIZE(my_objects)],
                          sizeof(struct my_new_obj), false);
    k_obj_type_stats_init(&my_obj_type, &my_obj_type_stats_desc);
}
```

Initializing a New Object Core

Kernel objects that have already been integrated into the object core framework automatically have their object cores initialized when the object is initialized. However, developers that wish to add their own objects into the framework need to both initialize the object core and register it. Registering an object that belongs to the type's permanent range has no effect, as it is reported from the range. The following code builds on the example above and initializes the object core.

```
void my_new_obj_init(struct my_new_obj *new_obj)
{
    ...
    k_obj_core_init(K_OBJ_CORE(new_obj), &my_obj_type);
    k_obj_core_link(K_OBJ_CORE(new_obj));
    k_obj_core_stats_register(K_OBJ_CORE(new_obj), &new_obj->raw_stats,
                              sizeof(struct my_obj_type_raw_info));
}
```

Walking a List of Object Cores

Two routines exist for walking the object cores of an object type. These are `k_obj_type_walk_locked()` and `k_obj_type_walk_unlocked()`. Both visit the permanent objects of the type first and the registered objects next. The following code builds upon the example above and prints the addresses of all the objects of that new object type.

```
int walk_op(struct k_obj_core *obj_core, void *data)
{
    uint8_t *ptr;

    ptr = obj_core;
    ptr -= obj_core->type->obj_core_offset;

    printk("%p\n", ptr);

    return 0;
}

void print_object_addresses(void)
{
    struct k_obj_type *obj_type;

    /* Find the object type */

    obj_type = k_obj_type_find(K_OBJ_TYPE_MY_NEW_TYPE);

    /* Walk the list of objects */

    k_obj_type_walk_unlocked(obj_type, walk_op, NULL);
}
```

Object Core Statistics Querying

The following code builds on the examples above and shows how an object integrated into the object core statistics framework can both retrieve queried data and reset the stats associated with the object.

```
struct my_new_obj my_obj;
```

(continues on next page)

(continued from previous page)

```
...

void my_func(void)
{
    struct my_obj_type_query_stats  my_stats;
    int  status;

    my_obj_type_init(&my_obj);

    ...

    status = k_obj_core_stats_query(K_OBJ_CORE(&my_obj),
                                    &my_stats, sizeof(my_stats));
    if (status != 0) {
        /* Failed to get stats */
        ...
    } else {
        k_obj_core_stats_reset(K_OBJ_CORE(&my_obj));
    }

    ...
}
```

3.7.4 Configuration Options

Related configuration options:

3.8 Time Utilities

3.8.1 Overview

Uptime in Zephyr is based on a tick counter. With the default CONFIG_TICKLESS_KERNEL, this counter advances at a nominally constant rate from zero at the instant the system started. The POSIX equivalent to this counter is something like CLOCK_MONOTONIC or, in Linux, CLOCK_MONOTONIC_RAW. k_uptime_get() provides a millisecond representation of this time.

Applications often need to correlate the Zephyr internal time with external time scales used in daily life, such as local time or Coordinated Universal Time. These systems interpret time in different ways and may have discontinuities due to leap seconds and local time offsets like daylight saving time.

Because of these discontinuities, as well as significant inaccuracies in the clocks underlying the cycle counter, the offset between time estimated from the Zephyr clock and the actual time in a "real" civil time scale is not constant and can vary widely over the runtime of a Zephyr application.

The time utilities API supports:

- *converting between time representations*
- *synchronizing and aligning time scales*
- *comparing, adding, and subtracting representations*

For terminology and concepts that support these functions see *Concepts Underlying Time Support in Zephyr*.

3.8.2 Time Utility APIs

Representation Transformation

Time scale instants can be represented in multiple ways including:

- Seconds since an epoch. POSIX representations of time in this form include `time_t` and `struct timespec`, which are generally interpreted as a representation of "UNIX Time" (see **RFC 8536 Section 2**).
- Calendar time as a year, month, day, hour, minutes, and seconds relative to an epoch. POSIX representations of time in this form include `struct tm`.

Keep in mind that these are simply time representations that must be interpreted relative to a time scale which may be local time, UTC, or some other continuous or discontinuous scale.

Some necessary transformations are available in standard C library routines. For example, `time_t` measuring seconds since the POSIX EPOCH is converted to `struct tm` representing calendar time with gmtime(). Sub-second timestamps like `struct timespec` can also use this to produce the calendar time representation and deal with sub-second offsets separately.

The inverse transformation is not standardized: APIs like `mktime()` expect information about time zones. Zephyr provides this transformation with `timeutil_timegm()` and `timeutil_timegm64()`.

To convert between `struct timespec` and `k_timeout_t` durations, use `timespec_to_timeout()` and `timespec_from_timeout()`.

```
k_timeout_t to;
struct timespec ts;

timespec_from_timeout(K_FOREVER, &ts);
to = timespec_to_timeout(&ts); /* to == K_FOREVER */

timespec_from_timeout(K_MSEC(100), &ts);
to = timespec_to_timeout(&ts); /* to == K_MSEC(100) */
```

Time Representation APIs

Time Scale Synchronization

There are several factors that affect synchronizing time scales:

- The rate of discrete instant representation change. For example, Zephyr uptime is tracked in ticks which advance at events that nominally occur at `CONFIG_SYS_CLOCK_TICKS_PER_SEC` Hertz, while an external time source may provide data in whole or fractional seconds (e.g. microseconds).
- The absolute offset required to align the two scales at a single instant.
- The relative error between observable instants in each scale, required to align multiple instants consistently. For example, a reference clock that's conditioned by a 1-pulse-per-second GPS signal will be much more accurate than a Zephyr system clock driven by a RC oscillator with a +/- 250 ppm error.

Synchronization or alignment between time scales is done with a multi-step process:

- An instant in a time scale is represented by an (unsigned) 64-bit integer, assumed to advance at a fixed nominal rate.
- `timeutil_sync_config` records the nominal rates of a reference time scale/source (e.g. TAI) and a local time source (e.g. `k_uptime_ticks()`).
- `timeutil_sync_instant` records the representation of a single instant in both the reference and local time scales.
- `timeutil_sync_state` provides storage for an initial instant, a recently received second observation, and a skew that can adjust for relative errors in the actual rate of each time scale.

- `timeutil_sync_ref_from_local()` and `timeutil_sync_local_from_ref()` convert instants in one time scale to another taking into account skew that can be estimated from the two instances stored in the state structure by `timeutil_sync_estimate_skew()`.

Time Synchronization APIs

`timespec` Manipulation

Checking the validity of a `timespec` can be done with `timespec_is_valid()`.

```
struct timespec ts = {
    .tv_sec = 0,
    .tv_nsec = -1, /* out of range! */
};

if (!timespec_is_valid(&ts)) {
    /* error-handing code */
}
```

In some cases, invalid `timespec` objects may be re-normalized using `timespec_normalize()`.

```
if (!timespec_normalize(&ts)) {
    /* error-handling code */
}

/* ts should be normalized */
__ASSERT(timespec_is_valid(&ts) == true, "expected normalized timespec");
```

It is possible to compare two `timespec` objects for equality using `timespec_equal()`.

```
if (timespec_equal(then, now)) {
    /* time is up! */
}
```

It is possible to compare and fully order (valid) `timespec` objects using `timespec_compare()`.

```
int cmp = timespec_compare(a, b);

switch (cmp) {
case 0:
    /* a == b */
    break;
case -1:
    /* a < b */
    break;
case +1:
    /* a > b */
    break;
}
```

It is possible to add, subtract, and negate `timespec` objects using `timespec_add()`, `timespec_sub()`, and `timespec_negate()`, respectively. Like `timespec_normalize()`, these functions will output a normalized `timespec` when doing so would not result in overflow. On success, these functions return `true`. If overflow would occur, the functions return `false`.

```
/* a += b */
if (!timespec_add(&a, &b)) {
    /* overflow */
}
```

(continues on next page)

(continued from previous page)

```
/* a -= b */
if (!timespec_sub(&a, &b)) {
    /* overflow */
}

/* a = -a */
if (!timespec_negate(&a)) {
    /* overflow */
}
```

Timespec Utility APIs

3.8.3 Concepts Underlying Time Support in Zephyr

Terms from ISO/TC 154/WG 5 N0038 (ISO/WD 8601-1) and elsewhere:

- A *time axis* is a representation of time as an ordered sequence of instants.
- A *time scale* is a way of representing an instant relative to an origin that serves as the epoch.
- A time scale is *monotonic* (increasing) if the representation of successive time instants never decreases in value.
- A time scale is *continuous* if the representation has no abrupt changes in value, e.g. jumping forward or back when going between successive instants.
- Civil time generally refers to time scales that legally defined by civil authorities, like local governments, often to align local midnight to solar time.

Relevant Time Scales

International Atomic Time (TAI) is a time scale based on averaging clocks that count in SI seconds. TAI is a monotonic and continuous time scale.

Universal Time (UT) is a time scale based on Earth's rotation. UT is a discontinuous time scale as it requires occasional adjustments (leap seconds) to maintain alignment to changes in Earth's rotation. Thus the difference between TAI and UT varies over time. There are several variants of UT, with UTC being the most common.

UT times are independent of location. UT is the basis for Standard Time (or "local time") which is the time at a particular location. Standard time has a fixed offset from UT at any given instant, primarily influenced by longitude, but the offset may be adjusted ("daylight saving time") to align standard time to the local solar time. In a sense local time is "more discontinuous" than UT.

POSIX Time (see **RFC 8536 Section 2**) is a time scale that counts seconds since the "POSIX epoch" at 1970-01-01T00:00:00Z (i.e. the start of 1970 UTC). UNIX Time is an extension of POSIX time using negative values to represent times before the POSIX epoch. Both of these scales assume that every day has exactly 86400 seconds. In normal use instants in these scales correspond to times in the UTC scale, so they inherit the discontinuity.

The continuous analogue is UNIX Leap Time which is UNIX time plus all leap-second corrections added after the POSIX epoch (when TAI-UTC was 8 s).

Example of Time Scale Differences A positive leap second was introduced at the end of 2016, increasing the difference between TAI and UTC from 36 seconds to 37 seconds. There was no leap second introduced at the end of 1999, when the difference between TAI and UTC was only 32 seconds. The following table shows relevant civil and epoch times in several scales:

UTC Date	UNIX time	TAI Date	TAI-UTC	UNIX Leap Time
1970-01-01T00:00:00Z	0	1970-01-01T00:00:08	+8	0
1999-12-31T23:59:28Z	946684768	2000-01-01T00:00:00	+32	946684792
1999-12-31T23:59:59Z	946684799	2000-01-01T00:00:31	+32	946684823
2000-01-01T00:00:00Z	946684800	2000-01-01T00:00:32	+32	946684824
2016-12-31T23:59:59Z	1483228799	2017-01-01T00:00:35	+36	1483228827
2016-12-31T23:59:60Z	undefined	2017-01-01T00:00:36	+36	1483228828
2017-01-01T00:00:00Z	1483228800	2017-01-01T00:00:37	+37	1483228829

Functional Requirements The Zephyr tick counter has no concept of leap seconds or standard time offsets and is a continuous time scale. However it can be relatively inaccurate, with drifts as much as three minutes per hour (assuming an RC timer with 5% tolerance).

There are two stages required to support conversion between Zephyr time and common human time scales:

- Translation between the continuous but inaccurate Zephyr time scale and an accurate external stable time scale;
- Translation between the stable time scale and the (possibly discontinuous) civil time scale.

The API around `timeutil_sync_state_update()` supports the first step of converting between continuous time scales.

The second step requires external information including schedules of leap seconds and local time offset changes. This may be best provided by an external library, and is not currently part of the time utility APIs.

Selecting an External Source and Time Scale If an application requires civil time accuracy within several seconds then UTC could be used as the stable time source. However, if the external source adjusts to a leap second there will be a discontinuity: the elapsed time between two observations taken at 1 Hz is not equal to the numeric difference between their timestamps.

For precise activities a continuous scale that is independent of local and solar adjustments simplifies things considerably. Suitable continuous scales include:

- GPS time: epoch of 1980-01-06T00:00:00Z, continuous following TAI with an offset of TAI-GPS=19 s.
- Bluetooth Mesh time: epoch of 2000-01-01T00:00:00Z, continuous following TAI with an offset of -32.
- UNIX Leap Time: epoch of 1970-01-01T00:00:00Z, continuous following TAI with an offset of -8.

Because C and Zephyr library functions support conversion between integral and calendar time representations using the UNIX epoch, UNIX Leap Time is an ideal choice for the external time scale.

The mechanism used to populate synchronization points is not relevant: it may involve reading from a local high-precision RTC peripheral, exchanging packets over a network using a protocol like NTP or PTP, or processing NMEA messages received a GPS with or without a 1pps signal.

`timespec` Concepts

Originally from POSIX, `struct timespec` has been a part of the C standard since C11. The definition of `struct timespec` is as shown below.

```
struct timespec {
    time_t tv_sec;  /* seconds */
    long   tv_nsec; /* nanoseconds */
};
```

The `tv_nsec` field is only valid with values in the range `[0, 999999999]`. The `tv_sec` field is the number of seconds since the epoch. If `struct timespec` is used to express a difference, the `tv_sec` field may fall into a negative range.

3.9 Precision Timing

The precision timing subsystem provides a small set of reusable mechanisms for PTP, gPTP, and other users that control high-resolution clocks. Enable it with `CONFIG_PRECISION_TIMING`.

Note

The API is at *experimental* maturity and may still change. A protocol does not change maturity by using this subsystem.

The subsystem deliberately does not implement synchronization policy. PTP and gPTP continue to own their protocol state machines, clock selection, step thresholds, sample acceptance, lock detection, source-loss handling, and diagnostics.

3.9.1 Precision time

`precision_time_t` is a signed 64-bit nanosecond value. Checked addition and subtraction helpers report overflow. The type does not identify a time domain or timescale; modelling TAI, UTC, PHCs, monotonic time, and protocol relationships is outside this API.

3.9.2 Precision clock

`precision_clock` dispatches four mandatory clock operations:

- read the current time;
- set an absolute time;
- apply a phase adjustment; and
- set a rate offset from the nominal frequency as parts per million with a 16-bit binary fractional field.

All operations must be implemented by a clock adapter. Adjustment ranges and other hardware constraints remain the responsibility of the underlying clock implementation.

`precision_clock_ptp_adapter` exposes an existing Zephyr PTP clock device through this interface. It performs the required conversion between `net_ptp_time` and `precision_time_t`; it does not add capability discovery or synchronization state.

3.9.3 PI controller

`precision_pi` is an instance-based proportional-integral controller. Each instance stores its own gains and integral term. For every error sample, the update is equivalent to:

```
integral += ki * error;
output = kp * error + integral;
```

The controller does not decide whether an error should be stepped, rejected, or used for rate adjustment. It also does not track synchronization, acquisition, lock, holdover, source timeout, or clock faults. Callers own those decisions and reset the accumulated integral term when their policy requires it.

The PTP and gPTP integrations initialize their controllers from `CONFIG_PRECISION_TIMING_PI_KP` and `CONFIG_PRECISION_TIMING_PI_KI`. The integer values express the gains in thousandths. Direct users of `precision_pi_init()` may provide different gains for each controller instance.

3.9.4 Protocol integration

PTP and the gPTP default clock-update path each keep their existing policy and use a `precision_pi` for the shared calculation. They initialize a PTP-clock adapter once and use `precision_clock` operations to access the PHC.

3.9.5 Sample

The precision_timing sample demonstrates checked time arithmetic, a software-backed precision clock, and PI-driven rate adjustment.

3.10 Utilities

This page contains reference documentation for `<sys/util.h>`, which provides miscellaneous utility functions and macros.

Utility Functions

3.11 Iterable Sections

This page contains the reference documentation for the iterable sections APIs, which can be used for defining iterable areas of equally-sized data structures, that can be iterated on using `STRUCT_SECTION_FOREACH`.

3.11.1 Overview

An iterable section is a group of statically-defined instances of the same struct that the linker places into a single contiguous output section. The runtime can then iterate over all instances without having to maintain an explicit list.

Zephyr currently supports two linker-script pipelines: a template-based one that consumes `.ld` scripts registered via `zephyr_linker_sources()`, and a CMake generated one that consumes `zephyr_iterable_section()` calls. To work on all supported toolchains, a new iterable must currently be declared in both.

When `CONFIG_CMAKE_LINKER_GENERATOR=y`, the output sections for iterable sections are emitted from the `zephyr_iterable_section()` calls. Any `ITERABLE_SECTION_RAM/ROM` definitions in `.ld` snippets registered via `zephyr_linker_sources()` are ignored. When `CONFIG_CMAKE_LINKER_GENERATOR=n`, the reverse holds true: `zephyr_iterable_section()` calls are not consumed and the `.ld` scripts provide the section definitions.

Because upstream Zephyr must build under both configurations, a new iterable section must be declared in both places.

To create an iterable section requires three pieces that must agree on the struct name and RAM vs. ROM placement:

1. **C code**: defines the struct and instantiates entries using `STRUCT_SECTION_ITERABLE` (or its `const` variant for ROM).
2. **Linker placement**: declared in one of two ways (*both required upstream*):
   - **CMake**: `zephyr_iterable_section()` consumed by the CMake-generated pipeline.
   - **Linker script**: `ITERABLE_SECTION_RAM/ROM` registered with `zephyr_linker_sources()` consumed by the template-based pipeline.

3.11.2 Step 1: Define the data in C

Define the struct in a common header and provide a helper macro that instantiates entries with `STRUCT_SECTION_ITERABLE`:

```
struct my_data {
        int a, b;
};

#define DEFINE_DATA(name, _a, _b) \
        STRUCT_SECTION_ITERABLE(my_data, name) = { \
                .a = _a, \
                .b = _b, \
        }

...

DEFINE_DATA(d1, 1, 2);
DEFINE_DATA(d2, 3, 4);
DEFINE_DATA(d3, 5, 6);
```

For ROM-resident iterables, the instances must be declared `const` so the compiler emits them into a read-only input section. The C declaration and the CMake placement (see Step 2) must agree on RAM vs. ROM placement.

3.11.3 Step 2: Declare the section in CMake

The `NAME` argument to `zephyr_iterable_section()` must match the struct name passed to `STRUCT_SECTION_ITERABLE`. The `GROUP` argument selects the linker group that the resulting output section is placed inside.

RAM-resident example:

```
# CMakeLists.txt
zephyr_iterable_section(NAME my_data GROUP DATA_REGION ${XIP_ALIGN_WITH_INPUT})
```

ROM-resident example (instances declared `const` in C):

```
# CMakeLists.txt
zephyr_iterable_section(NAME my_data GROUP RODATA_REGION)
```

See `zephyr_iterable_section()` in `cmake/modules/extensions.cmake` for the full argument list and a more detailed explanation of the available `GROUP` options.

3.11.4 Step 3: Provide a linker-script

The linker script uses `ITERABLE_SECTION_RAM` or `ITERABLE_SECTION_ROM` to emit the actual section.

RAM-resident:

```
/* sections-ram.ld */
#include <zephyr/linker/iterable_sections.h>

ITERABLE_SECTION_RAM(my_data, Z_LINK_ITERABLE_SUBALIGN)
```

ROM-resident:

```
/* sections-rom.ld */
#include <zephyr/linker/iterable_sections.h>

ITERABLE_SECTION_ROM(my_data, Z_LINK_ITERABLE_SUBALIGN)
```

Register the linker-script from `CMakeLists.txt`:

```
zephyr_linker_sources(<location> <path-to-ld-file>)
```

See `zephyr_linker_sources()` in `cmake/modules/extensions.cmake` for the full argument list and a more detailed explanation of the available `<location>` options.

3.11.5 Iterating over the entries

Once the section is in place, iterate over its entries with `STRUCT_SECTION_FOREACH`:

```
STRUCT_SECTION_FOREACH(my_data, data) {
        printk("%p: a: %d, b: %d\n", data, data->a, data->b);
}
```

Note

The linker is going to place the entries sorted by name, so the example above would visit `d1`, `d2` and `d3` in that order, regardless of how they were defined in the code.

3.11.6 API Reference

Iterable Sections APIs

3.12 Code And Data Relocation

3.12.1 Overview

This feature will allow relocating .text, .rodata, .data, and .bss sections from required files and place them in the required memory region. The memory region and file are given to the *scripts/build/gen_relocate_app.py* script in the form of a string. This script is always invoked from inside cmake.

This script provides a robust way to re-order the memory contents without actually having to modify the code. In simple terms this script will do the job of `__attribute__((section("name")))` for a bunch of files together.

A regular expression filter can be used to select only the required sections to be relocated.

3.12.2 Details

The memory region and file are given to the *scripts/build/gen_relocate_app.py* script through a file where each line specifies a list of files to be placed in the given region.

An example of such a file is:

```
SRAM2:/home/xyz/zephyr/samples/hello_world/src/main.c,
SRAM1:/home/xyz/zephyr/samples/hello_world/src/main2.c,
```

This script is invoked with the following parameters: `python3 gen_relocate_app.py -i input_file -o generated_linker -c generated_code`

Kconfig `CONFIG_CODE_DATA_RELOCATION` option, when enabled in `prj.conf`, will invoke the script and do the required relocation.

This script also trigger the generation of `linker_relocate.ld` and `code_relocation.c` files. The `linker_relocate.ld` file creates appropriate sections and links the required functions or variables from all the selected files.

Note

The text section is split into 2 parts in the main linker script. The first section will have some info regarding vector tables and other debug related info. The second section will have the complete text section. This is needed to force the required functions and data variables to the correct locations. This is due to the behavior of the linker. The linker will only link once and hence this text section had to be split to make room for the generated linker script.

The `code_relocation.c` file has code that is needed for initializing data sections, and a copy of the text sections (if XIP). Also this contains code needed for bss zeroing and for data copy operations from ROM to required memory type.

The procedure to invoke this feature is:

- Enable CONFIG_CODE_DATA_RELOCATION in the prj.conf file
- Inside the CMakeLists.txt file in the project, mention all the files that need relocation.

  zephyr_code_relocate(FILES src/main.c LOCATION SRAM2)

  Where the first argument is the file/files and the second argument is the memory where it must be placed.

> **Note**
>
> function zephyr_code_relocate() can be called as many times as required.

Additional Configurations

This section shows additional configuration options that can be set in CMakeLists.txt.

- If the memory is SRAM1, SRAM2, CCD, or AON, then place the full object in the sections. For example:

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2)
zephyr_code_relocate(FILES src/file2.c LOCATION SRAM1)
```

- If the memory type is appended with _DATA, _TEXT, _RODATA, _BSS or _NOINIT, only the selected memory is placed in the required memory region. For example:

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_DATA)
zephyr_code_relocate(FILES src/file2.c LOCATION SRAM2_TEXT)
```

- Multiple regions can also be appended together such as: SRAM2_DATA_BSS_NOINIT. This will place all data: value-initialized, zero-initialized and uninitialized inside SRAM2.
- Multiple files can be passed to the FILES argument, or CMake generator expressions can be used to relocate a comma-separated list of files.

```
file(GLOB sources "file*.c")
zephyr_code_relocate(FILES ${sources} LOCATION SRAM2)
zephyr_code_relocate(FILES $<TARGET_PROPERTY:my_tgt,SOURCES> LOCATION SRAM2)
```

Section Filtering

By default, all sections of the specified files will be relocated. If FILTER is used, a regular expression is provided to select only the sections to be relocated.

The regular expression applies to sections names which can be used to select the file's symbols when this one has been built with -ffunction-sections and -fdata-sections which is the case by default.

```
zephyr_code_relocate(FILES src/file1.c FILTER ".*\\.func1|.*\\.func2"␣
↪LOCATION SRAM2_TEXT)
```

The example above will only relocate func1() and func2() of file src/file1.c

NOKEEP flag

By default, all relocated functions and variables will be marked with KEEP() when generating linker_relocate.ld. Therefore, if any input file happens to contain unused symbols, then they will not be discarded by the linker, even when it is invoked with --gc-sections. If you'd like to override this behavior, you can pass NOKEEP to your zephyr_code_relocate() call.

```
zephyr_code_relocate(FILES src/file1.c LOCATION SRAM2_TEXT NOKEEP)
```

The example above will help ensure that any unused code found in the .text sections of `file1.c` will not stick to SRAM2.

NOCOPY flag

When a `NOCOPY` option is passed to the `zephyr_code_relocate()` function, the relocation code is not generated in `code_relocation.c`. This flag can be used when we want to move the content of a specific file (or set of files) to a XIP area.

This example will place the .text section of the `xip_external_flash.c` file to the `EXTFLASH` memory region where it will be executed from (XIP). The .data will be relocated as usual into SRAM.

```
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION␣
↪EXTFLASH_TEXT NOCOPY)
zephyr_code_relocate(FILES src/xip_external_flash.c LOCATION SRAM_DATA)
```

Relocating libraries

Libraries can be relocated using the LIBRARY argument to `zephyr_code_relocation()` with the library name. For example, the following snippet will relocate serial drivers to SRAM2:

```
zephyr_code_relocate(LIBRARY drivers__serial LOCATION SRAM2)
```

Tips

Take care if relocating kernel/arch files, some contain early initialization code that executes before code relocation takes place.

Additional MPU/MMU configuration may be required to ensure that the destination memory region is configured to allow code execution.

Samples/ Tests

A test showcasing this feature is provided at `$ZEPHYR_BASE/tests/application_development/code_relocation`

This test shows how the code relocation feature is used.

This test will place .text, .data, .bss from 3 files to various parts in the SRAM using a custom linker file derived from `include/zephyr/arch/arm/cortex_m/scripts/linker.ld`

A sample showcasing the NOCOPY flag is provided here: code_relocation_nocopy.

3.13 Scope-based Cleanup Helpers

- *Overview*
- *Core Concepts*
  - *Scoped Variables*
  - *Scoped Guards*
  - *Scoped Defers*
- *Defining Scoped Types*

- *Custom Scoped Variables*
- *Scoped Guards*
- *Block-Scoped Guards*
- *Conditional Guards*
- *Scoped Defers*

- *Usage Notes*
  - *Order of Cleanup*
  - *Scope Rules*
- *API Reference*

3.13.1 Overview

The Cleanup Helper API provides a mechanism for automatic resource cleanup when variables go out of scope. This is similar to RAII in C++ or defer statements in Go. By leveraging compiler support for the `__cleanup` attribute, this API helps prevent resource leaks and simplifies error handling by ensuring cleanup code is executed automatically.

It is required to set `CONFIG_SCOPE_CLEANUP_HELPERS` to enable this feature, which is particularly useful for:

- Automatic unlocking of mutexes and semaphores
- Automatic freeing of dynamically allocated memory
- Ensuring cleanup actions occur on all code paths (including early returns)
- Reducing boilerplate cleanup code

Warning

The cleanup mechanism is implemented using the `__cleanup` attribute. If the toolchain doesn't support this attribute, the API is not available.

For this reason this API is intended solely for user applications and not for the kernel itself or other subsystems.

3.13.2 Core Concepts

The cleanup API provides three main abstractions:

Scoped Variables

A scoped variable defines a type with automatic init and exit behavior. Variables declared with a scoped variable type are initialized using an init function and automatically cleaned up using an exit function when they go out of scope.

Scoped Guards

Scoped guards are specialized scoped variables that automatically acquire a lock or resource on initialization and release it when going out of scope. This pattern is commonly used with mutexes, semaphores, and other synchronization primitives.

Scoped Defers

Scoped defers execute a specified function when the variable goes out of scope, without acquiring anything on initialization. This is similar to the `defer` statement in languages like Go.

3.13.3 Defining Scoped Types

Custom Scoped Variables

Use `SCOPE_VAR_DEFINE` to define a custom scoped variable type with init and exit functions:

```
static inline struct flash_area *flash_area_init(int area_id)
{
    struct flash_area *fa;

    if (flash_area_open(area_id, &fa) < 0) {
        return NULL;
    }

    return fa;
}

static inline void flash_area_exit(struct flash_area *fa)
{
    if (fa != NULL) {
        flash_area_close(fa);
    }
}

// Define the scoped variable type
SCOPE_VAR_DEFINE(flash_area, struct flash_area *, flash_area_exit(_T),
                 flash_area_init(area_id), int area_id);

static int some_function(void)
{
    // Declare 'fa' with automatic cleanup
    scope_var(flash_area, fa)(PARTITION_ID(storage_partition));
    if (fa == NULL) {
        return -EINVAL;  // Exit function is still called
    }

    // Use fa normally
    printk("Has driver: %d\n", flash_area_has_driver(fa));

    // No need to manually close - exit function is called automatically
    return 0;
}
```

The `_T` variable in the exit function expression contains the value of the variable being cleaned up.

Scoped Guards

Use `SCOPE_GUARD_DEFINE` to define a guard that acquires a lock on initialization and releases it on scope exit:

```
// Example guard definition (already provided by <zephyr/cleanup/kernel.h>)
SCOPE_GUARD_DEFINE(k_mutex, struct k_mutex *,
```

(continues on next page)

(continued from previous page)

```
                    (void)k_mutex_lock(_T, K_FOREVER),
                    (void)k_mutex_unlock(_T));

static K_MUTEX_DEFINE(lock);

void critical_section(void)
{
    scope_guard(k_mutex)(&lock);

    // Lock is held here
    // Perform critical operations

    // Lock is automatically released when guard goes out of scope
}
```

Block-Scoped Guards

While `scope_guard` holds a guard until the end of the *enclosing* scope, `scoped_guard` binds the guard to the brace block that immediately follows, releasing it as soon as that block is exited. This makes short critical sections explicit and keeps the lock object next to the code it protects:

```
static K_MUTEX_DEFINE(lock);

void worker(void)
{
    // ... work that does not need the lock ...

    scoped_guard(k_mutex, &lock) {
        // lock held only inside these braces
    }
    // lock released here

    // ... more work without the lock held ...
}
```

The block runs exactly once. The lock is released on any exit from the block, including `break`, `return` and `goto`. Note that `continue` leaves the block (it behaves like `break`) rather than re-running it.

Conditional Guards

Guards defined with `SCOPE_GUARD_DEFINE` always acquire the lock (they block with `K_FOREVER`). To express a guard whose acquisition may fail (for example a non-blocking `K_NO_WAIT` try-lock), use `SCOPE_COND_GUARD_DEFINE` together with `scoped_cond_guard`. The acquire expression is evaluated for success: on failure the guard stores `NULL`, the supplied fail statement runs, and the block is skipped.

```
// Example guard definition (already provided by <zephyr/cleanup/kernel.h>)
SCOPE_COND_GUARD_DEFINE(k_mutex_try, struct k_mutex *,
                        k_mutex_lock(_T, K_NO_WAIT) == 0,
                        (void)k_mutex_unlock(_T));

static K_MUTEX_DEFINE(lock);

int try_critical_section(void)
{
```

(continues on next page)

(continued from previous page)

```
    scoped_cond_guard(k_mutex_try, return -EBUSY, &lock) {
        // runs only if the lock was acquired
        // released automatically when the block is exited
    }

    return 0;
}
```

The fail statement can be any statement, such as `break`, `return -EBUSY`, or `{}` to silently skip the block.

Scoped Defers

Use `SCOPE_DEFER_DEFINE` to define a defer that executes a cleanup function:

```
// Define a defer for a custom cleanup function
static void cleanup_resources(void)
{
    // Cleanup code here
}

SCOPE_DEFER_DEFINE(cleanup_resources);

void some_function(void)
{
    scope_defer(cleanup_resources)();

    // Do work...

    // cleanup_resources() is called automatically
}
```

For functions with parameters:

```
// Example deferred k_free (already provided by <zephyr/cleanup/kernel.h>)
SCOPE_DEFER_DEFINE(k_free, void *);

void allocate_and_use(void)
{
    void *ptr = k_malloc(100);
    scope_defer(k_free)(ptr);

    // Use ptr...

    // k_free(ptr) is called automatically
}
```

3.13.4 Usage Notes

Order of Cleanup

Cleanup functions are called in reverse order of declaration (LIFO - Last In, First Out), which matches the natural nesting of resources:

```
{
    scope_guard(k_mutex)(&lock);          // Acquired first
```

(continues on next page)

(continued from previous page)

```
    void *ptr = k_malloc(100);
    scope_defer(k_free)(ptr);              // Registered second

    // Do work...

}  // ptr is freed first, then mutex is unlocked
```

Scope Rules

Cleanup occurs when the variable goes out of scope, which includes:

- Reaching the end of a block
- Early return statements
- Break or continue in loops
- Goto statements that jump out of scope

```
void example_with_early_exit(struct k_mutex *lock)
{
    scope_guard(k_mutex)(lock);

    if (error_condition) {
        return;  // Guard cleanup happens here
    }

    // Normal path

}  // Guard cleanup also happens here
```

3.13.5 API Reference

Cleanup Helper Interface

Chapter 4

Services

Zephyr provides a comprehensive set of subsystems and associated services that applications can leverage. These services expose standardized APIs that abstract away hardware implementation details, making applications portable across different platforms.

Connectivity

4.1 Connectivity

4.1.1 Networking

The networking section contains information regarding the network stack of the Zephyr kernel. Use the information to understand the principles behind the operation of the stacks and how they were implemented.

Overview

- *Supported Features*
- *Source Tree Layout*

Supported Features The networking IP stack is modular and highly configurable via build-time configuration options. You can minimize system memory consumption by enabling only those network features required by your application. Almost all features can be disabled if not needed.

- **IPv6** (RFC 8200) is supported. Various IPv6 sub-options can be enabled or disabled depending on networking needs.
  - Developer can set the number of unicast and multicast IPv6 addresses that are active at the same time.
  - The IPv6 address for the device can be set either statically or dynamically using SLAAC (Stateless Address Auto Configuration, RFC 4862).
  - The system also supports multiple IPv6 prefixes and the maximum IPv6 prefix count can be configured at build time.
  - The IPv6 neighbor cache can be disabled if not needed, and its size can be configured at build time.
  - The IPv6 neighbor discovery support (RFC 4861) is enabled by default.

  - Multicast Listener Discovery v2 support (**RFC 3810**) is enabled by default.
  - IPv6 header compression (6lo) is available for IPv6 connectivity for IEEE 802.15.4 networks (**RFC 4944**).
  - DHCPv6 (Dynamic Host Configuration Protocol for IPv6) (**RFC 8415**) client functionality is supported.
  - The IPv6 privacy extension (**RFC 8981**) is supported.

- **IPv4** (**RFC 791**) is supported. It cannot be used by IEEE 802.15.4 as this network technology supports only IPv6. IPv4 can be used for example in Ethernet, Wi-Fi and Cellular based networks.
  - DHCP (Dynamic Host Configuration Protocol) client and server is supported (**RFC 2131**).
  - The IPv4 address can also be configured manually. Static IPv4 addresses are supported by default.
  - IPv4 NAT (Network Address Translation) is supported. Packets can hop between interfaces by performing SNAT and DNAT. Connection tracking and iptable rules are used to filter and forward packets across subnets.
- **Dual stack support.** The networking stack allows a developer to configure the system to use both IPv6 and IPv4 at the same time.
- **UDP** User Datagram Protocol (**RFC 768**) is supported. The developer can send UDP datagrams (client side support) or create a listener to receive UDP packets destined to certain port (server side support).
- **TCP** Transmission Control Protocol (**RFC 793**) is supported. Both server and client roles can be used the application. The amount of TCP sockets that are available to applications can be configured at build time. Selective acknowledgment (**RFC 2018**) is supported for received data (`CONFIG_NET_TCP_SACK`).
- **BSD Sockets API** Support for a subset of a *BSD sockets compatible API* is implemented. Both blocking and non-blocking datagram (UDP) and stream (TCP) sockets are supported. Packet sockets (`AF_PACKET`) are also supported.
- **Secure Sockets API** Experimental support for TLS/DTLS secure protocols and configuration options for sockets API. Secure functions for the implementation are provided by Mbed TLS library.
- **MQTT** Message Queue Telemetry Transport (ISO/IEC PRF 20922) versions 3.1.1 and 5.0 are supported. A sample mqtt-publisher client application for MQTT v3.1.1 and v5.0 is provided.
- **MQTT-SN** MQTT for Sensor Networks version 1.2 is supported. A sample mqtt-sn-publisher client application is provided.
- **CoAP** Constrained Application Protocol (**RFC 7252**) is supported. Both coap-client and coap-server sample applications are provided.
- **LwM2M** OMA Lightweight Machine-to-Machine Protocol (LwM2M specification 1.0.2) is supported via the “Bootstrap”, “Client Registration”, “Device Management & Service Enablement” and “Information Reporting” interfaces. The required core LwM2M objects are implemented as well as several IPSO Smart Objects. (LwM2M specification 1.1.1) is supported in similar manner when enabled with a Kconfig option. lwm2m-client sample implements the library as an example.
- **HTTP** Hypertext Transfer Protocol client and server are supported. *HTTP Client* library supports HTTP/1.1 (**RFC 2616**). *HTTP Server* library supports HTTP/1.1 (**RFC 2616**) and HTTP/2 (**RFC 9113**). sockets-http-client and sockets-http-server samples are provided.
- **Websocket** (**RFC 6455**) client is supported. sockets-websocket-client sample is provided.

- **DNS** Domain Name Service (RFC 1035) client functionality is supported. Applications can use the DNS API to query domain name information or IP addresses from the DNS server. Both IPv4 (A) and IPv6 (AAAA) records can be queried. Both multicast DNS (mDNS) (RFC 6762) and link-local multicast name resolution (LLMNR, RFC 4795) are supported. The DNS Service Discovery (RFC 6763) is also supported.
- **Network Management API.** Applications can use network management API to listen management events generated by core network stack when for example IP address is added to the device, or network interface is coming up etc.
- **Wi-Fi Management API.** Applications can use Wi-Fi management API to manage the interface, in example to connect to Wi-Fi network and to scan available Wi-Fi networks.
- **Wi-Fi Network Manager API.** Wi-Fi Network Managers can now register themselves to the Wi-Fi stack. The Network Managers can then implement the Wi-Fi Management API and manage the Wi-Fi interface.
- **Multiple Network Technologies.** The Zephyr OS can be configured to support multiple network technologies at the same time simply by enabling them in Kconfig: for example, Ethernet, Wi-Fi and 802.15.4 support. Note that no automatic IP routing functionality is provided between these technologies. Applications can send data according to their needs to desired network interface.
- **Minimal Copy Network Buffer Management.** It is possible to have minimal copy network data path. This means that the system tries to avoid copying application data when it is sent to the network.
- **Virtual LAN support.** Virtual LANs (VLANs) allow partitioning of physical ethernet networks into logical networks. See *VLAN support* for more details.
- **Network traffic classification.** The sent and received network packets can be prioritized depending on application needs. See *traffic classification* for more details.
- **Time Sensitive Networking.** Both the gPTP (generalized Precision Time Protocol) and PTP (Precision Time Protocol, IEEE 1588) are supported. See *gPTP support* and *PTP support* for more details.
- **SNTP** Simple Network Time Protocol (RFC 5905) client is supported. sntp-client sample is provided.
- **SOCKS5** proxy version 5 (RFC 1928) is supported.
- **TFTP** Trivial File Transfer Protocol (RFC 1350) client is supported. tftp-client sample is provided.
- **MIDI2** MIDI 2.0 network UDP transport is supported. netmidi2 sample is provided.
- **OCPP** Open Charge Point Protocol is supported. ocpp sample is provided.
- **Prometheus** Metric Server functionality is supported. prometheus is provided.
- **Network shell.** The network shell provides helpers for figuring out network status, enabling/disabling features, and issuing commands like ping or DNS resolving. The net-shell is useful when developing network software. See *network shell* for more details.
- **zperf** is an iPerf v2 network performance and bandwidth measurement tool. Both client and server functionality is supported. zperf sample is provided.

Additionally these network technologies (link layers) are supported in Zephyr OS:

- IEEE 802.15.4
- Bluetooth
- Ethernet, IEEE 802.3
- Wi-Fi, IEEE 802.11
- Cellular / PPP (RFC 1661)

- Thread (openthread samples are provided)
- CAN bus for SocketCAN
- SLIP (IP over serial line). Used for testing with QEMU. It provides ethernet interface to host system (like Linux) and test applications can be run in Linux host and send network data to Zephyr OS device.

Source Tree Layout The networking stack source code tree is organized as follows:

subsys/net/
Various optional network stack components like connection manager, packet filter code and hostname handling are located here.

subsys/net/ip/
This is where the core network stack code is located.

subsys/net/l2
This is where the IP stack layer 2 code is located. This includes generic support for Ethernet, IEEE 802.15.4 and Wi-Fi.

subsys/net/lib/
Application-level protocols (DNS, MQTT, etc.) and additional stack components (BSD Sockets, etc.).

include/zephyr/net/
Public API header files. These are the header files applications need to include to use IP networking functionality.

samples/net/
Sample networking code. This is a good reference to get started with network application development.

tests/net/
Test applications. These applications are used to verify the functionality of the IP stack, but are not the best source for sample code (see samples/net/ instead).

Network Stack Architecture

Network Packet Processing Statistics This page describes how to get information about network packet processing statistics inside network stack.

Network stack contains infrastructure to figure out how long the network packet processing takes either in sending or receiving path. There are two Kconfig options that control this. For transmit (TX) path the option is called `CONFIG_NET_PKT_TXTIME_STATS` and for receive (RX) path the options is called `CONFIG_NET_PKT_RXTIME_STATS`. Note that for TX, all kind of network packet statistics is collected. For RX, only UDP, TCP or raw packet type network packet statistics is collected.

After enabling these options, the *net stats* network shell command will show this information:

```
Avg TX net_pkt (11484) time 67 us
Avg RX net_pkt (11474) time 43 us
```

Note

The values above and below are from emulated qemu_x86 board and UDP traffic

The TX time tells how long it took for network packet from its creation to when it was sent to the network. The RX time tells the time from its creation to when it was passed to the application. The values are in microseconds. The statistics will be collected per traffic class if there

are more than one transmit or receive queues defined in the system. These are controlled by CONFIG_NET_TC_TX_COUNT and CONFIG_NET_TC_RX_COUNT options.

If you enable CONFIG_NET_PKT_TXTIME_STATS_DETAIL or CONFIG_NET_PKT_RXTIME_STATS_DETAIL options, then additional information for TX or RX network packets are collected when the network packet traverses the IP stack.

After enabling these options, the *net stats* will show this information:

```
Avg TX net_pkt (18902) time 63 us    [0->22->15->23=60 us]
Avg RX net_pkt (18892) time 42 us    [0->9->6->11->13=39 us]
```

The numbers inside the brackets contain information how many microseconds it took for a network packet to go from previous state to next.

In the TX example above, the values are averages over **18902** packets and contain this information:

- Packet was created by application so the time is **0**.
- Packet is about to be placed to transmit queue. The time it took from network packet creation to this state, is **22** microseconds in this example.
- The correct TX thread is invoked, and the packet is read from the transmit queue. It took **15** microseconds from previous state.
- The network packet was just sent and the network stack is about to free the network packet. It took **23** microseconds from previous state.
- In total it took on average **60** microseconds to get the network packet sent. The value **63** tells also the same information, but is calculated differently so there is slight difference because of rounding errors.

In the RX example above, the values are averages over **18892** packets and contain this information:

- Packet was created network device driver so the time is **0**.
- Packet is about to be placed to receive queue. The time it took from network packet creation to this state, is **9** microseconds in this example.
- The correct RX thread is invoked, and the packet is read from the receive queue. It took **6** microseconds from previous state.
- The network packet is then processed and placed to correct socket queue. It took **11** microseconds from previous state.
- The last value tells how long it took from there to the application. Here the value is **13** microseconds.
- In total it took on average **39** microseconds to get the network packet sent. The value **42** tells also the same information, but is calculated differently so there is slight difference because of rounding errors.

The Zephyr network stack is a native network stack specifically designed for Zephyr OS. It consists of layers, each meant to provide certain services to other layers. Network stack functionality is highly configurable via Kconfig options.

- *High level overview of the network stack*
- *Network data flow*
  - *Data receiving (RX)*
  - *Data sending (TX)*

- *Network packet processing statistics*

High level overview of the network stack The network stack is layered and consists of the following parts:

- **Network Application.** The network application can either use the provided application-level protocol libraries or access the *BSD socket API* directly to create a network connection, send or receive data, and close a connection. The application can also use the *network management API* to configure the network and set related parameters such as network link options, starting a scan (when applicable), listen network configuration events, etc. The *network interface API* can be used to set IP address to a network interface, taking the network interface down, etc.
- **Network Protocols.** This provides implementations for various protocols such as
  - Application-level network protocols like CoAP, LwM2M, and MQTT. See *application protocols chapter* for information about them.
  - Core network protocols like IPv6, IPv4, UDP, TCP, ICMPv4, and ICMPv6. You access these protocols by using the *BSD socket API*.
- **Network Interface Abstraction.** This provides functionality that is common in all the network interfaces, such as setting network interface down, etc. There can be multiple network interfaces in the system. See *network interface overview* for more details.
- **L2 Network Technologies.** This provides a common API for sending and receiving data to and from an actual network device. See *L2 overview* for more details.

  These network technologies include *Ethernet*, *IEEE 802.15.4*, *Bluetooth*, *CANBUS*, etc.

  Some of these technologies support IPv6 header compression (6Lo), see **RFC 6282** for details. For example ARP (**RFC 826**) for IPv4 is done by the *Ethernet component*.
- **Network Device Drivers.** The actual low-level device drivers handle the physical sending or receiving of network packets.

Network data flow An application typically consists of one or more *threads* that execute the application logic. When using the *BSD socket API*, the following things will happen.

Data receiving (RX)

1. A network data packet is received by a device driver.
2. The device driver allocates enough network buffers to store the received data. The network packet is placed in the proper RX queue (implemented by *k_fifo*). By default there is only one receive queue in the system, but it is possible to have up to 8 receive queues. These queues will process incoming packets with different priority. See *Traffic Classification* for more details. The receive queues also act as a way to separate the data processing pipeline (bottom-half) as the device driver is running in an interrupt context and it must do its processing as fast as possible.
3. The network packet is then passed to the correct L2 driver. The L2 driver can check if the packet is proper and modify it if needed, e.g. strip L2 header and frame check sequence, etc.
4. The packet is processed by a network interface. The network statistics are collected if enabled by `CONFIG_NET_STATISTICS`.
5. The packet is then passed to L3 processing. If the packet is IP based, then the L3 layer checks if the packet is a proper IPv6 or IPv4 packet.

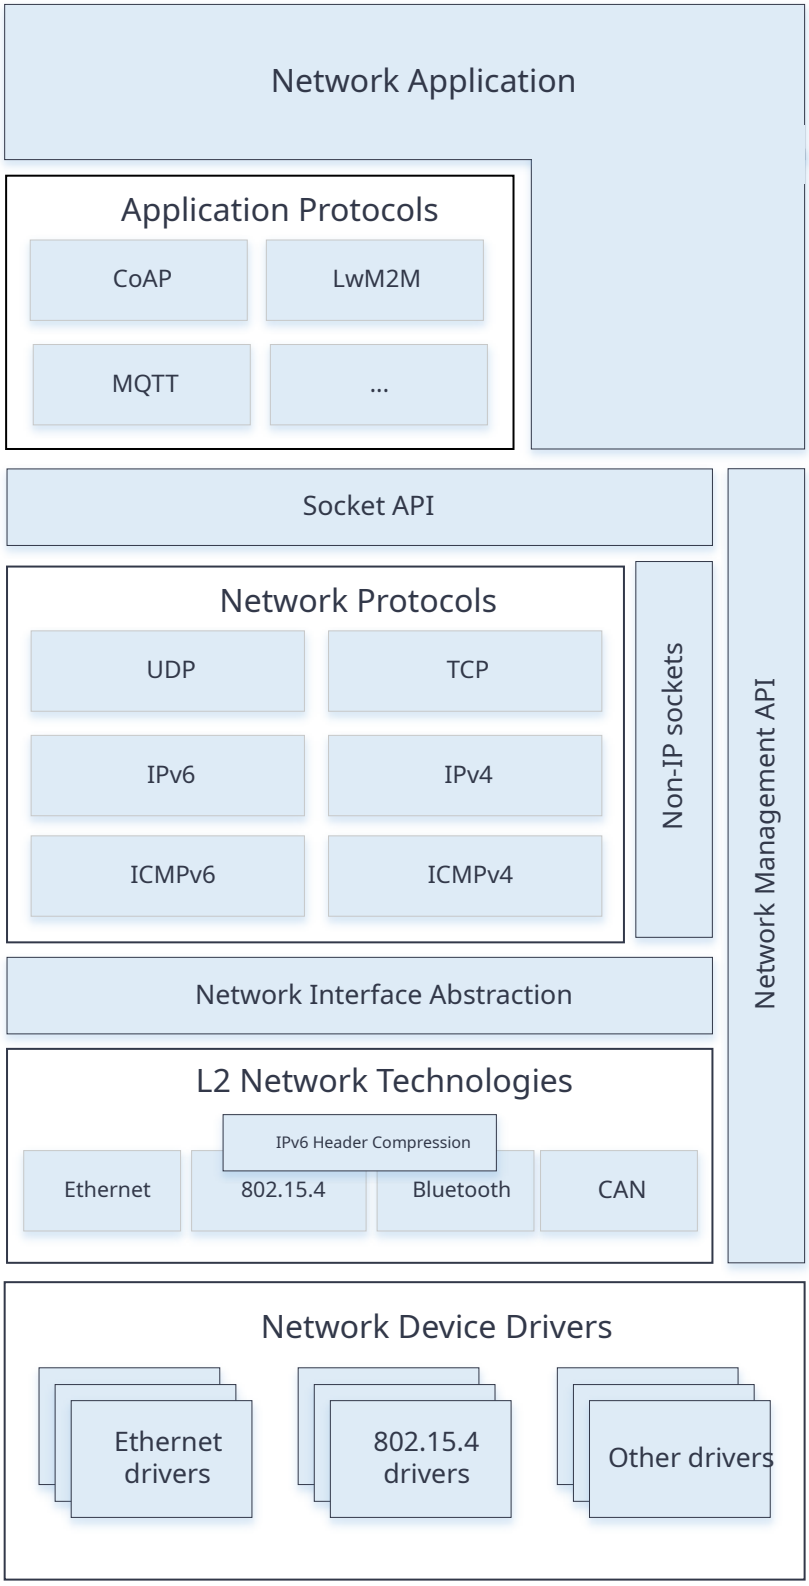

Fig. 1: Network stack overview

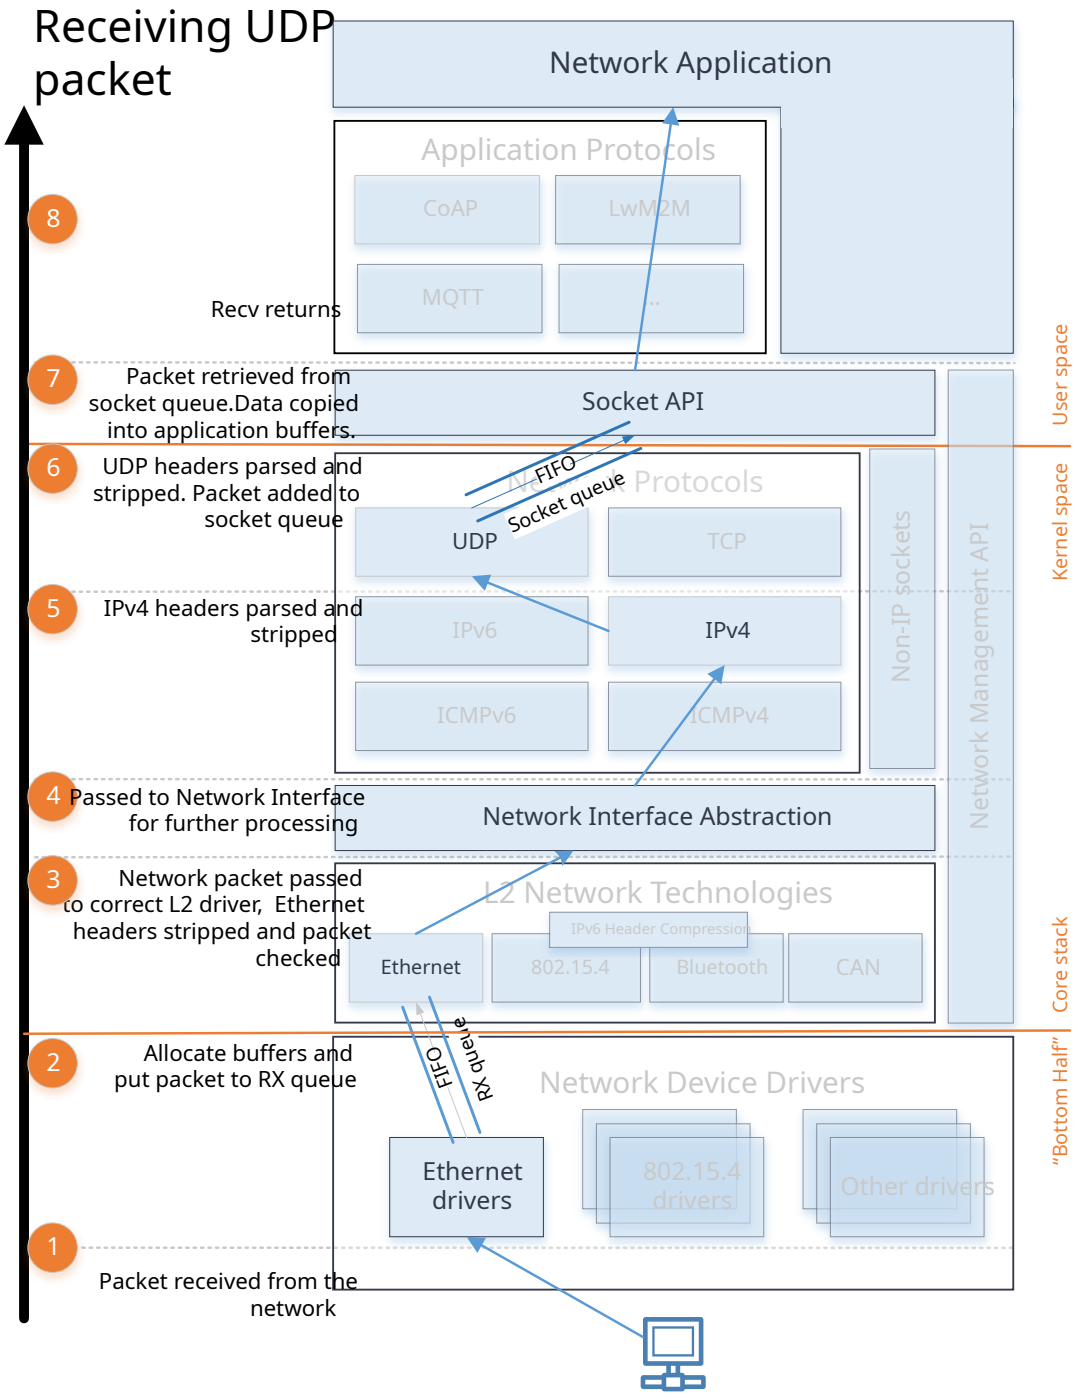

Fig. 2: Network RX data flow

6. A socket handler then finds an active socket to which the network packet belongs and puts it in a queue for that socket, in order to separate the networking code from the application. Typically the application is run in userspace context and the network stack is run in kernel context.
7. The application will then receive the data and can process it as needed. The application should have used the *BSD socket API* to create a socket that will receive the data.

Data sending (TX)

1. The application should use the *BSD socket API* when sending the data.
2. The application data is prepared for sending to kernel space and then copied to internal net_buf structures.
3. Depending on the socket type, a protocol header is added in front of the data. For example, if the socket is a UDP socket, then a UDP header is constructed and placed in front of the data.
4. An IP header is added to the network packet for a UDP or TCP packet.
5. The network stack will check that the network interface is properly set for the network packet, and also will make sure that the network interface is enabled before the data is queued to be sent.
6. The network packet is then classified and placed to the proper transmit queue (implemented by *k_fifo*). By default there is only one transmit queue in the system, but it is possible to have up to 8 transmit queues. These queues will process the sent packets with different priority. See *Traffic Classification* for more details. After the transmit packet classification, the packet is checked by the correct L2 layer module. The L2 module will do additional checks for the data and it will also create any L2 headers for the network packet. If everything is ok, the data is given to the network device driver to be sent out.
7. The device driver will send the packet to the network.

Note that in both the TX and RX data paths, the queues (*k_fifo's*) form separation points where data is passed from one *thread* to another. These *threads* might run in different contexts (*kernel* vs. *userspace*) and with different *priorities*.

Network packet processing statistics See information about network processing statistics *here*.

Network Configuration Guide

- *Network Buffer Configuration Options*
- *Connection Options*
- *Socket Options*
- *TLS Options*
- *IPv4/6 Options*
- *TCP Options*
- *Traffic Class Options*
- *Stack Size Options*

This document describes how various network configuration options can be set according to available resources in the system.

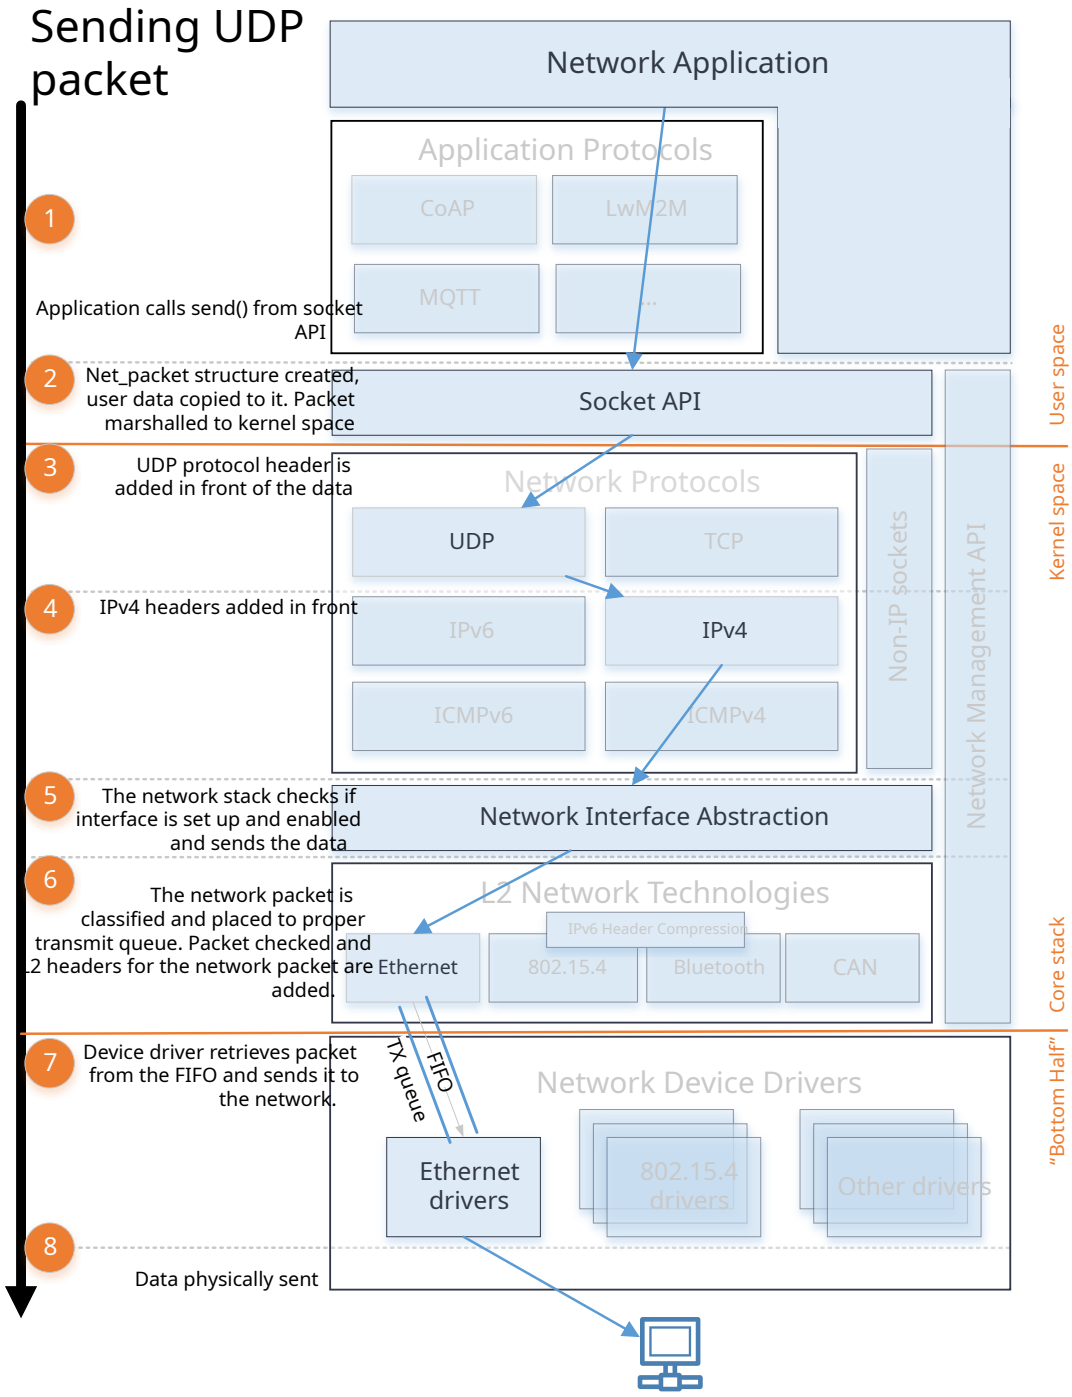

Fig. 3: Network TX data flow

Network Buffer Configuration Options The network buffer configuration options control how much data we are able to either send or receive at the same time.

`CONFIG_NET_PKT_RX_COUNT`
: Maximum amount of network packets we can receive at the same time.

`CONFIG_NET_PKT_TX_COUNT`
: Maximum amount of network packet sends pending at the same time.

`CONFIG_NET_BUF_RX_COUNT`
: How many network buffers are allocated for receiving data. Each net_buf contains a small header and either a fixed or variable length data buffer. The `CONFIG_NET_BUF_DATA_SIZE` is used when `CONFIG_NET_BUF_FIXED_DATA_SIZE` is set. This is the default setting. The default size of the buffer is 128 bytes.

  The `CONFIG_NET_BUF_VARIABLE_DATA_SIZE` is an experimental setting. There each net_buf data portion is allocated from a memory pool and can be the amount of data we have received from the network. When data is received from the network, it is placed into net_buf data portion. Depending on device resources and desired network usage, user can tweak the size of the fixed buffer by setting `CONFIG_NET_BUF_DATA_SIZE`, and the size of the data pool size by setting `CONFIG_NET_PKT_BUF_RX_DATA_POOL_SIZE` and `CONFIG_NET_PKT_BUF_TX_DATA_POOL_SIZE` if variable size buffers are used.

  When using the fixed size data buffers, the memory consumption of network buffers can be tweaked by selecting the size of the data part according to what kind of network data we are receiving. If one sets the data size to 256, but only receives packets that are 32 bytes long, then we are "wasting" 224 bytes for each packet because we cannot utilize the remaining data. One should not set the data size too low because there is some overhead involved for each net_buf. For these reasons the default network buffer size is set to 128 bytes.

  The variable size data buffer feature is marked as experimental as it has not received as much testing as the fixed size buffers. Using variable size data buffers tries to improve memory utilization by allocating minimum amount of data we need for the network data. The extra cost here is the amount of time that is needed when dynamically allocating the buffer from the memory pool.

  For example, in Ethernet the maximum transmission unit (MTU) size is 1500 bytes. If one wants to receive two full frames, then the net_pkt RX count should be set to 2, and net_buf RX count to (1500 / 128) * 2 which is 24. If TCP is being used, then these values need to be higher because we can queue the packets internally before delivering to the application.

`CONFIG_NET_BUF_TX_COUNT`
: How many network buffers are allocated for sending data. This is similar setting as the receive buffer count but for sending.

Connection Options

`CONFIG_NET_MAX_CONN`
: This option tells how many network connection endpoints are supported. For example each TCP connection requires one connection endpoint. Similarly each listening UDP connection requires one connection endpoint. Also various system services like DHCP and DNS need connection endpoints to work. The network shell command **net conn** can be used at runtime to see the network connection information.

`CONFIG_NET_MAX_CONTEXTS`
: Number of network contexts to allocate. Each network context describes a network 5-tuple that is used when listening or sending network traffic. Each BSD socket in the system uses one network context.

Socket Options

CONFIG_ZVFS_POLL_MAX
: Maximum number of supported poll() entries. One needs to select proper value here depending on how many BSD sockets are polled in the system.

CONFIG_ZVFS_OPEN_MAX
: Maximum number of open file descriptors, this includes files, sockets, special devices, etc. One needs to select proper value here depending on how many BSD sockets are created in the system.

CONFIG_ZVFS_EVENTFD_MAX
: Maximum number of ZVFS eventfd's. Several networking subsystems (e.g. the HTTP server, CoAP server, LwM2M engine, PTP, SSH and the socket service) allocate an eventfd to wake up their poll loop. Each such subsystem declares its requirement through a CONFIG_ZVFS_EVENTFD_ADD_SIZE_* option, and the actual eventfd count is the larger of this option and the sum of all those requirements. Only set this option explicitly if an application creates additional eventfds on its own.

CONFIG_NET_SOCKETPAIR_BUFFER_SIZE
: This option is used by socketpair() function. It sets the size of the internal intermediate buffer, in bytes. This sets the limit how large messages can be passed between two socketpair endpoints.

TLS Options

CONFIG_NET_SOCKETS_TLS_MAX_CONTEXTS
: Maximum number of TLS/DTLS contexts. Each TLS/DTLS connection needs one context.

CONFIG_NET_SOCKETS_TLS_MAX_CREDENTIALS
: This variable sets maximum number of TLS/DTLS credentials that can be used with a specific socket.

CONFIG_NET_SOCKETS_TLS_MAX_CIPHERSUITES
: Maximum number of TLS/DTLS ciphersuites per socket. This variable sets maximum number of TLS/DTLS ciphersuites that can be used with specific socket, if set explicitly by socket option. By default, all ciphersuites that are available in the system are available to the socket.

CONFIG_NET_SOCKETS_TLS_MAX_APP_PROTOCOLS
: Maximum number of supported application layer protocols. This variable sets maximum number of supported application layer protocols over TLS/DTLS that can be set explicitly by a socket option. By default, no supported application layer protocol is set.

CONFIG_NET_SOCKETS_TLS_MAX_CLIENT_SESSION_COUNT
: This variable specifies maximum number of stored TLS/DTLS sessions, used for TLS/DTLS session resumption.

CONFIG_TLS_MAX_CREDENTIALS_NUMBER
: Maximum number of TLS credentials that can be registered. Make sure that this value is high enough so that all the certificates can be loaded to the store.

IPv4/6 Options

CONFIG_NET_IF_MAX_IPV4_COUNT
: Maximum number of IPv4 network interfaces in the system. This tells how many network interfaces there will be in the system that will have IPv4 enabled. For example if you have two network interfaces, but only one of them can use IPv4 addresses, then this value can be set to 1. If both network interface could use IPv4, then the setting should be set to 2.

CONFIG_NET_IF_MAX_IPV6_COUNT
: Maximum number of IPv6 network interfaces in the system. This is similar setting as the IPv4 count option but for IPv6.

TCP Options

CONFIG_NET_TCP_TIME_WAIT_DELAY
: How long to wait in TCP *TIME_WAIT* state (in milliseconds). To avoid a (low-probability) issue when delayed packets from previous connection get delivered to next connection reusing the same local/remote ports, RFC 793 (TCP) suggests to keep an old, closed connection in a special *TIME_WAIT* state for the duration of 2*MSL (Maximum Segment Lifetime). The RFC suggests to use MSL of 2 minutes, but notes

  This is an engineering choice, and may be changed if experience indicates it is desirable to do so.

  For low-resource systems, having large MSL may lead to quick resource exhaustion (and related DoS attacks). At the same time, the issue of packet misdelivery is largely alleviated in the modern TCP stacks by using random, non-repeating port numbers and initial sequence numbers. Due to this, Zephyr uses much lower value of 1500ms by default. Value of 0 disables *TIME_WAIT* state completely.

CONFIG_NET_TCP_RETRY_COUNT
: Maximum number of TCP segment retransmissions. The following formula can be used to determine the time (in ms) that a segment will be buffered awaiting retransmission:

$$\sum_{n=0}^{\texttt{NET_TCP_RETRY_COUNT}} \left(1 \ll n\right) \times \texttt{NET_TCP_INIT_RETRANSMISSION_TIMEOUT}$$

  With the default value of 9, the IP stack will try to retransmit for up to 1:42 minutes. This is as close as possible to the minimum value recommended by RFC 1122 (1:40 minutes). Only 5 bits are dedicated for the retransmission count, so accepted values are in the 0-31 range. It's highly recommended to not go below 9, though.

  Should a retransmission timeout occur, the receive callback is called with `-ETIMEDOUT` error code and the context is dereferenced.

CONFIG_NET_TCP_MAX_SEND_WINDOW_SIZE
: Maximum sending window size to use. This value affects how the TCP selects the maximum sending window size. The default value 0 lets the TCP stack select the value according to amount of network buffers configured in the system. Note that if there are multiple active TCP connections in the system, then this value might require finetuning (lowering), otherwise multiple TCP connections could easily exhaust net_buf pool for the queued TX data.

CONFIG_NET_TCP_MAX_RECV_WINDOW_SIZE
: Maximum receive window size to use. This value defines the maximum TCP receive window size. Increasing this value can improve connection throughput, but requires more receive buffers available in the system for efficient operation. The default value 0 lets the TCP stack select the value according to amount of network buffers configured in the system.

CONFIG_NET_TCP_RECV_QUEUE_TIMEOUT
: How long to queue received data (in ms). If we receive out-of-order TCP data, we queue it. This value tells how long the data is kept before it is discarded if we have not been able to pass the data to the application. If set to 0, then receive queueing is not enabled. The value is in milliseconds.

  Note that we only queue data sequentially in current version i.e., there should be no holes in the queue. For example, if we receive SEQs 5,4,3,6 and are waiting SEQ 2, the data in segments 3,4,5,6 is queued (in this order), and then given to application when we receive SEQ 2. But if we receive SEQs 5,4,3,7 then the SEQ 7 is discarded because the list would not be sequential as number 6 is be missing.

Traffic Class Options It is possible to configure multiple traffic classes (queues) when receiving or sending network data. Each traffic class queue is implemented as a thread with different priority. This means that higher priority network packet can be placed to a higher priority network

queue in order to send or receive it faster or slower. Because of thread scheduling latencies, in practice the fastest way to send a packet out, is to directly send the packet without using a dedicated traffic class thread. This is why by default the CONFIG_NET_TC_TX_COUNT option is set to 0 if userspace is not enabled. If userspace is enabled, then the minimum TX traffic class count is 1. Reason for this is that the userspace application does not have enough permissions to deliver the message directly.

In receiving side, it is recommended to have at least one receiving traffic class queue. Reason is that typically the network device driver is running in IRQ context when it receives the packet, in which case it should not try to deliver the network packet directly to the upper layers, but to place the packet to the traffic class queue. If the network device driver is not running in IRQ context when it gets the packet, then the RX traffic class option CONFIG_NET_TC_RX_COUNT could be set to 0.

Stack Size Options There several network specific threads in a network enabled system. Some of the threads might depend on a configure option which can be used to enable or disable a feature. Each thread stack size is optimized to allow normal network operations.

The network management API is using a dedicated thread by default. The thread is responsible to deliver network management events to the event listeners that are setup in the system if the CONFIG_NET_MGMT and CONFIG_NET_MGMT_EVENT options are enabled. If the options are enabled, the user is able to register a callback function that the net_mgmt thread is calling for each network management event. By default the net_mgmt event thread stack size is rather small. The idea is that the callback function does minimal things so that new events can be delivered to listeners as fast as possible and they are not lost. The net_mgmt event thread stack size is controlled by CONFIG_NET_MGMT_EVENT_QUEUE_SIZE option. It is recommended to not do any blocking operations in the callback function.

The network thread stack utilization can be monitored from kernel shell by the **kernel threads** command.

Networking with the host system

Networking with native_sim board

- *Using virtual/TAP Ethernet driver*
  - *Prerequisites*
  - *Basic Setup*
- *Using offloaded sockets*
  - *Step 1 - Start app in native_sim board*
  - *Step 2 - run echo-client from net-tools*
- *Setting interface name and IPv4 parameters from command line*

Using virtual/TAP Ethernet driver This paragraph describes how to set up a virtual network between a (Linux) host and a Zephyr application running in a native_sim board.

In this example, the sockets-echo-server sample application from the Zephyr source distribution is run in native_sim board. The Zephyr native_sim board instance is connected to a Linux host using a tuntap device which is modeled in Linux as an Ethernet network interface.

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the tools/net-tools directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Basic Setup For the steps below, you will need three terminal windows:

- Terminal #1 is terminal window with net-tools being the current directory (`cd net-tools`)
- Terminal #2 is your usual Zephyr development terminal, with the Zephyr environment initialized.
- Terminal #3 is the console to the running Zephyr native_sim instance (optional).

Step 1 - Create Ethernet interface Before starting native_sim with network emulation, a network interface should be created.

In terminal #1, type:

```
./net-setup.sh
```

You can tweak the behavior of the net-setup.sh script. See various options by running `net-setup.sh` like this:

```
./net-setup.sh --help
```

Step 2 - Start app in native_sim board Build and start the `echo_server` sample application.

In terminal #2, type:

```
west build -b native_sim samples/net/sockets/echo_server
west build -t run
```

Step 3 - Connect to console (optional) The console window should be launched automatically when the Zephyr instance is started but if it does not show up, you can manually connect to the console. The native_sim board will print a string like this when it starts:

```
UART connected to pseudotty: /dev/pts/5
```

You can manually connect to it like this:

```
screen /dev/pts/5
```

Using offloaded sockets The main advantage over *Using virtual/TAP Ethernet driver* is not needing to setup a virtual network interface on the host machine. This means that no leveraged (root) privileges are needed.

Step 1 - Start app in native_sim board Build and start the `echo_server` sample application:

```
west build -b native_sim samples/net/sockets/echo_server -- -
↪DEXTRA_CONF_FILE=overlay-nsos.conf
west build -t run
```

Step 2 - run echo-client from net-tools On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Note

Native Simulator with the offloaded sockets network driver is using the same network interface/namespace as any other (Linux) application that uses BSD sockets API. This means that sockets-echo-server and `echo-client` applications will communicate over localhost/loopback interface (address `127.0.0.1`).

To run UDP test, type:

```
./echo-client 127.0.0.1
```

For TCP test, type:

```
./echo-client -t 127.0.0.1
```

Setting interface name and IPv4 parameters from command line By default the Ethernet interface name used by native_sim is determined by the `host-interface` property of the `zephyr,native-tap` devicetree node, but it is also possible to set it from the command line using `--eth-if=<interface_name>`.

The same applies to the IPv4 address, gateway and netmask. They can be set from the command line using `--ipv4-addr=<ip_address>`, `--ipv4-gw=<gateway>` and `--ipv4-nm=<netmask>`.

These options apply to the first interface. When multiple `zephyr,native-tap` interfaces are defined, each additional interface has its own per-interface options prefixed with the devicetree node name, e.g. `--<node>_eth-if` and `--<node>_ipv4-addr`.

Note that the configuration `CONFIG_NET_CONFIG_MY_IPV4_ADDR` and the command line arguments work in parallel. This means that if both are set, the interface might end up with two IP addresses. In most cases, it does make sense to only use one of both at the same time.

This can be useful if the application has to be run in multiple instances and recompiling it for each instance would be troublesome.

```
./zephyr.exe --eth-if=zeth2 --ipv4-addr=192.0.2.2 --ipv4-gw=192.0.0.1
--ipv4-nm=255.255.0.0
```

Note

These command line options can also be supplied at build time through the `CONFIG_NATIVE_EXTRA_CMDLINE_ARGS` configuration option.

Networking with QEMU Ethernet

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create Ethernet interface*
  - *Step 2 - Start app in QEMU board*

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in QEMU.

In this example, the sockets-echo-server sample application from the Zephyr source distribution is run in QEMU. The Zephyr instance is connected to a Linux host using a tuntap device which is modeled in Linux as an Ethernet network interface.

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Basic Setup For the steps below, you will need two terminal windows:

- Terminal #1 is terminal window with net-tools being the current directory (`cd net-tools`)
- Terminal #2 is your usual Zephyr development terminal, with the Zephyr environment initialized.

When configuring the Zephyr instance, you must select the correct Ethernet driver for QEMU connectivity:

- For `qemu_x86`, select `Intel(R) PRO/1000 Gigabit Ethernet driver` Ethernet driver. Driver is called `e1000` in Zephyr source tree.
- For `qemu_cortex_m3`, select `TI Stellaris MCU family ethernet driver` Ethernet driver. Driver is called `stellaris` in Zephyr source tree.
- For `mps2_an385`, select `SMSC911x/9220 Ethernet driver` Ethernet driver. Driver is called `smsc911x` in Zephyr source tree.
- For `qemu_cortex_a53`, `Intel(R) PRO/1000 Gigabit Ethernet driver` Ethernet driver is selected by default.
- Additionally, the sockets-echo-server sample contains overlay files for the VIRTIO Network device on `qemu_x86_64`.

Step 1 - Create Ethernet interface Before starting QEMU with network connectivity, a network interface should be created in the host system.

In terminal #1, type:

```
./net-setup.sh
```

You can tweak the behavior of the `net-setup.sh` script. See various options by running `net-setup.sh` like this:

```
./net-setup.sh --help
```

Step 2 - Start app in QEMU board Build and start the sockets-echo-server sample application. In this example, the qemu_x86 board is used.

In terminal #2, type:

```
west build -b qemu_x86 samples/net/sockets/echo_server -- -
↪DEXTRA_CONF_FILE=overlay-e1000.conf
west build -t run
```

Alternatively, if you decided to use the VIRTIO Network device on qemu_x86_64:

```
west build -b qemu_x86_64 samples/net/sockets/echo_server -- -
↪DDTC_OVERLAY_FILE=virtnet.overlay -DEXTRA_CONF_FILE=overlay-virtnet.conf
west build -t run
```

Exit QEMU by pressing `CTRL+A x`.

Networking with QEMU

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create helper socket*
  - *Step 2 - Start TAP device routing daemon*
  - *Step 3 - Start app in QEMU*
  - *Step 4 - Run apps on host*
  - *Step 5 - Stop supporting daemons*
- *Setting up Zephyr and NAT/masquerading on host to access Internet*
- *Network connection between two QEMU VMs*
  - *Terminal #1:*
  - *Terminal #2:*
- *Running multiple QEMU VMs of the same sample*
  - *Terminal #1:*
  - *Terminal #2:*

This page describes how to set up a virtual network between a (Linux) host and a Zephyr application running in a QEMU virtual machine (built for Zephyr targets such as qemu_x86 and qemu_cortex_m3). Some virtual ARM boards (such as qemu_cortex_a53) only support a single UART, in this case QEMU Ethernet is preferred, see *Networking with QEMU Ethernet* for details.

In this example, the sockets-echo-server sample application from the Zephyr source distribution is run in QEMU. The QEMU instance is connected to a Linux host using a serial port, and SLIP is used to transfer data between the Zephyr application and Linux (over a chain of virtual connections).

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
sudo apt install -y socat libpcap-dev
git clone https://github.com/zephyrproject-rtos/net-tools
cd net-tools
make
```

Note

If you get an error about AX_CHECK_COMPILE_FLAG, install package `autoconf-archive` package on Debian/Ubuntu.

Basic Setup For the steps below, you will need at least 4 terminal windows:

- Terminal #1 is your usual Zephyr development terminal, with the Zephyr environment initialized.

- Terminals #2, #3, and #4 are terminal windows with net-tools being the current directory (`cd net-tools`)

Step 1 - Create helper socket Before starting QEMU with network emulation, a Unix socket for the emulation should be created.

In terminal #2, type:

```
./loop-socat.sh
```

Step 2 - Start TAP device routing daemon In terminal #3, type:

```
sudo ./loop-slip-tap.sh
```

For applications requiring DNS, you may need to restart the host's DNS server at this point, as described in *Setting up Zephyr and NAT/masquerading on host to access Internet*.

Step 3 - Start app in QEMU Build and start the `echo_server` sample application.

In terminal #1, type:

```
west build -b qemu_x86 samples/net/sockets/echo_server
west build -t run
```

If you see an error from QEMU about unix:/tmp/slip.sock, it means you missed Step 1 above.

Step 4 - Run apps on host Now in terminal #4, you can run various tools to communicate with the application running in QEMU.

You can start with pings:

```
ping 192.0.2.1
ping6 2001:db8::1
```

You can use the netcat ("nc") utility, connecting using UDP:

```
echo foobar | nc -6 -u 2001:db8::1 4242
foobar
```

```
echo foobar | nc -u 192.0.2.1 4242
foobar
```

If echo_server is compiled with TCP support (now enabled by default for the echo_server sample, CONFIG_NET_TCP=y):

```
echo foobar | nc -6 -q2 2001:db8::1 4242
foobar
```

Note

Use Ctrl+C to exit.

You can also use the telnet command to achieve the above.

Step 5 - Stop supporting daemons When you are finished with network testing using QEMU, you should stop any daemons or helpers started in the initial steps, to avoid possible networking or routing problems such as address conflicts in local network interfaces. For example, stop them if you switch from testing networking with QEMU to using real hardware, or to return your host laptop to normal Wi-Fi use.

To stop the daemons, press Ctrl+C in the corresponding terminal windows (you need to stop both `loop-slip-tap.sh` and `loop-socat.sh`).

Exit QEMU by pressing `CTRL+A x`.

Setting up Zephyr and NAT/masquerading on host to access Internet To access the internet from a Zephyr application, some additional setup on the host may be required. This setup is common for both application running in QEMU and on real hardware, assuming that a development board is connected to the development host. If a board is connected to a dedicated router, it should not be needed.

To access the internet from a Zephyr application using IPv4, a gateway should be set via DHCP or configured manually. For applications using the "Settings" facility (with the config option `CONFIG_NET_CONFIG_SETTINGS` enabled), set the `CONFIG_NET_CONFIG_MY_IPV4_GW` option to the IP address of the gateway. For apps not using the "Settings" facility, set up the gateway by calling the `net_if_ipv4_set_gw()` at runtime. For example: `CONFIG_NET_CONFIG_MY_IPV4_GW="192.0.2.2"`

To access the internet from a custom application running in QEMU, NAT (masquerading) should be set up for QEMU's source address. Assuming `192.0.2.1` is used and the Zephyr network interface is `zeth`, the following command should be run as root:

```
iptables -t nat -A POSTROUTING -j MASQUERADE -s 192.0.2.1/24
iptables -I FORWARD 1 -i zeth -j ACCEPT
iptables -I FORWARD 1 -o zeth -m state --state RELATED,ESTABLISHED -j ACCEPT
```

Additionally, IPv4 forwarding should be enabled on the host, and you may need to check that other firewall (iptables) rules don't interfere with masquerading. To enable IPv4 forwarding the following command should be run as root:

```
sysctl -w net.ipv4.ip_forward=1
```

Some applications may also require a DNS server. A number of Zephyr-provided samples assume by default that the DNS server is available on the host (IP `192.0.2.2`), which, in modern Linux distributions, usually runs at least a DNS proxy. When running with QEMU, it may be required to restart the host's DNS, so it can serve requests on the newly created TAP interface. For example, on Debian-based systems:

```
service dnsmasq restart
```

An alternative to relying on the host's DNS server is to use one in the network. For example, `8.8.8.8` is a publicly available DNS server. You can configure it using `CONFIG_DNS_SERVER1` option.

Network connection between two QEMU VMs Unlike the VM-to-Host setup described above, VM-to-VM setup is automatic. For sample applications that support this mode (such as the echo_server and echo_client samples), you will need two terminal windows, set up for Zephyr development.

Terminal #1:

```
west build -b qemu_x86 -o server samples/net/sockets/echo_server
```

This will start QEMU, waiting for a connection from a client QEMU.

Terminal #2:

```
west build -b qemu_x86 -o client samples/net/sockets/echo_client
```

This will start a second QEMU instance, where you should see logging of data sent and received in both.

Running multiple QEMU VMs of the same sample If you find yourself wanting to run multiple instances of the same Zephyr sample application, which do not need to talk to each other, use the `QEMU_INSTANCE` argument.

Start `socat` and `tunslip6` manually (instead of using the `loop-xxx.sh` scripts) for as many instances as you want. Use the following as a guide, replacing MAIN or OTHER.

Terminal #1:

```
socat PTY,link=/tmp/slip.devMAIN UNIX-LISTEN:/tmp/slip.sockMAIN &
sudo $ZEPHYR_BASE/../tools/net-tools/tunslip6 -t tapMAIN -T -s /tmp/slip.devMAIN␣
↪2001:db8::1/64 &
# Now run Zephyr
make -Cbuild run QEMU_INSTANCE=MAIN
```

Terminal #2:

```
socat PTY,link=/tmp/slip.devOTHER UNIX-LISTEN:/tmp/slip.sockOTHER &
sudo $ZEPHYR_BASE/../tools/net-tools/tunslip6 -t tapOTHER -T -s /tmp/slip.devOTHER␣
↪2001:db8::1/64 &
make -Cbuild run QEMU_INSTANCE=OTHER
```

USB Device Networking

- *Basic Setup*
  - *Choosing IP addresses*
  - *Setting IPv4 address and routing*
  - *Setting IPv6 address and routing*
- *Testing connection*

This page describes how to set up networking between a Linux host and a Zephyr application running on USB supported devices.

The board is connected to Linux host using USB cable and provides an Ethernet interface to the host. The sockets-echo-server application from the Zephyr source distribution is run on supported board. The board is connected to a Linux host using a USB cable providing an Ethernet interface to the host.

Basic Setup To communicate with the Zephyr application over a newly created Ethernet interface, we need to assign IP addresses and set up a routing table for the Linux host. After plugging a USB cable from the board to the Linux host, the `cdc_ether` driver registers a new Ethernet device with a provided MAC address.

You can check that network device is created and MAC address assigned by running dmesg from the Linux host.

```
cdc_ether 1-2.7:1.0 eth0: register 'cdc_ether' at usb-0000:00:01.2-2.7, CDC␣
↪Ethernet Device, 00:00:5e:00:53:01
```

We need to set it up and assign IP addresses as explained in the following section.

Choosing IP addresses To establish network connection to the board we need to choose IP address for the interface on the Linux host.

It make sense to choose addresses in the same subnet we have in Zephyr application. IP addresses usually set in the project configuration files and may be checked also from the shell with following commands. Connect a serial console program (such as puTTY) to the board, and enter this command to the Zephyr shell:

```
shell> net iface

Interface 0xa800e580 (Ethernet)
===============================
Link addr : 00:00:5E:00:53:00
MTU       : 1500
IPv6 unicast addresses (max 2):
        fe80::200:5eff:fe00:5300 autoconf preferred infinite
        2001:db8::1 manual preferred infinite
...
IPv4 unicast addresses (max 1):
        192.0.2.1 manual preferred infinite
```

This command shows that one IPv4 address and two IPv6 addresses have been assigned to the board. We can use either IPv4 or IPv6 for network connection depending on the board network configuration.

Next step is to assign IP addresses to the new Linux host interface, in the following steps `enx00005e005301` is the name of the interface on my Linux system.

Setting IPv4 address and routing

```
# ip address add dev enx00005e005301 192.0.2.2
# ip link set enx00005e005301 up
# ip route add 192.0.2.0/24 dev enx00005e005301
```

Setting IPv6 address and routing

```
# ip address add dev enx00005e005301 2001:db8::2
# ip link set enx00005e005301 up
# ip -6 route add 2001:db8::/64 dev enx00005e005301
```

Testing connection From the host we can test the connection by pinging Zephyr IP address of the board with:

```
$ ping 192.0.2.1
PING 192.0.2.1 (192.0.2.1) 56(84) bytes of data.
64 bytes from 192.0.2.1: icmp_seq=1 ttl=64 time=2.30 ms
64 bytes from 192.0.2.1: icmp_seq=2 ttl=64 time=1.43 ms
64 bytes from 192.0.2.1: icmp_seq=3 ttl=64 time=2.45 ms
...
```

Networking with QEMU User

- *Introduction*
- *Using SLIRP with Zephyr*
- *Limitations*

This page is intended to serve as a starting point for anyone interested in using QEMU SLIRP with Zephyr.

Introduction SLIRP is a network backend which provides the complete TCP/IP stack within QEMU and uses that stack to implement a virtual NAT'd network. As there are no dependencies on the host, SLIRP is simple to setup.

By default, QEMU uses the `10.0.2.X/24` network and runs a gateway at `10.0.2.2`. All traffic intended for the host network has to travel through this gateway, which will filter out packets based on the QEMU command line parameters. This gateway also functions as a DHCP server for all GOS, allowing them to be automatically assigned with an IP address starting from `10.0.2.15`.

More details about User Networking can be obtained from here: https://wiki.qemu.org/Documentation/Networking#User_Networking_.28SLIRP.29

Using SLIRP with Zephyr In order to use SLIRP with Zephyr, the user has to set the Kconfig option to enable User Networking.

```
CONFIG_NET_QEMU_USER=y
```

Once this configuration option is enabled, all QEMU launches will use SLIRP. In the default configuration, Zephyr only enables User Networking, and does not pass any arguments to it. This means that the Guest will only be able to communicate to the QEMU gateway, and any data intended for the host machine will be dropped by QEMU.

In general, QEMU User Networking can take in a lot of arguments including,

- Information about host/guest port forwarding. This must be provided to create a communication channel between the guest and host.
- Information about network to use. This may be valuable if the user does not want to use the default `10.0.2.X` network.
- Tell QEMU to start DHCP server at user-defined IP address.
- ID and other information.

As this information varies with every use case, it is difficult to come up with good defaults that work for all. Therefore, Zephyr Implementation offloads this to the user, and expects that they will provide arguments based on requirements. For this, there is a Kconfig string which can be populated by the user.

```
CONFIG_NET_QEMU_USER_EXTRA_ARGS="net=192.168.0.0/24,hostfwd=tcp::8080-:8080"
```

This option is appended as-is to the QEMU command line. Therefore, any problems with this command line will be reported by QEMU only. Here's what this particular example will do,

- Make QEMU use the `192.168.0.0/24` network instead of the default.
- Enable forwarding of any TCP data received from port 8080 of host to port 8080 of guest, and vice versa.

Limitations If the user does not have any specific networking requirements other than the ability to access a web page from the guest, user networking (slirp) is a good choice. However, it has several limitations

- There is a lot of overhead so the performance is poor.
- The guest is not directly accessible from the host or the external network.
- In general, ICMP traffic does not work (so you cannot use ping within a guest).
- As port mappings need to be defined before launching qemu, clients which use dynamically generated ports cannot communicate with external network.
- There is a bug in the SLIRP implementation which filters out all IPv6 packets from the guest. See https://bugs.launchpad.net/qemu/+bug/1724590 for details. Therefore, IPv6 will not work with User Networking.

Networking with multiple Zephyr instances

- *Prerequisites*
- *Basic Setup*
  - *Step 1 - Create configuration files*
  - *Step 2 - Create Ethernet interfaces*
  - *Step 3 - Setup network bridging*
  - *Step 4 - Start Zephyr instances*

This page describes how to set up a virtual network between multiple Zephyr instances. The Zephyr instances could be running inside QEMU or could be native_sim board processes. The Linux host can be used to route network traffic between these systems.

Prerequisites On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

Basic Setup For the steps below, you will need five terminal windows:

- Terminal #1 and #2 are terminal windows with net-tools being the current directory (`cd net-tools`)
- Terminal #3, where you setup bridging in Linux host
- Terminal #4 and #5 are your usual Zephyr development terminal, with the Zephyr environment initialized.

As there are multiple ways to setup the Zephyr network, the example below uses `qemu_x86` board with `e1000` Ethernet controller and native_sim board to simplify the setup instructions. You can use other QEMU boards and drivers if needed, see *Networking with QEMU Ethernet* for details. You can also use two or more native_sim board Zephyr instances and connect them together.

Step 1 - Create configuration files Before starting QEMU with network connectivity, a network interfaces for each Zephyr instance should be created in the host system. The default setup for creating network interface cannot be used here as that is for connecting one Zephyr instance to Linux host.

For Zephyr instance #1, create file called `zephyr1.conf` to `net-tools` project, or to some other suitable directory.

```
# Configuration file for setting IP addresses for a network interface.
INTERFACE="$1"
HWADDR="00:00:5e:00:53:11"
IPV6_ADDR_1="2001:db8:100::2"
IPV6_ROUTE_1="2001:db8:100::/64"
IPV4_ADDR_1="198.51.100.2/24"
IPV4_ROUTE_1="198.51.100.0/24"
ip link set dev $INTERFACE up
ip link set dev $INTERFACE address $HWADDR
ip -6 address add $IPV6_ADDR_1 dev $INTERFACE nodad
ip -6 route add $IPV6_ROUTE_1 dev $INTERFACE
ip address add $IPV4_ADDR_1 dev $INTERFACE
ip route add $IPV4_ROUTE_1 dev $INTERFACE > /dev/null 2>&1
```

For Zephyr instance #2, create file called `zephyr2.conf` to `net-tools` project, or to some other suitable directory.

```
# Configuration file for setting IP addresses for a network interface.
INTERFACE="$1"
HWADDR="00:00:5e:00:53:22"
IPV6_ADDR_1="2001:db8:200::2"
IPV6_ROUTE_1="2001:db8:200::/64"
IPV4_ADDR_1="203.0.113.2/24"
IPV4_ROUTE_1="203.0.113.0/24"
ip link set dev $INTERFACE up
ip link set dev $INTERFACE address $HWADDR
ip -6 address add $IPV6_ADDR_1 dev $INTERFACE nodad
ip -6 route add $IPV6_ROUTE_1 dev $INTERFACE
ip address add $IPV4_ADDR_1 dev $INTERFACE
ip route add $IPV4_ROUTE_1 dev $INTERFACE > /dev/null 2>&1
```

Step 2 - Create Ethernet interfaces The following `net-setup.sh` commands should be typed in net-tools directory (`cd net-tools`).

In terminal #1, type:

```
./net-setup.sh -c zephyr1.conf -i zeth.1
```

In terminal #2, type:

```
./net-setup.sh -c zephyr2.conf -i zeth.2
```

Step 3 - Setup network bridging In terminal #3, type:

```
sudo brctl addbr zeth-br
sudo brctl addif zeth-br zeth.1
sudo brctl addif zeth-br zeth.2
sudo ifconfig zeth-br up
```

Step 4 - Start Zephyr instances In this example we start sockets-echo-server and sockets-echo-client sample applications. You can use other applications too as needed.

In terminal #4, if you are using QEMU, type this:

```
west build -d build/server -b qemu_x86 -t run \
   samples/net/sockets/echo_server -- \
```

(continues on next page)

(continued from previous page)

```
   -DEXTRA_CONF_FILE=overlay-e1000.conf \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"203.0.113.1\" \
   -DCONFIG_ETH_QEMU_IFACE_NAME=\"zeth.1\" \
   -DCONFIG_NET_QEMU_DEVICE_EXTRA_ARGS=\"mac=00:00:5e:00:53:01\"
```

or if you want to use native_sim board, type this:

```
west build -d build/server -b native_sim \
   samples/net/sockets/echo_server -- \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"203.0.113.1\"
build/server/zephyr/zephyr.exe --eth-if=zeth.1 --mac-addr=00:00:5e:00:53:01
```

In terminal #5, if you are using QEMU, type this:

```
west build -d build/client -b qemu_x86 -t run \
   samples/net/sockets/echo_client -- \
   -DEXTRA_CONF_FILE=overlay-e1000.conf \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"198.51.100.1\" \
   -DCONFIG_ETH_QEMU_IFACE_NAME=\"zeth.2\" \
   -DCONFIG_NET_QEMU_DEVICE_EXTRA_ARGS=\"mac=00:00:5e:00:53:02\"
```

or if you want to use native_sim board, type this:

```
west build -d build/client -b native_sim \
   samples/net/sockets/echo_client -- \
   -DCONFIG_NET_CONFIG_MY_IPV4_ADDR=\"203.0.113.1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV4_ADDR=\"198.51.100.1\" \
   -DCONFIG_NET_CONFIG_MY_IPV6_ADDR=\"2001:db8:200::1\" \
   -DCONFIG_NET_CONFIG_PEER_IPV6_ADDR=\"2001:db8:100::1\" \
   -DCONFIG_NET_CONFIG_MY_IPV4_GW=\"198.51.100.1\"
build/client/zephyr/zephyr.exe --eth-if=zeth.2 --mac-addr=00:00:5e:00:53:02
```

Also if you have firewall enabled in your host, you need to allow traffic between `zeth.1`, `zeth.2` and `zeth-br` interfaces.

Ethernet bridge with native_sim board This document describes how to set up a bridged Ethernet network between a (Linux) host and a Zephyr application running in a native_sim board.

This setup is useful when testing the Ethernet bridging feature that can be enabled with `CONFIG_NET_ETHERNET_BRIDGE` Kconfig option. In this setup, the net-tools configuration creates two host network interfaces `zeth0` and `zeth1` and connects them to Zephyr's native_sim application.

First create the host interfaces. In this example two interfaces are created.

```
cd $ZEPHYR_BASE/../tools/net-tools
./net-setup.sh -c zeth-multiface.conf -i zeth0 -t 2
```

The `-c` tells which configuration file to use, where `zeth-multiface.conf` is tailored for generating multiple network interfaces in the host. The `-i` option tells what is the first host interface name. The `-t` tells how many network interfaces to create.

Example output of the host interfaces:

```
zeth0: flags=4099<UP,BROADCAST,MULTICAST>  mtu 1500
       inet 192.0.2.2  netmask 255.255.255.255  broadcast 0.0.0.0
       inet6 2001:db8::2  prefixlen 128  scopeid 0x0<global>
       inet6 fe80::200:5eff:fe00:5300  prefixlen 64  scopeid 0x20<link>
       ether 00:00:5e:00:53:00  txqueuelen 1000  (Ethernet)
       RX packets 33  bytes 2408 (2.4 KB)
       RX errors 0  dropped 0  overruns 0  frame 0
       TX packets 49  bytes 4092 (4.0 KB)
       TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0

zeth1: flags=4099<UP,BROADCAST,MULTICAST>  mtu 1500
       inet 198.51.100.1  netmask 255.255.255.255  broadcast 0.0.0.0
       inet6 fe80::200:5eff:fe00:5301  prefixlen 64  scopeid 0x20<link>
       inet6 2001:db8:2::1  prefixlen 128  scopeid 0x0<global>
       ether 00:00:5e:00:53:01  txqueuelen 1000  (Ethernet)
       RX packets 21  bytes 1340 (1.3 KB)
       RX errors 0  dropped 0  overruns 0  frame 0
       TX packets 45  bytes 3916 (3.9 KB)
       TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

Then create a sample and enable Ethernet bridging support. In this example we create sockets-echo-server sample application.

Bridging needs a second TAP interface. Create a devicetree overlay file `second-iface.overlay` that adds a second `zephyr,native-tap` interface:

```
/ {
    zeth1: zeth1 {
        compatible = "zephyr,native-tap";
        status = "okay";
        zephyr,random-mac-address;
        host-interface = "zeth1";
    };
};
```

Then build and run the application, pointing at the overlay:

```
west build -p -b native_sim -d ../build/echo-server \
   samples/net/sockets/echo_server -- \
   -DCONFIG_UART_NATIVE_PTY_AUTOATTACH_DEFAULT_CMD="\"gnome-terminal -- screen
↪%s\"" \
   -DCONFIG_NET_ETHERNET_BRIDGE=y \
   -DCONFIG_NET_ETHERNET_BRIDGE_SHELL=y \
   -DEXTRA_DTC_OVERLAY_FILE=second-iface.overlay \
   -DCONFIG_NET_IF_MAX_IPV6_COUNT=2 \
   -DCONFIG_NET_IF_MAX_IPV4_COUNT=2
../build/echo-server/zephyr/zephyr.exe -attach_uart
```

This will create and run sockets-echo-server with bridging enabled but not yet configured. To configure the bridging, you either need to use the bridge shell or call the bridging API directly from the application. We setup the bridging using the bridge shell like this:

```
net bridge addif 1 3 2
net iface up 1
```

In the above example, the bridge interface index is 1, and interfaces 2 and 3 are Ethernet interfaces which are linked to interfaces `zeth0` and `zeth1` in the host side.

The network interfaces look like this in Zephyr's side:

```
net iface
Hostname: zephyr

Interface bridge0 (0x8090ebc) (Virtual) [1]
===================================
Virtual name : <enabled>
No attached network interface.
Link addr : 3B:DB:31:0F:CC:B6
MTU       : 1500
Flags     : NO_AUTO_START
Device    : BRIDGE_0 (0x8088354)
Promiscuous mode : disabled
IPv6 not enabled for this interface.
IPv4 not enabled for this interface.

Interface eth0 (0x8090fcc) (Ethernet) [2]
===================================
Link addr : 02:00:5E:00:53:D2
MTU       : 1500
Flags     : AUTO_START,IPv4,IPv6
Device    : zeth0 (0x808837c)
Promiscuous mode : disabled
Ethernet capabilities supported:
        TXTIME
        Promiscuous mode
Ethernet PHY device: <none> (0)
IPv6 unicast addresses (max 3):
        fe80::5eff:fe00:53d2 autoconf preferred infinite
        2001:db8::1 manual preferred infinite
IPv6 multicast addresses (max 4):
        ff02::1
        ff02::1:ff00:53d2
        ff02::1:ff00:1
IPv6 prefixes (max 2):
        <none>
IPv6 hop limit           : 64
IPv6 base reachable time : 30000
IPv6 reachable time      : 18476
IPv6 retransmit timer    : 0
IPv4 unicast addresses (max 1):
        192.0.2.1/255.255.255.0 manual preferred infinite
IPv4 multicast addresses (max 2):
        224.0.0.1
IPv4 gateway : 0.0.0.0

Interface eth1 (0x80910dc) (Ethernet) [3]
===================================
Link addr : 02:00:5E:00:53:87
MTU       : 1500
Flags     : AUTO_START,IPv4,IPv6
Device    : zeth1 (0x8088368)
Promiscuous mode : disabled
Ethernet capabilities supported:
```

(continues on next page)

(continued from previous page)

```
        TXTIME
        Promiscuous mode
Ethernet PHY device: <none> (0)
IPv6 unicast addresses (max 3):
        fe80::5eff:fe00:5387 autoconf preferred infinite
IPv6 multicast addresses (max 4):
        ff02::1
        ff02::1:ff00:5387
IPv6 prefixes (max 2):
        <none>
IPv6 hop limit           : 64
IPv6 base reachable time : 30000
IPv6 reachable time      : 25158
IPv6 retransmit timer    : 0
IPv4 unicast addresses (max 1):
        <none>
IPv4 multicast addresses (max 2):
        224.0.0.1
IPv4 gateway : 0.0.0.0
```

The `net bridge` command will show the current status of the bridging:

```
net bridge
Bridge Status   Config   Interfaces
1      up       ok       2 3
```

The `addif` command adds Ethernet interfaces 2 and 3 to the bridge interface 1. After the `addif` command, the bridging is still disabled because the bridge interface is not up by default. The `net iface up` command will turn on bridging.

If you have wireshark running in host side and monitoring `zeth0` and `zeth1`, you should see the same network traffic in both host interfaces.

Note that interface index numbers are not fixed, the bridge and Ethernet interface index values might be different in your setup.

The bridging can be disabled by taking the bridge interface down, and the Ethernet interfaces can be removed from the bridge using `delif` command.

```
net iface down 1
net bridge delif 1 2 3
```

Networking with QEMU and IEEE 802.15.4

- *Basic Setup*
  - *Step 1 - Compile and start echo-server*
  - *Step 2 - Compile and start echo-client*

This page describes how to set up a virtual network between two QEMUs that are connected together via UART and are running IEEE 802.15.4 link layer between them. Note that this only works in Linux host.

Basic Setup For the steps below, you will need two terminal windows:

- Terminal #1 is terminal window with `echo-server` Zephyr sample application.

- Terminal #2 is terminal window with `echo-client` Zephyr sample application.

If you want to capture the transferred network data, you must compile the `monitor_15_4` program in the `tools/net-tools` directory.

Open a terminal window and type:

```
cd $ZEPHYR_BASE/../tools/net-tools
make monitor_15_4
```

Step 1 - Compile and start echo-server In terminal #1, type:

```
west build -b qemu_x86 -d build/server samples/net/sockets/echo_server -- -
↪DEXTRA_CONF_FILE=overlay-qemu_802154.conf
west build -t server -d build/server
```

If you want to capture the network traffic between the two QEMUs, type:

```
west build -b qemu_x86 -d build/server samples/net/sockets/echo_server -- -G'Unix␣
↪Makefiles' -DEXTRA_CONF_FILE=overlay-qemu_802154.conf -DPCAP=capture.pcap
west build -t server -d build/server
```

Note that the `make` must be used for `server` target if packet capture option is set in command line. The `build/server/capture.pcap` file will contain the transferred data.

Step 2 - Compile and start echo-client In terminal #2, type:

```
west build -b qemu_x86 -d build/client samples/net/sockets/echo_client -- -
↪DEXTRA_CONF_FILE=overlay-qemu_802154.conf
west build -t client -d build/client
```

You should see data passed between the two QEMUs. Exit QEMU by pressing `CTRL+A x`.

Networking with Arm FVP User Mode

- *Introduction*
- *Using Arm FVP User Mode Networking with Zephyr*
- *Limitations*

This page is intended to serve as a starting point for anyone interested in using Arm FVP user mode networking with Zephyr.

Introduction User mode networking emulates a built-in IP router and DHCP server, and routes TCP and UDP traffic between the guest and host. It uses the user mode socket layer of the host to communicate with other hosts. This allows the use of a significant number of IP network services without requiring administrative privileges, or the installation of a separate driver on the host on which the model is running.

By default, Arm FVP uses the `172.20.51.0/24` network and runs a gateway at `172.20.51.254`. This gateway also functions as a DHCP server for the GOS, allowing it to be automatically assigned with an IP address `172.20.51.1`.

More details about Arm FVP user mode networking can be obtained from here: https://developer.arm.com/documentation/100964/latest/Introduction-to-Fast-Models/User-mode-networking

Using Arm FVP User Mode Networking with Zephyr Arm FVP user mode networking can be enabled in any applications and it doesn't need any configurations on the host system. This feature has been enabled in DHCPv4 client sample. See dhcpv4-client sample application.

Limitations

- You can use TCP and UDP over IP, but not ICMP (ping).
- User mode networking does not support forwarding UDP ports on the host to the model.
- You can only use DHCP within the private network.
- You can only make inward connections by mapping TCP ports on the host to the model. This is common to all implementations that provide host connectivity using NAT.
- Operations that require privileged source ports, for example NFS in its default configuration, do not work.
- If setup fails, or the parameter syntax is incorrect, there is no error reporting.

While developing networking software, it is usually necessary to connect and exchange data with the host system like a Linux desktop computer. Depending on what board is used for development, the following options are possible:

- QEMU using SLIP (Serial Line Internet Protocol).
  - Here IP packets are exchanged between Zephyr and the host system via serial port. This is the legacy way of transferring data. It is also quite slow so use it only when necessary. See *Networking with QEMU* for details.
- QEMU using built-in Ethernet driver.
  - Here IP packets are exchanged between Zephyr and the host system via QEMU's built-in Ethernet driver. Not all QEMU boards support built-in Ethernet so in some cases, you might need to use the SLIP method for host connectivity. See *Networking with QEMU Ethernet* for details.
- QEMU using SLIRP (Qemu User Networking).
  - QEMU User Networking is implemented using "slirp", which provides a full TCP/IP stack within QEMU and uses that stack to implement a virtual NAT'd network. As this support is built into QEMU, it can be used with any model and requires no admin privileges on the host machine, unlike TAP. However, it has several limitations including performance which makes it less valuable for practical purposes. See *Networking with QEMU User* for details.
- Arm FVP (User Mode Networking).
  - User mode networking emulates a built-in IP router and DHCP server, and routes TCP and UDP traffic between the guest and host. It uses the user mode socket layer of the host to communicate with other hosts. This allows the use of a significant number of IP network services without requiring administrative privileges, or the installation of a separate driver on the host on which the model is running. See *Networking with Arm FVP User Mode* for details.
- native_sim board.
  - The Zephyr instance can be executed as a user space process in the host system. This is the most convenient way to debug the Zephyr system as one can attach host debugger directly to the running Zephyr instance. This requires that there is an adaptation driver in Zephyr for interfacing with the host system. Two possible network drivers can be used for this purpose, a TAP virtual Ethernet driver and an offloaded sockets driver. See *Networking with native_sim board* for details.
- USB device networking.

  - Here, the Zephyr instance is run on a real board and the connectivity to the host system is done via USB. See *USB Device Networking* for details.
- Connecting multiple Zephyr instances together.
  - If you have multiple Zephyr instances, either QEMU or native_sim ones, and want to create a connection between them, see *Networking with multiple Zephyr instances* for details.
- Simulating IEEE 802.15.4 network between two QEMUs.
  - Here, two Zephyr instances are running and there is IEEE 802.15.4 link layer run over an UART between them. See *Networking with QEMU and IEEE 802.15.4* for details.
- Simulating Ethernet bridge network with native_sim.
  - Here, one Zephyr instance is running with Ethernet bridge enabled via `CONFIG_NET_ETHERNET_BRIDGE` Kconfig option. There exists two host network interfaces `zeth0` and `zeth1` and the network packets are bridged between those two interfaces. See *Ethernet bridge with native_sim board* for details.

Monitor Network Traffic

- *Host Configuration*
- *Zephyr Configuration*
- *Wireshark Configuration*

It is useful to be able to monitor the network traffic especially when debugging a connectivity issues or when developing new protocol support in Zephyr. This page describes how to set up a way to capture network traffic so that user is able to use Wireshark or similar tool in remote host to see the network packets sent or received by a Zephyr device.

See also the net-capture sample application from the Zephyr source distribution for configuration options that need to be enabled.

Host Configuration The instructions here describe how to setup a Linux host to capture Zephyr network RX and TX traffic. Similar instructions should work also in other operating systems.

On the Linux Host, find the Zephyr net-tools project, which can either be found in a Zephyr standard installation under the `tools/net-tools` directory or installed stand alone from its own git repository:

```
git clone https://github.com/zephyrproject-rtos/net-tools
```

The `net-tools` project provides a configure file to setup IP-to-IP tunnel interface so that we can transfer monitoring data from Zephyr to host.

In terminal #1, type:

```
./net-setup.sh -c zeth-tunnel.conf
```

This script will create following IPIP tunnel interfaces:

Interface name	Description
`zeth-ip6ip`	IPv6-over-IPv4 tunnel
`zeth-ipip`	IPv4-over-IPv4 tunnel
`zeth-ipip6`	IPv4-over-IPv6 tunnel
`zeth-ip6ip6`	IPv6-over-IPv6 tunnel

Zephyr will send captured network packets to one of these interfaces. The actual interface will depend on how the capturing is configured. You can then use Wireshark to monitor the proper network interface.

After the tunneling interfaces have been created, you can use for example `net-capture.py` script from `net-tools` project to print or save the captured network packets. The `net-capture.py` provides an UDP listener, it can print the captured data to screen and optionally can also save the data to a pcap file.

```
$ ./net-capture.py -i zeth-ip6ip -w capture.pcap
[20210408Z14:33:08.959589] Ether / IP / ICMP 192.0.2.1 > 192.0.2.2 echo-request 0 /
↪ Raw
[20210408Z14:33:08.976178] Ether / IP / ICMP 192.0.2.2 > 192.0.2.1 echo-reply 0 /␣
↪Raw
[20210408Z14:33:16.176303] Ether / IPv6 / ICMPv6 Echo Request (id: 0x9feb seq: 0x0)
[20210408Z14:33:16.195326] Ether / IPv6 / ICMPv6 Echo Reply (id: 0x9feb seq: 0x0)
[20210408Z14:33:21.194979] Ether / IPv6 / ICMPv6ND_NS / ICMPv6 Neighbor Discovery␣
↪Option - Source Link-Layer Address 02:00:5e:00:53:3b
[20210408Z14:33:21.217528] Ether / IPv6 / ICMPv6ND_NA / ICMPv6 Neighbor Discovery␣
↪Option - Destination Link-Layer Address 00:00:5e:00:53:ff
[20210408Z14:34:10.245408] Ether / IPv6 / UDP 2001:db8::2:47319 > 2001:db8::1:4242␣
↪/ Raw
[20210408Z14:34:10.266542] Ether / IPv6 / UDP 2001:db8::1:4242 > 2001:db8::2:47319␣
↪/ Raw
```

The `net-capture.py` has following command line options:

```
Listen captured network data from Zephyr and save it optionally to pcap file.
./net-capture.py \
     -i | --interface <network interface>
             Listen this interface for the data
     [-p | --port <UDP port>]
             UDP port (default is 4242) where the capture data is received
     [-q | --quiet]
             Do not print packet information
     [-t | --type <L2 type of the data>]
             Scapy L2 type name of the UDP payload, default is Ether
     [-w | --write <pcap file name>]
             Write the received data to file in PCAP format
```

Instead of the `net-capture.py` script, you can for example use `netcat` to provide an UDP listener so that the host will not send port unreachable message to Zephyr:

```
nc -l -u 2001:db8:200::2 4242 > /dev/null
```

The IP address above is the inner tunnel endpoint, and can be changed and it depends on how the Zephyr is configured. Zephyr will send UDP packets containing the captured network packets to the configured IP tunnel, so we need to terminate the network connection like this.

Zephyr Configuration In this example, we use the `native_sim` board. You can also use any other board that supports networking.

In terminal #3, type:

```
west build -b native_sim samples/net/capture -- -
↪DCONFIG_UART_NATIVE_PTY_AUTOATTACH_DEFAULT_CMD=\""gnome-terminal -- screen %s"\"
```

To see the Zephyr console and shell, start Zephyr instance like this:

```
build/zephyr/zephyr.exe -attach_uart
```

Any other application can be used too, just make sure that suitable configuration options are enabled (see `samples/net/capture/prj.conf` file for examples).

The network capture can be configured automatically if needed, but currently the `capture` sample application does not do that. User has to use `net-shell` to setup and enable the monitoring.

The network packet monitoring needs to be setup first. The `net-shell` has `net capture setup` command for doing that. The command syntax is

```
net capture setup <remote-ip-addr> <local-ip-addr> <peer-ip-addr>
     <remote> is the (outer) endpoint IP address
     <local> is the (inner) local IP address
     <peer> is the (inner) peer IP address
     Local and Peer IP addresses can have UDP port number in them (optional)
     like 198.0.51.2:9000 or [2001:db8:100::2]:4242
```

In Zephyr console, type:

```
net capture setup 192.0.2.2 2001:db8:200::1 2001:db8:200::2
```

This command will create the tunneling interface. The `192.0.2.2` is the remote host where the tunnel is terminated. The address is used to select the local network interface where the tunneling interface is attached to. The `2001:db8:200::1` tells the local IP address for the tunnel, the `2001:db8:200::2` is the peer IP address where the captured network packets are sent. The port numbers for UDP packet can be given in the setup command like this for IPv6-over-IPv4 tunnel

```
net capture setup 192.0.2.2 [2001:db8:200::1]:9999 [2001:db8:200::2]:9998
```

and like this for IPv4-over-IPv4 tunnel

```
net capture setup 192.0.2.2 198.51.100.1:9999 198.51.100.2:9998
```

If the port number is omitted, then `4242` UDP port is used as a default.

The current monitoring configuration can be checked like this:

```
uart:~$ net capture
Network packet capture disabled
                Capture  Tunnel
Device          iface    iface   Local                  Peer
NET_CAPTURE0    -        1      [2001:db8:200::1]:4242  [2001:db8:200::2]:4242
```

which will print the current configuration. As we have not yet enabled monitoring, the `Capture iface` is not set.

Then we need to enable the network packet monitoring like this:

```
net capture enable 2
```

The `2` tells the network interface which traffic we want to capture. In this example, the `2` is the `native_sim` board Ethernet interface. Note that we send the network traffic to the same interface that we are monitoring in this example. The monitoring system avoids to capture already captured network traffic as that would lead to recursion. You can use `net iface` command to see what network interfaces are available. Note that you cannot capture traffic from the tunnel interface as that would cause recursion loop. The captured network traffic can be sent to some other network interface if configured so. Just set the `<remote-ip-addr>` option properly in `net capture setup` so that the IP tunnel is attached to desired network interface. The capture status can be checked again like this:

```
uart:~$ net capture
Network packet capture enabled
                Capture  Tunnel
Device          iface    iface   Local                  Peer
NET_CAPTURE0    2        1      [2001:db8:200::1]:4242  [2001:db8:200::2]:4242
```

After enabling the monitoring, the system will send captured (either received or sent) network packets to the tunnel interface for further processing.

The monitoring can be disabled like this:

```
net capture disable
```

which will turn currently running monitoring off. The monitoring setup can be cleared like this:

```
net capture cleanup
```

It is not necessary to use `net-shell` for configuring the monitoring. The *network capture API* functions can be called by the application if needed.

Wireshark Configuration The Wireshark tool can be used to monitor the captured network traffic in a useful way.

You can monitor either the tunnel interfaces or the `zeth` interface. In order to see the actual captured data inside an UDP packet, see Wireshark decapsulate UDP document for instructions.

Network Tracing

User can enable network core stack and socket API calls tracing.

The `CONFIG_TRACING_NET_CORE` option controls the core network stack tracing. This option is enabled by default if tracing and networking are enabled. The system will start to collect the receiving and sending call verdicts i.e., whether the network packet was successfully sent or received. It will also collect packet sending or receiving timings i.e., how long it took to deliver the network packet, and the network interface, priority and traffic class used.

The `CONFIG_TRACING_NET_SOCKETS` option can be used to track BSD socket call usage in the system. It is enabled if tracing and BSD socket API support are enabled. The system will start to collect what BSD socket API calls are made and what parameters the API calls are using and returning.

See the *tracing documentation* for how to use the tracing service.

Protocol conformance testing with TTCN-3

- *How it fits together*
- *The suites*
- *Known gaps*
  - *DNS-SD legacy unicast queries*
  - *MQTT 5.0, packet identifiers and re-sending*
  - *Overlapping DNS queries*
- *Continuous integration*
- *Other TTCN-3 suites*

Zephyr's network protocols are covered from two directions. The tests under tests/net exercise the implementation from the inside, in C, built into the same image. Conformance suites written in TTCN-3 come at it from the outside: they speak the protocol over a real network interface, and check what Zephyr sends against what the standard requires.

The two catch different things. A test written against the implementation tends to encode what the implementation does. A suite written against the standard does not know what the implementation does, which is the point.

TTCN-3 is a language standardised by ETSI for writing tests. The suites here are compiled with Eclipse Titan, an open source TTCN-3 compiler, and are kept in the `net-tools` repository under `ttcn3`, alongside the other host side tools used for network testing.

Running the conformance suites

- *What a run needs*
- *Installing Titan*
  - *Building Titan from source*
- *Running the suites with the script*
- *Setting up the network interfaces*
  - *`zeth`, the shared interface*
  - *`zethL2`, the address-less interface*
- *Running the suites with Twister*
  - *Running as root*
  - *Why a run is serial*
- *Running a suite by hand*
- *Reading the result*
- *When a suite is skipped*
- *Troubleshooting*
  - *The suite does not compile*
  - *The suite sees nothing and times out*
  - *A run hangs or is cut off*
  - *Leftover state*

A run goes like this. Twister builds the system under test and starts it, the harness builds the TTCN-3 suite with Titan, the suite talks to the running application over a tap interface, and Titan's verdict becomes the test result.

What a run needs

- **A Titan installation**, with `TTCN3_DIR` pointing at it. See *Installing Titan*.
- **The third party TTCN-3 modules**, fetched once with `ttcn3/fetch-modules.sh`. They are cloned at pinned commits and are not part of the `net-tools` repository.
- **A checkout of net-tools**, which a west workspace already has: it is in `west.yml` under the `tools` group, which is not filtered out.
- **make**, because that is how Titan builds a suite.

- **The `zeth` interface**, or `zethL2` for a suite that works below the IP layer. See *Setting up the network interfaces*.
- **Root**, for a suite that cannot avoid a privileged port or a packet socket.
- **expect**, for a suite that runs through Titan's main controller.

The suites lists which suites need which of these, and scripts/net/run-conformance-tests.sh `--list` prints the same.

The harness looks for net-tools in `NET_TOOLS_BASE` if that is set, otherwise at `../tools/net-tools/ttcn3` relative to `ZEPHYR_BASE` and then one directory further up. All of this is checked before anything is built, and a missing piece skips the test with a reason rather than failing it.

Installing Titan Most distributions package a Titan, and that is what continuous integration installs:

```
sudo apt install --no-install-recommends eclipse-titan expect
export TTCN3_DIR=/usr
```

The packaged version trails the protocol modules the suites build against, so if a suite fails to compile, build a current Titan from source instead.

Building Titan from source `net-tools/docker/Dockerfile.ttcn3` builds Titan into `/opt/titan` and is the reference for doing it by hand, either as a container or as a recipe to follow. It is a local option, not what continuous integration uses.

Two things a hand built Titan has to get right. Titan is configured through a `Makefile.personal` in its source tree rather than a `configure` script, and `TTCN3_DIR` there is the install prefix. And `make install` has to be serial: parts of the runtime include headers that another part generates, and a parallel make loses that race.

Running the suites with the script scripts/net/run-conformance-tests.sh does what the next two sections describe in one command, and is the easiest way to run the suites: it finds net-tools, fetches the modules if they are missing, creates whichever interfaces the selected suites need, re-runs itself under `sudo` if a selected suite needs root, runs Twister once, and tears the interfaces down again.

```
export TTCN3_DIR=/usr
./scripts/net/run-conformance-tests.sh
```

Naming suites runs only those, which is the quick way to stay unprivileged while working on one:

```
./scripts/net/run-conformance-tests.sh mdns dns
```

`--list` shows the suites and what each one needs, `--keep` leaves the interfaces up for the next run, and `--start` and `--stop` do only that half. `--help` lists the rest, along with the directories it detected.

Because a privileged run creates files as root, the script hands the Twister output directory and the suite build directories back to the invoking user before it exits.

Setting up the network interfaces The suites use two tap interfaces, because a suite working below the IP layer cannot share a link with a host that answers for itself.

`zeth`, the shared interface Used by the suites that work over sockets, where the tester is just another host on the link:

```
cd $ZEPHYR_BASE/../tools/net-tools
sudo ./net-setup.sh --config zeth.conf start
```

The host holds `192.0.2.2/24` and `2001:db8::2`; Zephyr answers on `192.0.2.1` and `2001:db8::1`. Tear it down with `stop` in place of `start`.

zethL2, the address-less interface Used by the suites that work below the IP layer:

```
sudo ./net-setup.sh --config zeth-l2.conf --iface zethL2 start
```

This interface is deliberately given no IP address. Linux answers address resolution and neighbour discovery for any address it holds on any interface unless it is told otherwise, and an answer from the host would be indistinguishable from an answer from Zephyr. The tester speaks raw frames, so it needs no address of its own.

The configuration sets three sysctls to stop the host joining in: `arp_ignore=8` so it answers address resolution for no local address at all, `arp_announce=2` so it never answers with an address this interface does not hold, and `disable_ipv6=1` so there are no neighbour advertisements or router solicitations.

The name `zethL2` is not freely choosable; see *The test network*.

Running the suites with Twister Fetch the third party modules once. The script is safe to re-run:

```
cd $ZEPHYR_BASE/../tools/net-tools
./ttcn3/fetch-modules.sh
```

Then run the tests:

```
export TTCN3_DIR=/usr
cd $ZEPHYR_BASE
./scripts/twister -p native_sim --enable-slow -T tests/net/conformance
```

`--enable-slow` is required: the suites mark themselves slow, because a full run takes tens of minutes. `native_sim` is the only platform they allow.

A single suite is selected by its test identifier, which is `net.conformance.<suite>`:

```
./scripts/twister -p native_sim --enable-slow -T tests/net/conformance \
    -s net.conformance.mdns
```

They also carry the `net` and `conformance` tags, so `--tag conformance` picks up all of them.

Running as root Some suites have to be run as root. DHCP is defined on ports 67 and 68 and there is no way to move it elsewhere, so the tester cannot avoid binding a privileged port; and reading frames off a link needs a packet socket. Those tests skip themselves when they are not run with enough privilege.

Use `sudo -E` so that `TTCN3_DIR` and the rest of the environment survive. A run is either wholly privileged or wholly not — see *The harness* for why the two cannot be mixed.

Why a run is serial Every system under test answers to the same address on the same interface, so only one conformance test can be running at a time. They take an exclusive lock on the interface and wait for each other, which means a run of the whole directory is serial however many jobs Twister is given.

Running a suite by hand Twister is convenient but slow to go round. While writing or debugging a suite, run the two halves yourself.

Start the system under test and leave it running:

```
cd $ZEPHYR_BASE
west build -p -b native_sim -d ../build/mdns tests/net/conformance/mdns
../build/mdns/zephyr/zephyr.exe
```

Build and run the suite against it:

```
cd $ZEPHYR_BASE/../tools/net-tools/ttcn3
./build.sh mdns
cd suites/mdns/build
./mdns ../mdns.cfg
```

For a suite whose test cases create parallel test components, start it through the main controller instead:

```
ttcn3_start ./coap ../coap.cfg
```

A single test case is run by naming it:

```
./mdns ../mdns.cfg MDNS_Suite.tc_a_query
```

Addresses, the interface and the timeouts all come from the `[MODULE_PARAMETERS]` section of the suite's configuration file, so a run can be moved to a different link by editing one file rather than the suite.

One thing the harness does that you have to do yourself: put Titan's library directory on `LD_LIBRARY_PATH`.

Reading the result A Titan run ends with a count of each verdict and a verdict for the run:

```
Verdict statistics: 0 none (0.00 %), 7 pass (100.00 %), 0 inconc (0.00 %), 0 fail␣
↪(0.00 %), 0 error (0.00 %).
Test execution summary: 7 test cases were executed. Overall verdict: pass
```

`inconc` means a test case could not reach a conclusion, usually because something it depended on did not happen. It is not a pass. `error` means the suite itself failed, rather than the system under test.

The evidence is in two places. Titan writes a log per suite into the build directory, named from the `LogFile` setting in the configuration file. Twister writes `twister_harness.log` under its output directory, which carries the whole suite output at `INFO`.

When a suite is skipped Everything a suite needs is checked before anything is built, and a missing piece skips the test rather than failing it. The reasons, in the order they are checked:

Reason	What to do
`TTCN3_DIR is unset`	Install Titan and export `TTCN3_DIR`; see *Installing Titan*
`make is not installed`	Install make; Titan builds a suite with a generated makefile
`no TTCN-3 suites under ...`	net-tools was not found; set `NET_TOOLS_BASE`
`... has no <suite> suite`	The net-tools checkout predates the suite; update it
`third party modules are missing`	Run `ttcn3/fetch-modules.sh`
`the <iface> interface does not exist`	Create it with `net-setup.sh`; see *Setting up the network interfaces*
`ttcn3_start is not in TTCN3_DIR/bin`	Install `expect` and a Titan that ships the main controller
`has to be run as root`	Re-run under `sudo -E`, or use the script

Set `NET_CONFORMANCE_REQUIRED` in the environment to turn each of these into a failure. That is for a run whose purpose is the suites, such as the nightly job, where a test that did not run must not pass for one that did.

Troubleshooting

The suite does not compile Almost always a packaged Titan that trails the protocol modules the suite builds against. Build Titan from source.

The suite sees nothing and times out Check that the application and the suite are on the same interface: a suite working below IP wants `zethL2`, and the application has to be built with a `host-interface` property naming the same interface, which the test sets in `boards/native_sim.overlay`. If the host is answering on the link instead of Zephyr, the `zethL2` sysctls did not take; confirm with `sysctl net.ipv4.conf.zethL2.arp_ignore`.

A run hangs or is cut off Four timeouts nest around a run, and which one fires says where the problem is: 30 seconds for the application's ready line, 1800 seconds for the suite build, 600 seconds for the suite run, and 900 seconds for the Twister test as a whole. A suite that overruns is killed along with its whole process group, so no main controller is left behind.

Leftover state Tear the interfaces down with `net-setup.sh` and `stop`. The lock the tests take is a file named `zephyr-net-conformance-<euid>.lock` in the temporary directory; it is released when the process exits, so a stale one is harmless.

How the conformance tests are put together

- *The pieces*
- *The Zephyr side*
  - *The system under test*
  - *Twister integration*
- *The harness*
  - *Holding the interface*
  - *Suite traits*
  - *Building and running the suite*

- *Turning a verdict into a result*
- *The host side*
  - *Layout*
  - *How a suite is built*
  - *The shared TTCN-3 layer*
  - *The ethernet test port*
  - *Third party modules*
- *The test network*
- *Adding a suite*
  - *Choosing the shape*
  - *The host side*
  - *The Zephyr side*
  - *Recording what does not match*
  - *Trying it out*

There are four moving parts, spread over two repositories, and they meet only on the wire: a Zephyr application, a Twister and pytest harness, a shell wrapper around Eclipse Titan, and the TTCN-3 suite itself.

The pieces

Twister
: Builds the system under test, starts it, and runs the pytest harness against it. It contributes the test identifier, the platform restriction and the 900 second budget for the whole thing.

pytest harness
: tests/net/conformance/ttcn3_runner.py, shared by every test. It decides whether the suite can run at all, takes the interface lock, builds the suite, runs it and reads the verdict.

System under test
: An ordinary Zephyr application with the protocol enabled. Nothing about the test is compiled into it.

build.sh and Eclipse Titan
: The host side build. Titan compiles TTCN-3 to C++ and generates a makefile; `build.sh` arranges the sources so that it can.

TTCN-3 suite executable
: The test itself, driving the protocol from the outside.

Tap interface
: The only thing the two halves share. There is no control channel, no shared memory and no test hook in the Zephyr image.

The Zephyr side

The system under test Each application is deliberately ordinary: enable the protocol, do whatever keeps traffic flowing that the suite needs to observe, and print a distinctive ready line. That line is the only contract between the application and the harness — it is how the harness knows the stack is up before the suite starts sending.

A suite directory holds:

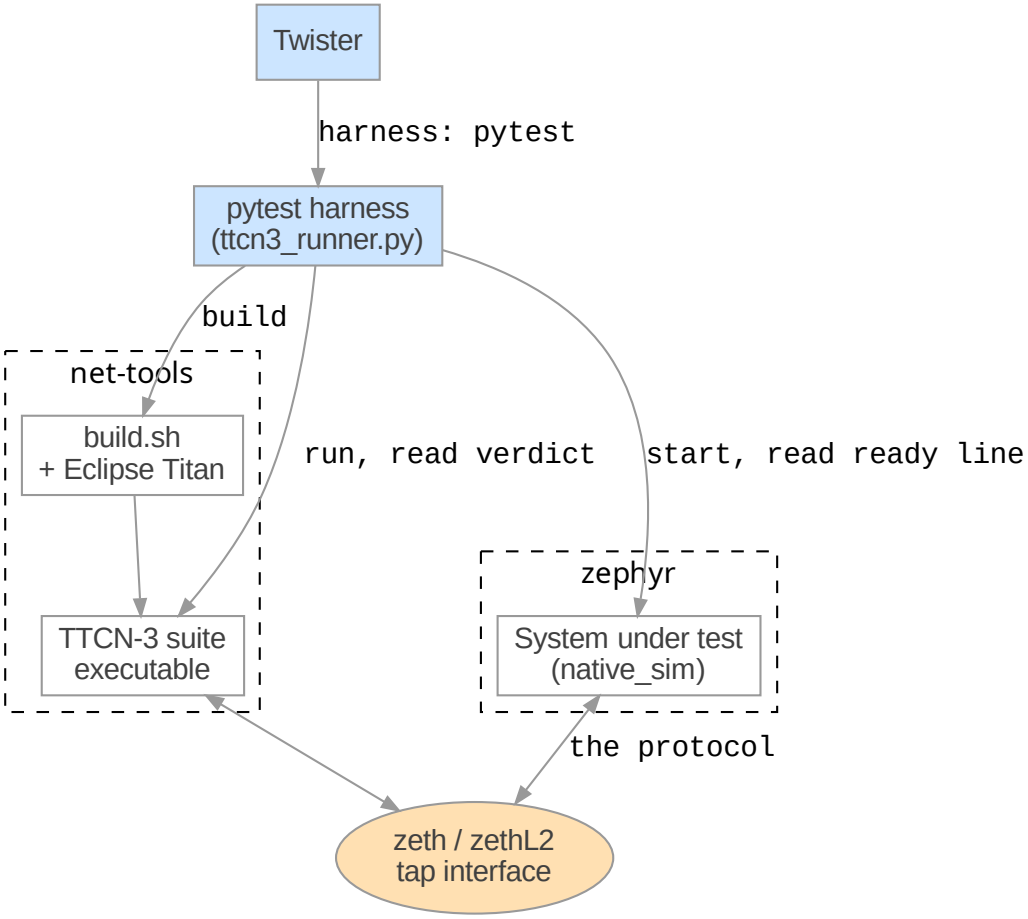

Fig. 4: What builds what, and where the two halves meet

```
tests/net/conformance/<suite>/
    CMakeLists.txt
    prj.conf
    README.rst
    tests.yaml
    src/main.c
    pytest/pytest.ini
    pytest/conftest.py
    pytest/test_<suite>_conformance.py
```

Twister integration Every `tests.yaml` shares the same block:

```
common:
  harness: pytest
  slow: true
  timeout: 900
  platform_allow:
    - native_sim
  integration_platforms:
    - native_sim
```

`harness: pytest` hands the run to the harness rather than reading console output for a ztest summary. `slow: true` keeps the suites out of an ordinary Twister run, since a full pass takes tens of minutes. The 900 second timeout has to cover building the suite as well as running it. `native_sim` is the only platform because the tap driver is what puts the system under test on a real link.

The test itself is three lines: request the lock, wait for the ready line, run the suite.

```
def test_mdns_conformance(network_lock, dut, suite_binary):
    dut.readlines_until(regex='mDNS responder ready', timeout=30.0)
    run_suite(suite_binary, SUITE)
```

The `network_lock` argument comes first on purpose; see below. `conftest.py` is the same in every test directory and does one thing: put the shared runner on `sys.path` and re-export the lock fixture.

Fig. 5: One conformance test, from lock to verdict

The harness Everything below lives in tests/net/conformance/ttcn3_runner.py.

Holding the interface Twister runs each test in its own pytest process, so excluding one test from another has to work between processes. The harness takes an exclusive `flock` on a lock file in a session scoped fixture.

The ordering matters as much as the lock. The fixture is requested *before* the `dut` fixture, so the system under test is not even started while another conformance test holds the interface — two applications answering to `192.0.2.1` at once would confuse both suites.

The lock file name carries the effective user id. A privileged suite runs as root, and root cannot open a lock file another user left behind in a sticky temporary directory. Since a run is wholly privileged or wholly not, a lock per user still excludes everything that could collide — which is also why a privileged and an unprivileged run must not be started at the same time.

Suite traits Three facts about a suite are read from `suites/<name>/build.conf`:

`MODE=parallel`
: The test cases create parallel test components, so the suite is run through Titan's main controller rather than as a single executable, and `expect` has to be installed.

`PRIVILEGED=yes`
: The suite binds a privileged port or opens a packet socket, so the run has to be root.

`L2=yes`
: The suite works below the IP layer, so it wants `zethL2` rather than `zeth`.

The same file is sourced as a shell fragment by `build.sh`, which is why it is written as shell assignments; the harness only matches substrings in it.

Building and running the suite Building is `build.sh <suite>` with a 1800 second budget, producing `suites/<suite>/build/<suite>`.

Running has to cope with Titan being installed two different ways. A distribution package puts its libraries in *TTCN3_DIR*`/lib/titan`, a source build in *TTCN3_DIR*`/lib`; the harness picks whichever exists and prepends it to `LD_LIBRARY_PATH`, and prepends *TTCN3_DIR*`/bin` to `PATH`. A parallel suite is started with `ttcn3_start`, any other suite directly.

The suite is started in a new session, so that a suite which overruns can be killed along with everything it started — a main controller left running would hold the interface for the next test.

Turning a verdict into a result Two regular expressions match the lines Titan prints at the end of a run, and three things are asserted: that a verdict was printed at all, that at least one test case ran, and that the overall verdict is `pass`. A suite that produced no output, or that ran nothing because every case was filtered out, fails rather than quietly passing. See *Reading the result* for what the verdicts mean.

The host side Everything below is in the `net-tools` repository, under `ttcn3`.

Layout

```
ttcn3/
    common/            shared TTCN-3 modules and the ethernet test port
    modules/           third party modules, cloned, not in git
    modules.txt        which modules, at which commit
    fetch-modules.sh   clone or check out the pinned commits
    build.sh           build one suite
    suites/<name>/     the suite, its sources.txt and its .cfg
```

How a suite is built `build.sh` wipes the suite's build directory and rebuilds it flat, symlinking every source it needs side by side in one directory.

The flatness is not tidiness, it is a workaround. The makefile Titan generates builds a dependency rule with `sed`, using the target stem as the pattern, and that breaks as soon as a source is named through a path containing a slash. Every source therefore has to be reachable by its bare name.

The link order is the suite's own sources, then `common`, then the module sources named in `common/sources.txt`, then those in the suite's own `sources.txt`. Then `ttcn3_makefilegen` generates the makefile — with `-s` for a single mode suite, without it for a parallel one — and `make` builds it.

The shared TTCN-3 layer `Zephyr_SUT` holds the module parameters every suite shares. A suite never writes an address or a timeout into itself; it takes them from here, so that a run can be moved to a different link by editing one configuration file.

Parameter	Default	Meaning
tsp_sut_ipv4	192.0.2.1	Where Zephyr answers
tsp_sut_ipv6	2001:db8::1	Where Zephyr answers, IPv6
tsp_tester_ipv4	192.0.2.2	Where the suite answers
tsp_tester_ipv6	2001:db8::2	Where the suite answers, IPv6
tsp_tester_interface	zeth	Needed for link local multicast
tsp_sut_hostname	zephyr	The name the responder owns
tsp_response_timeout	5.0	How long an answer may take
tsp_silence_timeout	2.0	How long silence is watched for

Zephyr_Transport provides the Zephyr_Tester component, with an IPL4asp port and helpers to listen, open, send, receive with a guard timer, and assert that nothing arrives. A socket based suite extends that component rather than opening sockets itself.

ARP_Types is hand written, and lives in common rather than in the arp suite, because any suite working below IP has to answer address resolution itself on a link where nothing else will. The Titan project publishes no ARP module.

The ethernet test port Titan publishes a raw link layer test port, LANL2asp, which this does not use. It captures with libpcap and opens the handle with a zero read timeout, which on Linux means "wait until a capture block fills". On a link as quiet as a test link the frames never reach the test, and there is no parameter to change it.

common/Ethernet_PT.cc reads a packet socket instead, which hands up every frame as it arrives. It takes three test port parameters: interface, which is required; source_address, defaulting to the interface's own; and ethertype, which when set passes only that type up.

Third party modules The suites build against the protocol modules and test ports the Titan project publishes, rather than defining their own message formats. Eleven repositories are used, each pinned to a commit in modules.txt and cloned on demand by fetch-modules.sh. They are not vendored, and the clones are ignored by git, so a suite that passes today still builds tomorrow. Moving a pin is a one line edit and a re-run.

The upstream modules are EPL-2.0 while everything written here is Apache-2.0. Both are OSI approved, which is what Zephyr asks of tooling that never becomes part of a Zephyr image; see *Contributing External Components*.

The test network zeth is an ordinary tap with addresses on both sides, and a suite using it is just another host on the link. zethL2 has no address at all, and the host is configured not to answer on it, so that the only thing replying to address resolution is Zephyr. *Setting up the network interfaces* covers creating them.

Warning

The name zethL2 is written into three places that have to agree, and nothing checks that they do:

- L2_INTERFACE in tests/net/conformance/ttcn3_runner.py, which decides which interface has to exist before the test runs
- host-interface in the boards/native_sim.overlay of each test on zethL2, which decides where the system under test appears
- system.pt.interface in the configuration file of each suite on zethL2, which decides where the suite listens

A mismatch shows up as a suite that sees no frames and times out, not as an error.

Adding a suite A suite has two halves, one in each repository, and one decision to make before either.

Choosing the shape **Sockets or raw frames.** A suite that can say what it means over UDP or TCP extends `Zephyr_Tester`, uses the `IPL4asp` port, runs on `zeth` and needs no privilege. A suite that has to see or send the frame itself uses `Ethernet_Port`, runs on `zethL2`, has to be root, and has to answer address resolution itself because nothing else on that link will. Prefer sockets; the raw path costs a second interface and a password prompt.

Single or parallel. Single mode unless the test cases create parallel test components. Parallel costs Titan's main controller and a dependency on `expect`, and it makes the suite harder to run by hand.

The host side Create `suites/<name>` containing the TTCN-3 source, a `sources.txt` naming the module sources the suite needs, and a `<name>.cfg` with the module parameters and the list of test cases to execute. A suite that only runs test cases from a third party module needs no source of its own — `coap` is the worked example.

Take addresses and timeouts from `Zephyr_SUT`. Add any new upstream module to `modules.txt` with a pinned commit. Add a `build.conf` if the suite is parallel, privileged or works below IP.

The Zephyr side Create an application under tests/net/conformance with the layout shown above. The `src/main.c` enables the protocol, generates whatever traffic the suite needs to observe, and prints a distinctive ready line. `tests.yaml` copies the common block and names the test `net.conformance.<name>`.

Of the three pytest files, `pytest.ini` and `conftest.py` are copied verbatim; `test_<name>_conformance.py` differs only in the suite name and the ready line it waits for.

Recording what does not match Where a suite asserts behaviour that does not match the standard, say so at the point the assertion is made, so that the divergence is recorded rather than frozen in silently. Ground that no suite covers at all belongs in *Known gaps*, and a new suite is a good moment to add a row to *The suites*.

Trying it out Run the two halves by hand first, as in *Running a suite by hand*, and only go through Twister once the suite passes. Expect the first build to be slow, and remember that a missing prerequisite skips the test rather than failing it — a suite that seems to pass instantly probably never ran.

How it fits together The Zephyr side of a conformance test is only the system under test: an ordinary application, configured to enable the protocol being tested. Nothing about the test is compiled into it, there is no control channel, and the suite drives it entirely over the network.

Those applications, and the harness that runs a suite against them, live under tests/net/conformance. Twister builds and starts the application, and a small pytest harness builds the suite with Titan, runs it, and turns Titan's verdict into a test result.

Each test skips itself when Titan, the third party TTCN-3 modules or the network interface is missing, so the suites are harmless in a run that has not been set up for them. See *Running the conformance suites* for what a run needs, and *How the conformance tests are put together* for how the parts are put together.

The suites Which interface a suite uses, and whether it has to be run as root, follow from what it does: a suite that works below the IP layer reads frames from a packet socket on a link of its own.

Suite	System under test	Interface	Runs as
mdns	tests/net/conformance/mdns	zeth	any user
dnssd	tests/net/conformance/dnssd	zeth	any user
dns	tests/net/conformance/dns	zeth	any user
sntp	tests/net/conformance/sntp	zeth	any user
mqtt	tests/net/conformance/mqtt	zeth	any user
coap	tests/net/conformance/coap	zeth	any user
dhcpv4	tests/net/conformance/dhcpv4	zeth	root
dhcpv4_server	tests/net/conformance/dhcpv4_server	zeth	root
arp	tests/net/conformance/arp	zethL2	root
ndp	tests/net/conformance/ndp	zethL2	root
tcp	tests/net/conformance/tcp	zethL2	root

Adding a suite is described in *Adding a suite*.

Known gaps Where a suite asserts behaviour that does not match the standard, it says so at the point the assertion is made, so that the divergence is recorded rather than frozen in silently. What follows is the other kind of gap: ground no suite covers yet.

DNS-SD legacy unicast queries The hostname side of the mDNS responder answers a legacy unicast query the way **RFC 6762** section 6.7 asks. The service discovery side does not: it builds its own messages, sets the cache flush bit on the records that belong to one instance, uses the lifetimes it would have used for a multicast answer, and echoes neither the identifier nor the question. Fixing it means reworking name compression offsets that are all computed from a fixed header size.

The `dnssd` suite records this rather than asserting the standard, in `f_check_legacy_shape`, so that a test does not sit failing until somebody gets to it. Each check there says what would have to change with it.

MQTT 5.0, packet identifiers and re-sending The `mqtt` suite covers MQTT 3.1.1. Zephyr also implements MQTT 5.0 (`CONFIG_MQTT_VERSION_5_0`), and the Titan project publishes no protocol module for it, so covering it would mean writing the message types before writing any test.

Packet identifiers and re-sending are not covered either. Zephyr's client leaves both to the application: `mqtt_publish()` sends the identifier and the duplicate flag it is given, so a test of either would test the system under test's own counter rather than the client.

Overlapping DNS queries The resolver renews its source port before sending to a server that has nothing outstanding, which with the default of one query at a time means every query. Queries that overlap on one server still share a port, so the check in the `dns` suite would not catch a regression in that case. See **RFC 5452** section 9.2.

Continuous integration These suites are not part of the ordinary Twister run: they need a Titan installation, a network interface facing the device, and a checkout of the suites, none of which a normal build has. They are also slow, and they cannot run at the same time as each other.

They run nightly instead, from .github/workflows/net_conformance.yml, which can also be started by hand from the Actions tab. The job installs the packaged Titan and sets `TTCN3_DIR=/usr`, brings up both interfaces in a container holding `NET_ADMIN` and the tap device, and runs the whole directory as root so that no suite is skipped. It sets `NET_CONFORMANCE_REQUIRED`, so a suite that cannot run fails rather than skips: a run that tested nothing must not look like one that passed. The Twister report and the harness logs are kept as artifacts.

Other TTCN-3 suites The Eclipse Titan project publishes protocol modules and test ports for a large number of protocols, as separate repositories under gitlab.eclipse.org/eclipse/titan. The suites here build against those rather than defining their own message formats.

Some complete suites exist there too. `titan.misc` contains a CoAP conformance suite that can be run against the coap-server sample; see *CoAP* for that one.

An older TTCN-3 suite for TCP, written at Intel for the TCP rewrite, informed what the `tcp` suite covers, but none of its code is used. It drove Zephyr through a JSON control channel and asserted the stack's internal state names, and the option that channel needed has been removed; see the 4.5 migration guide.

Networking APIs

Zephyr provides support for the standard BSD socket APIs (defined in include/zephyr/net/socket.h) for the applications to use. See *BSD socket API* for more details.

Apart of the standard API, Zephyr provides a set of custom networking APIs and libraries for the application to use. See the list below for details.

> **Note**
>
> The legacy connectivity API in include/zephyr/net/net_context.h should not be used by applications.

Overview Zephyr offers an implementation of a subset of the BSD Sockets API (a part of the POSIX standard). This API allows to reuse existing programming experience and port existing simple networking applications to Zephyr.

Here are the key requirements and concepts which governed BSD Sockets compatible API implementation for Zephyr:

- Has minimal overhead, similar to the requirement for other Zephyr subsystems.
- Is namespaced by default, to avoid name conflicts with well-known names like `close()`, which may be part of libc or other POSIX compatibility libraries. If enabled by `CONFIG_POSIX_API`, it will also expose POSIX compatible APIs.

BSD Sockets compatible API is enabled using `CONFIG_NET_SOCKETS` config option and implements the following operations: `socket()`, `close()`, `recv()`, `recvfrom()`, `send()`, `sendto()`, `connect()`, `bind()`, `listen()`, `accept()`, `fcntl()` (to set non-blocking mode), `getsockopt()`, `setsockopt()`, `poll()`, `select()`, `getaddrinfo()`, `getnameinfo()`.

Based on the namespacing requirements above, these operations are by default exposed as functions with `zsock_` prefix, e.g. `zsock_socket()` and `zsock_close()`. If the config option `CONFIG_POSIX_API` is defined, all the functions will be also exposed as aliases without the prefix. This includes the functions like `close()` and `fcntl()` (which may conflict with functions in libc or other libraries, for example, with the filesystem libraries).

Another entailment of the design requirements above is that the Zephyr API aggressively employs the short-read/short-write property of the POSIX API whenever possible (to minimize complexity and overheads). POSIX allows for calls like `recv()` and `send()` to actually process (receive or send) less data than requested by the user (on `SOCK_STREAM` type sockets). For example, a call `recv(sock, 1000, 0)` may return 100, meaning that only 100 bytes were read (short read), and the application needs to retry call(s) to receive the remaining 900 bytes.

The BSD Sockets API uses file descriptors to represent sockets. File descriptors are small integers, consecutively assigned from zero, shared among sockets, files, special devices (like stdin/stdout), etc. Internally, there is a table mapping file descriptors to internal object pointers. The file descriptor table is used by the BSD Sockets API even if the rest of the POSIX subsystem (filesystem, stdin/stdout) is not enabled.

Zephyr supports multiple types of BSD sockets, the following table summarizes what socket types are available:

Family	Type	Protocol	Description
AF_INET AF_INET6	SOCK_	IPPROTO_	Enabled if `CONFIG_NET_UDP` is set. Allows to send and receive UDP datagrams.
		IPPROTO_	Enabled if `CONFIG_NET_SOCKETS_ENABLE_DTLS` is set. Allows to send and receive DTLS datagrams.
	SOCK_	IPPROTO_	Enabled if `CONFIG_NET_TCP` is set. Allows to send and receive TCP data stream.
		IPPROTO_	Enabled if `CONFIG_NET_SOCKETS_SOCKOPT_TLS` is set. Allows to send and receive TLS data stream.
	SOCK_	IPPROTO_ <proto>	Enabled if `CONFIG_NET_SOCKETS_INET_RAW` is set. Allows to send and receive IPv4/IPv6 datagrams. Packets are filtered by L4 protocol specified. IPPROTO_IP is a wildcard protocol to receive all IP datagrams.
AF_PAC	SOCK_	ETH_P_ <proto>	Enabled if `CONFIG_NET_SOCKETS_PACKET_DGRAM` is set. Allows to send and receive packets without L2 header. Packets are filtered by L3 protocol specified. ETH_P_ALL is a wildcard protocol to receive all packets.
	SOCK_	ETH_P_	Enabled if `CONFIG_NET_SOCKETS_PACKET` is set. Allows to send and receive packets with L2 header included.
AF_CAN	SOCK_	CAN_RA	Enabled if `CONFIG_NET_SOCKETS_CAN` is set. Allows to send and receive CAN packets.

See sockets-echo-server and sockets-echo-client sample applications to learn how to create a sim-

ple server or client BSD socket based application.

IPv4 and IPv6 socket options Zephyr supports IP-level socket options through `zsock_setsockopt()` and `zsock_getsockopt()` at the `NET_IPPROTO_IP` (IPv4) and `NET_IPPROTO_IPV6` (IPv6) protocol levels. Option availability may depend on Kconfig settings and socket address family.

IPv4 options
Socket options for IPv4

IPv6 options
Socket options for IPv6

The `ZSOCK_IP_DONTFRAG` and `ZSOCK_IPV6_DONTFRAG` options are used internally by the QUIC stack during DPLPMTUD probing (see *Path MTU Discovery (DPLPMTUD)*).

Secure Sockets Zephyr provides an extension of standard POSIX socket API, allowing to create and configure sockets with TLS protocol types, facilitating secure communication. Secure functions for the implementation are provided by Mbed TLS library. Secure sockets implementation allows use of both TLS and DTLS protocols with standard socket calls. See `net_ip_protocol_secure` type for supported secure protocol versions.

To enable secure sockets, set the `CONFIG_NET_SOCKETS_SOCKOPT_TLS` option. To enable DTLS support, use `CONFIG_NET_SOCKETS_ENABLE_DTLS` option.

TLS credentials subsystem TLS credentials must be registered in the system before they can be used with secure sockets. See `tls_credential_add()` for more information.

When a specific TLS credential is registered in the system, it is assigned with numeric value of type `sec_tag_t`, called a tag. This value can be used later on to reference the credential during secure socket configuration with socket options.

The following TLS credential types can be registered in the system:

- `TLS_CREDENTIAL_CA_CERTIFICATE`
- `TLS_CREDENTIAL_PUBLIC_CERTIFICATE`
- `TLS_CREDENTIAL_PRIVATE_KEY`
- `TLS_CREDENTIAL_PSK`
- `TLS_CREDENTIAL_PSK_ID`

An example registration of CA certificate (provided in `ca_certificate` array) looks like this:

```
ret = tls_credential_add(CA_CERTIFICATE_TAG, TLS_CREDENTIAL_CA_CERTIFICATE,
                         ca_certificate, sizeof(ca_certificate));
```

By default certificates in DER format are supported. PEM support can be enabled in Mbed TLS settings.

Secure Socket Creation A secure socket can be created by specifying secure protocol type, for instance:

```
sock = socket(AF_INET, SOCK_STREAM, IPPROTO_TLS_1_2);
```

The protocol version specified when creating the secure socket indicates the minimum TLS version used for the TLS session.

Once created, it can be configured with socket options. For instance, the CA certificate and hostname can be set:

```
sec_tag_t sec_tag_opt[] = {
        CA_CERTIFICATE_TAG,
};

ret = setsockopt(sock, SOL_TLS, TLS_SEC_TAG_LIST,
                 sec_tag_opt, sizeof(sec_tag_opt));
```

```
char host[] = "google.com";

ret = setsockopt(sock, SOL_TLS, TLS_HOSTNAME, host, sizeof(host));
```

Once configured, socket can be used just like a regular TCP socket.

Note

Due to mbed TLS internal data buffering and `mbedtls_ssl_write()` function requirements, when a non-blocking `zsock_send()` returns `EAGAIN`, it is expected that the consecutive call to `zsock_send()` will contain the same data as the original call.

Several samples in Zephyr use secure sockets for communication. For a sample use see e.g. echo-server sample application or HTTP GET sample application.

Secure Sockets options Secure sockets offer the following options for socket management:

Socket options for TLS

- HTTP ClientImplement an HTTP(S) client that issues a variety of HTTP requests.
- HTTP GET using plain socketsImplement an HTTP(S) client using plain BSD sockets.

Socket offloading Zephyr allows to register custom socket implementations (called offloaded sockets). This allows for seamless integration for devices which provide an external IP stack and expose socket-like API.

Socket offloading can be enabled with `CONFIG_NET_SOCKETS_OFFLOAD` option. A network driver that wants to register a new socket implementation should use `NET_SOCKET_OFFLOAD_REGISTER` macro. The macro accepts the following parameters:

- **`socket_name`**
  An arbitrary name for the socket implementation.
- **`prio`**
  Socket implementation's priority. The higher the priority, the earlier this particular implementation will be processed when creating a new socket. Lower numeric value indicates higher priority.
- **`_family`**
  Socket family implemented by the offloaded socket. `AF_UNSPEC` indicates any family.
- **`_is_supported`**
  A filtering function, used to verify whether a particular socket family, type and protocol are supported by the offloaded socket implementation.
- **`_handler`**
  A function compatible with `socket()` API, used to create an offloaded socket.

Every offloaded socket implementation should also implement a set of socket APIs, specified in `socket_op_vtable` struct.

The function registered for socket creation should allocate a new file descriptor using `zvfs_reserve_fd()` function. Any additional actions, specific to the creation of a particular offloaded socket implementation, should take place after the file descriptor is allocated. As a final step, if the offloaded socket was created successfully, the file descriptor should be finalized with `zvfs_finalize_typed_fd()`, or `zvfs_finalize_fd()` functions. The finalize function allows to register a `socket_op_vtable` structure implementing socket APIs for an offloaded socket along with an optional socket context data pointer.

Finally, when an offloaded network interface is initialized, it should indicate that the interface is offloaded with `net_if_socket_offload_set()` function. The function registers the function used to create an offloaded socket (the same as the one provided in `NET_SOCKET_OFFLOAD_REGISTER`) at the network interface.

Offloaded socket creation When application creates a new socket with `socket()` function, the network stack iterates over all registered socket implementations (native and offloaded). Higher priority socket implementations are processed first. For each registered socket implementation, an address family is verified, and if it matches (or the socket was registered as `AF_UNSPEC`), the corresponding `_is_supported` function is called to verify the remaining socket parameters. The first implementation that fulfills the socket requirements (i. e. `_is_supported` returns true) will create a new socket with its `_handler` function.

The above indicates the importance of the socket priority. If multiple socket implementations support the same set of socket family/type/protocol, the first implementation processed by the system will create a socket. Therefore it's important to give the highest priority to the implementation that should be the system default.

The socket priority for native socket implementation is configured with Kconfig. Use `CONFIG_NET_SOCKETS_TLS_PRIORITY` to set the priority for the native TLS sockets. Use `CONFIG_NET_SOCKETS_PRIORITY_DEFAULT` to set the priority for the remaining native sockets.

Dealing with multiple offloaded interfaces As the `socket()` function does not allow to specify which network interface should be used by a socket, it's not possible to choose a specific implementation in case multiple offloaded socket implementations, supporting the same type of sockets, are available. The same problem arises when both native and offloaded sockets are available in the system.

To address this problem, a special socket implementation (called socket dispatcher) was introduced. The sole reason for this module is to postpone the socket creation for until the first operation on a socket is performed. This leaves an opening to use `SO_BINDTODEVICE` socket option, to bind a socket to a particular network interface (and thus offloaded socket implementation). The socket dispatcher can be enabled with `CONFIG_NET_SOCKETS_OFFLOAD_DISPATCHER` Kconfig option.

When enabled, the application can specify the network interface to use with `setsockopt()` function:

```
/* A "dispatcher" socket is created */
sock = socket(AF_INET, SOCK_DGRAM, IPPROTO_UDP);

struct ifreq ifreq = {
   .ifr_name = "SimpleLink"
};

/* The socket is "dispatched" to a particular network interface
 * (offloaded or not).
 */
setsockopt(sock, SOL_SOCKET, SO_BINDTODEVICE, &ifreq, sizeof(ifreq));
```

Similarly, if TLS is supported by both native and offloaded sockets, TLS_NATIVE socket option can be used to indicate that a native TLS socket should be created. The underlying socket can then be bound to a particular network interface:

```
/* A "dispatcher" socket is created */
sock = socket(AF_INET, SOCK_STREAM, IPPROTO_TLS_1_2);

int tls_native = 1;

/* The socket is "dispatched" to a native TLS socket implmeentation.
 * The underlying socket is a "dispatcher" socket now.
 */
setsockopt(sock, SOL_TLS, TLS_NATIVE, &tls_native, sizeof(tls_native));

struct ifreq ifreq = {
   .ifr_name = "SimpleLink"
};

/* The underlying socket is "dispatched" to a particular network interface
 * (offloaded or not).
 */
setsockopt(sock, SOL_SOCKET, SO_BINDTODEVICE, &ifreq, sizeof(ifreq));
```

In case no SO_BINDTODEVICE socket option is used on a socket, the socket will be dispatched according to the default priority and filtering rules on a first socket API call.

Socket Services

- *Overview*
- *API Description*
- *Application Overview*
- *API Reference*

Overview The socket service API can be used to install a handler that is called if there is data received on a socket. The API helps to avoid creating a dedicated thread for each TCP or UDP service that the application provides. Instead one thread is created that serves data to multiple listening sockets which saves memory as only one thread needs to be created in the system in this case.

See sockets-service-echo sample application to learn how to create a simple BSD socket based server application using the sockets service API. The source code for this sample application can be found at: samples/net/sockets/echo_service.

API Description Socket service API is enabled using `CONFIG_NET_SOCKETS_SERVICE` config option and implements the following operations:

- `NET_SOCKET_SERVICE_SYNC_DEFINE`

  Define a network socket service. This socket service is created with extern scope so it can be used from multiple C source files.

- `NET_SOCKET_SERVICE_SYNC_DEFINE_STATIC`

  Define a network socket service with static scope. This socket service can only be used within one C source file.

- `net_socket_service_register()`

  Register pollable sockets for this service. User must create the sockets before this call.

- `net_socket_service_unregister()`

  Remove pollable sockets for this service. User can close the sockets after this call.

- `net_socket_service_handler_t`

  User specified callback which is called when data is received on the listening socket.

Application Overview If the socket service API is enabled, an application must create the service like this:

```
#define MAX_BUF_LEN 1500
#define MAX_SERVICES 1

static void udp_service_handler(struct net_socket_service_event *pev)
{
     struct pollfd *pfd = &pev->event;
     int client = pfd->fd;
     struct sockaddr_in6 addr;
```

(continues on next page)

(continued from previous page)

```
	socklen_t addrlen = sizeof(addr);

	/* In this example we use one static buffer in order to avoid
	 * having a large stack.
	 */
	static char buf[MAX_BUF_LEN];

	len = recvfrom(client, buf, sizeof(buf), 0,
		       (struct sockaddr *)&addr, &addrlen);
	if (len <= 0) {
		/* Error */
		...
		return;
	}

	/* Do something with the received data. The pev variable contains
	 * user data that was stored in the socket service when it was
	 * registered.
	 */
}

NET_SOCKET_SERVICE_SYNC_DEFINE_STATIC(service_udp, udp_service_handler,␣
↪MAX_SERVICES);
```

The application needs to create the sockets, then register them to the socket service after which the socket service thread will start to call the callback for any incoming data.

```
/* Create one or multiple sockets */

struct pollfd sockfd_udp[1] = { 0 };
int sock, ret;

sock = socket(AF_INET6, SOCK_DGRAM, IPPROTO_UDP);
if (sock < 0) {
	LOG_ERR("socket: %d", -errno);
	return -errno;
}

/* Set possible socket options after creation */
...

/* Then bind the socket to local address */
if (bind(sock, (struct sockaddr *)addr, sizeof(*addr)) < 0) {
	LOG_ERR("bind: %d", -errno);
	return -errno;
}

/* Set the polled sockets */
sockfd_udp[0].fd = sock;
sockfd_udp[0].events = POLLIN;

/* Register UDP socket to service handler */
ret = net_socket_service_register(&service_udp, sockfd_udp,
                                  ARRAY_SIZE(sockfd_udp), NULL);
if (ret < 0) {
	LOG_ERR("Cannot register socket service handler (%d)", ret);
```

(continues on next page)

(continued from previous page)

```
	return ret;
}

/* Application logic happens here. When application is ready to
 * quit, one should unregister the socket service and close the
 * socket.
 */

(void)net_socket_service_unregister(&service_udp);
close(sock);
```

The TCP socket needs slightly different logic as we need to add any accepted socket to the listening socket by calling the `net_socket_service_register()` for the accepted socket.

```
struct sockaddr_in6 client_addr;
socklen_t client_addr_len = sizeof(client_addr);
struct pollfd sockfd_tcp[1] = { 0 };
int client;

/* TCP socket service is created similar way as the UDP one */
sock = socket(AF_INET6, SOCK_STREAM, IPPROTO_TCP);
if (sock < 0) {
	LOG_ERR("socket: %d", -errno);
	return -errno;
}

if (bind(sock, (struct sockaddr *)addr, sizeof(*addr)) < 0) {
	LOG_ERR("bind: %d", -errno);
	return -errno;
}

if (listen(sock, 5) < 0) {
	LOG_ERR("listen: %d", -errno);
	return -errno;
}

while (1) {
	client = accept(tcp_sock, (struct sockaddr *)&client_addr,
			&client_addr_len);
	if (client < 0) {
		LOG_ERR("accept: %d", -errno);
		continue;
	}

	inet_ntop(client_addr.sin6_family, &client_addr.sin6_addr,
		  addr_str, sizeof(addr_str));
	LOG_INF("Connection from %s (%d)", addr_str, client);

	sockfd_tcp[0].fd = client;
	sockfd_tcp[0].events = POLLIN;

	/* Register all the sockets to service handler */
	ret = net_socket_service_register(&service_tcp, sockfd_tcp,
					  ARRAY_SIZE(sockfd_tcp), NULL);
	if (ret < 0) {
		LOG_ERR("Cannot register socket service handler (%d)", ret);
```

(continues on next page)

(continued from previous page)

```
            break;
        }
}
```

For any closed TCP client connection we need to remove the closed socket from the polled socket list.

```
/* If the TCP socket is closed while reading the data in the handler,
 * mark it as non pollable.
 */
if (sockfd_tcp[0].fd == client) {
        sockfd_tcp[0].fd = -1;

        /* Update the handler so that client connection is
         * not monitored any more.
         */
        (void)net_socket_service_register(&service_tcp, sockfd_tcp,
                                          ARRAY_SIZE(sockfd_tcp), NULL);
        close(client);

        LOG_INF("Connection from %s closed", addr_str);
}
```

Please see a more complete example in the `echo_service` sample source code at samples/net/sockets/echo_service/src/main.c.

DNS Resolve

- *Overview*
- *Network management events*
- *Sample usage*
- *API Reference*

Overview The DNS resolver implements a basic DNS resolver according to **RFC 1035**. Supported DNS answers are IPv4/IPv6 addresses and CNAME.

If a CNAME is received, the DNS resolver will create another DNS query. The number of additional queries is controlled by the `CONFIG_DNS_RESOLVER_ADDITIONAL_QUERIES` Kconfig variable.

The multicast DNS (mDNS) client resolver support can be enabled by setting `CONFIG_MDNS_RESOLVER` Kconfig option. See **RFC 6762** for more details about mDNS.

The link-local multicast name resolution (LLMNR) client resolver support can be enabled by setting the `CONFIG_LLMNR_RESOLVER` Kconfig variable. See **RFC 4795** for more details about LLMNR.

For more information about DNS configuration variables, see: subsys/net/lib/dns/Kconfig. The DNS resolver API can be found at include/zephyr/net/dns_resolve.h.

DNS-based service discovery queries described in **RFC 6763** can be done by `dns_resolve_service()` API. The returned service descriptions are passed to user supplied callback and the API sets the address family to `AF_LOCAL` to indicate that the value is not an IPv4 or IPv6 address but a service description.

Example:

```
#include <zephyr/net/dns_resolve.h>

#define MAX_STR_LEN CONFIG_DNS_RESOLVER_MAX_NAME_LEN

static void dns_result_cb(enum dns_resolve_status status,
                          struct dns_addrinfo *info,
                          void *user_data)
{
     if (status == DNS_EAI_CANCELED) {
             /* dns: Timeout while resolving name */
             return;
     }

     if (status == DNS_EAI_INPROGRESS && info) {
             char str[MAX_STR_LEN + 1];

             if (info->ai_family == NET_AF_INET) {
                     net_addr_ntop(NET_AF_INET,
                                   &net_sin(&info->ai_addr)->sin_addr,
                                   str, NET_IPV4_ADDR_LEN);
             } else if (info->ai_family == NET_AF_INET6) {
                     net_addr_ntop(NET_AF_INET6,
                                   &net_sin6(&info->ai_addr)->sin6_addr,
                                   str, NET_IPV6_ADDR_LEN);
             } else if (info->ai_family == AF_LOCAL) {
                     /* service discovery */
                     memset(str, 0, MAX_STR_LEN);
                     memcpy(str, info->ai_canonname,
                            MIN(info->ai_addrlen, MAX_STR_LEN));
             } else {
                     strncpy(str, "Invalid proto family", MAX_STR_LEN + 1);
             }

             str[MAX_STR_LEN] = '\0';

             printk("dns: %s\n", str);
             return;
     }
```

(continues on next page)

(continued from previous page)

```
	if (status == DNS_EAI_ALLDONE) {
		printk("dns: All results received\n");
		return;
	}

	if (status == DNS_EAI_FAIL) {
		printk("dns: No such name found.\n");
		return;
	}

	printk("dns: Unhandled status %d received (errno %d)\n", status, errno);
}

#define DNS_TIMEOUT (MSEC_PER_SEC * 5) /* in ms */

static void discover_service(void)
{
	int ret = dns_resolve_service(dns_resolve_get_default(),
				      "_http._tcp.dns-sd.org",
				      NULL, dns_result_cb,
				      NULL, DNS_TIMEOUT);
	...
}
```

The above query would return output like this:

As the service discovery query could return long strings and the packet size could be large, you might need to adjust following Kconfig options:

- `CONFIG_DNS_RESOLVER_MAX_ANSWER_SIZE`. This tells the maximum size of the answer, typical value for this option could be 1024. The default size for this option is 512 bytes.
- `CONFIG_DNS_RESOLVER_MAX_NAME_LEN`. This tells the maximum length of the returned name. The value depends on your expected data size, typical value might be 128 bytes.

Network management events The DNS resolver raises the following `NET_MGMT_EVENT` events:

- `NET_EVENT_DNS_SERVER_ADD` — a single DNS server slot was added to the resolver. Raised once per slot, with the originating interface as the event payload.
- `NET_EVENT_DNS_SERVER_DEL` — a single DNS server slot was removed, with the originating interface as the event payload.
- `NET_EVENT_DNS_SERVERS_RECONFIGURED` — the DNS server configuration was refreshed via `dns_resolve_reconfigure()` or `dns_resolve_reconfigure_with_interfaces()`. Raised on every successful call regardless of whether individual server slots actually changed, with `NULL` iface (system-level event).

`ADD` and `DEL` are *delta* events: when `dns_resolve_reconfigure()` is called with a server set identical to the existing one, neither `ADD` nor `DEL` fires — the resolver intentionally suppresses them to avoid cancelling in-flight queries on DHCP-offer retransmit and IPv6 RA. Consumers that need a "DNS configuration is ready again" gate after a network event (for example, after a PPP iface re-establishes and pushes the same DNS servers via IPCP on every PM resume cycle) should listen for `NET_EVENT_DNS_SERVERS_RECONFIGURED` rather than `NET_EVENT_DNS_SERVER_ADD`.

Sample usage See dns-resolve sample application for details.

Datagram PLPMTUD API

- *Overview*
- *Configuration*
- *Usage model*
- *API Reference*

Overview Zephyr provides a generic **Datagram Packetization Layer Path MTU Discovery** (DPLPMTUD) implementation based on **RFC 8899**. It is intended for UDP-based transports (QUIC, CoAP over UDP, custom protocols) that must discover how large a datagram payload can be without relying on local IP fragmentation.

The subsystem splits responsibilities as follows:

Generic stack (`subsys/net/ip/dplpmtud.c`)

- Per-destination search state: validated PLPMTU, probe size, retry count, bounds
- Binary search between the base PLPMTU (1200 bytes) and the path ceiling
- Integration with the existing PMTU destination cache (ICMP PTB in, validated size out)
- Black-hole handling when the PMTU cache reports an MTU below the base PLPMTU

Transport consumer

- Construct probe datagrams at the size returned by `net_dplpmtud_get_path_probe_size()`
- Send probes with don't fragment enabled (see *IPv4 and IPv6 socket options* and `ZSOCK_IP_DONTFRAG` / `ZSOCK_IPV6_DONTFRAG`)
- Map transport ACK/loss to `net_dplpmtud_on_path_probe_acked()` and `net_dplpmtud_on_path_probe_lost()`

QUIC is the first in-tree consumer. Other transports can use the same API without duplicating the RFC 8899 state machine.

Configuration Enable DPLPMTUD per address family:

- `CONFIG_NET_IPV4_PMTU` and `CONFIG_NET_IPV4_PMTU_DPLPMTUD` for IPv4
- `CONFIG_NET_IPV6_PMTU` and `CONFIG_NET_IPV6_PMTU_DPLPMTUD` for IPv6

Both families also require `CONFIG_NET_UDP`. The umbrella option `CONFIG_NET_PMTU_DPLPMTUD` is selected when either family option is enabled.

ICMP-based PMTU reduction (Packet Too Big) remains available through `CONFIG_NET_IPV4_PMTU_PTB` and `CONFIG_NET_IPV6_PMTU_PTB`. DPLPMTUD complements PTB by actively probing for larger sizes when the path allows it.

The number of concurrent paths tracked matches CONFIG_NET_IPV4_PMTU_DESTINATION_CACHE_ENTRIES and CONFIG_NET_IPV6_PMTU_DESTINATION_CACHE_ENTRIES respectively.

Usage model Initialize one net_dplpmtud_path per remote destination (or reuse the handle for the lifetime of a connection):

```
struct net_dplpmtud_path path;
uint16_t max_plpmtu = 1452U; /* transport / peer limit, or 0 if uncapped */
int mtu;
int probe;
int ret;

ret = net_dplpmtud_init_path(&path, &remote_addr, max_plpmtu);
if (ret < 0) {
    /* handle error */
}

mtu = net_dplpmtud_get_path_mtu(&path);
if (mtu < 0) {
    mtu = NET_DPLPMTUD_BASE_PLPMTU;
}

/* Application data must fit in @a mtu bytes (transport framing excluded). */
```

Probe lifecycle:

1. Call net_dplpmtud_get_path_probe_size(). A return value of 0 means no probe is needed. The path must already be initialized; getters do not create cache entries.
2. If net_dplpmtud_path_probe_in_flight() is false, build and send a probe datagram of that size with don't fragment set (socket option or per-datagram control message in zsock_sendmsg()).
3. Call net_dplpmtud_on_path_probe_sent() to reserve the probe in the generic state machine, then transmit the probe datagram.
4. If the send fails, call net_dplpmtud_on_path_probe_lost() so core and transport state stay aligned.
5. On transport confirmation, call net_dplpmtud_on_path_probe_acked() or net_dplpmtud_on_path_probe_lost().

Update net_dplpmtud_set_path_max_plpmtu() when the transport learns a new ceiling (for example a QUIC max_udp_payload_size transport parameter).

Call net_dplpmtud_note_path_blackhole() if the transport detects a black hole independent of ICMP. PTB updates below the base PLPMTU are applied automatically through the PMTU cache.

Network Management

- *Overview*
- *Requesting a defined procedure*
- *Listening to network events*

- *Defining a network management procedure*
- *Signaling a network event*
- *API Reference*

Overview The Network Management APIs allow applications, as well as network layer code itself, to call defined network routines at any level in the IP stack, or receive notifications on relevant network events. For example, by using these APIs, application code can request a scan be done on a Wi-Fi- or Bluetooth-based network interface, or request notification if a network interface IP address changes.

The Network Management API implementation is designed to save memory by eliminating code at build time for management routines that are not used. Distinct and statically defined APIs for network management procedures are not used. Instead, defined procedure handlers are registered by using a `NET_MGMT_REGISTER_REQUEST_HANDLER` macro. Procedure requests are done through a single `net_mgmt()` API that invokes the registered handler for the corresponding request.

The current implementation is experimental and may change and improve in future releases.

Requesting a defined procedure All network management requests are of the form `net_mgmt(mgmt_request, ...)`. The `mgmt_request` parameter is a bit mask that tells which stack layer is targeted, if a `net_if` object is implied, and the specific management procedure being requested. The available procedure requests depend on what has been implemented in the stack.

To avoid extra cost, all `net_mgmt()` calls are direct. Though this may change in a future release, it will not affect the users of this function.

Listening to network events You can receive notifications on network events by registering a callback function and specifying a set of events used to filter when your callback is invoked. The callback will have to be unique for a pair of layer and code, whereas on the command part it will be a mask of events.

At runtime two functions are available, `net_mgmt_add_event_callback()` for registering the callback function, and `net_mgmt_del_event_callback()` for unregistering a callback. A helper function, `net_mgmt_init_event_callback()`, can be used to ease the initialization of the callback structure.

Additionally `NET_MGMT_REGISTER_EVENT_HANDLER` can be used to register a callback handler at compile time.

When an event occurs that matches a callback's event set, the associated callback function is invoked with the actual event code. This makes it possible for different events to be handled by the same callback function, if desired.

Warning

Event set filtering allows false positives for events that have the same layer and layer code. A callback handler function **must** check the event code (passed as an argument) against the specific network events it will handle, **regardless** of how many events were in the set passed to `net_mgmt_init_event_callback()`.

Note that in order to receive events from multiple layers, one must have multiple listeners registered, one for each layer being listened. The callback handler function can be shared between different layer events.

(False positives can occur for events which have the same layer and layer code.)

An example follows.

```
/*
 * Set of events to handle.
 * See e.g. include/zephyr/net/net_event.h for some NET_EVENT_xxx values.
 */
#define EVENT_IFACE_SET (NET_EVENT_IF_xxx | NET_EVENT_IF_yyy)
#define EVENT_IPV4_SET (NET_EVENT_IPV4_xxx | NET_EVENT_IPV4_yyy)

struct net_mgmt_event_callback iface_callback;
struct net_mgmt_event_callback ipv4_callback;

void callback_handler(struct net_mgmt_event_callback *cb,
                      uint64_t mgmt_event,
                      struct net_if *iface)
{
        if (mgmt_event == NET_EVENT_IF_xxx) {
                /* Handle NET_EVENT_IF_xxx */
        } else if (mgmt_event == NET_EVENT_IF_yyy) {
                /* Handle NET_EVENT_IF_yyy */
        } else if (mgmt_event == NET_EVENT_IPV4_xxx) {
                /* Handle NET_EVENT_IPV4_xxx */
        } else if (mgmt_event == NET_EVENT_IPV4_yyy) {
                /* Handle NET_EVENT_IPV4_yyy */
        } else {
                /* Spurious (false positive) invocation. */
        }
}

void register_cb(void)
{
        net_mgmt_init_event_callback(&iface_callback, callback_handler,
                                     EVENT_IFACE_SET);
        net_mgmt_init_event_callback(&ipv4_callback, callback_handler,
                                     EVENT_IPV4_SET);
        net_mgmt_add_event_callback(&iface_callback);
        net_mgmt_add_event_callback(&ipv4_callback);
}
```

Or similarly using `NET_MGMT_REGISTER_EVENT_HANDLER`.

Note

The `info` and `info_length` arguments are only usable if `CONFIG_NET_MGMT_EVENT_INFO` is enabled. Otherwise these are `NULL` and zero.

```
/*
 * Set of events to handle.
 */
#define EVENT_IFACE_SET (NET_EVENT_IF_xxx | NET_EVENT_IF_yyy)
#define EVENT_IPV4_SET (NET_EVENT_IPV4_xxx | NET_EVENT_IPV4_yyy)

static void event_handler(uint64_t mgmt_event, struct net_if *iface,
                          void *info, size_t info_length,
                          void *user_data)
{
```

(continues on next page)

(continued from previous page)

```
        if (mgmt_event == NET_EVENT_IF_xxx) {
                /* Handle NET_EVENT_IF_xxx */
        } else if (mgmt_event == NET_EVENT_IF_yyy) {
                /* Handle NET_EVENT_IF_yyy */
        } else if (mgmt_event == NET_EVENT_IPV4_xxx) {
                /* Handle NET_EVENT_IPV4_xxx */
        } else if (mgmt_event == NET_EVENT_IPV4_yyy) {
                /* Handle NET_EVENT_IPV4_yyy */
        } else {
                /* Spurious (false positive) invocation. */
        }
}

NET_MGMT_REGISTER_EVENT_HANDLER(iface_event_handler, EVENT_IFACE_SET,
                                event_handler, NULL);
NET_MGMT_REGISTER_EVENT_HANDLER(ipv4_event_handler, EVENT_IPV4_SET,
                                event_handler, NULL);
```

See include/zephyr/net/net_event.h for available generic core events that can be listened to.

Defining a network management procedure You can provide additional management procedures specific to your stack implementation by defining a handler and registering it with an associated mgmt_request code.

Management request code are defined in relevant places depending on the targeted layer or eventually, if l2 is the layer, on the technology as well. For instance, all IP layer management request code will be found in the include/zephyr/net/net_event.h header file. But in case of an L2 technology, let's say Ethernet, these would be found in include/zephyr/net/ethernet.h

You define your handler modeled with this signature:

```
static int your_handler(uint64_t mgmt_event, struct net_if *iface,
                        void *data, size_t len);
```

and then register it with an associated mgmt_request code:

```
NET_MGMT_REGISTER_REQUEST_HANDLER(<mgmt_request code>, your_handler);
```

This new management procedure could then be called by using:

```
net_mgmt(<mgmt_request code>, ...);
```

Signaling a network event You can signal a specific network event using the `net_mgmt_event_notify()` function and provide the network event code. See include/zephyr/net/net_mgmt.h for details. As for the management request code, event code can be also found on specific L2 technology mgmt headers, for example include/zephyr/net/ieee802154_mgmt.h would be the right place if 802.15.4 L2 is the technology one wants to listen to events.

Network Statistics

- *Overview*
- *API Reference*

Overview Network statistics are collected if `CONFIG_NET_STATISTICS` is set. Individual component statistics for IPv4 or IPv6 can be turned off if those statistics are not needed. See various options in subsys/net/ip/Kconfig.stats file for details.

By default, the system collects network statistics per network interface. This can be controlled by `CONFIG_NET_STATISTICS_PER_INTERFACE` option.

The `CONFIG_NET_STATISTICS_USER_API` option can be set if the application wants to collect statistics for further processing. The network management interface API is used for that. See *Network Management* for details.

The `CONFIG_NET_STATISTICS_ETHERNET` option can be set to collect generic Ethernet statistics. If the `CONFIG_NET_STATISTICS_ETHERNET_VENDOR` option is set, then Ethernet device driver can collect Ethernet device specific statistics. These statistics can then be transferred to application for processing.

If the `CONFIG_NET_SHELL` option is set, then network shell can show statistics information with `net stats` command.

- *Use*
- *API Reference*

Overview Zephyr's network infrastructure mostly uses the millisecond-resolution uptime clock to track timeouts, with both deadlines and durations measured with 32-bit unsigned values. The 32-bit value rolls over at 49 days 17 hours 2 minutes 47.296 seconds.

Timeout processing is often affected by latency, so that the time at which the timeout is checked may be some time after it should have expired. Handling this correctly without arbitrary expectations of maximum latency requires that the maximum delay that can be directly represented be a 31-bit non-negative number (`INT32_MAX`), which overflows at 24 days 20 hours 31 minutes 23.648 seconds.

Most network timeouts are shorter than the delay rollover, but a few protocols allow for delays that are represented as unsigned 32-bit values counting seconds, which corresponds to a 42-bit millisecond count.

The net_timeout API provides a generic timeout mechanism to correctly track the remaining time for these extended-duration timeouts.

Use The simplest use of this API is:

1. Configure a network timeout using `net_timeout_set()`.
2. Use `net_timeout_evaluate()` to determine how long it is until the timeout occurs. Schedule a timeout to occur after this delay.
3. When the timeout callback is invoked, use `net_timeout_evaluate()` again to determine whether the timeout has completed, or whether there is additional time remaining. If the latter, reschedule the callback.
4. While the timeout is running, use `net_timeout_remaining()` to get the number of seconds until the timeout expires. This may be used to explicitly update the timeout, which should be done by canceling any pending callback and restarting from step 1 with the new timeout.

The `net_timeout` contains a `sys_snode_t` that allows multiple timeout instances to be aggregated to share a single kernel timer element. The application must use `net_timeout_evaluate()` on all instances to determine the next timeout event to occur.

`net_timeout_deadline()` may be used to reconstruct the full-precision deadline of the timeout. This exists primarily for testing but may have use in some applications, as it does allow a millisecond-resolution calculation of remaining time.

Networking Context The net_context API is not meant for application use. Application should use *BSD Sockets* API instead.

Promiscuous Mode

- *Overview*
- *Sample usage*
- *API Reference*

Overview Promiscuous mode is a mode for a network interface controller that causes it to pass all traffic it receives to the application rather than passing only the frames that the controller is specifically programmed to receive. This mode is normally used for packet sniffing as used to diagnose network connectivity issues by showing an application all the data being transferred over the network. (See the Wikipedia article on promiscuous mode for more information.)

The network promiscuous APIs are used to enable and disable this mode, and to wait for and receive a network data to arrive. Not all network technologies or network device drivers support promiscuous mode.

Sample usage First the promiscuous mode needs to be turned ON by the application like this:

```
ret = net_promisc_mode_on(iface);
if (ret < 0) {
        if (ret == -EALREADY) {
                printf("Promiscuous mode already enabled\n");
        } else {
                printf("Cannot enable promiscuous mode for "
                       "interface %p (%d)\n", iface, ret);
        }
}
```

If there is no error, then the application can start to wait for network data:

```
while (true) {
        pkt = net_promisc_mode_wait_data(K_FOREVER);
        if (pkt) {
                print_info(pkt);
        }

        net_pkt_unref(pkt);
}
```

Finally the promiscuous mode can be turned OFF by the application like this:

```
ret = net_promisc_mode_off(iface);
if (ret < 0) {
        if (ret == -EALREADY) {
                printf("Promiscuous mode already disabled\n");
        } else {
                printf("Cannot disable promiscuous mode for "
                       "interface %p (%d)\n", iface, ret);
        }
}
```

See net-promiscuous-mode for a more comprehensive example.

Simple Network Time Protocol Library

- *Overview*
- *API Reference*

Overview The SNTP library implements **RFC 4330**.

SNTP provides a way to synchronize clocks in computer networks.

The client (CONFIG_SNTP) queries the time from an SNTP server. The server (CONFIG_SNTP_SERVER) answers such queries on UDP port 123, on every enabled address family. The application is responsible for setting the system clock, and tells the server where its time comes from with sntp_server_clock_source(). Until it does so, the server answers with the leap indicator set to "clock not synchronized" and stratum 16, so that clients discard its timestamps.

SOCKS5 Proxy Support

- *Overview*
- *SOCKS5 API*
- *SOCKS5 Proxy Usage in MQTT*

Overview The SOCKS library implements SOCKS5 support, which allows Zephyr to connect to peer devices via a network proxy.

See this SOCKS5 Wikipedia article for a detailed overview of how SOCKS5 works.

For more information about the protocol itself, see **RFC 1928**.

SOCKS5 API The SOCKS5 support is enabled by CONFIG_SOCKS Kconfig variable. Application wanting to use the SOCKS5 must set the SOCKS5 proxy host address by calling setsockopt() like this:

```
static int set_proxy(int sock, const struct sockaddr *proxy_addr,
                     socklen_t proxy_addrlen)
{
    int ret;

    ret = setsockopt(sock, SOL_SOCKET, SO_SOCKS5,
                     proxy_addr, proxy_addrlen);
    if (ret < 0) {
            return -errno;
    }

    return 0;
}
```

SOCKS5 Proxy Usage in MQTT For MQTT client, there is `mqtt_client_set_proxy()` API that the application can call to setup SOCKS5 proxy. See mqtt-publisher sample application for usage example.

Trickle Timer Library

- *Overview*
- *API Reference*

Overview The Trickle timer library implements **RFC 6206**.

The Trickle algorithm allows nodes in a lossy shared medium (e.g., low-power and lossy networks) to exchange information in a highly robust, energy efficient, simple, and scalable manner.

API Reference
Trickle Algorithm Library

Websocket Client API

- *Overview*
- *Websocket Transport*
- *API Reference*

Overview The Websocket client library allows Zephyr to connect to a Websocket server. The Websocket client API can be used directly by application to establish a Websocket connection to server, or it can be used as a transport for other network protocols like MQTT.

See this Websocket Wikipedia article for a detailed overview of how Websocket works.

For more information about the protocol itself, see **RFC 6455**.

Websocket Transport The Websocket API allows it to be used as a transport for other high level protocols like MQTT. The Zephyr MQTT client library can be configured to use Websocket transport by enabling `CONFIG_MQTT_LIB_WEBSOCKET` and `CONFIG_WEBSOCKET_CLIENT` Kconfig options.

First a socket needs to be created and connected to the Websocket server:

```
sock = socket(family, SOCK_STREAM, IPPROTO_TCP);
...
ret = connect(sock, addr, addr_len);
...
```

The Websocket transport socket is then created like this:

```
ws_sock = websocket_connect(sock, &config, timeout, user_data);
```

The Websocket socket can then be used to send or receive data, and the Websocket client API will encapsulate the sent or received data to/from Websocket packet payload. Both the `websocket_xxx()` API or normal BSD socket API functions can be used to send and receive application data.

```
ret = websocket_send_msg(ws_sock, buf_to_send, buf_len,
                         WEBSOCKET_OPCODE_DATA_BINARY, true, true,
                         K_FOREVER);
...
ret = send(ws_sock, buf_to_send, buf_len, 0);
```

If normal BSD socket functions are used, then currently only TEXT data is supported. In order to send BINARY data, the `websocket_send_msg()` must be used.

When done, the Websocket transport socket must be closed. User should handle the lifecycle(close/reuse) of tcp socket after websocket_disconnect.

```
ret = close(ws_sock);
or
ret = websocket_disconnect(ws_sock);
```

Network Packet Capture

- *Overview*
- *Cooked Mode Capture*
- *Sample usage*
- *API Reference*

Overview The `net_capture` API allows user to monitor the network traffic in one of the Zephyr network interfaces and send that traffic to external system for analysis. The monitoring can be setup either manually using `net-shell` or automatically by using the `net_capture` API.

Cooked Mode Capture If capturing is enabled and configured, the system will automatically capture network traffic for a given network interface. If you would like to capture network data when there is no network interface involved, then you need to use the cooked mode capture API.

In cooked mode capture, arbitrary network packets can be captured and there does not need to be network interface involved. For example low level HDLC packets in PPP can be captured, as the HDLC L2 layer data is stripped away when using the normal network interface based capture. Also CANBUS or Bluetooth network data could be captured although currently there is no support in the network stack to capture those.

The cooked mode capture works like this:

- An `any` network interface is created. It acts as a sink where the cooked mode captured packets are written by the cooked mode capture API.
- A `cooked` virtual network interface is attached on top of this `any` interface.
- The `cooked` interface must be configured to capture certain L2 packet types using the network interface configuration API.

- When cooked mode capture API is used, the caller must specify what is the layer 2 protocol type of the captured data. The cooked mode capture API is then able to determine what to capture when receiving such a L2 packet.
- The network packet capturing infrastructure is then setup so that the `cooked` interface is marked as captured network interface. The packets received by the `cooked` interface via the `any` interface are then automatically placed to the capture IP tunnel and sent to remote host for analysis.

For example, in the sample capture application, these network interfaces are created:

```
Interface any (0x808ab3c) (Dummy) [1]
==============================
Virtual interfaces attached to this : 2
Device    : NET_ANY (0x80849a4)

Interface cooked (0x808ac94) (Virtual) [2]
================================
Virtual name : Cooked mode capture
Attached  : 1 (Dummy / 0x808ab3c)
Device    : NET_COOKED (0x808497c)

Interface eth0 (0x808adec) (Ethernet) [3]
================================
Virtual interfaces attached to this : 4
Device    : zeth0 (0x80849b8)
IPv6 unicast addresses (max 4):
     fe80::5eff:fe00:53e6 autoconf preferred infinite
     2001:db8::1 manual preferred infinite
IPv4 unicast addresses (max 2):
     192.0.2.1/255.255.255.0 overridable preferred infinite

Interface net0 (0x808af44) (Virtual) [4]
================================
Virtual name : Capture tunnel
Attached  : 3 (Ethernet / 0x808adec)
Device    : IP_TUNNEL0 (0x8084990)
IPv6 unicast addresses (max 4):
     2001:db8:200::1 manual preferred infinite
     fe80::efed:6dff:fef2:b1df autoconf preferred infinite
     fe80::56da:1eff:fe5e:bc02 autoconf preferred infinite
```

In this example, the `192.0.2.2` is the address of the outer end point of the host that terminates the tunnel. Zephyr uses this address to select the internal interface to use for the tunnel. In this example it is interface 3.

The interface 2 is a virtual interface that runs on top of interface 1. The cooked capture packets are written by the capture API to sink interface 1. The packets propagate to interface 2 because it is linked to the first interface. The `net capture enable 2` net-shell command will cause the packets sent to interface 2 to be written to capture interface 4, which in turn then capsulates the packets and tunnels them to peer via the Ethernet interface 3.

The above IP addresses might change if you change the addresses in the sample samples/net/capture/overlay-tunnel.conf file.

Sample usage See net-capture sample application and *Monitor Network Traffic* for details.

Network Packet Management

Packet Management

- *Overview*
  - *Architectural notes*
  - *Concurrency and Thread Safety*
- *Memory management*
  - *Allocation*
  - *Buffer allocation*
  - *Deallocation*
- *Operations*
  - *Read and Write access*
  - *Data access*
- *API Reference*

Overview Network packets are the main data the networking stack manipulates. Such data is represented through the net_pkt structure which provides a means to hold the packet, write and read it, as well as necessary metadata for the core to hold important information. Such an object is called net_pkt in this document.

The data structure and the whole API around it are defined in include/zephyr/net/net_pkt.h.

Architectural notes There are two network packets flows within the stack, **TX** for the transmission path, and **RX** for the reception one. In both paths, each net_pkt is written and read from the beginning to the end, or more specifically from the headers to the payload.

Concurrency and Thread Safety The `net_pkt` structure and its associated APIs are **not thread-safe**. The network stack relies on a strict **Exclusive Ownership** model. When a network packet is created or received, it is owned by a single thread or execution context at any given time.

Concurrency is managed using the following primary patterns:

- **Ownership Transfer via FIFOs:** The most common lifecycle of a `net_pkt` involves passing it between isolated execution contexts (e.g., from an RX driver thread to the IP stack). Once a packet is enqueued, the sender drops its reference and loses access.
- **Shallow Cloning ("net_pkt_shallow_clone"):** If a packet must be retained by one layer (such as TCP for potential retransmission) while simultaneously processed by another, `net_pkt_shallow_clone()` is used to create a new wrapper pointing to the same underlying read-only data (the data buffers themselves are thread-safely reference counted).
- **Coarse-Grained Protocol Locks:** When packets are deliberately held in memory queues, they are protected by higher-level subsystem locks (such as connection mutexes).

The `atomic_ref` field within `struct net_pkt` is for memory lifecycle management (preventing Use-After-Free conditions) and is not a lock for concurrent mutation.

Memory management

Allocation All net_pkt objects come from a pre-defined pool of struct net_pkt. Such pool is defined via

```
NET_PKT_SLAB_DEFINE(name, count)
```

Note, however, one will rarely have to use it, as the core provides already two pools, one for the TX path and one for the RX path.

Allocating a raw net_pkt can be done through:

```
pkt = net_pkt_alloc(timeout);
```

However, by its nature, a raw net_pkt is useless without a buffer and needs various metadata information to become relevant as well. It requires at least to get the network interface it is meant to be sent through or through which it was received. As this is a very common operation, a helper exist:

```
pkt = net_pkt_alloc_on_iface(iface, timeout);
```

A more complete allocator exists, where both the net_pkt and its buffer can be allocated at once:

```
pkt = net_pkt_alloc_with_buffer(iface, size, family, proto, timeout);
```

See below how the buffer is allocated.

Buffer allocation The net_pkt object does not define its own buffer, but instead uses an existing object for this: `net_buf`. (See *Network Buffers* for more information). However, it mostly hides the usage of such a buffer because net_pkt brings network awareness to buffer allocation and, as we will see later, its operation too.

To allocate a buffer, a net_pkt needs to have at least its network interface set. This works if the family of the packet is unknown at the time of buffer allocation. Then one could do:

```
net_pkt_alloc_buffer(pkt, size, proto, timeout);
```

Where proto could be 0 if unknown (there is no IPPROTO_UNSPEC).

As seen previously, the net_pkt and its buffer can be allocated at once via `net_pkt_alloc_with_buffer()`. It is actually the most widely used allocator.

The network interface, the family, and the protocol of the packet are used by the buffer allocation to determine if the requested size can be allocated. Indeed, the allocator will use the network interface to know the MTU and then the family and protocol for the headers space (if only these 2 are specified). If the whole fits within the MTU, the allocated space will be of the requested size plus, eventually, the headers space. If there is insufficient MTU space, the requested size will be shrunk so the possible headers space and new size will fit within the MTU.

For instance, on an Ethernet network interface, with an MTU of 1500 bytes:

```
pkt = net_pkt_alloc_with_buffer(iface, 800, NET_AF_INET4, IPPROTO_UDP, K_FOREVER);
```

will successfully allocate 800 + 20 + 8 bytes of buffer for the new net_pkt where:

```
pkt = net_pkt_alloc_with_buffer(iface, 1600, NET_AF_INET4, IPPROTO_UDP, K_FOREVER);
```

will successfully allocate 1500 bytes, and where 20 + 8 bytes (IPv4 + UDP headers) will not be used for the payload.

On the receiving side, when the family and protocol are not known:

```
pkt = net_pkt_rx_alloc_with_buffer(iface, 800, AF_UNSPEC, 0, K_FOREVER);
```

will allocate 800 bytes and no extra header space. But a:

```
pkt = net_pkt_rx_alloc_with_buffer(iface, 1600, AF_UNSPEC, 0, K_FOREVER);
```

will allocate 1514 bytes, the MTU + Ethernet header space.

One can increase the amount of buffer space allocated by calling `net_pkt_alloc_buffer()`, as it will take into account the existing buffer. It will also account for the header space if net_pkt's family is a valid one, as well as the proto parameter. In that case, the newly allocated buffer space will be appended to the existing one, and not inserted in the front. Note however such a use case is rather limited. Usually, one should know from the start how much size should be requested.

Deallocation Each net_pkt is reference counted. At allocation, the reference is set to 1. The reference count can be incremented with `net_pkt_ref()` or decremented with `net_pkt_unref()`. When the count drops to zero the buffer is also un-referenced and net_pkt is automatically placed back into the free net_pkt_slabs

If net_pkt's buffer is needed even after net_pkt deallocation, one will need to reference once more all the chain of net_buf before calling last net_pkt_unref. See *Network Buffers* for more information.

Operations There are two ways to access the net_pkt buffer, explained in the following sections: basic read/write access and data access, the latter being the preferred way.

Read and Write access As said earlier, though net_pkt uses net_buf for its buffer, it provides its own API to access it. Indeed, a network packet might be scattered over a chain of net_buf objects, the functions provided by net_buf are then limited for such case. Instead, net_pkt provides functions which hide all the complexity of potential non-contiguous access.

Data movement into the buffer is made through a cursor maintained within each net_pkt. All read/write operations affect this cursor. Note as well that read or write functions are strict on their length parameters: if it cannot r/w the given length it will fail. Length is not interpreted as an upper limit, it is instead the exact amount of data that must be read or written.

As there are two paths, TX and RX, there are two access modes: write and overwrite. This might sound a bit unusual, but is in fact simple and provides flexibility.

In write mode, whatever is written in the buffer affects the length of actual data present in the buffer. Buffer length should not be confused with the buffer size which is a limit any mode cannot pass. In overwrite mode then, whatever is written must happen on valid data, and will not affect the buffer length. By default, a newly allocated net_pkt is on write mode, and its cursor points to the beginning of its buffer.

Let's see now, step by step, the functions and how they behave depending on the mode.

When freshly allocated with a buffer of 500 bytes, a net_pkt has 0 length, which means no valid data is in its buffer. One could verify this by:

```
len = net_pkt_get_len(pkt);
```

Now, let's write 8 bytes:

```
net_pkt_write(pkt, data, 8);
```

The buffer length is now 8 bytes. There are various helpers to write a byte, or big endian uint16_t, uint32_t.

```
net_pkt_write_u8(pkt, &foo);
net_pkt_write_be16(pkt, &ba);
net_pkt_write_be32(pkt, &bar);
```

Logically, net_pkt's length is now 15. But if we try to read at this point, it will fail because there is nothing to read at the cursor where we are at in the net_pkt. It is possible, while in write mode, to read what has been already written by resetting the cursor of the net_pkt. For instance:

```
net_pkt_cursor_init(pkt);
net_pkt_read(pkt, data, 15);
```

This will reset the cursor of the pkt to the beginning of the buffer and then let you read the actual 15 bytes present. The cursor is then again pointing at the end of the buffer.

To set a large area with the same byte, a memset function is provided:

```
net_pkt_memset(pkt, 0, 5);
```

Our net_pkt has now a length of 20 bytes.

Switching between modes can be achieved via `net_pkt_set_overwrite()` function. It is possible to switch mode back and forth at any time. The net_pkt will be set to overwrite and its cursor reset:

```
net_pkt_set_overwrite(pkt, true);
net_pkt_cursor_init(pkt);
```

Now the same operators can be used, but it will be limited to the existing data in the buffer, i.e. 20 bytes.

If it is necessary to know how much space is available in the net_pkt call:

```
net_pkt_available_buffer(pkt);
```

Or, if headers space needs to be accounted for, call:

```
net_pkt_available_payload_buffer(pkt, proto);
```

If you want to place the cursor at a known position use the function `net_pkt_skip()`. For example, to go after the IP header, use:

```
net_pkt_cursor_init(pkt);
net_pkt_skip(pkt, net_pkt_ip_header_len(pkt));
```

Data access Though the API shown previously is rather simple, it involves always copying things to and from the net_pkt buffer. In many occasions, it is more relevant to access the information stored in the buffer contiguously, especially with network packets which embed headers.

These headers are, most of the time, a known fixed set of bytes. It is then more natural to have a structure representing a certain type of header. In addition to this, if it is known the header size appears in a contiguous area of the buffer, it will be way more efficient to cast the actual position in the buffer to the type of header. Either for reading or writing the fields of such header, accessing it directly will save memory.

Net pkt comes with a dedicated API for this, built on top of the previously described API. It is able to handle both contiguous and non-contiguous access transparently.

There are two macros used to define a data access descriptor: `NET_PKT_DATA_ACCESS_DEFINE` when it is not possible to tell if the data will be in a contiguous area, and

NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE when it is guaranteed the data is in a contiguous area.

Let's take the example of IP and UDP. Both IPv4 and IPv6 headers are always found at the beginning of the packet and are small enough to fit in a net_buf of 128 bytes (for instance, though 64 bytes could be chosen).

```
NET_PKT_DATA_ACCESS_CONTIGUOUS_DEFINE(ipv4_access, struct net_ipv4_hdr);
struct net_ipv4_hdr *ipv4_hdr;

ipv4_hdr = (struct net_ipv4_hdr *)net_pkt_get_data(pkt, &ipv4_access);
```

It would be the same for struct net_ipv4_hdr. For a UDP header it is likely not to be in a contiguous area in IPv6 for instance so:

```
NET_PKT_DATA_ACCESS_DEFINE(udp_access, struct net_udp_hdr);
struct net_udp_hdr *udp_hdr;

udp_hdr = (struct net_udp_hdr *)net_pkt_get_data(pkt, &udp_access);
```

At this point, the cursor of the net_pkt points at the beginning of the requested data. On the RX path, these headers will be read but not modified so to proceed further the cursor needs to advance past the data. There is a function dedicated for this:

```
net_pkt_acknowledge_data(pkt, &ipv4_access);
```

On the TX path, however, the header fields have been modified. In such a case:

```
net_pkt_set_data(pkt, &ipv4_access);
```

If the data are in a contiguous area, it will advance the cursor relevantly. If not, it will write the data and the cursor will be updated. Note that `net_pkt_set_data()` could be used in the RX path as well, but it is slightly faster to use `net_pkt_acknowledge_data()` as this one does not care about contiguity at all, it just advances the cursor via `net_pkt_skip()` directly.

MAC Address Configuration Ethernet drivers can delegate most MAC address handling during initialization to `net_eth_mac_config` and `net_eth_mac_load()`. The structure is typically stored in the driver configuration and initialized with `NET_ETH_MAC_DT_CONFIG_INIT` or

NET_ETH_MAC_DT_INST_CONFIG_INIT, which translate the devicetree properties into one of the following behaviors:

- NET_ETH_MAC_STATIC – use the full local-mac-address property.
- NET_ETH_MAC_RANDOM – generate a random locally administered MAC address, optionally using the bytes provided in zephyr,mac-address-prefix as the first octets.
- NET_ETH_MAC_NVMEM – read the remaining bytes from the "mac-address" *NVMEM* cell, again optionally prefixed by zephyr,mac-address-prefix.
- NET_ETH_MAC_DEFAULT – fall back to the driver's default logic (for example, a factory-programmed MAC address stored in peripheral registers).

Driver integration Embed the net_eth_mac_config structure inside the driver's configuration and a static buffer inside the driver's data:

```
struct my_eth_config {
    struct net_eth_mac_config mac_cfg;
    /* more config fields */
};

struct my_eth_data {
    uint8_t mac_addr[NET_ETH_ADDR_LEN];
    /* more data fields */
};

static const struct my_eth_config my_eth_config_0 = {
    .mac_cfg = NET_ETH_MAC_DT_INST_CONFIG_INIT(0),
};
static struct my_eth_data my_eth_data_0;
```

During initialization, call net_eth_mac_load() before registering the address with the network interface. The helper copies any statically provided bytes, fills the remaining octets, and performs the necessary validation. Drivers can still fall back to SoC-specific storage when no configuration was provided:

```
static int my_eth_init(const struct device *dev)
{
    const struct my_eth_config *cfg = dev->config;
    struct my_eth_data *data = dev->data;
    int ret;

    ret = net_eth_mac_load(&cfg->mac_cfg, data->mac_addr);
    if (ret == -ENODATA) {
        ret = my_eth_hw_read_mac(dev, data->mac_addr);
    }

    return ret;
}

static void my_eth_iface_init(struct net_if *iface)
{
    const struct device *dev = net_if_get_device(iface);
    struct my_eth_data *data = dev->data;

    net_if_set_link_addr(iface, data->mac_addr, sizeof(data->mac_addr),␣
↪NET_LINK_ETHERNET);
}
```

Devicetree examples The examples below show how to pick a MAC address configuration for an ethernet controller node such as `&eth0`.

Static MAC address

```
&eth0 {
    local-mac-address = [00 11 22 33 44 55];
};
```

Random MAC address with prefix

```
&eth0 {
    zephyr,mac-address-prefix = [00 04 25];
    zephyr,random-mac-address;
};
```

NVMEM-provided MAC address with prefix MAC address can be retrieved from a non-volatile memory, typically an EEPROM, thanks to the *NVMEM API*.

```
&eth0 {
    zephyr,mac-address-prefix = [00 12 34];
    nvmem-cells = <&macaddr_cell>;
    nvmem-cell-names = "mac-address";
};

&eeprom0 {
    nvmem-layout {
        compatible = "fixed-layout";
        #address-cells = <1>;
        #size-cells = <1>;

        macaddr_cell: cell@0 {
            reg = <0x0 0x6>;
            #nvmem-cell-cells = <0>;
        };
    };
};
```

When no MAC-related properties are present, `net_eth_mac_load()` returns `-ENODATA` and the driver is expected to use its existing mechanism (for example, reading the hardware registers or using a build-time constant).

Changing the MAC address at runtime Applications that need to set MAC addresses dynamically (for example to adopt an address obtained from a management interface) need to enable the networking management API with `CONFIG_NET_MGMT` and use `net_mgmt` with `NET_REQUEST_ETHERNET_SET_MAC_ADDRESS`. The request internally calls the driver's `ethernet_api.set_config()` implementation.

```
static int app_set_mac_address(const struct device *dev)
{
    struct net_if *iface = net_if_lookup_by_dev(dev);
    struct ethernet_req_params params = {
        .mac_address = { { 0x02, 0x00, 0x5E, 0x01, 0x02, 0x03 } },
    };

    /* Make sure the iface is down */
```

(continues on next page)

(continued from previous page)

```
    return net_mgmt(NET_REQUEST_ETHERNET_SET_MAC_ADDRESS, iface,
                    &params, sizeof(params));
}
```

Virtual LAN (VLAN) Support

- *Overview*
- *API Reference*

Overview Virtual LAN (VLAN) is a partitioned and isolated computer network at the data link layer (OSI layer 2). For ethernet network this refers to IEEE 802.1Q

In Zephyr, each individual VLAN is modeled as a virtual network interface. This means that there is an ethernet network interface that corresponds to a real physical ethernet port in the system. A virtual network interface is created for each VLAN, and this virtual network interface connects to the real network interface. This is similar to how Linux implements VLANs. The *eth0* is the real network interface and *vlan0* is a virtual network interface that is run on top of *eth0*.

VLAN support must be enabled at compile time by setting option `CONFIG_NET_VLAN` and `CONFIG_NET_VLAN_COUNT` to reflect how many network interfaces there will be in the system. For example, if there is one network interface without VLAN support, and two with VLAN support, the `CONFIG_NET_VLAN_COUNT` option should be set to 3.

Even if VLAN is enabled in a `prj.conf` file, the VLAN needs to be activated at runtime by the application. The VLAN API provides a `net_eth_vlan_enable()` function to do that. The application needs to give the network interface and desired VLAN tag as a parameter to that function. The VLAN tagging for a given network interface can be disabled by a `net_eth_vlan_disable()` function. The application needs to configure the VLAN network interface itself, such as setting the IP address, etc.

See also the VLAN sample application for API usage example. The source code for that sample application can be found at samples/net/ethernet/vlan.

The net-shell module contains *net vlan add* and *net vlan del* commands that can be used to enable or disable VLAN tags for a given network interface.

See the IEEE 802.1Q spec for more information about ethernet VLANs.

IEEE 802.1Qav

Overview Credit-based shaping is an alternative scheduling algorithm used in network schedulers to achieve fairness when sharing a limited network resource. Zephyr has support for configuring a credit-based shaper described in the IEEE 802.1Qav-2009 standard. Zephyr does not implement the actual shaper; it only provides a way to configure the shaper implemented by the Ethernet device driver.

Enabling 802.1Qav To enable 802.1Qav shaper, the Ethernet device driver must declare that it supports credit-based shaping. The Ethernet driver's capability function must return `ETHERNET_QAV` value for this purpose. Typically also priority queues `ETHERNET_PRIORITY_QUEUES` need to be supported.

```
static enum ethernet_hw_caps eth_get_capabilities(const struct device *dev)
{
        ARG_UNUSED(dev);

        return ETHERNET_QAV | ETHERNET_PRIORITY_QUEUES |
               ETHERNET_HW_VLAN | ETHERNET_LINK_10BASE |
               ETHERNET_LINK_100BASE;
}
```

See `sam-e70-xplained` board Ethernet driver drivers/ethernet/eth_sam_gmac.c for an example.

Configuring 802.1Qav The application can configure the credit-based shaper like this:

```
#include <zephyr/net/net_if.h>
#include <zephyr/net/ethernet.h>
#include <zephyr/net/ethernet_mgmt.h>

static void qav_set_status(struct net_if *iface,
                           int queue_id, bool enable)
{
        struct ethernet_req_params params;
        int ret;

        memset(&params, 0, sizeof(params));

        params.qav_param.queue_id = queue_id;
        params.qav_param.enabled = enable;
        params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_STATUS;
```

(continues on next page)

(continued from previous page)

```
        /* Disable or enable Qav for a queue */
        ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
                       iface, &params,
                       sizeof(struct ethernet_req_params));
        if (ret) {
                LOG_ERR("Cannot %s Qav for queue %d for interface %p",
                        enable ? "enable" : "disable",
                        queue_id, iface);
        }
}

static void qav_set_bandwidth_and_slope(struct net_if *iface,
                                        int queue_id,
                                        unsigned int bandwidth,
                                        unsigned int idle_slope)
{
        struct ethernet_req_params params;
        int ret;

        memset(&params, 0, sizeof(params));

        params.qav_param.queue_id = queue_id;
        params.qav_param.delta_bandwidth = bandwidth;
        params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_DELTA_BANDWIDTH;

        ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
                       iface, &params,
                       sizeof(struct ethernet_req_params));
        if (ret) {
                LOG_ERR("Cannot set Qav delta bandwidth %u for "
                        "queue %d for interface %p",
                        bandwidth, queue_id, iface);
        }

        params.qav_param.idle_slope = idle_slope;
        params.qav_param.type = ETHERNET_QAV_PARAM_TYPE_IDLE_SLOPE;

        ret = net_mgmt(NET_REQUEST_ETHERNET_SET_QAV_PARAM,
                       iface, &params,
                       sizeof(struct ethernet_req_params));
        if (ret) {
                LOG_ERR("Cannot set Qav idle slope %u for "
                        "queue %d for interface %p",
                        idle_slope, queue_id, iface);
        }
}
```

Overview Ethernet is a networking technology commonly used in local area networks (LAN). For more information, see this Ethernet Wikipedia article.

Zephyr supports following Ethernet features:

- 10, 100 and 1000 Mbit/sec links
- Auto negotiation
- Half/full duplex

- Promiscuous mode
- TX and RX checksum offloading
- MAC address filtering
- *MAC address configuration*
- *Virtual LANs*
- *Priority queues*
- *IEEE 802.1AS (gPTP)*
- *IEEE 802.1Qav (credit based shaping)*
- *LLDP (Link Layer Discovery Protocol)*

Not all Ethernet device drivers support all of these features. You can see what is supported by `net iface` net-shell command. It will print currently supported Ethernet features.

IEEE 802.15.4

- *Introduction*
- *Supported Drivers*
- *API Reference*
  - *IEEE 802.15.4 API Overview*
  - *IEEE 802.15.4 Management API*
  - *IEEE 802.15.4 Driver API*
  - *IEEE 802.15.4 L2 / Native Stack API*
  - *OpenThread L2 Adaptation Layer API*

Introduction IEEE 802.15.4 is a technical standard which defines the operation of low-rate wireless personal area networks (LR-WPANs). For a more detailed overview of this standard, see the IEEE 802.15.4 Wikipedia article.

The most recent version of the standard is accessible through the IEEE GET Program. You need to create a free IEEE account and can then downloading it.

We're currently following the IEEE 802.15.4-2020 specification. This version is backwards compatible with IEEE 802.15.4-2015, parts of which are contained in the Thread protocol stack. The 2020 version also includes prior extensions that were accepted into the standard, namely IEEE 802.15.4g (SUN FSK) and IEEE 802.15.4e (TSCH) which are of relevance to industrial IoT and automation. For recent developments in UWB ranging technology, see IEEE 802.15.4z which is not yet integrated into the standard's mainline.

Whenever sections from the standard are cited in the documentation, they refer to IEEE 802.15.4-2020 section, table and figure numbering - unless otherwise specified.

Zephyr supports both, native IEEE 802.15.4 and Thread, with 6LoWPAN. Zephyr's *Thread protocol* implementation is based on OpenThread. The IPv6 header compression in 6LoWPAN is used for native IEEE 802.15.4.

Supported Drivers Zephyr includes a number of in-tree IEEE 802.15.4 radio drivers for various hardware platforms. The following table provides an overview of all available drivers, their vendors, supported frequency bands, bus interfaces, and the Kconfig option used to enable each driver.

Table 1: IEEE 802.15.4 In-Tree Radio Drivers

Driver	Vendor	Compatible	Frequency Band	Bus
CC1200	Texas Instruments	`ti,cc1200`	Sub-GHz	SPI
CC13xx/CC26xx	Texas Instruments	`ti,cc13xx-cc26xx-ieee802154`	2.4 GHz	On-chip
CC13xx/CC26xx Sub-GHz	Texas Instruments	`ti,cc13xx-cc26xx-ieee802154-`	Sub-GHz	On-chip
CC2520	Texas Instruments	`ti,cc2520`	2.4 GHz	SPI
DW1000	Decawave (Qorvo)	`decawave,dw1000`	UWB (3.5–6.5 GHz)	SPI
ESP32	Espressif	`espressif,esp32-ieee802154`	2.4 GHz	On-chip
KW41Z	NXP	`nxp,kw41z-ieee802154`	2.4 GHz	On-chip
MCR20A	NXP	`nxp,mcr20a`	2.4 GHz	SPI
MCXW	NXP	`nxp,mcxw-ieee802154`	2.4 GHz	On-chip
nRF5	Nordic Semiconductor	`nordic,nrf-ieee802154`	2.4 GHz	On-chip
RF2XX (AT86RF2xx)	Atmel (Microchip)	`atmel,rf2xx`	2.4 GHz / Sub-GHz	SPI
STM32WBA	STMicroelectronics	`st,stm32wba-ieee802154`	2.4 GHz	On-chip
Telink B91	Telink Semiconductor	`telink,b91-zb`	2.4 GHz	On-chip
UART Pipe	Virtual (QEMU)	`zephyr,ieee802154-uart-pipe`	N/A (emulated)	UART

Note

The UART Pipe driver is a virtual driver used for testing IEEE 802.15.4 networking in QEMU environments. It is not intended for use with real radio hardware.

For detailed configuration options of each driver, refer to the corresponding Kconfig file in drivers/ieee802154/.

IEEE 802.15.4 Management API This is the main subsystem-specific API of interest to IEEE 802.15.4 **application developers** as it allows to configure the IEEE 802.15.4 subsystem at run-time. Other relevant interfaces for application developers are the typical shell, socket, Kconfig and devicetree APIs that can be accessed through Zephyr's generic subsystem-independent documentation. Look out for IEEE802154/ieee802154 prefixes there.

IEEE 802.15.4 Net Management

IEEE 802.15.4 Driver API This is the main API of interest to IEEE 802.15.4 **driver developers**.

IEEE 802.15.4 Drivers

IEEE 802.15.4 L2 / Native Stack API This documents the IEEE 802.15.4 L2 native stack, which neither applications nor drivers will ever access directly. It is called internally by Zephyr's upper network layers (L3+), its socket and network context abstractions. This API is therefore of interest to IEEE 802.15.4 **subsystem contributors** only.

IEEE 802.15.4 L2

OpenThread L2 Adaptation Layer API Zephyr's OpenThread L2 platform adaptation layer glues the external OpenThread stack together with Zephyr's IEEE 802.15.4 protocol agnostic driver API. This API is of interest to OpenThread L2 **subsystem contributors** only.

The OpenThread API is part of the *Thread protocol* subsystem and documented there.

Thread protocol

- *Overview*
- *Internet connectivity*
- *Sample usage*
- *Thread related APIs*
  - *OpenThread Driver API*
  - *OpenThread L2 Adaptation Layer API*
  - *OpenThread Platform API*

Overview Thread is a low-power mesh networking technology, designed specifically for home automation applications. It is an IPv6-based standard, which uses 6LoWPAN technology over IEEE 802.15.4 protocol. IP connectivity lets you easily connect a Thread mesh network to the internet with a Thread Border Router.

The Thread specification provides a high level of network security. Mesh networks built with Thread are secure - only authenticated devices can join the network and all communications within the mesh are encrypted. More information about Thread protocol can be found at Thread Group website.

Zephyr integrates an open source Thread protocol implementation called OpenThread, documented on the OpenThread website.

Internet connectivity A Thread Border Router is required to connect mesh network to the internet. An open source implementation of Thread Border Router is provided by the OpenThread community. See OpenThread Border Router guide for instructions on how to set up a Border Router.

Sample usage You can try using OpenThread with the Zephyr Echo server and Echo client samples, which provide out-of-the-box configuration for OpenThread. To enable OpenThread support in these samples, build them with `overlay-ot.conf` overlay config file. See sockets-echo-server and sockets-echo-client samples for details.

Zephyr also provides an openthread-shell, which is useful for testing and debugging Thread and its underlying IEEE 802.15.4 drivers.

Thread related APIs

OpenThread Driver API OpenThread L2 uses Zephyr's protocol agnostic IEEE 802.15.4 driver API internally. This API is of interest to **driver developers** that want to support OpenThread.

The driver API is part of the *IEEE 802.15.4 Driver API* subsystem and documented there.

OpenThread L2 Adaptation Layer API Zephyr's OpenThread L2 platform adaptation layer glues the external OpenThread stack together with Zephyr's IEEE 802.15.4 protocol agnostic driver API. This API is of interest to OpenThread L2 **subsystem contributors** only.

OpenThread Platform API The OpenThread platform API is defined by the OpenThread stack and implemented in Zephyr as an OpenThread module. Applications can use this implementation directly, or access it through the OpenThread L2 adaptation layer.

Using the OpenThread L2 Adaptation Layer API To use the OpenThread platform API via the OpenThread L2 adaptation layer, enable both the `CONFIG_NET_L2_OPENTHREAD` and `CONFIG_NETWORKING` Kconfig options by setting them to `y`. The adaptation layer will use the OpenThread radio API implementation found in `modules/openthread/platform/radio.c`. In this setup, the OpenThread stack is initialized and managed by the adaptation layer.

Using the OpenThread Platform API Directly You can also use the OpenThread platform API directly, bypassing the OpenThread L2 adaptation layer. However, this approach requires you to provide your own implementation of the OpenThread radio API that is compatible with your specific radio driver.

To use the OpenThread platform API directly, set the `CONFIG_OPENTHREAD` Kconfig option to `y`, and do **not** set `CONFIG_NET_L2_OPENTHREAD`. In this case, you must implement the following functions from the OpenThread radio API using your own radio driver:

- `otPlatRadioGetPromiscuous`

- otPlatRadioGetCcaEnergyDetectThreshold
- otPlatRadioGetTransmitPower
- otPlatRadioGetIeeeEui64
- otPlatRadioSetPromiscuous
- otPlatRadioGetCaps
- otPlatRadioGetTransmitBuffer
- otPlatRadioSetPanId
- otPlatRadioEnable
- otPlatRadioDisable
- otPlatRadioReceive
- otPlatRadioGetRssi
- otPlatRadioGetReceiveSensitivity
- otPlatRadioEnergyScan
- otPlatRadioSetExtendedAddress
- otPlatRadioSetShortAddress
- otPlatRadioAddSrcMatchExtEntry
- otPlatRadioTransmit
- otPlatRadioClearSrcMatchShortEntries
- otPlatRadioClearSrcMatchExtEntries
- otPlatRadioEnableSrcMatch
- otPlatRadioAddSrcMatchShortEntry
- otPlatRadioClearSrcMatchShortEntry
- otPlatRadioClearSrcMatchExtEntry

Additionally, you must implement the following functions from the OpenThread radio API (see include/zephyr/net/openthread.h) to handle radio initialization and event processing:

- platformRadioInit()
- platformRadioProcess()

To initialize the OpenThread stack in this approach, either call the ot_platform_init() function in your application, or enable the CONFIG_OPENTHREAD_SYS_INIT Kconfig option to automatically initialize OpenThread during system startup. You can set the initialization priority using the CONFIG_OPENTHREAD_SYS_INIT_PRIORITY Kconfig option.

Point-to-Point Protocol (PPP) Support

- *Overview*
- *Testing*

Overview Point-to-Point Protocol (PPP) is a data link layer (layer 2) communications protocol used to establish a direct connection between two nodes. PPP is used over many types of serial links since IP packets cannot be transmitted over a modem line on their own, without some data link protocol.

In Zephyr, each individual PPP link is modelled as a network interface. This is similar to how Linux implements PPP.

PPP support must be enabled at compile time by setting option `CONFIG_NET_L2_PPP`. The PPP implementation supports only these protocols:

- LCP (Link Control Protocol, **RFC 1661**)
- HDLC (High-level data link control, **RFC 1662**)
- IPCP (IP Control Protocol, **RFC 1332**)
- IPV6CP (IPv6 Control Protocol, **RFC 5072**)

For using PPP with a cellular modem, see cellular-modem sample for additional information.

Testing See the net-tools README file for more details on how to test the Zephyr PPP against pppd running in Linux.

Wi-Fi Management

Overview The Wi-Fi management API is used to manage Wi-Fi networks. It supports below modes:

- IEEE802.11 Station (STA)
- IEEE802.11 Access Point (AP)
- IEEE802.11 P2P (Wi-Fi Direct)

Only personal mode security is supported with below types:

- Open
- OWE
- WEP
- WPA2-PSK
- WPA2-PSK-256
- WPA3-SAE

The Wi-Fi management API is implemented in the `wifi_mgmt` module as a part of the networking L2 stack. Currently, two types of Wi-Fi drivers are supported:

- Networking or socket offloaded drivers
- Native L2 Ethernet drivers

Compiled Features To support applications that only require a certain subset of Wi-Fi features, `CONFIG_WIFI_USAGE_MODE` can be used as a hint for drivers to limit the functionality that needs to be compiled in. The following usage hints are available:

- `CONFIG_WIFI_USAGE_MODE_STA` (Connecting to an access point)
- `CONFIG_WIFI_USAGE_MODE_AP` (Being an access point)
- `CONFIG_WIFI_USAGE_MODE_STA_AP` (Both being and connecting to an access point)
- `CONFIG_WIFI_USAGE_MODE_SCAN_ONLY` (Access point SSID scanning only)

Note

Support for a requested usage mode is hardware dependent.

Wi-Fi shell The Wi-Fi shell provides commands for testing and exploring the Wi-Fi management API through an interactive interface, without requiring a dedicated application. Enable the `CONFIG_NET_L2_WIFI_SHELL` option to add the `wifi` command.

The main Wi-Fi shell subcommands include:

Table 2: Wi-Fi shell subcommands

Subcommand	Description
`scan`	Scan for Wi-Fi networks.
`connect`	Connect to a Wi-Fi network.
`disconnect`	Disconnect from a Wi-Fi network.
`status`	Show the Wi-Fi interface status.

Use `wifi --help` to list all available subcommands and `wifi <subcommand> --help` for command-specific help. See wifi-shell for a sample application that enables the Wi-Fi shell.

Warning

By default, the Wi-Fi shell scan command does not limit scan results. Due to the UART shell backend being slow, printing all scan results may cause network management events to be dropped. To avoid the warning, adjust `CONFIG_NET_MGMT_EVENT_QUEUE_TIMEOUT` or `CONFIG_NET_MGMT_EVENT_QUEUE_SIZE` if needed.

Wi-Fi PSA crypto supported build To enable PSA crypto API supported Wi-Fi build, the `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ALT` and the `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_MBEDTLS_PSA` need to be set.

Wi-Fi feature to crypto mapping For a mapping of Wi-Fi features (WPA3-SAE, DPP, SAE-PK, WPA2-PSK, Enterprise EAP, etc.) to crypto primitives (bignum, ECDH, TLS, hashes, AES) and which use **Legacy crypto** vs **PSA crypto**, see the dedicated sub-page:

Wi-Fi feature to crypto mapping This page maps Wi-Fi features supported in Zephyr (via the hostap-based wpa_supplicant) to the underlying MbedTLS crypto primitives. Use it to see which features need bignum, ECDH, TLS, etc., and which code paths use **Legacy crypto** (MbedTLS legacy APIs) vs **PSA crypto** (Platform Security Architecture APIs) when `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_MBEDTLS_PSA` is enabled.

The implementation lives in the hostap module: `crypto_mbedtls_alt.c` (generic crypto) and `tls_mbedtls_alt.c` (TLS/EAP). Only the MbedTLS backend is considered here.

Feature set (from hostap Kconfig) Features are gated by Kconfig. Relevant options include:

- CONFIG_WIFI_NM_WPA_SUPPLICANT_WEP — WEP (legacy)
- CONFIG_WIFI_NM_WPA_SUPPLICANT_WPA3_COMMON — WPA3-SAE when Internal or External is selected (WIFI_NM_WPA_SUPPLICANT_WPA3_IMPLEMENTATION; default Internal). CONFIG_WIFI_NM_WPA_SUPPLICANT_WPA3 is promptless and turns on the internal bignum SAE path when Internal is chosen (set the implementation choice in prj.conf, not this symbol).
- CONFIG_WIFI_NM_WPA_SUPPLICANT_DPP — Wi-Fi Easy Connect (DPP)
- CONFIG_WIFI_NM_WPA_SUPPLICANT_WPS — Wi-Fi Protected Setup
- CONFIG_WIFI_NM_WPA_SUPPLICANT_P2P — P2P / Wi-Fi Direct (implies WPS)
- CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_ENTERPRISE — EAP (EAP-TLS, EAP-TTLS-MSCHAPV2, EAP-PEAP-MSCHAPV2, EAP-PEAP-GTC, EAP-PEAP-TLS)

WPA2-PSK and WPA2-PSK-256 are available whenever crypto is not set to CRYPTO_NONE.

Feature crypto primitives (MbedTLS)

Table 3: Wi-Fi feature to crypto mapping

Feature	Crypto primitives	Legacy crypto	PSA crypto
WPA3-SAE	• Bignum (mpi), modulo, exponentiation • EC group • HMAC-SHA256 • AES (CCMP). SAE uses Dragonfly (PWE) with bignum + modulo.	• Bignum (mbedtls_mpi) • EC • HMAC, AES (unless PSA build)	• Hashes, HMAC, AES when PSA enabled • Bignum/EC still legacy
SAE-PK	Same as WPA3-SAE plus ECDH and EC key operations (certificate-based SAE).	ECDH/EC key ops (legacy MbedTLS or PSA ECDH depending on config).	• ECDH can use PSA • Bignum/SAE core remain legacy
DPP (Easy Connect)	• ECDH (P-256, P-384, P-521) • EC key gen/sign/verify • Hashes, AES. DPP2 adds PKCS#7; DPP3 adds HPKE.	• ECDH, EC, RSA (if used) • X.509/CSR in TLS/crypto layer	• Hashes, HMAC, AES via PSA • ECDH/EC may use PSA • TLS/CSR/PKCS#7/HPKE layer legacy
WPA2-PSK / WPA2-PSK-256	• PBKDF2-SHA1 (or SHA256 for -256) • HMAC • AES (CCMP) • OMAC1-AES (key wrap)	All via mbedtls (PBKDF2, HMAC, AES, CMAC) if PSA disabled.	PBKDF2, HMAC, AES, OMAC1 implemented via PSA when PSA enabled.
WEP	• RC4/ARC4 (stream cipher) • Optionally AES for some wrappers. Deprecated.	Legacy MbedTLS only (no PSA path for WEP in current code).	N/A (WEP not migrated to PSA).
WPS	• DH (finite-field) • Bignum • Hashes, HMAC, AES, TLS-PRF. Registrar uses TLS.	• DH (mbedtls_dhm), bignum (mbedtls_mpi) • TLS in tls_mbedtls_alt	• Hashes, HMAC, AES, PBKDF2 via PSA • DH/bignum and TLS legacy
EAP-TLS / EAP-TTLS / EAP-PEAP	• TLS 1.2 (and optionally 1.3) • RSA • X.509 parse/verify • Hashes, HMAC, AES (cipher suites)	• Full TLS stack (mbedtls_ssl_*, mbedtls_x509_*) • RSA • No PSA in tls_mbedtls_alt	• TLS layer remains legacy • Underlying hashes/HMAC/AES can use PSA in crypto_mbedtls_alt

Note

WEP must be explicitly enabled with `CONFIG_WIFI_NM_WPA_SUPPLICANT_WEP`. It is deprecated and insecure; use only for legacy networks.

Summary: Legacy vs PSA (MbedTLS backend) When `CONFIG_WIFI_NM_WPA_SUPPLICANT_CRYPTO_MBEDTLS_PSA` is enabled, the implementation in `crypto_mbedtls_alt.c` (and `supp_psa_api.h` / `supp_psa_api.c`) splits as below. Use this table to see which operations use **PSA** vs **Legacy** MbedTLS.

Table 4: Legacy vs PSA by crypto operation

Operation	API	Used by / notes
Message digests (MD5, SHA1, SHA256, SHA384, SHA512)	PSA	
HMAC (all above hash types)	PSA	
PBKDF2-SHA1	PSA	WPA2-PSK key derivation
AES (block, CBC, CTR, OMAC1-AES)	PSA	Key wrap, CCMP, etc.
Bignum (crypto_bignum_*)	Legacy	SAE, EAP-PWD, EAP-EKE, EAP-IKEV2, WPS; no PSA bignum in hostap
ECDH / EC key operations	Legacy	DPP, SAE-PK, EAP-PWD (EC). May be PSA-backed when `MBEDTLS_ECDH_C` / `CONFIG_PSA_WANT_ALG_ECDH`; wrapper layer common
TLS/SSL	Legacy	EAP-TLS, EAP-TTLS, EAP-PEAP; full stack in `tls_mbedtls_alt.c`
RSA	Legacy	TLS, X.509
X.509 / CSR	Legacy	Parse and generation
WEP	Legacy	No PSA path

So: **WPA2-PSK and WPA2-PSK-256** use only PSA for their crypto; **WPA3-SAE**, **DPP**, **SAE-PK**, **WPS**, and **Enterprise EAP** still rely on legacy bignum, EC, or TLS. See the feature table above for per-feature impact.

Wi-Fi Enterprise test: X.509 Certificate management Wi-Fi enterprise security requires use of X.509 certificates, two methods of installing certificates are supported:

Compile time certificates Test certificates in PEM format are committed to the repo at samples/net/wifi/test_certs and the during the build process the certificates are converted to a C header file that is included by the Wi-Fi shell module.

If you want to use your own certificates, you can replace the existing certificates with your own certificates in the same directory.

```
$ export WIFI_TEST_CERTS_DIR=samples/net/wifi/test_certs/rsa3k
$ cp client.pem $WIFI_TEST_CERTS_DIR
$ cp client-key.pem $WIFI_TEST_CERTS_DIR
$ cp ca.pem $WIFI_TEST_CERTS_DIR
$ cp client2.pem $WIFI_TEST_CERTS_DIR
$ cp client-key2.pem $WIFI_TEST_CERTS_DIR
$ cp ca2.pem $WIFI_TEST_CERTS_DIR
$ west build -p -b <board> samples/net/wifi -S wifi-enterprise
```

For RSA 2048-bit certificates, use `rsa2k_no_des`.

```
$ export WIFI_TEST_CERTS_DIR=samples/net/wifi/test_certs/rsa2k_no_des
```

or you can set the `WIFI_TEST_CERTS_DIR` environment variable to point to the directory containing your certificates.

```
$ west build -p -b <board> samples/net/wifi -S wifi-enterprise -- -
↪DWIFI_TEST_CERTS_DIR=<path_to_your_certificates>
```

Run time certificates The Wi-Fi shell module uses TLS credentials subsystem to store and manage the certificates. The certificates can be added at runtime using the shell commands, see *TLS Credentials Shell* for more details. The sample or application need to enable the `CONFIG_WIFI_SHELL_RUNTIME_CERTIFICATES` option to use this feature.

To facilitate installation of the certificates, a helper script is provided, see below for usage.

```
$ ./scripts/utils/wifi_ent_cert_installer.py -p␣
↪samples/net/wifi/test_certs/rsa2k_no_des
```

The script will install the certificates to the TLS credentials store in the device over UART and using TLS credentials shell commands.

To initiate a Wi-Fi connection using enterprise security, use one of the following commands depending on the EAP method:

- EAP-TLS

```
uart:~$ wifi connect -s <SSID> -c <channel> -k 7 -w 2 -a <Anonymous identity>␣
↪--key1-pwd <Password EAP phase1> --key2-pwd <Password EAP phase2>
```

- EAP-TTLS-MSCHAPV2

```
uart:~$ wifi connect -s <SSID> -c <channel> -k 14 -K <Private key Password> --
↪eap-id1 <Client Identity> --eap-pwd1 <Client Password> -a <Anonymous␣
↪identity>
```

- EAP-PEAP-MSCHAPV2

```
uart:~$ wifi connect -s <SSID> -c <channel> -k 12 -K <Private key Password> --
↪eap-id1 <Client Identity> --eap-pwd1 <Client Password> -a <Anonymous␣
↪identity>
```

Server certificate is also provided in the same directory for testing purposes. Any AAA server can be used for testing purposes, for example, `FreeRADIUS` or `hostapd`.

Server certificate domain name verification The authentication server's identity is verified by validating the domain name in the X.509 certificate received from the server, using the `Common Name` (CN) field.

- Exact domain match — Verifies that the certificate's CN exactly matches the specified domain.
- Domain suffix match — Allows a certificate whose CN ends with the specified domain suffix.

To initiate a Wi-Fi connection using enterprise security with server certificate validation, use one of the following commands, depending on the desired validation mode:

- Exact domain match

```
wifi connect -s <SSID> -c <channel> -k 12 -K <Private key Password> -e
↪<Domain match>
```

- Domain suffix match

```
wifi connect -s <SSID> -c <channel> -k 12 -K <Private key Password> -x
↪<Domain suffix name>
```

Certificate requirements for EAP methods Different EAP methods have varying client-side certificate requirements, as outlined below:

- **EAP-TLS - Requires both a client certificate (and its private key) and a CA certificate on the client.**
  The client authenticates itself to the server using its certificate.
- **EAP-TTLS-MSCHAPV2 - Requires only the CA certificate on the client.**
  The client authenticates to the server using a username and password <MSCHAPV2> inside the TLS tunnel. No client certificate is needed.
- **EAP-PEAP-MSCHAPV2 - Requires only the CA certificate on the client.**
  Like TTLS, the client uses a username and password <MSCHAPV2> inside the TLS tunnel and does not require a client certificate.

Note

The certificates are for testing purposes only and should not be used in production. They are generated using FreeRADIUS raddb scripts.

Note

When using TLS credentials subsystem, by default the volatile backend i.e., `CONFIG_TLS_CREDENTIALS_BACKEND_VOLATILE` is chosen. When using the volatile backend, the certificates are stored in RAM and are lost on reboot, so the certificates need to be installed again after reboot. As an alternative, the PS (protected storage) backend i.e., `CONFIG_TLS_CREDENTIALS_BACKEND_PROTECTED_STORAGE` can be used to store the certificates in the non-volatile storage.

How to Generate Test Certificates Using FreeRADIUS The test certificates in `samples/net/wifi/test_certs/rsa2k_no_des` are generated using the FreeRADIUS raddb/certs scripts. You can generate your own certificates for testing as follows:

1. **Prerequisites** - Install OpenSSL and GNU Make. - Download the FreeRADIUS raddb/certs directory.
2. **Edit the Makefile** In the `raddb/certs` directory, edit the `Makefile` to add `-nodes` to the OpenSSL commands for server and client keys. This ensures the private keys are not password-protected (Zephyr Wi-Fi shell does not support private key passwords):

```
$(OPENSSL) req -new -out server.csr -keyout server.key -nodes -config ./
↪server.cnf
$(OPENSSL) req -new -out client.csr -keyout client.key -nodes -config ./
↪client.cnf
```

3. **(Optional) Edit the .cnf files** Customize `server.cnf` and `client.cnf` as needed for your environment.
4. **Generate Certificates** Run the following commands in the `raddb/certs` directory:

```
make destroycerts
make server
make client
```

5. **Rename Files for Zephyr** Match the filenames used in Zephyr samples:

FreeRADIUS Output	Zephyr Sample Name
ca.pem server.key server.pem client.key client.pem	ca.pem server-key.pem server.pem client-key.pem client.pem

6. **Copy the files** Place the renamed files in your Zephyr project's certificate directory (e.g., `samples/net/wifi/test_certs/rsa2k_no_des`). Encrypt private keys with AES (PBES2), not DES; see the existing `rsa2k_no_des` keys for reference.

Note

These certificates are for testing only and should not be used in production.

Wi-Fi P2P (Wi-Fi Direct) Wi-Fi P2P or Wi-Fi Direct enables devices to communicate directly with each other without requiring a traditional access point. This feature is particularly useful for device-to-device communication scenarios.

To enable and build with Wi-Fi P2P support:

```
$ west build -p -b <board> samples/net/wifi/shell -- -
↪DCONFIG_WIFI_NM_WPA_SUPPLICANT_P2P=y
```

Wi-Fi NAN (Neighbor Awareness Networking) Wi-Fi NAN (Neighbor Awareness Networking), also known as Wi-Fi Aware, enables devices to discover services and communicate with nearby devices without requiring a traditional access point or Internet connection. This feature uses a publish-subscribe model where devices can publish services or subscribe to discover services from nearby peers.

To enable and build with Wi-Fi NAN support:

```
$ west build -p -b <board> samples/net/wifi/shell -- -
↪DCONFIG_WIFI_NM_WPA_SUPPLICANT_NAN=y
```

Wi-Fi credentials Library

- *Overview*
- *Configuration*
- *Adding credentials*

- *Querying credentials*
- *Removing credentials*
- *Shell commands*
- *Limitations*
- *API documentation*

The Wi-Fi credentials library provides means to load and store Wi-Fi® network credentials.

Overview This library uses either Zephyr's settings subsystem or Platform Security Architecture (PSA) Internal Trusted Storage (ITS) to store credentials. It also holds a list of SSIDs in RAM to provide dictionary-like access using SSIDs as keys.

Configuration To use the Wi-Fi credentials library, enable the `CONFIG_WIFI_CREDENTIALS` Kconfig option.

You can pick the backend using the following options:

- `CONFIG_WIFI_CREDENTIALS_BACKEND_PSA` - Default option for non-secure targets, which includes a TF-M partition (non-minimal TF-M profile type).
- `CONFIG_WIFI_CREDENTIALS_BACKEND_SETTINGS` - Default option for secure targets.

To configure the maximum number of networks, use the `CONFIG_WIFI_CREDENTIALS_MAX_ENTRIES` Kconfig option.

The IEEE 802.11 standard does not specify the maximum length of SAE passwords. To change the default, use the `CONFIG_WIFI_CREDENTIALS_SAE_PASSWORD_LENGTH` Kconfig option.

Adding credentials You can add credentials using the `wifi_credentials_set_personal()` and `wifi_credentials_set_personal_struct()` functions. The former will build the internally used struct from given fields, while the latter takes the struct directly. If you add credentials with the same SSID twice, the older entry will be overwritten.

Querying credentials With an SSID, you can query credentials using the `wifi_credentials_get_by_ssid_personal()` and `wifi_credentials_get_by_ssid_personal_struct()` functions.

You can iterate over all stored credentials with the `wifi_credentials_for_each_ssid()` function. Deleting or overwriting credentials while iterating is allowed, since these operations do not change internal indices.

Removing credentials You can remove credentials using the `wifi_credentials_delete_by_ssid()` function.

Shell commands `wifi cred` is an extension to the Wi-Fi command line. It adds the following subcommands to interact with the Wi-Fi credentials library:

Table 5: Wi-Fi credentials shell subcommands

Subcommands	Description
add	Add a network to the credentials storage with following parameters: <-s –ssid "<SSID>">: SSID. [-c –channel]: Channel that needs to be scanned for connection. 0:any channel [-b, –band] 0: any band (2:2.4GHz, 5:5GHz, 6:6GHz) [-p, –passphrase]: Passphrase (valid only for secure SSIDs) [-k, –key-mgmt]: Key management type. 0:None, 1:WPA2-PSK, 2:WPA2-PSK-256, 3:SAE-HNP, 4:SAE-H2E, 5:SAE-AUTO, 6:WAPI," " 7:EAP-TLS, 8:WEP, 9: WPA-PSK, 10: WPA-Auto-Personal, 11: DPP [-w, –ieee-80211w]: MFP (optional: needs security type to be specified) : 0:Disable, 1:Optional, 2:Required. [-m, –bssid]: MAC address of the AP (BSSID). [-t, –timeout]: Duration after which connection attempt needs to fail. [-a, –identity]: Identity for enterprise mode. [-K, –key-passwd]: Private key passwd for enterprise mode. [-h, –help]: Print out the help for the connect command.
delete <SSID>	Removes network from credentials storage.
list	Lists networks in credential storage.
auto_connect	Automatically connects to any stored network.

Limitations The library has the following limitations:

- Although permitted by the IEEE 802.11 standard, this library does not support zero-length SSIDs.
- Wi-Fi Protected Access (WPA) Enterprise credentials are only partially supported.
- The number of networks stored is fixed compile time.

API documentation The following section provides an overview and reference for the Wi-Fi credentials API available in Zephyr:

Protocols

CoAP

- *Overview*
- *Sample Usage*

  - *CoAP Server*
  - *CoAP Client*
- *Testing*
  - *libcoap*
  - *TTCN3*
- *API Reference*

Overview The Constrained Application Protocol (CoAP) is a specialized web transfer protocol for use with constrained nodes and constrained (e.g., low-power, lossy) networks. It provides a convenient API for RESTful Web services that support CoAP's features. For more information about the protocol itself, see **RFC 7252**.

Zephyr provides a CoAP library which supports client and server roles. The library can be enabled with `CONFIG_COAP` Kconfig option and is configurable as per user needs. The Zephyr CoAP library is implemented using plain buffers. Users of the API create sockets for communication and pass the buffer to the library for parsing and other purposes. The library itself doesn't create any sockets for users.

On top of CoAP, Zephyr has support for LwM2M "Lightweight Machine 2 Machine" protocol, a simple, low-cost remote management and service enablement mechanism. See *Lightweight M2M (LwM2M)* for more information.

Supported RFCs:

- **RFC 7252** - The Constrained Application Protocol (CoAP)
- **RFC 6690** - Constrained RESTful Environments (CoRE) Link Format
- **RFC 7959** - Block-Wise Transfers in the Constrained Application Protocol (CoAP)
- **RFC 7641** - Observing Resources in the Constrained Application Protocol (CoAP)
- **RFC 8613** - Object Security for Constrained RESTful Environments (OSCORE)

Note

Not all parts of these RFCs are supported. Features are supported based on Zephyr requirements.

The Zephyr CoAP library also supports Object Security for Constrained RESTful Environments (OSCORE) as specified in **RFC 8613**. See *OSCORE Support (RFC 8613)* for more information.

Sample Usage

Note

A *CoAP server* subsystem is available, the following is for creating a custom server implementation.

CoAP Server To create a CoAP server, resources for the server need to be defined. The `.well-known/core` resource should be added before all other resources that should be included in the responses of the `.well-known/core` resource.

```
static struct coap_resource resources[] = {
    { .get = well_known_core_get,
      .path = COAP_WELL_KNOWN_CORE_PATH,
    },
    { .get  = sample_get,
      .post = sample_post,
      .del  = sample_del,
      .put  = sample_put,
      .path = sample_path
    },
    { },
};
```

An application reads data from the socket and passes the buffer to the CoAP library to parse the message. If the CoAP message is proper, the library uses the buffer along with resources defined above to call the correct callback function to handle the CoAP request from the client. It's the callback function's responsibility to either reply or act according to CoAP request.

```
coap_packet_parse(&request, data, data_len, options, opt_num);
...
coap_handle_request(&request, resources, options, opt_num,
                    client_addr, client_addr_len);
```

If `CONFIG_COAP_URI_WILDCARD` enabled, server may accept multiple resources using MQTT-like wildcard style:

- the plus symbol represents a single-level wild card in the path;
- the hash symbol represents the multi-level wild card in the path.

```
static const char * const led_set[] = { "led","+","set", NULL };
static const char * const btn_get[] = { "button","#", NULL };
static const char * const no_wc[] = { "test","+1", NULL };
```

It accepts /led/0/set, led/1234/set, led/any/set, /button/door/1, /test/+1, but returns -ENOENT for /led/1, /test/21, /test/1.

This option is enabled by default, disable it to avoid unexpected behaviour with resource path like '/some_resource/+/#'.

Note

A *CoAP client* subsystem is available, the following is for creating a custom client implementation.

CoAP Client If the CoAP client knows about resources in the CoAP server, the client can start prepare CoAP requests and wait for responses. If the client doesn't know about resources in the CoAP server, it can request resources through the `.well-known/core` CoAP message.

```
/* Initialize the CoAP message */
char *path = "test";
struct coap_packet request;
uint8_t data[100];
uint8_t payload[20];

coap_packet_init(&request, data, sizeof(data),
                 1, COAP_TYPE_CON, 8, coap_next_token(),
```

(continues on next page)

(continued from previous page)

```
                COAP_METHOD_GET, coap_next_id());

/* Append options */
coap_packet_append_option(&request, COAP_OPTION_URI_PATH,
                          path, strlen(path));

/* Append Payload marker if you are going to add payload */
coap_packet_append_payload_marker(&request);

/* Append payload */
coap_packet_append_payload(&request, (uint8_t *)payload,
                           sizeof(payload) - 1);

/* send over sockets */
```

Testing There are various ways to test Zephyr CoAP library.

libcoap libcoap implements a lightweight application-protocol for devices that are resource constrained, such as by computing power, RF range, memory, bandwidth, or network packet sizes. Sources can be found here libcoap. libcoap has a script (`examples/etsi_coaptest.sh`) to test coap-server functionality in Zephyr.

See the net-tools project for more details

The coap-server sample can be built and executed on QEMU as described in *Networking with QEMU*.

Use this command on the host to run the libcoap implementation of the ETSI test cases:

```
sudo ./libcoap/examples/etsi_coaptest.sh -i tap0 2001:db8::1
```

TTCN3 Eclipse has TTCN3 based tests to run against CoAP implementations.

Install eclipse-titan and set symbolic links for titan tools

```
sudo apt-get install eclipse-titan

cd /usr/share/titan

sudo ln -s /usr/bin bin
sudo ln /usr/bin/titanver bin
sudo ln -s /usr/bin/mctr_cli bin
sudo ln -s /usr/include/titan include
sudo ln -s /usr/lib/titan lib

export TTCN3_DIR=/usr/share/titan

git clone https://gitlab.eclipse.org/eclipse/titan/titan.misc.git

cd titan.misc
```

Follow the instruction to setup CoAP test suite from here:

- https://gitlab.eclipse.org/eclipse/titan/titan.misc
- https://gitlab.eclipse.org/eclipse/titan/titan.misc/-/tree/master/CoAP_Conf

After the build is complete, the coap-server sample can be built and executed on QEMU as described in *Networking with QEMU*.

Change the client (test suite) and server (Zephyr coap-server sample) addresses in coap.cfg file as per your setup.

Execute the test cases with following command.

```
ttcn3_start coaptests coap.cfg
```

Sample output of ttcn3 tests looks like this.

```
Verdict statistics: 0 none (0.00 %), 10 pass (100.00 %), 0 inconc (0.00 %), 0 fail␣
↪(0.00 %), 0 error (0.00 %).
Test execution summary: 10 test cases were executed. Overall verdict: pass
```

CoAP client

- *Overview*
  - *CoAP over TCP*
- *Sample Usage*
- *API Reference*

Overview The CoAP client library allows application to send CoAP requests and parse CoAP responses. The library can be enabled with `CONFIG_COAP_CLIENT` Kconfig option. The application is notified about the response via a callback that is provided to the API in the request. The CoAP client handles the communication over sockets. As the CoAP client doesn't create socket it is using, the application is responsible for creating the socket. Plain UDP or DTLS sockets are supported.

CoAP over TCP CoAP over reliable transports (TCP/TLS) is also supported as specified in **RFC 8323**. Enable it with `CONFIG_COAP_CLIENT_TCP`. The TCP client manages connection setup, CSM (Capabilities and Settings Message) exchange, and signaling (Ping/Pong, Release, Abort) internally. Unlike the UDP client, the application does not create the socket — instead it calls `coap_client_tcp_connect()` with the server address. See coap-client-tcp for a usage example.

Sample Usage The following is an example of a CoAP client initialization and request sending:

```
static struct coap_client client;
struct coap_client_request req = { 0 };
```

(continues on next page)

(continued from previous page)

```
coap_client_init(&client, NULL);

req.method = COAP_METHOD_GET;
req.confirmable = true;
strcpy(req.path, "test");
req.fmt = COAP_CONTENT_FORMAT_TEXT_PLAIN;
req.cb = response_cb;
req.payload = NULL;
req.len = 0;

/* Sock is a file descriptor referencing a socket, address is the net_sockaddr␣
↪struct for the
 * destination address of the request or NULL if the socket is already connected.
 */
ret = coap_client_req(&client, sock, &address, &req, -1);
```

Before any requests can be sent, the CoAP client needs to be initialized. After initialization, the application can send a CoAP request and wait for the response. Currently only one request can be sent for a single CoAP client at a time. There can be multiple CoAP clients.

The callback provided in the callback will be called in following cases:

- There is a response for the request
- The request failed for some reason

The callback contains a flag `last_block`, which indicates if there is more data to come in the response and means that the current response is part of a blockwise transfer. When the `last_block` is set to true, the response is finished and the client is ready for the next request after returning from the callback.

If the server responds to the request, the library provides the response to the application through the response callback registered in the request structure. As the response can be a blockwise transfer and the client calls the callback once per each block, the application should be to process all of the blocks to be able to process the response.

During a blockwise transfer the client compares the ETag option of the received blocks, as required by **RFC 7959**. When the resource representation changes in the middle of the transfer, the transfer is aborted and the callback is invoked with `result_code` set to `-EBADMSG`. Stricter than the RFC minimum, which only mandates comparing ETags the server provides, the transfer is also aborted when the ETag option appears or disappears between blocks, as such a mix of tagged and untagged blocks cannot be verified. The application should discard the partial data it received and may retry the request.

The following is an example of a very simple response handling function:

```
void response_cb(const struct coap_client_response_data *data, void *user_data)
{
    if (data->result_code >= 0) {
            LOG_INF("CoAP response from server %d", data->result_code);
            if (data->last_block) {
                    LOG_INF("Last packet received");
            }
    } else {
            LOG_ERR("Error in sending request %d", data->result_code);
    }
}
```

CoAP options may also be added to the request by the application. The following is an example of the application adding a Block2 option to the initial request, to suggest a maximum block size

to the server for a resource that it expects to be large enough to require a blockwise transfer (see RFC 7959 Figure 3: Block-Wise GET with Early Negotiation).

```
static struct coap_client client;
struct coap_client_request req = { 0 };

coap_client_init(&client, NULL);

req.method = COAP_METHOD_GET;
req.confirmable = true;
strcpy(req.path, "test");
req.fmt = COAP_CONTENT_FORMAT_TEXT_PLAIN;
req.cb = response_cb;
req.options[0] = coap_client_option_initial_block2();
req.num_options = 1;
req.payload = NULL;
req.len = 0;

ret = coap_client_req(&client, sock, &address, &req, -1);
```

Optionally, the application can register a payload callback instead of providing a payload pointer for the CoAP upload. In such cases, the CoAP client library will call this callback when preparing a PUT/POST request, so that the application can provide the payload in blocks, instead of having to provide a single contiguous buffer with the entire payload. An example callback, providing the content of the Lorem Ipsum string can look like this:

```
static int lorem_ipsum_cb(size_t offset, const uint8_t **payload, size_t *len,
                          bool *last_block, void *user_data)
{
    size_t data_left;

    if (offset > LOREM_IPSUM_STRLEN) {
        return -EINVAL;
    }

    *payload = LOREM_IPSUM + offset;

    data_left = LOREM_IPSUM_STRLEN - offset;
    if (data_left <= *len) {
        *len = data_left;
        *last_block = true;
    } else {
        *last_block = false;
    }

    return 0;
}
```

The callback can then be registered for the PUT/POST request instead of a payload pointer:

```
struct coap_client_request req = { 0 };

req.method = COAP_METHOD_PUT;
req.confirmable = true;
strcpy(req.path, "lorem-ipsum");
req.fmt = COAP_CONTENT_FORMAT_TEXT_PLAIN;
req.cb = response_cb;
req.payload_cb = lorem_ipsum_cb,
```

(continues on next page)

(continued from previous page)

```
ret = coap_client_req(&client, sock, &address, &req, -1);
```

CoAP server

- *Overview*
- *Setup*
- *Sample Usage*
- *Observable resources*
- *CoAP Events*
- *CoRE Link Format*
- *API Reference*

Overview Zephyr comes with a batteries-included CoAP server, which uses services to listen for CoAP requests. The CoAP services handle communication over sockets and pass requests to registered CoAP resources.

Setup Some configuration is required to make sure services can be started using the CoAP server. The `CONFIG_COAP_SERVER` option should be enabled in your project:

Listing 1: `prj.conf`

```
CONFIG_COAP_SERVER=y
```

All services are added to a predefined linker section and all resources for each service also get their respective linker sections. If you would have a service `my_service` it has to be prefixed with `coap_resource_` and added to a linker file:

Listing 2: `sections-ram.ld`

```
#include <zephyr/linker/iterable_sections.h>

ITERABLE_SECTION_RAM(coap_resource_my_service, Z_LINK_ITERABLE_SUBALIGN)
```

Add this linker file to your application using CMake:

Listing 3: CMakeLists.txt

```
# Support LD linker template
zephyr_linker_sources(DATA_SECTIONS sections-ram.ld)

# Support CMake linker generator
zephyr_iterable_section(NAME coap_resource_my_service
                        GROUP DATA_REGION ${XIP_ALIGN_WITH_INPUT})
```

You can now define your service as part of the application:

```
#include <zephyr/net/coap_service.h>

static const uint16_t my_service_port = 5683;

COAP_SERVICE_DEFINE(my_service, "0.0.0.0", &my_service_port,␣
↪COAP_SERVICE_AUTOSTART);
```

Note

Services defined with the COAP_SERVICE_AUTOSTART flag will be started together with the CoAP server thread. Services can be manually started and stopped with coap_service_start and coap_service_stop respectively.

Sample Usage The following is an example of a CoAP resource registered with our service:

```
#include <zephyr/net/coap_service.h>

static int my_get(struct coap_resource *resource, struct coap_packet *request,
                  struct net_sockaddr *addr, socklen_t addr_len)
{
    static const char *msg = "Hello, world!";
    uint8_t data[CONFIG_COAP_SERVER_MESSAGE_SIZE];
    struct coap_packet response;
    uint16_t id;
    uint8_t token[COAP_TOKEN_MAX_LEN];
    uint8_t tkl, type;

    type = coap_header_get_type(request);
    id = coap_header_get_id(request);
    tkl = coap_header_get_token(request, token);

    /* Determine response type */
    type = (type == COAP_TYPE_CON) ? COAP_TYPE_ACK : COAP_TYPE_NON_CON;

    coap_packet_init(&response, data, sizeof(data), COAP_VERSION_1, type, tkl,␣
↪token,
                     COAP_RESPONSE_CODE_CONTENT, id);

    /* Set content format */
    coap_append_option_int(&response, COAP_OPTION_CONTENT_FORMAT,
                           COAP_CONTENT_FORMAT_TEXT_PLAIN);

    /* Append payload */
    coap_packet_append_payload_marker(&response);
    coap_packet_append_payload(&response, (uint8_t *)msg, strlen(msg));
```

(continues on next page)

(continued from previous page)

```
    /* Send to response back to the client */
    return coap_resource_send(resource, &response, addr, addr_len, NULL);
}

static int my_put(struct coap_resource *resource, struct coap_packet *request,
                  struct net_sockaddr *addr, socklen_t addr_len)
{
    /* ... Handle the incoming request ... */

    /* Return a CoAP response code as a shortcut for an empty ACK message */
    return COAP_RESPONSE_CODE_CHANGED;
}

static const char * const my_resource_path[] = { "test", NULL };
COAP_RESOURCE_DEFINE(my_resource, my_service, {
    .path = my_resource_path,
    .get = my_get,
    .put = my_put,
});
```

Note

As demonstrated in the example above, a CoAP resource handler can return response codes to let the server respond with an empty ACK response.

Observable resources The CoAP server provides logic for parsing observe requests and stores these using the runtime data of CoAP services. An example using a temperature sensor can look like:

```
#include <zephyr/kernel.h>
#include <zephyr/drivers/sensor.h>
#include <zephyr/net/coap_service.h>

static void notify_observers(struct k_work *work);
K_WORK_DELAYABLE_DEFINE(temp_work, notify_observers);

static int send_temperature(struct coap_resource *resource,
                            const struct net_sockaddr *addr, socklen_t addr_len,
                            uint16_t age, uint16_t id, const uint8_t *token,␣
↪uint8_t tkl,
                            bool is_response)
{
    const struct device *dev = DEVICE_DT_GET(DT_ALIAS(ambient_temp0));
    uint8_t data[CONFIG_COAP_SERVER_MESSAGE_SIZE];
    struct coap_packet response;
    char payload[14];
    struct sensor_value value;
    double temp;
    uint8_t type;

    /* Determine response type */
    type = is_response ? COAP_TYPE_ACK : COAP_TYPE_CON;
```

(continues on next page)

(continued from previous page)

```
    if (!is_response) {
        id = coap_next_id();
    }

    coap_packet_init(&response, data, sizeof(data), COAP_VERSION_1, type, tkl,␣
↪token,
                     COAP_RESPONSE_CODE_CONTENT, id);

    if (age >= 2U) {
        coap_append_option_int(&response, COAP_OPTION_OBSERVE, age);
    }

    /* Set content format */
    coap_append_option_int(&response, COAP_OPTION_CONTENT_FORMAT,
                           COAP_CONTENT_FORMAT_TEXT_PLAIN);

    /* Get the sensor data */
    sensor_sample_fetch_chan(dev, SENSOR_CHAN_AMBIENT_TEMP);
    sensor_channel_get(dev, SENSOR_CHAN_AMBIENT_TEMP, &value);
    temp = sensor_value_to_double(&value);

    snprintk(payload, sizeof(payload), "%0.2f°C", temp);

    /* Append payload */
    coap_packet_append_payload_marker(&response);
    coap_packet_append_payload(&response, (uint8_t *)payload, strlen(payload));

    return coap_resource_send(resource, &response, addr, addr_len, NULL);
}

static int temp_get(struct coap_resource *resource, struct coap_packet *request,
                    struct net_sockaddr *addr, socklen_t addr_len)
{
    uint8_t token[COAP_TOKEN_MAX_LEN];
    uint16_t id;
    uint8_t tkl;
    int r;

    /* Let the CoAP server parse the request and add/remove observers if needed */
    r = coap_resource_parse_observe(resource, request, addr);

    id = coap_header_get_id(request);
    tkl = coap_header_get_token(request, token);

    return send_temperature(resource, addr, addr_len, r == 0 ? resource->age : 0,
                            id, token, tkl, true);
}

static void temp_notify(struct coap_resource *resource, struct coap_observer␣
↪*observer)
{
    send_temperature(resource, net_sad(&observer->addr), sizeof(observer->addr),␣
↪resource->age,
                     0, observer->token, observer->tkl, false);
}
```

(continues on next page)

(continued from previous page)

```
static const char * const temp_resource_path[] = { "sensors", "temp1", NULL };
COAP_RESOURCE_DEFINE(temp_resource, my_service, {
    .path = temp_resource_path,
    .get = temp_get,
    .notify = temp_notify,
});

static void notify_observers(struct k_work *work)
{
    if (sys_slist_is_empty(&temp_resource.observers)) {
        return;
    }

    coap_resource_notify(&temp_resource);
    k_work_reschedule(&temp_work, K_SECONDS(1));
}
```

CoAP Events By enabling `CONFIG_NET_MGMT_EVENT` the user can register for CoAP events. The following example simply prints when an event occurs.

```
#include <zephyr/sys/printk.h>
#include <zephyr/net/coap_mgmt.h>
#include <zephyr/net/coap_service.h>

#define COAP_EVENTS_SET (NET_EVENT_COAP_OBSERVER_ADDED |␣
↪NET_EVENT_COAP_OBSERVER_REMOVED | \
                         NET_EVENT_COAP_SERVICE_STARTED |␣
↪NET_EVENT_COAP_SERVICE_STOPPED)

void coap_event_handler(uint64_t mgmt_event, struct net_if *iface,
                        void *info, size_t info_length, void *user_data)
{
    switch (mgmt_event) {
    case NET_EVENT_COAP_OBSERVER_ADDED:
        printk("CoAP observer added");
        break;
    case NET_EVENT_COAP_OBSERVER_REMOVED:
        printk("CoAP observer removed");
        break;
    case NET_EVENT_COAP_SERVICE_STARTED:
        if (info != NULL && info_length == sizeof(struct net_event_coap_service)) {
            struct net_event_coap_service *net_event = info;

            printk("CoAP service %s started", net_event->service->name);
        } else {
            printk("CoAP service started");
        }
        break;
    case NET_EVENT_COAP_SERVICE_STOPPED:
        if (info != NULL && info_length == sizeof(struct net_event_coap_service)) {
            struct net_event_coap_service *net_event = info;

            printk("CoAP service %s stopped", net_event->service->name);
        } else {
            printk("CoAP service stopped");
```

(continues on next page)

(continued from previous page)

```
        }
        break;
    }
}

NET_MGMT_REGISTER_EVENT_HANDLER(coap_events, COAP_EVENTS_SET, coap_event_handler,␣
↪NULL);
```

CoRE Link Format The `CONFIG_COAP_SERVER_WELL_KNOWN_CORE` option enables handling the `.well-known/core` GET requests by the server. This allows clients to get a list of hypermedia links to other resources hosted in that server.

OSCORE Support (RFC 8613)

- *Overview*
- *Configuration*
- *Server Usage*
- *Known Limitations*
- *Security Context Derivation*
- *Security Considerations*
  - *Handling OSCORE When Not Supported*
- *API Reference*

Overview The Zephyr CoAP library provides support for Object Security for Constrained RESTful Environments (OSCORE) as specified in **RFC 8613**. OSCORE provides end-to-end protection of CoAP messages using COSE (CBOR Object Signing and Encryption).

OSCORE protects CoAP messages at the application layer, providing:

1. **Confidentiality**: Message payloads and sensitive options are encrypted
2. **Integrity**: Messages are authenticated with a MAC
3. **Replay protection**: Sequence numbers prevent replay attacks
4. **Proxy-friendly**: Outer options remain visible for routing

Unlike DTLS, OSCORE provides end-to-end security that survives proxy translation between different transport protocols (UDP, TCP, HTTP).

Additional OSCORE configuration options:

- `CONFIG_COAP_OSCORE_MAX_CONTEXTS`: Maximum number of OSCORE security contexts

- CONFIG_COAP_OSCORE_EXCHANGE_CACHE_SIZE: Number of OSCORE exchanges to track per service
- **CONFIG_COAP_OSCORE_EXCHANGE_LIFETIME_MS: Lifetime of tracked OSCORE exchanges used to protect**
  deferred (separate) responses
- CONFIG_COAP_OSCORE_CONTEXT_REUSE: Enable OSCORE support for context reuse across reboots
- CONFIG_COAP_OSCORE_MASTER_SECRET_MAX_LEN: Maximum OSCORE Master Secret length in bytes
- CONFIG_COAP_OSCORE_MASTER_SALT_MAX_LEN: Maximum OSCORE Master Salt length in bytes

Configuration Enable OSCORE support with CONFIG_COAP_OSCORE. This option depends on the uoscore-uedhoc module and PSA Crypto support:

```
CONFIG_COAP_OSCORE=y
CONFIG_UOSCORE=y
CONFIG_PSA_CRYPTO=y
```

The uoscore module automatically selects required PSA crypto algorithms (AES-CCM, HKDF-SHA256, etc.).

Server Usage To enable OSCORE on a CoAP service, define the service with COAP_SERVICE_DEFINE_OSCORE (or COAPS_SERVICE_DEFINE_OSCORE for DTLS). The macro statically allocates the per-service OSCORE exchange cache. Security contexts are created separately through the Zephyr OSCORE API and added to a shared pool; applications do not include the underlying uoscore-uedhoc headers directly. Incoming requests are matched to the correct context by their Recipient ID and ID Context, so a single service can serve multiple clients, each with its own context:

```
#include <zephyr/net/coap_oscore.h>
#include <zephyr/net/coap_service.h>

static struct coap_oscore_context *my_oscore_ctx;

static uint16_t my_service_port = 5683;

/* Final argument "true" requires OSCORE for all requests. */
COAP_SERVICE_DEFINE_OSCORE(my_service, NULL, &my_service_port,
                           COAP_SERVICE_AUTOSTART, true);

int my_service_oscore_init(void)
{
    /* coap_oscore_context_add() copies the key material, so these
     * buffers need not outlive the call and can live on the stack.
     */
    const uint8_t master_secret[16] = { /* ... */ };
    const uint8_t master_salt[8] = { /* ... */ };
    const uint8_t sender_id[] = { /* ... */ };
    const uint8_t recipient_id[] = { /* ... */ };

    struct coap_oscore_init_params params = {
        .master_secret = master_secret,
        .master_secret_len = sizeof(master_secret),
        .sender_id = sender_id,
        .sender_id_len = sizeof(sender_id),
```

(continues on next page)

(continued from previous page)

```
        .recipient_id = recipient_id,
        .recipient_id_len = sizeof(recipient_id),
        .master_salt = master_salt,
        .master_salt_len = sizeof(master_salt),
        .aead_alg = COAP_OSCORE_AEAD_AES_CCM_16_64_128,
        .hkdf = COAP_OSCORE_HKDF_SHA_256,
        .fresh_master_secret_salt = true,
    };

    /* Add the context to the shared pool once its key material is
     * available. Call once per client identity (Recipient ID).
     */
    return coap_oscore_context_add(&params, &my_oscore_ctx);
}
```

The number of contexts that can be allocated at once is controlled by `CONFIG_COAP_OSCORE_MAX_CONTEXTS`. Release a context with `coap_oscore_context_remove()`. Contexts are reference-counted: while an in-flight request, an active exchange, or an observer still references a context, `coap_oscore_context_remove()` returns `-EAGAIN` and the context is retained. Retry the removal once those references have been released.

When a service is OSCORE-enabled (created with an `OSCORE` macro and at least one context is added to the pool):

1. **Incoming requests**: The server automatically verifies and decrypts OSCORE-protected requests (**RFC 8613** Section 8.2). Resource handlers receive decrypted CoAP messages with Inner options visible.
2. **Outgoing responses**: The server automatically OSCORE-protects responses and notifications that originate from an OSCORE exchange (**RFC 8613** Section 8.3). Whether a given outgoing message must be protected is decided as follows:
   - **Synchronous responses, produced while the request is being handled, are matched** against the per-service exchange cache and protected when a matching entry is found. These entries expire after `CONFIG_COAP_OSCORE_EXCHANGE_LIFETIME_MS`. On a mixed service (OSCORE and non-OSCORE clients), sending a synchronous response after the exchange cache entry has expired will result in a plaintext response.
   - **Observe notifications are protected based on the observer's stored OSCORE** state, which lives for the duration of the observation.
   - **Deferred (separate) responses, produced after the request handler has** returned, are matched against the per-service exchange cache and protected when a matching entry is found. These entries expire after `CONFIG_COAP_OSCORE_EXCHANGE_LIFETIME_MS`. On a mixed service (OSCORE and non-OSCORE clients), sending a deferred response after the exchange cache entry has expired will result in a plaintext response.
3. **Error handling: OSCORE verification errors are sent as simple CoAP responses without** OSCORE processing (**RFC 8613** Section 8.2): - COSE decode failure 4.02 Bad Option - Security context not found 4.01 Unauthorized - Decryption failure 4.00 Bad Request
4. **Required OSCORE: If the service is defined with the `_oscore_required` argument** set to true, unprotected requests are rejected with 4.01 Unauthorized.
5. **Fail-closed behavior**: If OSCORE protection of a response fails, the server does not fall back to sending a plaintext response. On an OSCORE-required service, an outgoing response that cannot be matched to any OSCORE state is also dropped rather than sent in the clear. Observe notifications are never downgraded. On a mixed service, any response (synchronous

or deferred) whose exchange cache entry has expired can no longer be matched and is sent unprotected. In practice this affects deferred (separate) responses, because a synchronous response is matched against an entry that was just created while the request was handled (see item 2 and `CONFIG_COAP_OSCORE_EXCHANGE_LIFETIME_MS`).

Known Limitations

1. **Mixed-Service Expired-Exchange Plaintext**: On a mixed service (one that serves both OSCORE and non-OSCORE clients), a response whose exchange cache entry has expired can no longer be matched to its OSCORE state and is sent as plaintext. This affects both synchronous and deferred (separate) responses (see `CONFIG_COAP_OSCORE_EXCHANGE_LIFETIME_MS`). For any service that carries sensitive data, define it as OSCORE-required (pass the `_oscore_required` argument as true, e.g. via `COAP_SERVICE_DEFINE_OSCORE`) instead of running a mixed service. An OSCORE-required service rejects unprotected requests and drops responses that cannot be protected, so it never downgrades to plaintext.

Security Context Derivation OSCORE security contexts are derived from a small set of parameters (**RFC 8613** Section 3):

Required parameters:

- **Master Secret**: Shared secret (typically 16 bytes for AES-CCM-16-64-128)
- **Sender ID**: Unique identifier for the sender
- **Recipient ID**: Unique identifier for the recipient

Optional parameters:

- **Master Salt**: Additional entropy (recommended, typically 8 bytes)
- **ID Context**: Additional context identifier
- **AEAD Algorithm**: Defaults to AES-CCM-16-64-128
- **KDF**: Defaults to HKDF-SHA-256

These parameters are typically established through:

1. **Pre-shared keys**: Configured at device provisioning
2. **EDHOC**: Ephemeral Diffie-Hellman Over COSE (see uoscore-uedhoc module)

Security Considerations

1. **Sequence number overflow**: The sender sequence number (SSN) must not exceed 2^23-1 for AES-CCM-16-64-128. The uoscore library enforces this limit.
2. **Master secret protection**: Master secrets must be stored securely (e.g., in secure storage or derived from EDHOC).
3. **Persistence across reboots**: If the same master secret is reused after a reboot (i.e., master secrets are not re-derived, e.g., via EDHOC), the sender sequence number must be persisted to non-volatile memory to prevent nonce reuse, which would break confidentiality and integrity. The receiver's replay window does not need to be persisted: it is kept in memory and, after a reboot, is re-synchronized using the Echo option as described in **RFC 8613** Appendix B.1.2.

Handling OSCORE When Not Supported When OSCORE support is not enabled (`CONFIG_COAP_OSCORE` is not set), the Zephyr CoAP stack implements fail-closed behavior for the OSCORE option per **RFC 7252** Section 5.4.1:

Server behavior (when `CONFIG_COAP_OSCORE=n`):

- **CON requests** with OSCORE option: Returns **4.02 (Bad Option)** response
- **NON requests** with OSCORE option: Silently rejects (drops) the message
- **Responses** with OSCORE option: Sends RST for CON, silently drops NON/ACK

CoAP OSCORE API

FTP client

- *Overview*
- *Protocols*
- *Limitations*
- *API Reference*

Overview The FTP client library can be used to download or upload files to FTP server.

The FTP client library reports FTP control message and download data with two separate callback functions `ftp_client.ctrl_callback` and `ftp_client.data_callback`. The library can be configured to automatically send KEEPALIVE message to the server through a timer if `CONFIG_FTP_CLIENT_KEEPALIVE_TIME` is not zero. The KEEPALIVE message is sent periodically at the completion of the time interval indicated by the value of `CONFIG_FTP_CLIENT_KEEPALIVE_TIME`.

Protocols The library is implemented in accordance with the **RFC 959** specification.

Limitations The library implements only a minimal set of commands as of now. However, new command support can be easily added.

Due to the differences in the implementation of FTP servers, the library might need customization to work with a specific server.

HTTP Client

- *Overview*
- *Sample Usage*
- *API Reference*

Overview The HTTP client library allows you to send HTTP requests and parse HTTP responses. The library communicates over the sockets API but it does not create sockets on its own. It can be enabled with `CONFIG_HTTP_CLIENT` Kconfig option.

The application must be responsible for creating a socket and passing it to the library. Therefore, depending on the application's needs, the library can communicate over either a plain TCP socket (HTTP) or a TLS socket (HTTPS).

Sample Usage The API of the HTTP client library has a single function.

The following is an example of a request structure created correctly:

```
struct http_request req = { 0 };
static uint8_t recv_buf[512];

req.method = HTTP_GET;
req.url = "/";
req.host = "localhost";
req.protocol = "HTTP/1.1";
req.response = response_cb;
req.recv_buf = recv_buf;
req.recv_buf_len = sizeof(recv_buf);

/* sock is a file descriptor referencing a socket that has been connected
 * to the HTTP server.
 */
ret = http_client_req(sock, &req, 5000, NULL);
```

If the server responds to the request, the library provides the response to the application through the response callback registered in the request structure. As the library can provide the response in chunks, the application must be able to process these.

Together with the structure containing the response data, the callback function also provides information about whether the library expects to receive more data.

The following is an example of a very simple response handling function:

```
static int response_cb(struct http_response *rsp,
                       enum http_final_call final_data,
                       void *user_data)
{
    if (final_data == HTTP_DATA_MORE) {
        LOG_INF("Partial data received (%zd bytes)", rsp->data_len);
    } else if (final_data == HTTP_DATA_FINAL) {
        LOG_INF("All the data received (%zd bytes)", rsp->data_len);
    }

    LOG_INF("Response status %s", rsp->http_status);

    return 0;
}
```

See HTTP client sample application for more information about the library usage.

HTTP Server

- *Overview*
- *Server Setup*
- *Sample Usage*
  - *Services*
  - *Per-service configuration*
  - *Fallback Resources*
  - *Static resources*
  - *Static filesystem resources*
  - *Dynamic resources*
  - *Websocket resources*
  - *Accessing request headers*
- *API Reference*

Overview Zephyr provides an HTTP server library, which allows to register HTTP services and HTTP resources associated with those services. The server creates a listening socket for every registered service, and handles incoming client connections. It's possible to communicate over a plain TCP socket (HTTP) or a TLS socket (HTTPS). HTTP/1.1 (**RFC 2616**), HTTP/2 (**RFC 9113**) and HTTP/3 (**RFC 9114**) protocol versions are supported.

The server operation is generally transparent for the application, running in a background thread. The application can control the server activity with respective API functions.

Certain resource types (for example dynamic resource) provide resource-specific application callbacks, allowing the server to interact with the application (for instance provide resource content, or process request payload).

Currently, the following resource types are supported:

- Static resources - content defined compile-time, cannot be modified at runtime (`HTTP_RESOURCE_TYPE_STATIC`).
- Static file system resources - the path at which the filesystem is mounted, and the URL at which the filesystem is made available are fixed at build time, but the content within the filesystem can be changed dynamically. This means that the files can be created, modified or deleted by some other code outside the HTTP server (`HTTP_RESOURCE_TYPE_STATIC_FS`).
- Dynamic resources - content provided at runtime by respective application callback (`HTTP_RESOURCE_TYPE_DYNAMIC`).
- Websocket resources - allowing to establish Websocket connections with the server (`HTTP_RESOURCE_TYPE_WEBSOCKET`).

Zephyr provides a sample demonstrating HTTP(s) server operation and various resource types usage. See sockets-http-server for more information.

Server Setup A few prerequisites are needed in order to enable HTTP server functionality in the application.

First of all, the HTTP server has to be enabled in applications configuration file with `CONFIG_HTTP_SERVER` Kconfig option:

Listing 4: `prj.conf`

```
CONFIG_HTTP_SERVER=y
```

All HTTP services and HTTP resources are placed in a dedicated linker section. The linker section for services is predefined locally, however the application is responsible for defining linker sections for resources associated with respective services. Linker section names for resources should be prefixed with `http_resource_desc_`, appended with the service name.

Linker sections for resources should be defined in a linker file. For example, for a service named `my_service`, the linker section shall be defined as follows:

Listing 5: `sections-rom.ld`

```
#include <zephyr/linker/iterable_sections.h>

ITERABLE_SECTION_ROM(http_resource_desc_my_service, Z_LINK_ITERABLE_SUBALIGN)
```

Finally, the linker file and linker section have to be added to your application using CMake:

Listing 6: `CMakeLists.txt`

```
zephyr_linker_sources(SECTIONS sections-rom.ld)
zephyr_linker_section(NAME http_resource_desc_my_service
                      KVMA RAM_REGION GROUP RODATA_REGION)
```

Note

You need to define a separate linker section for each HTTP service registered in the system.

Sample Usage

Services The application needs to define an HTTP service (or multiple services), with the same name as used for the linker section with `HTTP_SERVICE_DEFINE` macro:

```
#include <zephyr/net/http/service.h>

static uint16_t http_service_port = 80;

HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10, NULL, NULL,␣
↪NULL);
```

Alternatively, an HTTPS service can be defined with `HTTPS_SERVICE_DEFINE`:

```
#include <zephyr/net/http/service.h>
#include <zephyr/net/tls_credentials.h>

#define HTTP_SERVER_CERTIFICATE_TAG 1

static uint16_t https_service_port = 443;
static const sec_tag_t sec_tag_list[] = {
    HTTP_SERVER_CERTIFICATE_TAG,
```

(continues on next page)

(continued from previous page)

```
};

HTTPS_SERVICE_DEFINE(my_service, "0.0.0.0", &https_service_port, 1, 10,
                     NULL, NULL, NULL, sec_tag_list, sizeof(sec_tag_list));
```

Per-service configuration HTTP services support individual service configuration, for now it includes only socket creation through the `http_service_config` structure. This allows applications to customize socket creation behavior, for example to set specific socket options or use custom socket types.

To use custom socket creation:

```
static int my_socket_create(const struct http_service_desc *svc, int af, int proto)
{
    int fd;

    /* Create socket with custom parameters */
    fd = zsock_socket(af, SOCK_STREAM, proto);
    if (fd < 0) {
        return fd;
    }

    /* Set custom socket options */
    /* Add any other custom socket configuration */

    return fd;
}

static const struct http_service_config my_service_config = {
    .socket_create = my_socket_create,
};

static uint16_t http_service_port = 80;

HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10,
                    NULL, NULL, &my_service_config);
```

The custom socket creation function receives: - `svc`: Pointer to the service descriptor - `af`: Address family (NET_AF_INET or NET_AF_INET6) - `proto`: Protocol (NET_IPPROTO_TCP or NET_IPPROTO_TLS_1_2 for HTTPS)

The function should return the socket file descriptor on success, or a negative error code on failure.

If no custom configuration is needed, simply pass `NULL` for the config parameter:

```
HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10,
                    NULL, NULL, NULL);
```

Fallback Resources The `_res_fallback` parameter can be used when defining an HTTP/HTTPS service to specify a fallback resource which will be used if no other resource matches the URL. This can be used for example to serve an index page for all unknown paths (useful for a single-page app which handles routing in the frontend), or for a customised 404 response.

```
static int default_handler(struct http_client_ctx *client, enum␣
↪http_transaction_status status,
```

(continues on next page)

(continued from previous page)

```
                    const struct http_request_ctx *request_ctx,
                    struct http_response_ctx *response_ctx, void *user_data)
{
    static const char response_404[] = "Oops, page not found!";

    if (status == HTTP_SERVER_REQUEST_DATA_FINAL) {
        response_ctx->status = 404;
        response_ctx->body = response_404;
        response_ctx->body_len = sizeof(response_404) - 1;
        response_ctx->final_chunk = true;
    }

    return 0;
}

static struct http_resource_detail_dynamic default_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_DYNAMIC,
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
    },
    .cb = default_handler,
    .user_data = NULL,
};

/* Register a fallback resource to handle any unknown path */
HTTP_SERVICE_DEFINE(my_service, "0.0.0.0", &http_service_port, 1, 10, NULL, &
↪default_detail, NULL);
```

Note

HTTPS services rely on TLS credentials being registered in the system. See *TLS credentials subsystem* for information on how to configure TLS credentials in the system.

Once HTTP(s) service is defined, resources can be registered for it with `HTTP_RESOURCE_DEFINE` macro.

Application can enable resource wildcard support by enabling `CONFIG_HTTP_SERVER_RESOURCE_WILDCARD` option. When this option is set, then it is possible to match several incoming HTTP requests with just one resource handler. The fnmatch() POSIX API function is used to match the pattern in the URL paths.

Example:

```
HTTP_RESOURCE_DEFINE(my_resource, my_service, "/foo*", &resource_detail);
```

This would match all URLs that start with a string `foo`. See POSIX.2 chapter 2.13 for pattern matching syntax description.

Static resources Static resource content is defined build-time and is immutable. The following example shows how gzip compressed webpage can be defined as a static resource in the application:

```
static const uint8_t index_html_gz[] = {
    #include "index.html.gz.inc"
};
```

(continues on next page)

(continued from previous page)

```
struct http_resource_detail_static index_html_gz_resource_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_STATIC,
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
        .content_encoding = "gzip",
    },
    .static_data = index_html_gz,
    .static_data_len = sizeof(index_html_gz),
};

HTTP_RESOURCE_DEFINE(index_html_gz_resource, my_service, "/",
                     &index_html_gz_resource_detail);
```

The resource content and content encoding is application specific. For the above example, a gzip compressed webpage can be generated during build, by adding the following code to the application's `CMakeLists.txt` file:

Listing 7: `CMakeLists.txt`

```
set(gen_dir ${ZEPHYR_BINARY_DIR}/include/generated/)
set(source_file_index src/index.html)
generate_inc_file_for_target(app ${source_file_index} ${gen_dir}/index.html.gz.inc␣
↪--gzip)
```

where `src/index.html` is the location of the webpage to be compressed.

Static filesystem resources Static filesystem resource content is defined build-time and is immutable. Note that only `GET` operation is supported, user is not able to upload files to the filesystem. The following example shows how the path can be defined as a static resource in the application:

```
struct http_resource_detail_static_fs static_fs_resource_detail = {
    .common = {
        .type                                = HTTP_RESOURCE_TYPE_STATIC_FS,
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
    },
    .fs_path = "/lfs1/www",
};

HTTP_RESOURCE_DEFINE(static_fs_resource, my_service, "*", &
↪static_fs_resource_detail);
```

All files located in /lfs1/www are made available to the client. If a file is gzipped, .gz must be appended to the file name (e.g. index.html.gz), then the server delivers index.html.gz when the client requests index.html and adds gzip content-encoding to the HTTP header.

The content type is evaluated based on the file extension. The server supports .html, .js, .css, .jpg, .png and .svg. More content types can be provided with the `HTTP_SERVER_CONTENT_TYPE` macro. All other files are provided with the content type text/html.

```
HTTP_SERVER_CONTENT_TYPE(json, "application/json")
```

When serving files from a static filesystem, the response chunk size can be configured using the `CONFIG_HTTP_SERVER_STATIC_FS_RESPONSE_SIZE` Kconfig option. This determines the size of individual chunks when transmitting file content to clients.

Dynamic resources For dynamic resource, a resource callback is registered to exchange data between the server and the application.

The following example code shows how to register a dynamic resource with a simple resource handler, which echoes received data back to the client:

```
static int dyn_handler(struct http_client_ctx *client, enum␣
↪http_transaction_status status,
                       const struct http_request_ctx *request_ctx,
                       struct http_response_ctx *response_ctx, void *user_data)
{
#define MAX_TEMP_PRINT_LEN 32
    static char print_str[MAX_TEMP_PRINT_LEN];
    enum http_method method = client->method;
    static size_t processed;

    __ASSERT_NO_MSG(request_ctx->data != NULL);

    if (status == HTTP_SERVER_TRANSACTION_ABORTED ||
        status == HTTP_SERVER_TRANSACTION_COMPLETE) {
        if (status == HTTP_SERVER_TRANSACTION_ABORTED) {
            LOG_DBG("Transaction aborted after %zd bytes.", processed);
        }
        processed = 0;
        return 0;
    }

    processed += request_ctx->data_len;

    snprintf(print_str, sizeof(print_str), "%s received (%zd bytes)",
             http_method_str(method), request_ctx->data_len);
    LOG_HEXDUMP_DBG(request_ctx->data, request_ctx->data_len, print_str);

    if (status == HTTP_SERVER_REQUEST_DATA_FINAL) {
        LOG_DBG("All data received (%zd bytes).", processed);
        processed = 0;
    }

    /* Echo data back to client */
    response_ctx->body = request_ctx->data;
    response_ctx->body_len = request_ctx->data_len;
    response_ctx->final_chunk = (status == HTTP_SERVER_REQUEST_DATA_FINAL);

    return 0;
}

struct http_resource_detail_dynamic dyn_resource_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_DYNAMIC,
        .bitmask_of_supported_http_methods =
            BIT(HTTP_GET) | BIT(HTTP_POST),
    },
    .cb = dyn_handler,
    .user_data = NULL,
};

HTTP_RESOURCE_DEFINE(dyn_resource, my_service, "/dynamic",
                     &dyn_resource_detail);
```

The resource callback may be called multiple times for a single request, hence the application should be able to keep track of the received data progress.

The `status` field informs the application about the progress in passing request payload from the server to the application. As long as the status reports `HTTP_SERVER_REQUEST_DATA_MORE`, the application should expect more data to be provided in a consecutive callback calls. Once all request payload has been passed to the application, the server reports `HTTP_SERVER_REQUEST_DATA_FINAL` status. In case of communication errors during request processing (for example client closed the connection before complete payload has been received), the server reports `HTTP_SERVER_TRANSACTION_ABORTED`. When the response has been sent completely to the client, the server reports `HTTP_SERVER_TRANSACTION_COMPLETE` status. Either of the two events indicate that the request processing is finished, and the application shall reset any progress recorded for the resource, and await a new request to come. The server guarantees that the resource can only be accessed by single client at a time.

The `request_ctx` parameter is used to pass request data to the application:

- The `data` and `data_len` fields pass request data to the application.
- The `headers`, `header_count` and `headers_status` fields pass request headers to the application, if `CONFIG_HTTP_SERVER_CAPTURE_HEADERS` is enabled. These fields are only populated in the first callback of a request; see *Accessing request headers* for details.

The `response_ctx` field is used by the application to pass response data to the HTTP server:

- The `status` field allows the application to send an HTTP response code. If not populated, the response code will be 200 by default.
- The `headers` and `header_count` fields can be used for the application to send any arbitrary HTTP headers. If not populated, only Transfer-Encoding and Content-Type are sent by default. The callback may override the Content-Type if desired.
- The `body` and `body_len` fields are used to send body data.
- The `final_chunk` field is used to indicate that the application has no more response data to send.

Headers and/or response codes may only be sent in the first populated `response_ctx`, after which only further body data is allowed in subsequent callbacks.

The server will call the resource callback until it provided all request data to the application, and the application reports there is no more data to include in the reply.

Websocket resources Websocket resources register an application callback, which is called when a Websocket connection upgrade takes place. The callback is provided with a socket descriptor corresponding to the underlying TCP/TLS connection. Once called, the application takes full control over the socket, i. e. is responsible to release it when done.

```
static int ws_socket;
static uint8_t ws_recv_buffer[1024];

int ws_setup(int sock, struct http_request_ctx *request_ctx, void *user_data)
{
    ws_socket = sock;
    return 0;
}

struct http_resource_detail_websocket ws_resource_detail = {
    .common = {
        .type = HTTP_RESOURCE_TYPE_WEBSOCKET,
        /* We need HTTP/1.1 Get method for upgrading */
        .bitmask_of_supported_http_methods = BIT(HTTP_GET),
    },
    .cb = ws_setup,
    .data_buffer = ws_recv_buffer,
```

(continues on next page)

(continued from previous page)

```
    .data_buffer_len = sizeof(ws_recv_buffer),
    .user_data = NULL, /* Fill this for any user specific data */
};

HTTP_RESOURCE_DEFINE(ws_resource, my_service, "/", &ws_resource_detail);
```

The above minimalistic example shows how to register a Websocket resource with a simple callback, used only to store the socket descriptor provided. Further processing of the Websocket connection is application-specific, hence outside of scope of this guide. See sockets-http-server for an example Websocket-based echo service implementation.

Accessing request headers The application can register an interest in any specific HTTP request headers. These headers are then stored for each incoming request, and can be accessed from within a dynamic resource callback.

Important

Captured request headers are delivered to the application **only in the first callback** for a given request. In any subsequent callback for the same request the `headers`, `header_count` and `headers_status` fields of `request_ctx` are cleared (`headers_status` becomes `HTTP_HEADER_STATUS_NONE`). Applications must copy out any header value they need during the first callback rather than reading it later.

Note that the first callback may or may not also carry request body data (this depends on the HTTP method and on transport framing). Do not condition header handling on the presence of body data: always inspect `headers_status` and stash the headers when it is not `HTTP_HEADER_STATUS_NONE`.

This feature must first be enabled with `CONFIG_HTTP_SERVER_CAPTURE_HEADERS` Kconfig option.

Then the application can register headers to be captured, and read the values from within the dynamic resource callback. The recommended pattern is to copy out the headers of interest in the first callback, then act on them once the full request body has been received:

```
HTTP_SERVER_REGISTER_HEADER_CAPTURE(capture_user_agent, "User-Agent");

static char user_agent[64];

static int dyn_handler(struct http_client_ctx *client, enum␣
↪http_transaction_status status,
                       const struct http_request_ctx *request_ctx,
                       struct http_response_ctx *response_ctx, void *user_data)
{
    /* Request headers are only present in the first callback, so copy out
     * any values needed later before they are gone.
     */
    if (request_ctx->headers_status != HTTP_HEADER_STATUS_NONE) {
        for (size_t i = 0; i < request_ctx->header_count; i++) {
            const struct http_header *hdr = &request_ctx->headers[i];

            LOG_INF("Captured header: '%s: %s'", hdr->name, hdr->value);

            if (strcasecmp(hdr->name, "User-Agent") == 0) {
                strncpy(user_agent, hdr->value, sizeof(user_agent) - 1);
            }
        }
```

(continues on next page)

(continued from previous page)

```
    }

    /* Process request body data (may be empty in the first callback). */

    if (status == HTTP_SERVER_REQUEST_DATA_FINAL) {
        /* Full request received: act on the body together with the header
         * values stashed above (e.g. user_agent).
         */
    }

    return 0;
}
```

Overview Lightweight Machine to Machine (LwM2M) is an application layer protocol designed with device management, data reporting and device actuation in mind. Based on CoAP/UDP, LwM2M is a standard defined by the Open Mobile Alliance and suitable for constrained devices by its use of CoAP packet-size optimization and a simple, stateless flow that supports a REST API.

One of the key differences between LwM2M and CoAP is that an LwM2M client initiates the connection to an LwM2M server. The server can then use the REST API to manage various interfaces with the client.

LwM2M uses a simple resource model with the core set of objects and resources defined in the specification.

The LwM2M library can be enabled with `CONFIG_LWM2M` Kconfig option.

Example LwM2M object and resources: Device *Object definition*

Object ID	Name	Instance	Mandatory
3	Device	Single	Mandatory

Resource definitions

`* R=Read, W=Write, E=Execute`

ID	Name	OP*	Instance	Mandatory	Type
0	Manufacturer	R	Single	Optional	String
1	Model	R	Single	Optional	String
2	Serial number	R	Single	Optional	String
3	Firmware version	R	Single	Optional	String
4	Reboot	E	Single	Mandatory	
5	Factory Reset	E	Single	Optional	
6	Available Power Sources	R	Multiple	Optional	Integer 0-7
7	Power Source Voltage (mV)	R	Multiple	Optional	Integer
8	Power Source Current (mA)	R	Multiple	Optional	Integer
9	Battery Level %	R	Single	Optional	Integer
10	Memory Free (Kb)	R	Single	Optional	Integer
11	Error Code	R	Multiple	Optional	Integer 0-8
12	Reset Error	E	Single	Optional	
13	Current Time	RW	Single	Optional	Time
14	UTC Offset	RW	Single	Optional	String
15	Timezone	RW	Single	Optional	String
16	Supported Binding	R	Single	Mandatory	String
17	Device Type	R	Single	Optional	String
18	Hardware Version	R	Single	Optional	String
19	Software Version	R	Single	Optional	String
20	Battery Status	R	Single	Optional	Integer 0-6
21	Memory Total (Kb)	R	Single	Optional	Integer
22	ExtDevInfo	R	Multiple	Optional	ObjLnk

The server could query the `Manufacturer` resource for `Device` object instance 0 (the default and only instance) by sending a `READ 3/0/0` operation to the client.

The full list of registered objects and resource IDs can be found in the OMA LwM2M registries.

Zephyr's LwM2M library lives in the subsys/net/lib/lwm2m, with a client sample in samples/net/lwm2m_client. For more information about the provided sample see: lwm2m-client. The sample can be configured to use normal insecure network sockets or sockets secured via DTLS.

The Zephyr LwM2M library implements the following items:

- engine to process networking events and core functions
- RD client which performs BOOTSTRAP and REGISTRATION functions
- SenML CBOR, SenML JSON, CBOR, TLV, JSON, and plain text formatting functions
- LwM2M Technical Specification Enabler objects such as Security, Server, Device, Firmware Update, etc.
- Extended IPSO objects such as Light Control, Temperature Sensor, and Timer

By default, the library implements LwM2M specification 1.0.2 and can be set to LwM2M specification 1.1.1 with a Kconfig option.

For more information about LwM2M specification releases visit the OMA LwM2M releases page.

Sample usage To use the LwM2M library, start by creating an LwM2M client context `lwm2m_ctx` structure:

```
/* LwM2M client context */
static struct lwm2m_ctx client;
```

Create callback functions for LwM2M resource executions:

```
static int device_reboot_cb(uint16_t obj_inst_id, uint8_t *args,
                            uint16_t args_len)
{
        LOG_INF("Device rebooting.");
        LOG_PANIC();
        sys_reboot(0);
        return 0; /* won't reach this */
}
```

The LwM2M RD client can send events back to the sample. To receive those events, setup a callback function:

```
static void rd_client_event(struct lwm2m_ctx *client,
                            enum lwm2m_rd_client_event client_event)
{
        switch (client_event) {

        case LWM2M_RD_CLIENT_EVENT_NONE:
                /* do nothing */
                break;

        case LWM2M_RD_CLIENT_EVENT_BOOTSTRAP_REG_FAILURE:
                LOG_DBG("Bootstrap registration failure!");
                break;

        case LWM2M_RD_CLIENT_EVENT_BOOTSTRAP_REG_COMPLETE:
                LOG_DBG("Bootstrap registration complete");
```

(continues on next page)

(continued from previous page)

```
                break;

        case LWM2M_RD_CLIENT_EVENT_BOOTSTRAP_TRANSFER_COMPLETE:
                LOG_DBG("Bootstrap transfer complete");
                break;

        case LWM2M_RD_CLIENT_EVENT_REGISTRATION_FAILURE:
                LOG_DBG("Registration failure!");
                break;

        case LWM2M_RD_CLIENT_EVENT_REGISTRATION_COMPLETE:
                LOG_DBG("Registration complete");
                break;

        case LWM2M_RD_CLIENT_EVENT_REG_TIMEOUT:
                LOG_DBG("Registration timeout!");
                break;

        case LWM2M_RD_CLIENT_EVENT_REG_UPDATE_COMPLETE:
                LOG_DBG("Registration update complete");
                break;

        case LWM2M_RD_CLIENT_EVENT_DEREGISTER_FAILURE:
                LOG_DBG("Deregister failure!");
                break;

        case LWM2M_RD_CLIENT_EVENT_DISCONNECT:
                LOG_DBG("Disconnected");
                break;

        case LWM2M_RD_CLIENT_EVENT_REG_UPDATE:
                LOG_DBG("Registration update");
                break;

        case LWM2M_RD_CLIENT_EVENT_DEREGISTER:
                LOG_DBG("Deregistration client");
                break;

        case LWM2M_RD_CLIENT_EVENT_SERVER_DISABLED:
                LOG_DBG("LwM2M server disabled");
          break;
        }
}
```

Next we assign `Security` resource values to let the client know where and how to connect as well as set the `Manufacturer` and `Reboot` resources in the `Device` object with some data and the callback we defined above:

```
/*
 * Server URL of default Security object = 0/0/0
 * Use leshan.eclipse.org server IP (5.39.83.206) for connection
 */
lwm2m_set_string(&LWM2M_OBJ(0, 0, 0), "coap://5.39.83.206");

/*
 * Security Mode of default Security object = 0/0/2
```

(continues on next page)

(continued from previous page)

```
 * 3 = NoSec mode (no security beware!)
 */
lwm2m_set_u8(&LWM2M_OBJ(0, 0, 2), 3);

#define CLIENT_MANUFACTURER "Zephyr Manufacturer"

/*
 * Manufacturer resource of Device object = 3/0/0
 * We use lwm2m_set_res_data() function to set a pointer to the
 * CLIENT_MANUFACTURER string.
 * Note the LWM2M_RES_DATA_FLAG_RO flag which stops the engine from
 * trying to assign a new value to the buffer.
 */
lwm2m_set_res_data(&LWM2M_OBJ(3, 0, 0), CLIENT_MANUFACTURER,
                   sizeof(CLIENT_MANUFACTURER),
                   LWM2M_RES_DATA_FLAG_RO);

/* Reboot resource of Device object = 3/0/4 */
lwm2m_register_exec_callback(&LWM2M_OBJ(3, 0, 4), device_reboot_cb);
```

Lastly, we start the LwM2M RD client (which in turn starts the LwM2M engine). The second parameter of `lwm2m_rd_client_start()` is the client endpoint name. This is important as it needs to be unique per LwM2M server:

```
(void)memset(&client, 0x0, sizeof(client));
lwm2m_rd_client_start(&client, "unique-endpoint-name", 0, rd_client_event);
```

LwM2M security modes The Zephyr LwM2M library can be used either without security or use DTLS to secure the communication channel. When using DTLS with the LwM2M engine, PSK (Pre-Shared Key) and X.509 certificates are the security modes that can be used to secure the communication. The engine uses LwM2M Security object (Id 0) to read the stored credentials and feed keys from the security object into the TLS credential subsystem, see *secure sockets documentation*. Enable the `CONFIG_LWM2M_DTLS_SUPPORT` Kconfig option to use the security.

Depending on the selected mode, the security object must contain following data:

PSK
: Security Mode (Resource ID 2) set to zero (Pre-Shared Key mode). Identity (Resource ID 3) contains PSK ID in binary form. Secret key (Resource ID 5) contains the PSK key in binary form. If the key or identity is provided as a hex string, it must be converted to binary before storing into the security object.

X509
: When X509 certificates are used, set Security Mode (ID 2) to `2` (Certificate mode). Identity (ID 3) is used to store the client certificate and Secret key (ID 5) must have a private key associated with the certificate. Server Public Key resource (ID 4) must contain a server certificate or CA certificate used to sign the certificate chain. If the `CONFIG_MBEDTLS_PEM_PARSE_C` / `CONFIG_MBEDTLS_PEM_WRITE_C` Kconfig options are enabled, certificates and private keys can be entered in PEM format. Otherwise, they must be in binary DER format.

NoSec
: When no security is used, set Security Mode (Resource ID 2) to `3` (NoSec).

In all modes, Server URI resource (ID 0) must contain the full URI for the target server. When DNS names are used, the DNS resolver must be enabled.

When DTLS is used, following options are recommended to reduce DTLS handshake traffic when connection is re-established:

- `CONFIG_LWM2M_DTLS_CID` enables DTLS Connection Identifier support. When server supports it, this completely removes the handshake when device resumes operation after long idle period. Greatly helps when NAT mappings have timed out.
- `CONFIG_LWM2M_TLS_SESSION_CACHING` uses session cache when before falling back to full DTLS handshake. Reduces few packets from handshake, when session is still cached on server side. Most significant effect is to avoid full registration.

LwM2M stack provides callbacks in the `lwm2m_ctx` structure. They are used to feed keys from the LwM2M security object into the TLS credential subsystem. By default, these callbacks can be left as NULL pointers, in which case default callbacks are used. When an external TLS stack, or non-default socket options are required, you can overwrite the `lwm2m_ctx.load_credentials()` or `lwm2m_ctx.set_socketoptions()` callbacks.

An example of setting up the security object for PSK mode:

```
/* "000102030405060708090a0b0c0d0e0f" */
static unsigned char client_psk[] = {
        0x00, 0x01, 0x02, 0x03, 0x04, 0x05, 0x06, 0x07,
        0x08, 0x09, 0x0a, 0x0b, 0x0c, 0x0d, 0x0e, 0x0f
};

static const char client_identity[] = "Client_identity";

lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 0),
↪"coaps://lwm2m.example.com");
lwm2m_set_u8(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 2), LWM2M_SECURITY_PSK);
/* Set the client identity as a string, but this could be binary as well */
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 3), client_identity);
/* Set the client pre-shared key (PSK) */
lwm2m_set_opaque(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 5), client_psk,␣
↪sizeof(client_psk));
```

An example of setting up the security object for X509 certificate mode:

```
static const char certificate[] = "-----BEGIN CERTIFICATE-----\nMIIB6jCCAY+gAw...";
static const char key[] = "-----BEGIN EC PRIVATE KEY-----\nMHcCAQ...";
static const char root_ca[] = "-----BEGIN CERTIFICATE-----\nMIIBaz...";

lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 0),
↪"coaps://lwm2m.example.com");
lwm2m_set_u8(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 2), LWM2M_SECURITY_CERT);
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 3), certificate);
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 5), key);
lwm2m_set_string(&LWM2M_OBJ(LWM2M_OBJECT_SECURITY_ID, 0, 4), root_ca);
```

Before calling `lwm2m_rd_client_start()` assign the tls_tag # where the LwM2M library should store the DTLS information prior to connection (normally a value of 1 is ok here).

```
(void)memset(&client, 0x0, sizeof(client));
client.tls_tag = 1; /* <---- */
lwm2m_rd_client_start(&client, "endpoint-name", 0, rd_client_event);
```

For a more detailed LwM2M client sample see: lwm2m-client.

Multi-thread usage Writing a value to a resource can be done using functions like lwm2m_set_u8. When writing to multiple resources, the function lwm2m_registry_lock will ensure that the client halts until all writing operations are finished:

```
lwm2m_registry_lock();
lwm2m_set_u32(&LWM2M_OBJ(1, 0, 1), 60);
lwm2m_set_u8(&LWM2M_OBJ(5, 0, 3), 0);
lwm2m_set_f64(&LWM2M_OBJ(3303, 0, 5700), value);
lwm2m_registry_unlock();
```

This is especially useful if the server is composite-observing the resources being written to. Locking will then ensure that the client only updates and sends notifications to the server after all operations are done, resulting in fewer messages in general.

Support for time series data LwM2M version 1.1 adds support for SenML CBOR and SenML JSON data formats. These data formats add support for time series data. Time series formats can be used for READ, NOTIFY and SEND operations. When data cache is enabled for a resource, each write will create a timestamped entry in a cache, and its content is then returned as a content in READ, NOTIFY or SEND operation for a given resource.

Data cache is only supported for resources with a fixed data size.

Supported resource types:

- Signed and unsigned 8-64-bit integers
- Float
- Boolean

Enabling and configuring Enable data cache by selecting `CONFIG_LWM2M_RESOURCE_DATA_CACHE_SUPPORT`. Application needs to allocate an array of `lwm2m_time_series_elem` structures and then enable the cache by calling `lwm2m_enable_cache()` for a given resource. Each resource must be enabled separately and each resource needs their own storage.

```
/* Allocate data cache storage */
static struct lwm2m_time_series_elem temperature_cache[10];
/* Enable data cache */
lwm2m_enable_cache(LWM2M_OBJ(IPSO_OBJECT_TEMP_SENSOR_ID, 0, SENSOR_VALUE_RID),
        temperature_cache, ARRAY_SIZE(temperature_cache));
```

Applications can inspect the available space in a cached resource with `lwm2m_cache_free_slots_get()`, which returns the number of samples that can still be stored or a negative errno value if the query fails.

LwM2M engine have room for four resources that have cache enabled. Limit can be increased by changing `CONFIG_LWM2M_MAX_CACHED_RESOURCES`. This affects a static memory usage of engine.

Data caches depends on one of the SenML data formats `CONFIG_LWM2M_RW_SENML_CBOR_SUPPORT` or `CONFIG_LWM2M_RW_SENML_JSON_SUPPORT` and needs `CONFIG_POSIX_TIMERS` so it can request a timestamp from the system.

Read and Write operations Full content of data cache is written into a payload when any READ, SEND or NOTIFY operation internally reads the content of a given resource. This has a side effect that any read callbacks registered for a that resource are ignored when cache is enabled. Data is written into a cache when any of the `lwm2m_set_*` functions are called. Applications can register a cache filter callback with `lwm2m_set_cache_filter()` to drop otherwise valid samples based on application-specific rules.

Limitations Cache size should be manually set so small that the content can fit normal packets sizes. When cache is full, new values are dropped.

Send scheduler helper objects The optional SEND scheduler extension exposes two objects (Send scheduler Control `10523` and Sampling Rules `10524`) that sit on top of cached resources to decide when samples should be kept and when the client should trigger a LwM2M SEND.

Enabling and wiring

- Select `CONFIG_LWM2M_SEND_SCHEDULER` (requires LwM2M 1.1 SEND support and `CONFIG_LWM2M_RESOURCE_DATA_CACHE_SUPPORT`).
- Send-scheduler objects register automatically; ensure caches are configured before starting the RD client.
- Attach `lwm2m_send_sched_cache_filter()` to every cached resource that should be governed by the scheduler using `lwm2m_set_cache_filter()`.
- Call `lwm2m_send_sched_handle_registration_event()` from the RD client callback when registration or registration-update completes (on `LWM2M_RD_CLIENT_EVENT_REGISTRATION_COMPLETE` and `LWM2M_RD_CLIENT_EVENT_REG_UPDATE_COMPLETE`) so cached samples are sent right after the registration exchange.

Scheduler Control object (10523) The single-instance control object configures global behaviour:

- `0: paused` – stop accepting samples in cache.
- `1: max-samples` – upper limit for cached samples across all resources; a SEND is forced when the limit is reached (`0` disables).
- `2: max-age` – maximum age in seconds of the oldest cached sample before a SEND is triggered (`0` disables).
- `3: flush` – Execute resource that immediately triggers a SEND for all configured rule paths.
- `4: flush-on-update` – when enabled (default), a successful registration or registration-update event triggers a SEND of cached resources.

Sampling Rules object (10524) Each instance describes one cached resource to watch. `/10524/X/0` holds the resource path and `/10524/X/1` contains up to four rule strings. Supported attributes:

- `gt=<float>` – trigger when the sample crosses above the threshold.
- `lt=<float>` – trigger when the sample crosses below the threshold.
- `st=<float>` – trigger when the absolute delta from the last reported value is greater than or equal to the threshold.
- `pmin=<int>` – minimum seconds between accepted samples.
- `pmax=<int>` – force a cached sample to be kept at least every `pmax` seconds, even without changes.

When no rules are configured for an instance, every incoming sample is cached. The scheduler also forces a SEND when a cache for a controlled resource runs out of space or when the global `max-samples`/`max-age` limits are reached.

LwM2M engine and application events The Zephyr LwM2M engine defines events that can be sent back to the application through callback functions. The engine state machine shows when the events are spawned. Events depicted in the diagram are listed in the table. The events are prefixed with `LWM2M_RD_CLIENT_EVENT_`.

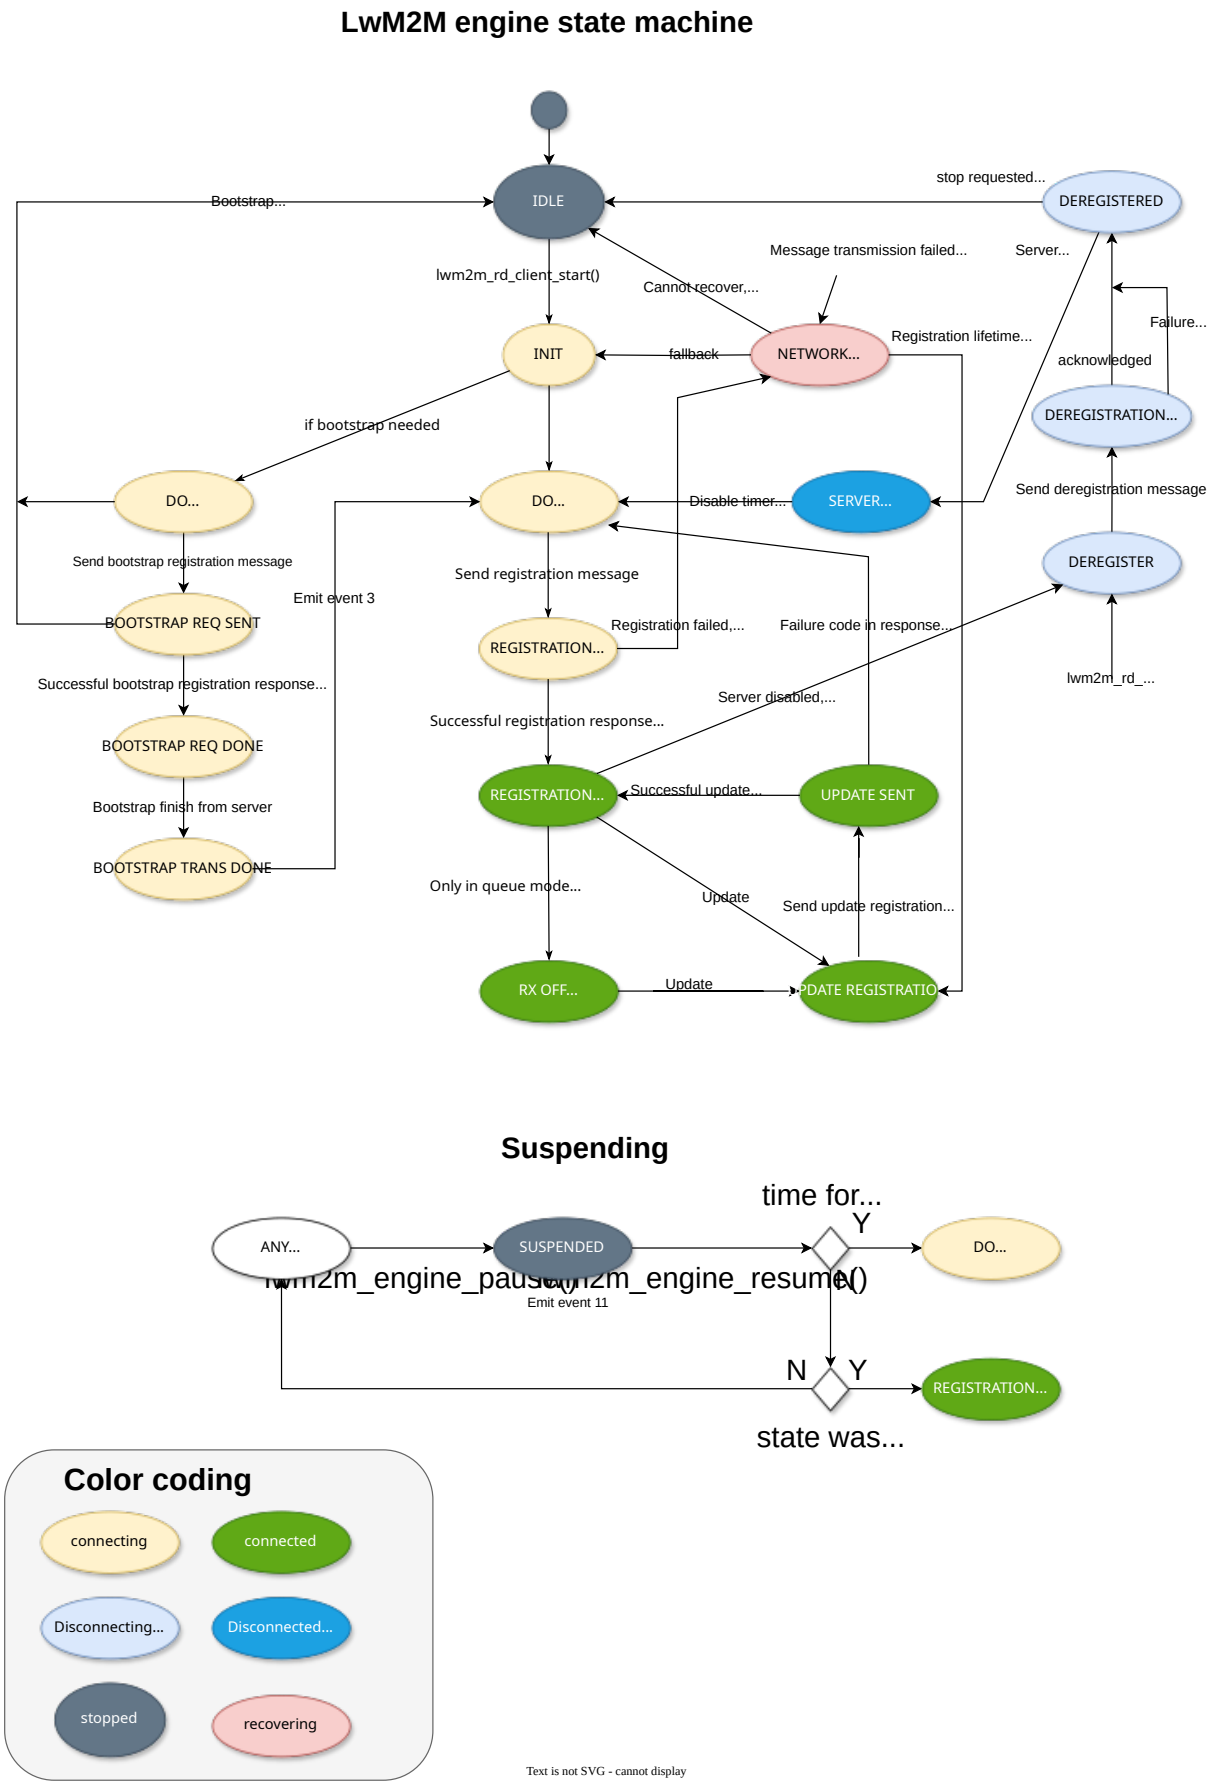

Fig. 6: State machine for the LwM2M engine

Table 6: LwM2M RD Client events

Ever ID	Event Name	Description
0	NONE	No event
1	BOOT-STRAP_REG_F	Bootstrap registration failed. Occurs if there is a timeout or failure in bootstrap registration.
2	BOOT-STRAP_REG_C	Bootstrap registration complete. Occurs after successful bootstrap registration.
3	BOOT-STRAP_TRANS	Bootstrap finish command received from the server.
4	REGISTRA-TION_FAILUR	Registration to LwM2M server failed. Occurs if server rejects the registration attempt.
5	REGISTRA-TION_COMPL	Registration to LwM2M server successful. Occurs after a successful registration reply from the LwM2M server or when session resumption is used.
6	REG_TIMEOU	Registration status lost. Occurs if there is socket errors or message timeouts. Client have lost connection to the server.
7	REG_UPDATE_	Registration update completed. Occurs after successful registration update reply from the LwM2M server.
8	DEREGIS-TER_FAILURE	Deregistration to LwM2M server failed. Occurs if there is a timeout or failure in the deregistration.
9	DISCON-NECT	LwM2M client have de-registered from server and is now stopped. Triggered only if the application have requested the client to stop.
10	QUEUE_MODI	Used only in queue mode, not actively listening for incoming packets. In queue mode the client is not required to actively listen for the incoming packets after a configured time period.
11	EN-GINE_SUSPEN	Indicate that client has now paused as a result of calling `lwm2m_engine_pause()`. State machine is no longer running and the handler thread is suspended. All timers are stopped so notifications are not triggered.
12	SERVER_DISA	Server have executed the disable command. Client will deregister and stay idle for the disable period.
13	NET-WORK_ERROI	Sending messages to the network failed too many times. Client cannot reach any servers or fallback to bootstrap. LwM2M engine cannot recover and have stopped.

The LwM2M client engine handles most of the state transitions automatically. The application needs to handle only the events that indicate that the client have stopped or is in a state where it cannot recover.

Table 7: How application should react to events

Event Name	How application should react
NONE	Ignore the event.
BOOT-STRAP_REG_FAIL	Try to recover network connection. Then restart the client by calling `lwm2m_rd_client_start()`. This might also indicate configuration issue.
BOOT-STRAP_REG_COM	No actions needed
BOOT-STRAP_TRANSFE	No actions needed
REGISTRA-TION_FAILURE	No actions needed. Client proceeds re-registration automatically. Might need a bootstrap or configuration fix. Cannot send or receive data.
REGISTRA-TION_COMPLETI	No actions needed. Application can send or receive data.
REG_TIMEOUT	No actions needed. Client proceeds to re-registration automatically. Cannot send or receive data.
REG_UPDATE_CO	No actions needed Application can send or receive data.
DEREGIS-TER_FAILURE	No actions needed, client proceeds to idle state automatically. Cannot send or receive data.
DISCONNECT	Engine have stopped as a result of calling `lwm2m_rd_client_stop()`. If connection is required, the application should restart the client by calling `lwm2m_rd_client_start()`.
QUEUE_MODE_R	No actions needed. Application can send but cannot receive data. Any data transmission will trigger a registration update.
EN-GINE_SUSPENDE	Engine can be resumed by calling `lwm2m_engine_resume()`. Cannot send or receive data.
SERVER_DISABLI	No actions needed, client will re-register once the disable period is over. Cannot send or receive data.
NET-WORK_ERROR	Try to recover network connection. Then restart the client by calling `lwm2m_rd_client_start()`. This might also indicate configuration issue.

Sending of data in the table above refers to calling `lwm2m_send_cb()` or by writing into one of the observed resources where observation would trigger a notify message. Receiving of data refers to receiving read, write or execute operations from the server. Application can register callbacks for these operations.

Configuring lifetime and activity period In LwM2M engine, there are three Kconfig options and one runtime value that configures how often the client will send LwM2M Update message.

Table 8: Update period variables

Variable	Effect
LwM2M regis-tration lifetime	The lifetime parameter in LwM2M specifies how long a device's registration with an LwM2M server remains valid. Device is expected to send LwM2M Update message before the lifetime exprires.
`CON-FIG_LWM2M_ENGIN`	Default lifetime value, unless set by the bootstrap server. Also defines lower limit that client accepts as a lifetime.
`CON-FIG_LWM2M_UPDAT`	How long the client can stay idle before sending a next update.
`CON-FIG_LWM2M_SECON`	Minimum time margin to send the update message before the registration lifetime expires.

By default, the client uses `CONFIG_LWM2M_SECONDS_TO_UPDATE_EARLY` to calculate how many seconds before the expiration of lifetime it is going to send the registration update. The problem with default mode is when the server changes the lifetime of the registration. This is then affecting the period of updates the client is doing. If this is used with the QUEUE mode, which is

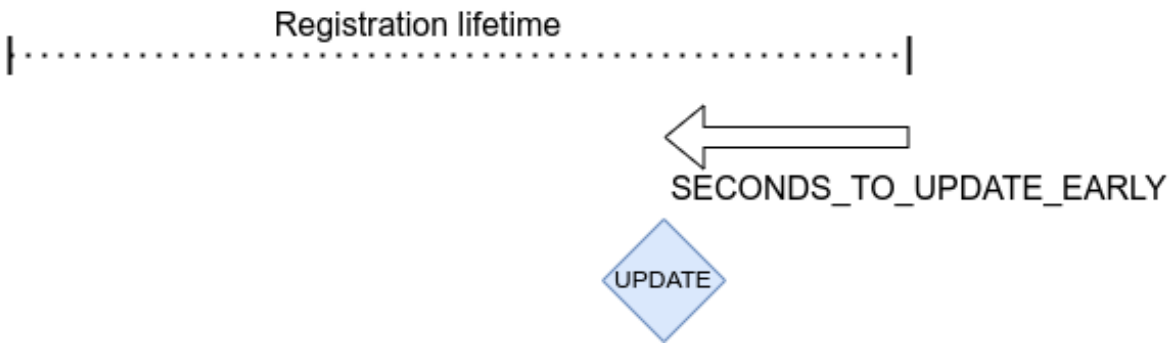

Fig. 7: Default way of calculating when to update registration.

typical in IPv4 networks, it is also affecting the period of when the device is reachable from the server.

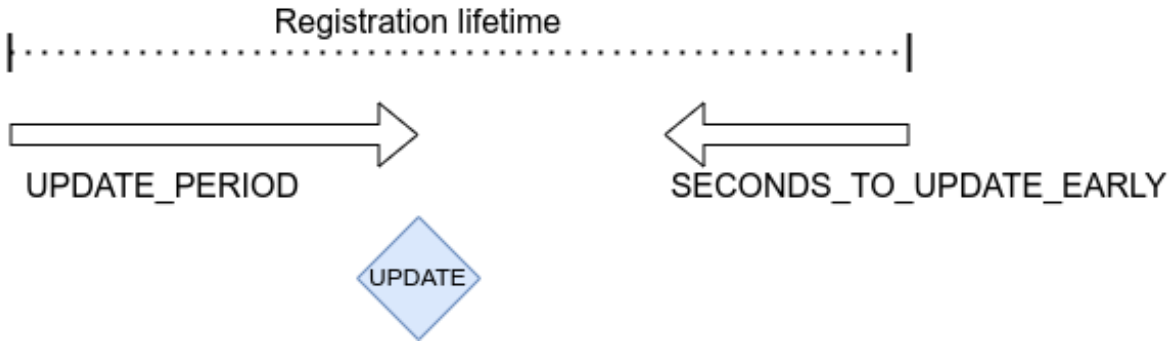

Fig. 8: Update time is controlled by UPDATE_PERIOD.

When also the `CONFIG_LWM2M_UPDATE_PERIOD` is set, time to send the update message is the earliest when any of these values expire. This allows setting long lifetime for the registration and configure the period accurately, even if server changes the lifetime parameter.

In runtime, the update frequency is limited to once in 15 seconds to avoid flooding.

LwM2M shell For testing the client it is possible to enable Zephyr's shell and LwM2M specific commands which support changing the state of the client. Operations supported are read, write and execute resources. Client start, stop, pause and resume are also available. The feature is enabled by selecting `CONFIG_LWM2M_SHELL`. The shell is meant for testing so productions systems should not enable it.

One imaginable scenario, where to use the shell, would be executing client side actions over UART when a server side tests would require those. It is assumed that not all tests are able to trigger required actions from the server side.

```
uart:~$ lwm2m
lwm2m - LwM2M commands
Subcommands:
  send    :send PATHS
          LwM2M SEND operation

  exec    :exec PATH [PARAM]
          Execute a resource

  read    :read PATH [OPTIONS]
          Read value from LwM2M resource
```

(continues on next page)

(continued from previous page)

```
          -x   Read value as hex stream (default)
          -s   Read value as string
          -b   Read value as bool (1/0)
          -uX  Read value as uintX_t
          -sX  Read value as intX_t
          -f   Read value as float
          -t   Read value as time_t

  write   :write PATH [OPTIONS] VALUE
          Write into LwM2M resource
          -s   Write value as string (default)
          -b   Write value as bool
          -uX  Write value as uintX_t
          -sX  Write value as intX_t
          -f   Write value as float
          -t   Write value as time_t

  create  :create PATH
          Create object or resource instance

  delete  :delete PATH
          Delete object or resource instance

  cache   :cache PATH NUM
          Enable data cache for resource
          PATH is LwM2M path
          NUM how many elements to cache

  start   :start EP_NAME [BOOTSTRAP FLAG]
          Start the LwM2M RD (Registration / Discovery) Client
          -b   Set the bootstrap flag (default 0)

  stop    :stop [OPTIONS]
          Stop the LwM2M RD (De-register) Client
          -f   Force close the connection

  update  :Trigger Registration Update of the LwM2M RD Client

  pause   :LwM2M engine thread pause
  resume  :LwM2M engine thread resume
  lock    :Lock the LwM2M registry
  unlock  :Unlock the LwM2M registry
  obs     : List observations
  ls      : ls [PATH]
          List objects, instances, resources
```

Overview The Model Context Protocol (MCP) is an open standard for connecting AI applications to external data sources and tools. It defines a JSON-RPC-based communication protocol between MCP clients (AI agents) and MCP servers (capability providers).

The Zephyr MCP Server library implements the server role of the MCP specification (version 2025-11-25). It allows networked Zephyr devices to expose tools that AI agents can discover and invoke over HTTP. The library builds on existing Zephyr subsystems: the HTTP server library for transport and the JSON library for serialization.

Note

This library is marked *experimental*. Only the tool service with text responses is implemented. Additional features, like more content types, session management, SSE streaming, authorization and other services are planned for future releases.

Architecture

Application
: Registers tools and implements their callbacks. Tool execution results are submitted back to the core via `mcp_server_submit_tool_message()`.

MCP Server Core
: Implements the MCP protocol state machines. Manages client connections, a tool registry, execution tracking, and a configurable worker thread pool. A health monitor thread enforces timeouts and triggers cancellations.

JSON Processing
: Serializes outgoing responses and deserializes incoming JSON-RPC requests using the Zephyr JSON library.

Transport Layer
: Abstracts the network protocol. The included HTTP transport uses the Zephyr HTTP server library. A mock transport is available for unit testing.

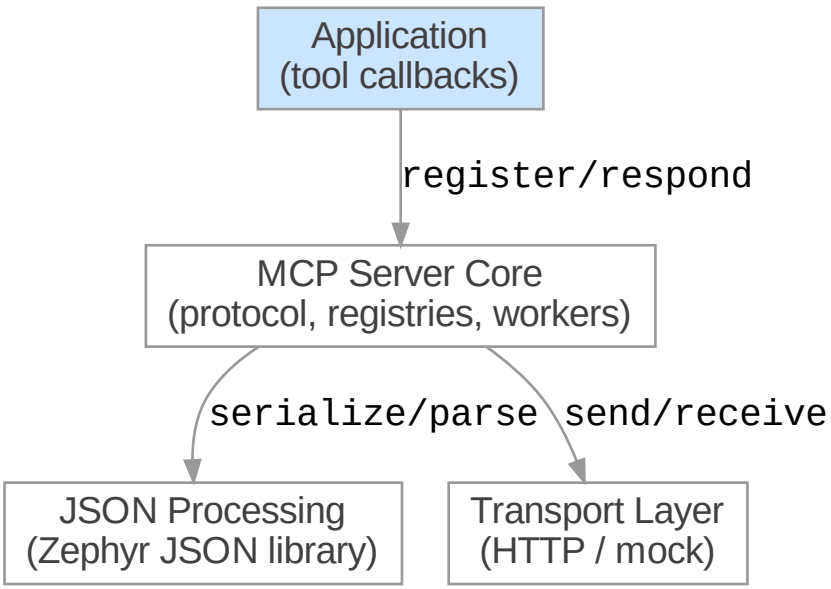

Fig. 9: MCP Server layered architecture

HTTP Transport and Asynchronous Responses Zephyr's HTTP server runs in a single thread and processes one request at a time across all connections. A resource callback must return before the server can handle the next request from any client. Because tool execution may take longer than acceptable for blocking the entire server, the MCP HTTP transport implements a polling-to-SSE fallback:

1. On a POST request, the transport polls internally for a tool response up to `CONFIG_MCP_HTTP_TIMEOUT_MS` (checked every `CONFIG_MCP_HTTP_POLL_INTERVAL_MS`).
2. If a response is ready within this window, it is returned directly as `application/json`.
3. If the timeout expires, the transport switches to SSE mode: it returns a `text/event-stream` response containing only an event ID (no data). This signals the client that the response is pending and it should start polling with periodic GET requests (interval controlled by `CONFIG_MCP_HTTP_SSE_RETRY_MS`).
4. The client then issues the periodic GET requests with a `Last-Event-Id` header. If a result is ready, the server sends the response and ends the SSE stream. If the result is not ready, the server sends a retry response again.

Note

This is not full SSE streaming. The mechanism only delivers deferred responses for requests that could not complete within the initial HTTP timeout. Server-initiated notifications and streaming tool output are not supported in this phase.

Configuration Enable the library with `CONFIG_MCP_SERVER`. The transport is selected through `CONFIG_MCP_TRANSPORT_HTTP` (default) or `CONFIG_MCP_TRANSPORT_MOCK` (testing only).

Minimal `prj.conf`:

```
CONFIG_NETWORKING=y
CONFIG_NET_TCP=y
CONFIG_HTTP_SERVER=y
CONFIG_MCP_SERVER=y
CONFIG_MCP_TRANSPORT_HTTP=y
```

Key configuration groups:

Scalability
: CONFIG_MCP_MAX_CLIENTS, CONFIG_MCP_MAX_CLIENT_REQUESTS, CONFIG_MCP_MAX_TOOLS, CONFIG_MCP_REQUEST_WORKERS

Timeouts
: CONFIG_MCP_TOOL_EXEC_TIMEOUT_MS, CONFIG_MCP_TOOL_IDLE_TIMEOUT_MS, CONFIG_MCP_TOOL_CANCEL_TIMEOUT_MS, CONFIG_MCP_CLIENT_TIMEOUT_MS CONFIG_MCP_HTTP_TIMEOUT_MS

Memory allocation
: CONFIG_MCP_ALLOC_SLAB (default) provides deterministic, fragmentation-free allocation using pre-allocated slabs. CONFIG_MCP_ALLOC_HEAP uses k_malloc/k_free for on-demand allocation at the cost of possible fragmentation.

Usage

Server Setup

```c
#include <zephyr/net/mcp/mcp_server.h>
#include <zephyr/net/mcp/mcp_server_http.h>

static mcp_server_ctx_t server;

int main(void)
{
    server = mcp_server_init();
    mcp_server_http_init(server);

    /* Register tools here */

    mcp_server_start(server);
    mcp_server_http_start(server);
    return 0;
}
```

Tool Registration

```c
static int my_tool_cb(enum mcp_tool_event_type event,
                      const char *arguments,
                      const char *execution_token)
{
    if (event == MCP_TOOL_CANCEL_REQUEST) {
        struct mcp_tool_message ack = {
            .type = MCP_USR_TOOL_CANCEL_ACK,
        };

        mcp_server_submit_tool_message(server, &ack, execution_token);

        /* Handle cancellation here */
    }
```

(continues on next page)

(continued from previous page)

```
    struct mcp_tool_message resp = {
        .type = MCP_USR_TOOL_RESPONSE,
        .data = "Tool execution result",
        .length = strlen("Tool execution result"),
        .is_error = false,
    };
    return mcp_server_submit_tool_message(server, &resp, execution_token);
}

static const struct mcp_tool_record my_tool = {
    .metadata = {
        .name = "my_tool",
        .input_schema = "{\"type\":\"object\",\"properties\":{}}",
    },
    .callback = my_tool_cb,
};

mcp_server_add_tool(server, &my_tool);
```

The `.data` field accepts a plain text string. The server wraps it into an MCP-compliant `"text"` content item automatically. Maximum length is `CONFIG_MCP_TOOL_RESULT_MAX_LEN`.

Tool Callback Patterns

Blocking
: Short-running tools execute directly in the worker thread and call `mcp_server_submit_tool_message()` before returning. The worker stack size is `CONFIG_MCP_REQUEST_WORKER_STACK_SIZE`.

Asynchronous
: Long-running tools should spawn a dedicated thread, return immediately from the callback, and submit the response later using the provided execution token. Periodic pings (`MCP_USR_TOOL_PING`) prevent the health monitor from cancelling idle executions.

Cancellation
: When the health monitor or a client requests cancellation, the callback is invoked with `MCP_TOOL_CANCEL_REQUEST`. The tool should stop work and submit `MCP_USR_TOOL_CANCEL_ACK`.

Tool Removal Tools can be removed at runtime with `mcp_server_remove_tool()`. The call returns `-EBUSY` if the tool is currently executing; retry later.

Limitations The following MCP features are not yet implemented:

- Resources, prompts, sampling, roots, and session management
- Server-initiated notifications and streaming tool output
- Image and embedded-resource content types (only `"text"` is supported)
- Full SSE transport (only deferred response delivery is supported)

Testing Unit tests are available under tests/net/lib/mcp/. They use the mock transport (`CONFIG_MCP_TRANSPORT_MOCK`) to exercise protocol logic without a network stack.

Sample See mcp-server-hello-world for a working example that registers multiple tools including GPIO-based LED control.

MQTT

- *Overview*
- *Sample usage*
- *Using MQTT with TLS*
- *API Reference*

Overview MQTT (Message Queuing Telemetry Transport) is an application layer protocol which works on top of the TCP/IP stack. It is a lightweight publish/subscribe messaging transport for machine-to-machine communication. For more information about the protocol itself, see https://mqtt.org/.

Zephyr provides an MQTT client library built on top of BSD sockets API. The library can be enabled with `CONFIG_MQTT_LIB` Kconfig option and is configurable at a per-client basis, with support for MQTT versions 3.1.0, 3.1.1 and 5.0. The Zephyr MQTT implementation can be used with either plain sockets communicating over TCP, or with secure sockets communicating over TLS. See *BSD Sockets* for more information about Zephyr sockets.

MQTT clients require an MQTT server to connect to. Such a server, called an MQTT Broker, is responsible for managing client subscriptions and distributing messages published by clients. There are many implementations of MQTT brokers, one of them being Eclipse Mosquitto. See https://mosquitto.org/ for more information about the Eclipse Mosquitto project.

Sample usage To create an MQTT client, a client context structure and buffers need to be defined:

```
/* Buffers for MQTT client. */
static uint8_t rx_buffer[256];
static uint8_t tx_buffer[256];

/* MQTT client context */
static struct mqtt_client client_ctx;
```

Multiple MQTT client instances can be created in the application and managed independently. Additionally, a structure for MQTT Broker address information is needed. This structure must be accessible throughout the lifespan of the MQTT client and can be shared among MQTT clients:

```
/* MQTT Broker address information. */
static struct net_sockaddr_storage broker;
```

An MQTT client library will notify MQTT events to the application through a callback function created to handle respective events:

```
void mqtt_evt_handler(struct mqtt_client *client,
                      const struct mqtt_evt *evt)
```

(continues on next page)

(continued from previous page)

```
{
   switch (evt->type) {
      /* Handle events here. */
   }
}
```

For a list of possible events, see *API Reference*.

The client context structure needs to be initialized and set up before it can be used. An example configuration for TCP transport is shown below:

```
mqtt_client_init(&client_ctx);

/* MQTT client configuration */
client_ctx.broker = &broker;
client_ctx.evt_cb = mqtt_evt_handler;
client_ctx.client_id.utf8 = (uint8_t *)"zephyr_mqtt_client";
client_ctx.client_id.size = sizeof("zephyr_mqtt_client") - 1;
client_ctx.password = NULL;
client_ctx.user_name = NULL;
client_ctx.protocol_version = MQTT_VERSION_3_1_1;
client_ctx.transport.type = MQTT_TRANSPORT_NON_SECURE;

/* MQTT buffers configuration */
client_ctx.rx_buf = rx_buffer;
client_ctx.rx_buf_size = sizeof(rx_buffer);
client_ctx.tx_buf = tx_buffer;
client_ctx.tx_buf_size = sizeof(tx_buffer);
```

After the configuration is set up, the MQTT client can connect to the MQTT broker. Call the `mqtt_connect` function, which will create the appropriate socket, establish a TCP/TLS connection, and send an `MQTT CONNECT` message. When notified, the application should call the `mqtt_input` function to process the response received. Note, that `mqtt_input` is a non-blocking function, therefore the application should use socket `poll` to wait for the response. If the connection was successful, `MQTT_EVT_CONNACK` will be notified to the application through the callback function.

```
rc = mqtt_connect(&client_ctx);
if (rc != 0) {
   return rc;
}

fds[0].fd = client_ctx.transport.tcp.sock;
fds[0].events = ZSOCK_POLLIN;
poll(fds, 1, 5000);

mqtt_input(&client_ctx);

if (!connected) {
   mqtt_abort(&client_ctx);
}
```

In the above code snippet, the MQTT callback function should set the `connected` flag upon a successful connection. If the connection fails at the MQTT level or a timeout occurs, the connection will be aborted, and the underlying socket closed.

After the connection is established, an application needs to call `mqtt_input` and `mqtt_live` functions periodically to process incoming data and upkeep the connection. If an MQTT message is received, an MQTT callback function will be called and an appropriate event notified.

The connection can be closed by calling the `mqtt_disconnect` function.

Zephyr provides sample code utilizing the MQTT client API. See mqtt-publisher for more information.

Using MQTT with TLS The Zephyr MQTT library can be used with TLS transport for secure communication by selecting a secure transport type (`MQTT_TRANSPORT_SECURE`) and some additional configuration information:

```
client_ctx.transport.type = MQTT_TRANSPORT_SECURE;

struct mqtt_sec_config *tls_config = &client_ctx.transport.tls.config;

tls_config->peer_verify = TLS_PEER_VERIFY_REQUIRED;
tls_config->cipher_list = NULL;
tls_config->sec_tag_list = m_sec_tags;
tls_config->sec_tag_count = ARRAY_SIZE(m_sec_tags);
tls_config->hostname = MQTT_BROKER_HOSTNAME;
tls_config->set_native_tls = true;
```

In this sample code, the `m_sec_tags` array holds a list of tags, referencing TLS credentials that the MQTT library should use for authentication. We do not specify `cipher_list`, to allow the use of all cipher suites available in the system. We set `hostname` field to broker hostname, which is required for server authentication. Finally, we enforce peer certificate verification by setting the `peer_verify` field.

Note, that TLS credentials referenced by the `m_sec_tags` array must be registered in the system first. For more information on how to do that, refer to *secure sockets documentation*.

Finally, `set_native_tls` can be optionally set to enable native TLS support instead of offloading TLS operations to an offloaded socket.

An example of how to use TLS with MQTT is also present in mqtt-publisher sample application.

MQTT-SN

- *Overview*
- *Sample usage*
- *Deviations from the standard*
- *API Reference*

Overview MQTT-SN is a variant of the well-known MQTT protocol - see *MQTT*.

In contrast to MQTT, MQTT-SN does not require a TCP transport, but is designed to be used over any message-based transport. Originally, it was mainly created with ZigBee in mind, but others like Bluetooth, UDP or even a UART can be used just as well.

Zephyr provides an MQTT-SN client library built on top of BSD sockets API. The library can be enabled with `CONFIG_MQTT_SN_LIB` Kconfig option and is configurable at a per-client basis, with support for MQTT-SN version 1.2. The Zephyr MQTT-SN implementation can be used with any message-based transport, but support for UDP is already built-in.

MQTT-SN clients require an MQTT-SN gateway to connect to. These gateways translate between MQTT-SN and MQTT. The Eclipse Paho project offers an implementation of a MQTT-SN gateway, but others are available too. https://www.eclipse.org/paho/index.php?page=components/mqtt-sn-transparent-gateway/index.php

The MQTT-SN spec v1.2 can be found here: https://www.oasis-open.org/committees/download.php/66091/MQTT-SN_spec_v1.2.pdf

Sample usage To create an MQTT-SN client, a client context structure and buffers need to be defined:

```
/* Buffers for MQTT client. */
static uint8_t rx_buffer[256];
static uint8_t tx_buffer[256];

/* MQTT-SN client context */
static struct mqtt_sn_client client;
```

Multiple MQTT-SN client instances can be created in the application and managed independently. Additionally, a structure for the transport is needed as well. The library already comes with an example implementation for UDP.

```
/* MQTT Broker address information. */
static struct mqtt_sn_transport tp;
```

The MQTT-SN library will inform clients about certain events using a callback.

```
static void evt_cb(struct mqtt_sn_client *client,
                   const struct mqtt_sn_evt *evt)
{
   switch(evt->type) {
   {
      /* Handle events here. */
   }
}
```

For a list of possible events, see *API Reference*.

The client context structure needs to be initialized and set up before it can be used. An example configuration for UDP transport is shown below:

```
struct mqtt_sn_data client_id = MQTT_SN_DATA_STRING_LITERAL("ZEPHYR");
struct net_sockaddr_in gateway = {0};

uint8_t tx_buf[256];
uint8_t rx_buf[256];

mqtt_sn_transport_udp_init(&tp, (struct net_sockaddr*)&gateway, sizeof((gateway)));
```

(continues on next page)

(continued from previous page)

```
mqtt_sn_client_init(&client, &client_id, &tp.tp, evt_cb, tx_buf, sizeof(tx_buf),␣
↪rx_buf, sizeof(rx_buf));
```

After the configuration is set up, the network address for the gateway to connect to must be defined. The MQTT-SN protocol offers functionality to discover gateways through an advertisement or a search mechanism. A user should do at least one of the following steps to define a Gateway for the library:

- Call the `mqtt_sn_add_gw()` function to manually define a Gateway address.
- Wait for an `MQTT_SN_EVT_ADVERTISE`.
- Call the `mqtt_sn_search()` function and wait for an `MQTT_SN_EVT_GWINFO` callback. Make sure to call the `mqtt_sn_input()` function periodically to process incoming messages.

Example `mqtt_sn_search()` function call:

```
err = mqtt_sn_search(&mqtt_client, 1);
k_sleep(K_SECONDS(10));
err = mqtt_sn_input(&mqtt_client);
__ASSERT(err == 0, "mqtt_sn_search() failed %d", err);
```

After the Gateway address has been defined or found, the MQTT-SN client can connect to the gateway. Call the `mqtt_sn_connect()` function, which will send a `CONNECT` MQTT-SN message. The application should periodically call the `mqtt_sn_input()` function to process the response received. The application does not have to call `mqtt_sn_input()` if it knows that no data has been received (e.g. when using Bluetooth). Note that `mqtt_sn_input()` is a non-blocking function, if the transport struct contains a `poll()` compatible function pointer. If the connection was successful, `MQTT_SN_EVT_CONNECTED` will be notified to the application through the callback function.

```
err = mqtt_sn_connect(&client, false, true);
__ASSERT(err == 0, "mqtt_sn_connect() failed %d", err);

while (1) {
        mqtt_sn_input(&client);
        if (connected) {
                mqtt_sn_publish(&client, MQTT_SN_QOS_0, &topic_p, false, &pubdata);
        }
        k_sleep(K_MSEC(500));
}
```

In the above code snippet, the gateway is connected to before publishing messages. If the connection fails at the MQTT level or a timeout occurs, the connection will be aborted and an error returned.

After the connection is established, an application needs to call `mqtt_input()` function periodically to process incoming data. Connection upkeep, on the other hand, is done automatically using a k_work item. If a MQTT message is received, an MQTT callback function will be called and an appropriate event notified.

The connection can be closed by calling the `mqtt_sn_disconnect()` function. This has no effect on the transport, however. If you want to close the transport (e.g. the socket), call `mqtt_sn_client_deinit()`, which will deinit the transport as well.

Zephyr provides sample code utilizing the MQTT-SN client API. See mqtt-sn-publisher for more information.

Deviations from the standard Certain parts of the protocol are not yet supported in the library.

Open Charge Point Protocol (OCPP)

- *Overview*
- *Sample usage*
- *API Reference*

Overview Open Charge Point Protocol (OCPP) is an application protocol for communication between Charge Points (Electric vehicle (EV) charging stations) and a central management system, also known as a charging station network. OCPP is a standard defined by The Open Charge Alliance and goal is to offer a uniform solution for the method of communication between charge point and central system. With this protocol it is possible to connect any central system with any charge point, regardless of the vendor.

Zephyr provides an OCPP Charge Point (CP) library built on top of websocket API with payload in json format. The library can be enabled with `CONFIG_OCPP` Kconfig option. Currently OCPP 1.6 with basic core profile is supported.

OCPP charge point (CP) require a Central System (CS) server to connect, an open source SteVe server shall be setup locally for development purpose, See SteVe server for more information about the setup.

The Zephyr OCPP CP library implements the following items:

- engine to process socket connectivity and events
- OCPP core functions to frame/parse payload, user notification for OCPP events, heartbeat notification

Sample usage Init ocpp library with overall CP and CS information. Prior to init an OCPP library, a network interface should be ready using ethernet or wifi or modem. A filled CP, CS structure and user callback needs to be passed in ocpp_init.

```
static int user_notify_cb(ocpp_notify_reason_t reason,
                          ocpp_io_value_t *io,
                          void *user_data)
{

     switch (reason) {
     case OCPP_USR_GET_METER_VALUE:
             ...
             break;

     case OCPP_USR_START_CHARGING:
             ...
             break;

             ...
```

(continues on next page)

(continued from previous page)

```
            ...
}

/* OCPP configuration */
ocpp_cp_info_t cpi = { "basic", "zephyr", .num_of_con = 1};
ocpp_cs_info_t csi =  {"192.168.1.3",   /* ip address */
                       "/steve/websocket/CentralSystemService/zephyr",
                       8180,
                       AF_INET};

ret = ocpp_init(&cpi, &csi, user_notify_cb, NULL);
```

A unique session must open for each physical connector before any ocpp transaction API call.

```
ocpp_session_handle_t sh = NULL;
ret = ocpp_session_open(&sh);
```

idtag is EV user's authentication token which should match with list on CS. Authorize request must call to ensure validity of idtag (if charging request originate from local CP) before start energy transfer to EV.

```
ocpp_auth_status_t status;
ret = ocpp_authorize(sh, idtag, &status, 500);
```

On successful, authorization status is available in status.

Apart from local CP, charging request may originate from CS is notified to user in callback with OCPP_USR_START_CHARGING, here authorize request call is optional. When the CS is ready to provide power to EV, a start transaction is notified to CS with meter reading and connector id using ocpp_start_transaction.

```
const int idcon = 1;
const int mval = 25; //meter reading in wh
ret = ocpp_start_transaction(sh, mval, idcon, 200);
```

Once the start transaction is success, user callback is invoked to get meter readings from the library. callback should be not be hold for longer time.

- *API Reference*
- *Features*
- *Workflow*
  - *Socket Creation*
  - *Connection Handling*
  - *Monitoring Start*
  - *Monitoring Status*
  - *Thread Management*
- *Enabling the Latmon Service*
- *Example Usage*

Overview Provides the functionality required for network-based latency monitoring, including socket management, client-server communication, and data exchange with the Latmus service running on the System Under Test (SUT).

The Latmon network service is responsible for establishing and managing network communication between the Latmon application (running on a Zephyr-based board) and the Latmus service (running on the SUT).

It uses TCP sockets for reliable communication and UDP sockets for broadcasting the IP address of the Latmon device.

API Reference

Latency Monitor

Related code samples

- Latmon ClientMeasures delta time between GPIO events and reports the latency metrics via latmon to the latmus service executing on the SUT.

Features

- **Socket Management**: Creates and manages TCP and UDP sockets for communication.
- **Client-Server Communication**: Handles incoming connections from the Latmus service.
- **Data Exchange**: Sends latency metrics and histogram data to the Latmus service.
- **IP Address Broadcasting**: Broadcasts the IP address of the Latmon device to facilitate discovery by the Latmus service.
- **Thread-Safe Design**: Uses Zephyr's kernel primitives (e.g., message queues and semaphores) for synchronization.

Workflow

Socket Creation The `net_latmon_get_socket()` function is called to create and configure a TCP socket to communicate with the Latmus service. A connection address can be specified as a parameter to bind the socket to a specific interface and port.

Connection Handling The `net_latmon_connect()` function waits for a connection from the Latmus service. If no connection is received within the timeout period, the service broadcasts its IP address using UDP and returns `-EAGAIN`. If the broadcast request cannot be sent, the function returns `-1`, and the client should quit.

Monitoring Start Once a connection is established, the `net_latmon_start()` function is called to start the monitoring process. This function uses a callback to calculate latency deltas and sends the data to the Latmus service.

Monitoring Status The `net_latmon_running()` function can be used to check if the monitoring process is active.

Thread Management The service uses Zephyr threads to handle incoming connections and manage the monitoring process.

Enabling the Latmon Service The following configuration option must be enabled in the `prj.conf` file.

- `CONFIG_NET_LATMON`

The following options may be configured to customize the Latmon service:

- `CONFIG_NET_LATMON_PORT` - Port number for the Latmon service.
- `CONFIG_NET_LATMON_XFER_THREAD_STACK_SIZE`
- `CONFIG_NET_LATMON_XFER_THREAD_PRIORITY`
- `CONFIG_NET_LATMON_THREAD_STACK_SIZE`
- `CONFIG_NET_LATMON_THREAD_PRIORITY`
- `CONFIG_NET_LATMON_MONITOR_THREAD_STACK_SIZE`
- `CONFIG_NET_LATMON_MONITOR_THREAD_PRIORITY`

Example Usage

```
#include <zephyr/net/latmon.h>
#include <zephyr/net/socket.h>

void main(void)
{
    struct in_addr ip;
    int server_socket, client_socket;

    /* Create and configure the server socket */
    server_socket = net_latmon_get_socket(NULL);

    while (1) {
        /* Wait for a connection from the Latmus service */
        client_socket = net_latmon_connect(server_socket, &ip);
        if (client_socket < 0) {
```

(continues on next page)

(continued from previous page)

```
            if (client_socket == -EAGAIN) {
                continue;
            }
            goto out;
        }

        /* Start the latency monitoring process */
        net_latmon_start(client_socket, measure_latency_cycles);
    }
out:
    close(server_socket);
}
```

- *API Reference*

Overview QUIC is a general-purpose, multiplexed transport protocol standardised in **RFC 9000**. It operates over UDP and provides ordered, reliable byte-stream delivery with integrated TLS 1.3 security (**RFC 9001**), stream multiplexing, and connection migration. Zephyr's QUIC implementation is available under `CONFIG_QUIC`.

Key properties relevant to embedded use:

- **Stream multiplexing**: Bidirectional and unidirectional streams share a single UDP socket, avoiding head-of-line blocking at the transport layer.
- **Integrated TLS 1.3**: The handshake is built into the connection establishment; no separate TLS layer is required.
- **Flow control**: Per-stream and per-connection credit-based flow control prevents fast senders from overwhelming constrained receivers.
- **Loss recovery**: A Probe Timeout (PTO) mechanism retransmits data without relying on ICMP or TCP-style ACK clocks.
- **Path MTU discovery**: Datagram Packetization Layer PMTU Discovery (DPLPMTUD, **RFC 9000** Section 14.3) probes the path after the handshake and raises the send size only after probes are acknowledged.
- **Socket Integration**: Uses standard Zephyr socket calls like `zsock_send`, `zsock_recv`, `zsock_recvmsg`, `zsock_sendmsg`, `zsock_close` for data transfer.
- **Dual stack**: Supports both IPv4 and IPv6 connections.

Note

QUIC support is currently **experimental** in Zephyr. Enable it with `CONFIG_QUIC=y` and be aware that APIs and Kconfig options may change between releases.

Architecture & Concepts To effectively use the library, it is helpful to understand the relationship between **Connections** and **Streams**.

- **QUIC Connection Socket**: Represents the "tunnel" to the peer. It handles the TLS handshake, congestion control, and connection termination. You typically do not send application data directly over this socket; you use it to create streams.
- **QUIC Stream Socket**: Represents a lightweight data channel inside the connection. This is where the actual application data (`send` or `recv`) flows.

Application Workflow The following sections outline how to write a generic Client and Server application using the library.

Client Application A client initiates a connection to a remote server, opens a stream, sends a request, and reads the response.

Step 1: Setup Addresses

```
struct net_sockaddr_in remote_addr = {
    .sin_family = NET_AF_INET,
    .sin_port = net_htons(4422),
};

zsock_inet_pton(NET_AF_INET, "192.0.2.1", &remote_addr.sin_addr);
```

Step 2: Open QUIC Connection

```
int conn_sock = quic_connection_open((struct net_sockaddr *)&remote_addr, NULL);
if (conn_sock < 0) {
    /* Handle error */
}

/* The TLS handshake occurs automatically upon the first stream creation. */
```

Step 3: Open a Stream

```
/* Create a bidirectional stream initiated by the client */
int stream_sock = quic_stream_open(conn_sock,
                                   QUIC_STREAM_CLIENT,
                                   QUIC_STREAM_BIDIRECTIONAL,
                                   0);
```

Step 4: Transfer Data

Use standard socket calls on the **stream socket**, not the connection socket.

```
zsock_send(stream_sock, "Hello Server", 12, 0);

char buffer[64];
zsock_recv(stream_sock, buffer, sizeof(buffer), 0);
```

Step 5: Cleanup

```
quic_stream_close(stream_sock);
quic_connection_close(conn_sock);
```

Server Application A server binds to a local port, waits for incoming connections, accepts streams, and processes data.

Step 1: Bind Connection Socket

```
struct net_sockaddr_in local_addr = {
   .sin_family = NET_AF_INET,
   .sin_port = net_htons(4422),
   .sin_addr.s_addr = NET_INADDR_ANY,
};

/* Create the listening context */
int conn_sock = quic_connection_open(NULL, (struct net_sockaddr *)&local_addr);
```

Step 2: Accept Incoming Streams

The `quic_connection_open()` socket acts as a "parent". Use `zsock_accept()` on the **connection socket** to retrieve a file descriptor for a new stream initiated by a peer.

```
struct net_sockaddr_in peer_addr;
net_socklen_t addrlen = sizeof(peer_addr);

/* Block until a client opens a stream */
int stream_sock = zsock_accept(conn_sock, (struct net_sockaddr *)&peer_addr, &
↪addrlen);

if (stream_sock >= 0) {
    /* Handle the new stream (read/write data) */
    char buf[128];
    int len = zsock_recv(stream_sock, buf, sizeof(buf), 0);

    /* Echo back */
    zsock_send(stream_sock, buf, len, 0);

    /* Close the stream when done, also zsock_close() can be used */
    quic_stream_close(stream_sock);
}
```

TLS & Security Configuration The QUIC transport uses Mbed TLS and PSA APIs for cryptographic operations. Security credentials (certificates, keys) are managed via the Zephyr **TLS Credentials** subsystem.

Managing Certificates Before opening a connection, you must register your certificates using `tls_credential_add()`.

1. **CA Certificate**: Required for clients to verify servers.
2. **Server Certificate & Private Key**: Required for servers.

Example: Loading Credentials

```
#include <zephyr/net/tls_credentials.h>

/* Tag ID to reference credentials later */
#define MY_SEC_TAG 1

static const char server_cert[] = ...; /* PEM or DER data */
static const char priv_key[] = ...;    /* PEM or DER data */

void setup_credentials(void) {
    tls_credential_add(MY_SEC_TAG, TLS_CREDENTIAL_PUBLIC_CERTIFICATE,
                       server_cert, sizeof(server_cert));
    tls_credential_add(MY_SEC_TAG, TLS_CREDENTIAL_PRIVATE_KEY,
                       priv_key, sizeof(priv_key));
}
```

Applying Credentials to QUIC You apply credentials to the QUIC socket using `zsock_setsockopt()` on the **connection socket** immediately after creation. The credentials must be set before the stream is created.

Peer certificate verification follows the same default policy as Zephyr TLS sockets: clients require successful peer verification by default, while servers default to not verifying client certificates unless `ZSOCK_TLS_PEER_VERIFY` is explicitly enabled. A client that does not load a CA certificate therefore fails the handshake by default; applications that deliberately skip server authentication must opt out with `ZSOCK_TLS_PEER_VERIFY = MBEDTLS_SSL_VERIFY_NONE`.

```
sec_tag_t sec_tag_list[] = { MY_SEC_TAG };

zsock_setsockopt(conn_sock, ZSOCK_SOL_TLS, ZSOCK_TLS_SEC_TAG_LIST,
                 sec_tag_list, sizeof(sec_tag_list));
```

Applying ALPN to QUIC The Application-Layer Protocol Negotiation (ALPN) is mandatory in QUIC. The ALPN is used to negotiate the application protocol that is run on top of two QUIC endpoints. You apply ALPN list to the QUIC socket using `zsock_setsockopt()` on the **connection socket** immediately after creation. The ALPN list must be set before the stream is created. Note that the list items must be constants, and they cannot be variables.

```
const char * const alpn_list[] = {
    "echo-quic",
    NULL
};

ret = zsock_setsockopt(quic_sock, ZSOCK_SOL_TLS, ZSOCK_TLS_ALPN_LIST,
                               alpn_list, sizeof(alpn_list));
if (ret < 0) {
    LOG_ERR("Failed to set ALPN (%d)", -errno);
}
```

Session Resumption and 0-RTT After a full handshake a server may issue a TLS 1.3 *NewSessionTicket*. A client can store the resulting session state and present it on a later connection to **resume** without a full handshake, and – when the server permits it – to send **0-RTT early data** in the very first flight, before the handshake completes.

0-RTT support is compiled in with `CONFIG_QUIC_0RTT` (**disabled by default**). Session resumption at 1-RTT works without it; enabling it adds the early-data offer/accept/replay handling.

Warning

0-RTT early data is **replayable** by a network attacker (RFC 9001 Section 9.2). Only send data for idempotent / replay-safe operations over 0-RTT, and be prepared for the peer to reject it (the data must then be retried after the handshake completes). The stack makes issued tickets single-use and applies an age-freshness window, but this anti-replay state is in-memory and per-instance only (it does not survive a restart and is not shared across server instances).

Client: export and reuse session state

After the handshake, read the resumable state from the connection socket and keep it. On a new connection, import it before opening the first stream. When 0-RTT is armed, the first stream data is carried as early data.

```
struct quic_session_state state;
net_socklen_t optlen = sizeof(state);

/* After the first connection's handshake completes: */
zsock_getsockopt(conn_sock, ZSOCK_SOL_QUIC, ZSOCK_QUIC_SO_SESSION_STATE,
                 &state, &optlen);

/* On a later connection, before the first stream is opened: */
zsock_setsockopt(new_conn_sock, ZSOCK_SOL_QUIC, ZSOCK_QUIC_SO_SESSION_STATE,
                 &state, sizeof(state));
```

Since `struct quic_session_state` carries the resumption secret, treat it as sensitive and store it securely. Its layout is versioned with `QUIC_SESSION_STATE_VERSION`.

Server: issue tickets and permit 0-RTT

Set these options on the listening (or server-side connection) socket before the handshake:

- `ZSOCK_QUIC_SO_SESSION_TICKET_ENABLE` (pointer to `int`) – non-zero makes the server send a NewSessionTicket after the handshake, enabling 1-RTT resumption.
- `ZSOCK_QUIC_SO_MAX_EARLY_DATA_SIZE` (pointer to `uint32_t`) – any non-zero value enables 0-RTT on newly issued tickets (and requires `CONFIG_QUIC_0RTT`, else `setsockopt()` fails with `ENOTSUP`). Per **RFC 9001** Section 4.6.1 the ticket always advertises the fixed `0xffffffff` sentinel; the amount of early data a client may actually send is bounded by the connection's flow-control (transport-parameter) limits, so this option is an enable switch, not a byte budget.

```
int enable = 1;
uint32_t early_data = 1; /* non-zero enables 0-RTT for issued tickets */

zsock_setsockopt(quic_sock, ZSOCK_SOL_QUIC, ZSOCK_QUIC_SO_SESSION_TICKET_ENABLE,
                 &enable, sizeof(enable));
zsock_setsockopt(quic_sock, ZSOCK_SOL_QUIC, ZSOCK_QUIC_SO_MAX_EARLY_DATA_SIZE,
                 &early_data, sizeof(early_data));
```

Per-stream early-data status

On a server, query whether a given stream carried accepted 0-RTT data with `ZSOCK_QUIC_SO_STREAM_EARLY_DATA` (pointer to `int`) on the **stream** socket. This lets a protocol layer apply replay protection (for example, HTTP/3 answers a non-idempotent early request with `425 Too Early`).

Path MTU Discovery (DPLPMTUD) Zephyr's QUIC stack performs **Datagram Packetization Layer Path MTU Discovery** (DPLPMTUD) as described in **RFC 9000** Section 14.3. The RFC 8899 search state lives in the generic *Datagram PLPMTUD API* subsystem; QUIC supplies probe packets (PING plus padding), don't-fragment UDP sends, and ACK/loss confirmation through its recovery machinery.

The goal is to find the largest UDP payload size that can traverse the path without IP-layer fragmentation, then use that size for application data packets.

Behavior After the TLS handshake completes, the stack may send **probe datagrams** containing a PING frame plus padding. Probes are sized to exercise larger path MTUs and are transmitted with **don't fragment** enabled on the underlying UDP socket (see `ZSOCK_IP_DONTFRAG` / `ZSOCK_IPV6_DONTFRAG` in *IPv4 and IPv6 socket options*). This is handled internally; applications do not need to configure the UDP socket used by QUIC.

The stack tracks three related limits:

- **Peer "max_udp_payload_size" transport parameter** - upper bound advertised by the remote endpoint during the handshake.
- **Local ceiling** - derived from the interface or socket MTU minus IP and UDP header overhead.
- **Validated send size** - the largest probe size confirmed by an ACK. This is what governs how large outgoing QUIC packets may be.

Send sizing starts at the **1200-byte minimum UDP payload** required by QUIC. When the validated size is below the local and peer ceilings, the stack performs a binary search for a larger working size. A probe ACK raises the validated limit; repeated probe loss narrows the search range. Stream frames are sized to fit within the current validated limit, so throughput on high-MTU paths improves automatically once probing succeeds.

Interaction with loss recovery DPLPMTUD probes are ack-eliciting and participate in the same loss-recovery machinery as stream data. On Probe Timeout (PTO), **in-flight stream frames are retransmitted first**; a DPLPMTUD probe is sent only when there is no stream data to retransmit (the same situation where a bare PING probe would be sent).

There is currently no application-facing QUIC API to enable, disable, or tune DPLPMTUD. Probing begins automatically after handshake completion whenever a larger path MTU may be available. Transports implementing their own UDP protocols can reuse the same generic API documented in *Datagram PLPMTUD API*.

Configure Options All options below live inside the `if QUIC` block and are only visible when `CONFIG_QUIC` is enabled.

Connection and Stream Counts

Option	Default	Description
`CONFIG_QUIC_MAX_CONTEXTS`	1	Maximum number of simultaneous QUIC connections in the system. Each context carries its own TLS state, flow-control windows, and sent-packet history. Memory scales linearly with this value.
`CONFIG_QUIC_MAX_STREAMS_BIDI`	3-5	Maximum bidirectional streams **per connection**. Streams are allocated at build time; unused stream slots still consume their TX/RX buffer allocation.
`CONFIG_QUIC_MAX_STREAMS_UNI`	0	Maximum unidirectional streams per connection. Set to `0` to disable unidirectional streams entirely and recover the associated buffer RAM.
`CONFIG_QUIC_MAX_ENDPOINTS`	2-3	Number of UDP endpoint sockets. A client connecting to a single server over one IP version needs 2; dual-stack server roles need 3. Consider enabling `CONFIG_QUIC_ENDPOINT_USE_IPV4_MAPPING_TO_IPV6` to share a single socket for both IPv4 and IPv6.
`CONFIG_QUIC_MAX_PEER_CIDS`	4	Number of peer Connection IDs tracked per connection. Reduce to 1 on very constrained devices if connection migration is not needed.

QUIC Transport Parameters (Flow Control) These values are advertised to the remote peer during the handshake (see **RFC 9000** Section 18.2). They govern how much data the **peer is permitted to send** before receiving a window update. Each value should match the corresponding local receive buffer size; advertising a window larger than the receive buffer causes buffer overflows, while advertising a window smaller than the buffer under-utilises available memory.

Option	Default	Description
CONFIG_QUIC_INITIAL_MAX_DATA	16384	Connection-level receive credit in bytes. Must be greater than or equal to any single stream's INITIAL_MAX_STREAM_DATA value, otherwise the connection window becomes the bottleneck. A good starting point is streams_bidi x INITIAL_MAX_STREAM_DATA_BIDI_LOCAL.
CONFIG_QUIC_INITIAL_MAX_STREAM_DATA_	16384	Initial receive window for locally initiated bidirectional streams. Set equal to CONFIG_QUIC_STREAM_RX_BUFFER_SIZE.
CONFIG_QUIC_INITIAL_MAX_STREAM_DATA_	16384	Initial receive window for peer-initiated bidirectional streams. Set equal to CONFIG_QUIC_STREAM_RX_BUFFER_SIZE.
CONFIG_QUIC_INITIAL_MAX_STREAM_DATA_	16384	Initial receive window for unidirectional streams opened by the peer. Only relevant when CONFIG_QUIC_MAX_STREAMS_UNI > 0.
CONFIG_QUIC_INITIAL_MAX_STREAMS_BIDI	QUIC_MAX	Maximum number of bidirectional streams the peer may open before receiving a MAX_STREAMS frame. Defaults to the local build-time limit.
CONFIG_QUIC_INITIAL_MAX_STREAMS_UNI	QUIC_MAX	Maximum number of unidirectional streams the peer may open.
CONFIG_QUIC_STREAM_RX_WINDOW_UPDATE_	25	Percentage of stream receive buffer consumed before a MAX_STREAM_DATA frame is sent to refill the peer's window. Lower values (e.g. 15 %) send updates more frequently, which improves throughput on high-latency links at the cost of additional control frames.

Buffer Sizes and RAM Allocation The following options directly control how much RAM the QUIC subsystem allocates at initialisation. See *Memory Model* for a detailed breakdown of how these interact.

Option	Default	Description
CONFIG_QUIC_ENDPOINT_PENDING_DATA_LI	1500	Receive staging buffer per endpoint in bytes. Should equal the network MTU. Combined with CONFIG_QUIC_PKT_COUNT, total endpoint RX staging = endpoints x pkt_count x this value.
CONFIG_QUIC_TX_BUFFER_SIZE	1500	Output packet assembly buffer per endpoint. Must be at least the network MTU (minimum 1280 for IPv6 compliance, maximum 1500). DPLPMTUD may limit the **validated** UDP payload below this value until a larger path MTU is confirmed; see *Path MTU Discovery (DPLPMTUD)*.
CONFIG_QUIC_CRYPTO_RX_BUFFER_SIZE	4096	Shared CRYPTO frame reassembly buffer per endpoint, used during the TLS handshake. Since QUIC progresses sequentially through encryption levels (Initial -> Handshake -> Application), a single buffer is reused across all levels. 4096 bytes is the minimum for interoperability with browsers: Chrome and Firefox may split a ClientHello across 10 or more CRYPTO frame fragments totalling up to ~4 KiB. Reduce to 2048 for embedded-to-embedded deployments with small certificates. Range: 1024-8192.
CONFIG_QUIC_CRYPTO_OOO_SLOTS	8	Number of out-of-order CRYPTO frame metadata slots per endpoint. Each slot (approximately 8 bytes) records the offset and length of one out-of-order fragment until the gap before it is filled. 8 slots are needed for browser interoperability; reduce to 4 for embedded-only deployments. Range: 4-16.
CONFIG_QUIC_STREAM_TX_BUFFER_SIZE	8192	Per-stream buffer holding sent but unacknowledged data. The QUIC sender cannot advance beyond the unacknowledged window, so this is the primary throughput-limiting parameter on high-latency links. Size to at least the bandwidth-delay product: throughput_bytes_per_ms x rtt_ms.
CONFIG_QUIC_STREAM_RX_BUFFER_SIZE	QUIC_STR	Per-stream receive buffer. Defaults to the TX buffer size, which is optimal for symmetric request/response patterns. Can be reduced independently for asymmetric workloads (e.g. download-only streams).
CONFIG_QUIC_STREAM_OOO_SLOTS	4	Number of out-of-order STREAM frame slots per stream. Each slot holds up to CONFIG_QUIC_STREAM_OOO_SEG_SIZE bytes. Set to 2 on loss-free local networks; increase to 8 or more on WAN links with significant reordering.
CONFIG_QUIC_STREAM_OOO_SEG_SIZE	1280	Maximum size of one buffered out-of-order segment. Setting this to the MTU avoids fragmentation of incoming frames. Can be reduced to 512 bytes when OOO delivery is uncommon.
CONFIG_QUIC_SENT_PKT_HISTORY_SIZE	64	Ring buffer depth of recently sent

Timeout Options

Option	Default	Description
CONFIG_QUIC_MAX_IDLE_TIMEOUT	30000	Milliseconds of inactivity after which the connection is silently closed. Both endpoints advertise their value; the smaller of the two takes effect. Set to 0 to disable idle timeout entirely. Recommended values: 5000 ms (loopback), 10000 ms (LAN), 30000 ms (WAN).
CONFIG_QUIC_CONNECT_TIMEOUT	3000	Milliseconds to wait for the handshake to complete before the `connect()` call fails. Should be at least 10x the expected RTT to accommodate packet loss during the handshake.
CONFIG_QUIC_MAX_PTO_TIMEOUT_MS	10000	Upper bound on the exponential PTO backoff in milliseconds. The PTO timer doubles on each consecutive probe timeout: `PTO_n = PTO_base x 2^n`. This cap prevents excessively long retransmission delays. Should not exceed CONFIG_QUIC_MAX_IDLE_TIMEOUT.

Service Thread Options

Option	Default	Description
CONFIG_QUIC_SERVICE_THREAD_PRIO	NUM_PRE	Thread priority of the QUIC service dispatcher. Values >= 0 are preemptive (0 = highest); values < 0 are cooperative.
CONFIG_QUIC_SERVICE_STACK_SIZE	4096	Stack size in bytes for the QUIC service thread. 4096 bytes is the default and is sufficient for Mbed TLS handshake operations. Reduce only if RAM is extremely constrained and profiling confirms the stack headroom is not needed.
CONFIG_QUIC_PKT_COUNT	QUIC_MA	Number of simultaneous pending packet receive operations. Defaults to the number of endpoints so that one packet per endpoint can be in flight concurrently. Increase (e.g. 2x endpoints) for higher-throughput scenarios.

Memory Model The table below shows how each RAM region scales with the configuration parameters. All sizes are in bytes unless noted.

Memory Region	Formula
Endpoint RX staging	QUIC_MAX_ENDPOINTS x QUIC_PKT_COUNT x QUIC_ENDPOINT_PENDING_DATA_LEN
Endpoint TX buffers	QUIC_MAX_ENDPOINTS x QUIC_TX_BUFFER_SIZE
Crypto RX buffers	QUIC_MAX_ENDPOINTS x QUIC_CRYPTO_RX_BUFFER_SIZE
Crypto OOO slots	QUIC_MAX_ENDPOINTS x QUIC_CRYPTO_OOO_SLOTS x 8
Stream TX buffers	(QUIC_MAX_CONTEXTS x (QUIC_MAX_STREAMS_BIDI + QUIC_MAX_STREAMS_UNI)) x QUIC_STREAM_TX_BUFFER_SIZE
Stream RX buffers	(QUIC_MAX_CONTEXTS x (QUIC_MAX_STREAMS_BIDI + QUIC_MAX_STREAMS_UNI)) x QUIC_STREAM_RX_BUFFER_SIZE
Stream OOO buffers	total_streams x QUIC_STREAM_OOO_SLOTS x QUIC_STREAM_OOO_SEG_SIZE
Sent-packet history	QUIC_MAX_CONTEXTS x QUIC_SENT_PKT_HISTORY_SIZE x 24
TLS transcript buffers	QUIC_MAX_CONTEXTS x QUIC_TLS_TRANSCRIPT_BUF_LEN
TLS context (Mbed TLS)	~8192 x QUIC_MAX_CONTEXTS (estimated; depends on ciphersuites)
Connection state	~512 x QUIC_MAX_CONTEXTS
Stream state	~128 x total_streams

Total estimated QUIC RAM (rough minimum for 1 connection, 3 bidi streams, 1500-byte stream buffers, LAN client defaults):

```
Endpoint RX staging :  2 x 1 x 1500 = 3 000 B
Endpoint TX         :  2 x 1500      = 3 000 B
Crypto RX buffers   :  2 x 2048      = 4 096 B  (embedded client, LAN)
Crypto OOO slots    :  2 x 4 x 8     =   256 B
Stream TX           :  3 x 1500      = 4 500 B
Stream RX           :  3 x 1500      = 4 500 B
OOO buffers         :  3 x 2 x 512   = 3 072 B
Sent-pkt history    :  1 x 16 x 24   =   384 B
TLS transcript      :  1 x 4096      = 4 096 B
TLS context         :  1 x 8192      = 8 192 B
State overhead      :  512 + 3x128   =   896 B
-----------------------------------------------
Approximate total                   ~ 35 992 B (~35 KiB)
```

The dominant cost at low stream counts is the Mbed TLS context per connection. At higher stream counts, the stream TX/RX buffers become dominant.

Kconfig Optimizer Choosing buffer sizes that are both memory-efficient and able to sustain target throughput requires balancing several interdependent parameters. To assist with this, Zephyr provides a Python optimizer script:

```
scripts/net/quic-kconfig-optimizer.py
```

The script accepts a description of the deployment scenario – connection counts, MTU, network type, expected RTT, and a RAM budget – and outputs a complete set of recommended CONFIG_ values together with an estimated RAM breakdown and a ready-to-paste prj.conf snippet.

Prerequisites The script requires Python 3.8 or later with no additional dependencies beyond the standard library.

```
python3 --version   # must be 3.8+
```

Usage: Interactive Mode Run the script without arguments to enter the guided interactive mode. Each prompt shows its default in square brackets; press Enter to accept it.

```
python3 scripts/net/quic-kconfig-optimizer.py
```

Example session:

```
============================================================
  Zephyr QUIC Kconfig Optimizer -- Interactive Mode
============================================================
  Press Enter to accept [default] values.

Max QUIC connections (QUIC_MAX_CONTEXTS) [1]: 2
Bidirectional streams per connection [3]:
Unidirectional streams per connection [0]:
Network MTU in bytes [1500]:
RAM budget in bytes (0 = no limit) [0]: 131072
Device role [client] (client/server/both):
IP version(s) [ipv4] (ipv4/ipv6/both):
Expected RTT in ms [10]: 50
Expected packet loss rate (%) [0.0]:
Typical application message size (bytes) [1024]: 4096
Expect out-of-order delivery? [no] (yes/no):
Network type [lan] (lan/wan/loopback):
```

Usage: Command-Line Mode All parameters can be supplied on the command line. When every required parameter is present, the script skips interactive prompts entirely, which makes it suitable for CI pipelines and scripted board bringup.

```
python3 scripts/net/quic-kconfig-optimizer.py \
    --contexts        2          \
    --streams-bidi    3          \
    --streams-uni     0          \
    --mtu             1500       \
    --ram-budget      131072     \
    --role            client     \
    --ip-version      ipv4       \
    --rtt-ms          50         \
    --loss-rate       0.0        \
    --app-message-size 4096      \
    --ooo-expected    no         \
    --network-type    lan
```

If only some parameters are provided, the script falls back to interactive mode for the missing ones.

```
# Pre-fill the constraints, fill the rest interactively
python3 scripts/net/quic-kconfig-optimizer.py \
    --contexts 1 --streams-bidi 3 --ram-budget 65536
```

Input Parameters

Parameter	CLI flag	Default	Description
Max connections	`--context`	1	Maps directly to `CONFIG_QUIC_MAX_CONTEXTS`. Memory for TLS contexts, connection state, and sent-packet history scales linearly with this value.
Bidi streams	`--streams`	3	Bidirectional streams per connection. Stream TX/RX buffers are allocated for every stream across every connection, so `contexts x streams_bidi x 2 x stream_buf` bytes are reserved at boot.
Uni streams	`--streams`	0	Unidirectional streams per connection. Set to 0 if not needed to avoid allocating the associated receive buffers.
MTU	`--mtu`	1500	Network maximum transmission unit in bytes. Sets the floor for `CONFIG_QUIC_TX_BUFFER_SIZE` and `CONFIG_QUIC_ENDPOINT_PENDING_DATA_LEN`. Use 1280 for networks where IPv6 minimum MTU compliance is required and no Path MTU Discovery is available.
RAM budget	`--ram-bud`	0 (unlimited)	Hard upper bound on estimated QUIC RAM usage in bytes. The script aborts with an error if the computed allocation exceeds this value. Set to 0 to skip the budget check and simply report the estimate.
Device role	`--role`	`client`	`client`, `server`, or `both`. Affects the recommended number of endpoints: servers and dual-stack devices typically need one extra endpoint.
IP version	`--ip-vers`	`ipv4`	`ipv4`, `ipv6`, or `both`. When `both` is selected and `CONFIG_QUIC_ENDPOINT_USE_IPV4_MAPPING_TO_IPV6` is not enabled, an additional endpoint is needed.
Expected RTT	`--rtt-ms`	10	Round-trip time in milliseconds between the device and the remote peer. Used to size `CONFIG_QUIC_CONNECT_TIMEOUT`, `CONFIG_QUIC_MAX_PTO_TIMEOUT_MS`, and the window-update threshold.
Packet loss rate	`--loss-ra`	0.0	Expected packet loss as a percentage (0-100). Loss >= 2 % doubles stream buffer sizes to keep the pipeline full; loss >= 5 % forces the sent-packet history to at least 128 entries for effective loss detection.
Message size	`--app-mes`	1024	Typical application payload in bytes. Stream buffers are sized to hold at least 2x this value so that one complete message can be in transit while the previous one is being acknowledged.
OOO expected	`--ooo-exp`	`no`	Whether out-of-order packet delivery is expected (`yes`/`no`). When `no`, OOO slots are reduced to 2 and segment size to 512 B, saving `total_streams x (default_slots - 2) x seg_size` bytes.
Network type	`--network`	`lan`	`lan`, `wan`, or `loopback`. Controls idle timeout, PTO ceiling, and whether stream buffers are doubled to fill the larger bandwidth-delay product of a WAN link.

Output Sections The optimizer prints five sections.

Input Parameters – echoes all supplied values for verification.

Recommended Kconfig Values – the computed `CONFIG_*` values grouped by category (connection counts, transport parameters, buffer sizes, timeouts).

Estimated RAM Usage – a table showing each memory region, its size, and a proportional ASCII bar chart. If a RAM budget was given, the utilisation percentage is shown.

prj.conf Snippet – a copy-pasteable block of Kconfig options ready to drop into a `prj.conf` or board-specific `.conf` overlay.

Additional Notes – deployment-specific warnings and suggestions derived from the input, for example if the service stack is likely to be too small, or if the connection-level flow-control window may become a bottleneck.

Example Output The following shows the output for a minimal client configuration: one connection, three bidirectional streams, Ethernet LAN, 10 ms RTT, 1 KiB messages, no OOO.

```

-------------------------------------------------------------------------
  prj.conf SNIPPET
-------------------------------------------------------------------------

CONFIG_QUIC_MAX_CONTEXTS=1
CONFIG_QUIC_MAX_STREAMS_BIDI=3
...
```

Minimal IoT sensor (client, IPv4 only, tight RAM budget) A sensor that opens one QUIC connection to a cloud endpoint, uses a single bidirectional stream to report telemetry, and has 48 KiB available for QUIC:

```
python3 scripts/net/quic-kconfig-optimizer.py \
    --contexts 1 --streams-bidi 1 --streams-uni 0 \
    --mtu 1280 --ram-budget 49152 \
    --role client --ip-version ipv4 \
    --rtt-ms 80 --loss-rate 0.5 \
    --app-message-size 256 \
    --ooo-expected no --network-type wan
```

The script will size stream buffers to 1500 B (minimum, since `2 x 256 = 512 < 1500`), set OOO slots to 2, and keep the sent-packet history at 16 entries – all chosen to minimise RAM while still

handling the expected 0.5 % loss on the WAN link.

Dual-stack server (IPv4 + IPv6, multiple clients) An edge gateway accepting up to four simultaneous client connections over both IPv4 and IPv6, with 256 KiB available for QUIC:

```
python3 scripts/net/quic-kconfig-optimizer.py \
    --contexts 4 --streams-bidi 3 --streams-uni 1 \
    --mtu 1500 --ram-budget 262144 \
    --role server --ip-version both \
    --rtt-ms 5 --loss-rate 0.0 \
    --app-message-size 8192 \
    --ooo-expected no --network-type lan
```

The script will recommend three endpoints (two for the listening sockets, one for each client family), and size stream buffers to 16 KiB (to hold 2 x 8192 B messages), which with 4 contexts and 4 streams each will dominate the RAM budget.

High-throughput WAN link with packet loss A data aggregator connected over a cellular WAN with measurable packet loss, requiring sustained throughput for firmware-update payloads:

```
python3 scripts/net/quic-kconfig-optimizer.py \
    --contexts 1 --streams-bidi 2 --streams-uni 0 \
    --mtu 1400 --ram-budget 0 \
    --role client --ip-version ipv4 \

```

Here the script doubles stream buffers (loss >= 2 %) and selects a window update threshold of 15 % (high-latency WAN) to keep the peer's send window open, maximising pipeline utilisation. It also sets OOO slots to 8 with 1280-byte segments to handle cellular reordering.

Tuning Guidelines **Start with the optimizer defaults, then measure.** The script's heuristics are conservative. Use the Zephyr network statistics (`CONFIG_NET_STATISTICS`) to observe actual stream window stalls and OOO events before deciding to increase buffer sizes.

Stream buffers are the biggest RAM cost. On multi-connection devices, `contexts x streams x 2 x stream_buf` dominates. Halving the stream buffer size saves proportionally. Only increase beyond the BDP if profiling shows persistent sender stalls.

The connection-level window must not be the bottleneck. `CONFIG_QUIC_INITIAL_MAX_DATA` must be greater than or equal to the largest per-stream window; otherwise the connection cap limits throughput even when individual stream windows are open.

CRYPTO buffers scale with endpoints, not connections. `CONFIG_QUIC_CRYPTO_RX_BUFFER_SIZE` and `CONFIG_QUIC_CRYPTO_OOO_SLOTS` are allocated once per endpoint, so their RAM cost is `QUIC_MAX_ENDPOINTS x buffer_size`. The 4096-byte default is required for browser interoperability (Chrome and Firefox fragment ClientHello into many small CRYPTO frames); reduce to 2048 for embedded-only deployments where the peer is also a Zephyr device.

IPv4-mapped IPv6. When both IPv4 and IPv6 are needed, enabling `CONFIG_QUIC_ENDPOINT_USE_IPV4_MAPPING_TO_IPV6` allows one UDP socket to serve both address families, reducing `CONFIG_QUIC_MAX_ENDPOINTS` by one and saving the associated buffer RAM.

Disable unused stream directions. If the application only uses client-initiated streams, set `CONFIG_QUIC_MAX_STREAMS_UNI` to 0. The optimizer accounts for this automatically.

OOO memory is per-stream. `QUIC_STREAM_OOO_SLOTS x QUIC_STREAM_OOO_SEG_SIZE x total_streams` can be significant. On a reliable LAN, setting `CONFIG_QUIC_STREAM_OOO_SLOTS` to 2 and `CONFIG_QUIC_STREAM_OOO_SEG_SIZE` to 512 is safe and saves several KiB per connection.

Network System Management

Network Configuration Library

- *Overview*
- *SNTP clock initialization*
- *Sample usage*
- *API Reference*

Overview The network configuration library sets up networking devices in a semi-automatic way during the system boot, based on user-supplied Kconfig options.

The following Kconfig options affect how configuration library will setup the system:

Table 9: Kconfig options for network configuration library

Option name	Description
CONFIG_NET_CONFIG_SETTINGS	This option controls whether the network system is configured or initialized at all. If not set, then the config library is not used for initialization and the application needs to do all the network related configuration itself. If this option is set, then the user can optionally configure static IP addresses to be set to the first network interface in the system. Typically setting static IP addresses is only usable in testing and should not be used in production code. See the config library Kconfig file subsys/net/lib/config/Kconfig for specific options to set the static IP addresses.
CONFIG_NET_CONFIG_AUTO_INIT	The networking system is automatically configured when the device is started.
CONFIG_NET_CONFIG_INIT_TIMEOUT	This tells how long to wait for the networking to be ready and available. If for example IPv4 address from DHCPv4 is not received within this limit, then a call to net_config_init() will return error during the device startup.
CONFIG_NET_CONFIG_NEED_IPV4	The network application needs IPv4 support to function properly. This option makes sure the network application is initialized properly in order to use IPv4. If CONFIG_NET_IPV4 is not enabled, then setting this option will automatically enable IPv4.
CONFIG_NET_CONFIG_NEED_IPV6	The network application needs IPv6 support to function properly. This option makes sure the network application is initialized properly in order to use IPv6. If CONFIG_NET_IPV6 is not enabled, then setting this option will automatically enable IPv6.
CONFIG_NET_CONFIG_NEED_IPV6_ROUTER	If IPv6 is enabled, then this option tells that the network application needs IPv6 router to exists before continuing. This means in practice that the application wants to wait until it receives IPv6 router advertisement message before continuing.
CONFIG_NET_CONFIG_MY_IPV6_ADDR	Local static IPv6 address assigned to the default network interface.
CONFIG_NET_CONFIG_PEER_IPV6_ADDR	Peer static IPv6 address. This is mainly useful in testing setups where the application can connect to a pre-defined host.
CONFIG_NET_CONFIG_MY_IPV4_ADDR	Local static IPv4 address assigned to the default network interface.
CONFIG_NET_CONFIG_MY_IPV4_NETMASK	Static IPv4 netmask assigned to the IPv4 address.
CONFIG_NET_CONFIG_MY_IPV4_GW	Static IPv4 gateway address assigned to the default network interface.
CONFIG_NET_CONFIG_PEER_IPV4_ADDR	Peer static IPv4 address. This is mainly useful in testing setups where the application can connect to a pre-defined host.

SNTP clock initialization If CONFIG_NET_CONFIG_CLOCK_SNTP_INIT is set, the library also initializes the system clock from an SNTP server, and optionally keeps it in sync with CONFIG_NET_CONFIG_SNTP_INIT_RESYNC.

The server to query is looked up in the following order:

1. The server set at runtime with net_config_sntp_set_server(). This requires CON-

FIG_NET_CONFIG_SNTP_INIT_SERVER_RUNTIME and is meant for applications that only learn which time server to use while running, for example after provisioning.

2. The server received via the DHCPv4 NTP server option, if CONFIG_NET_CONFIG_SNTP_INIT_SERVER_USE_DHCPV4_OPTION is set.
3. CONFIG_NET_CONFIG_SNTP_INIT_SERVER, which must be set if CONFIG_NET_CONFIG_CLOCK_SNTP_INIT is set but neither CONFIG_NET_CONFIG_SNTP_INIT_SERVER_RUNTIME nor CONFIG_NET_CONFIG_SNTP_INIT_SERVER_USE_DHCPV4_OPT is enabled.

Sample usage If CONFIG_NET_CONFIG_AUTO_INIT is set, then the configuration library is automatically enabled and run during the device boot. In this case, the library will call net_config_init() automatically and the application does not need to do any network configuration.

If you want to use the network configuration library but without automatic initialization, you can call net_config_init() manually. The flags parameter can be used to give hints to the library about what kind of functionality the application wishes to have before the actual application starts.

DHCPv6

- *Overview*
- *Prefix delegation*
- *Limitations*
- *API Reference*

Overview The Dynamic Host Configuration Protocol (DHCP) for IPv6 is a network management protocol used on IPv6 based networks. A DHCPv6 server dynamically assigns an IPv6 address and other network configuration parameters to each device on a network so they can communicate with other IP networks. See this DHCPv6 Wikipedia article for a detailed overview of how DHCPv6 works.

Zephyr supports both DHCPv6 client and server functionality, including IPv6 prefix delegation (IA_PD) as specified in RFC 8415.

Prefix delegation The DHCPv6 client can act as a *requesting router*: in addition to requesting a non-temporary address (IA_NA), it can request a delegated prefix (IA_PD) by setting `net_dhcpv6_params.request_prefix`. The delegated prefix is installed on the requesting interface.

To turn the node into a full requesting router that sub-delegates the prefix to one or more downstream links, list the downstream (LAN) interface indices in `net_dhcpv6_params.downstream_ifaces` and set `net_dhcpv6_params.downstream_count` to the number of entries. Each downstream interface is assigned a distinct `/64` carved from the delegated prefix (the Nth interface gets the Nth `/64`), which is then advertised on that interface via Router Advertisements, allowing downstream hosts to auto-configure addresses using SLAAC. The array holds at most `CONFIG_NET_DHCPV6_MAX_DOWNSTREAM` entries; a `net_dhcpv6_params.downstream_count` of 0 means the delegated prefix is only installed on the requesting interface. This requires `CONFIG_NET_IPV6_ND_RA_TX` (Router Advertisement transmit / router role) and, for traffic to be forwarded between the upstream and downstream interfaces, `CONFIG_NET_IPV6_FORWARDING`.

The delegation has to be short enough to contain a distinct `/64` for every downstream interface, that is, a delegated prefix of length `L` can serve at most `2^(64 - L)` downstream links. A delegation of exactly a `/64` can therefore serve a single link, and one longer than a `/64` cannot be sub-delegated at all. Downstream interfaces that cannot be given a distinct `/64` are skipped with a warning.

The DHCPv6 server (`CONFIG_NET_DHCPV6_SERVER`) implements the *delegating router* role, handing out addresses and delegated prefixes from configured pools. See dhcpv6-pd for a complete example of both roles.

Limitations The implementation deliberately leaves out a few things that RFC 8415 and RFC 4861 allow to be simplified:

- A Release sent when the client is stopped (`CONFIG_NET_DHCPV6_SEND_RELEASE_ON_STOP`) is best effort, it is transmitted once and is not retransmitted `REL_MAX_RC` times as described in **RFC 8415 Section 18.2.7**. A lease that is not released is reclaimed by the server once it expires.
- Unsolicited Router Advertisements are sent at the fixed interval configured with `CONFIG_NET_IPV6_ND_RA_TX_INTERVAL` instead of at a random interval between `MinRtrAdvInterval` and `MaxRtrAdvInterval`, and no initial burst of `MAX_INITIAL_RTR_ADVERTISEMENTS` is sent when an interface takes the router role. Solicited advertisements are rate limited and randomly delayed as required by **RFC 4861 Section 6.2.6**.

- The server assigns addresses and prefixes by varying a single byte of the configured pool base, so pools are limited to `CONFIG_NET_DHCPV6_SERVER_MAX_LEASES` entries and IA_PD pool prefix lengths have to be byte aligned.

Hostname Configuration

- *Overview*
- *API Reference*

Overview A networked device might need a hostname, for example, if the device is configured to be a mDNS responder (see *DNS Resolve* for details) and needs to respond to `<hostname>.local` DNS queries.

The `CONFIG_NET_HOSTNAME_ENABLE` must be set in order to store the hostname and enable the relevant APIs. If the option is enabled, then the default hostname is set to be `zephyr` by `CONFIG_NET_HOSTNAME` option.

If the same firmware image is used to flash multiple boards, then it is not practical to use the same hostname in all of the boards. In that case, one can enable `CONFIG_NET_HOSTNAME_UNIQUE` which will add a unique postfix to the hostname. By default the link local address of the first network interface is used as a postfix. In Ethernet networks, the link local address refers to MAC address. For example, if the link local address is `01:02:03:04:05:06`, then the unique hostname could be `zephyr010203040506`. If you want to set the prefix yourself, then call `net_hostname_set_postfix_str()` before the network interfaces are created. Alternatively, if you prefer a hexadecimal conversion for the prefix, then call `net_hostname_set_postfix()`. For example for the Ethernet networks, the initialization priority is set by `CONFIG_ETH_INIT_PRIORITY` so you would need to set the postfix before that. The postfix can be set only once.

Network Core Helpers

- *Overview*
- *API Reference*

Overview The network subsystem contains two functions for sending and receiving data from the network. The `net_recv_data()` is typically used by network device driver when the received network data needs to be pushed up in the network stack for further processing. All the data is received via a network interface which is typically created by the device driver.

For sending, the `net_send_data()` can be used. Typically applications do not call this function directly as there is the *BSD Sockets* API for sending and receiving network data.

Network Interface

- *Overview*
- *Network interface state management*
- *API Reference*

Overview The network interface is a nexus that ties the network device drivers and the upper part of the network stack together. All the sent and received data is transferred via a network interface. The network interfaces cannot be created at runtime. A special linker section will contain information about them and that section is populated at linking time.

Network interfaces are created by `NET_DEVICE_INIT()` macro. For Ethernet network, a macro called `ETH_NET_DEVICE_INIT()` should be used instead as it will create VLAN interfaces automatically if `CONFIG_NET_VLAN` is enabled. These macros are typically used in network device driver source code.

The network interface can be turned ON by calling `net_if_up()` and OFF by calling `net_if_down()`. When the device is powered ON, the network interface is also turned ON by default.

The network interfaces can be referenced either by a `struct net_if *` pointer or by a network interface index. The network interface can be resolved from its index by calling `net_if_get_by_index()` and from interface pointer by calling `net_if_get_by_iface()`.

The IP address for network devices must be set for them to be connectable. In a typical dynamic network environment, IP addresses are set automatically by DHCPv4, for example. If needed though, the application can set a device's IP address manually. See the API documentation below for functions such as `net_if_ipv4_addr_add()` that do that.

The `net_if_get_default()` returns a *default* network interface. What this default interface means can be configured via options like `CONFIG_NET_DEFAULT_IF_FIRST` and `CONFIG_NET_DEFAULT_IF_ETHERNET`. See Kconfig file subsys/net/ip/Kconfig what options are available for selecting the default network interface.

The transmitted and received network packets can be classified via a network packet priority. This is typically done in Ethernet networks when virtual LANs (VLANs) are used. Higher priority packets can be sent or received earlier than lower priority packets. The traffic class setup can be configured by `CONFIG_NET_TC_TX_COUNT` and `CONFIG_NET_TC_RX_COUNT` options.

If the CONFIG_NET_PROMISCUOUS_MODE is enabled and if the underlying network technology supports promiscuous mode, then it is possible to receive all the network packets that the network device driver is able to receive. See *Promiscuous Mode* API for more details.

Network interface state management Zephyr distinguishes between two interface states: administrative state and operational state, as described in RFC 2863. The administrative state indicate whether an interface is turned ON or OFF. This state is represented by NET_IF_UP flag and is controlled by the application. It can be changed by calling net_if_up() or net_if_down() functions. Network drivers or L2 implementations should not change administrative state on their own.

Bringing an interface up however not always means that the interface is ready to transmit packets. Because of that, operational state, which represents the internal interface status, was implemented. The operational state is updated whenever one of the following conditions take place:

- The interface is brought up/down by the application (administrative state changes).
- The interface is notified by the driver/L2 that PHY status has changed.
- The interface is notified by the driver/L2 that it joined/left a network.

The PHY status is represented with NET_IF_LOWER_UP flag and can be changed with net_if_carrier_on() and net_if_carrier_off(). By default, the flag is set on a newly initialized interface. An example of an event that changes the carrier state is Ethernet cable being plugged in or out.

The network association status is represented with NET_IF_DORMANT flag and can be changed with net_if_dormant_on() and net_if_dormant_off(). By default, the flag is cleared on a newly initialized interface. An example of an event that changes the dormant state is a Wi-Fi driver successfully connecting to an access point. In this scenario, driver should set the dormant state to ON during initialization, and once it detects that it connected to a Wi-Fi network, the dormant state should be set to OFF.

The operational state of an interface is updated as follows:

- `!net_if_is_admin_up()`

  Interface is in NET_IF_OPER_DOWN.

- `net_if_is_admin_up() && !net_if_is_carrier_ok()`

  Interface is in NET_IF_OPER_DOWN or NET_IF_OPER_LOWERLAYERDOWN if the interface is stacked (virtual).

- `net_if_is_admin_up() && net_if_is_carrier_ok() && net_if_is_dormant()`

  Interface is in NET_IF_OPER_DORMANT.

- `net_if_is_admin_up() && net_if_is_carrier_ok() && !net_if_is_dormant()`

  Interface is in NET_IF_OPER_UP.

Only after an interface enters NET_IF_OPER_UP state the NET_IF_RUNNING flag is set on the interface indicating that the interface is ready to be used by the application.

L2 Layer Management

- *Overview*
- *L2 layer API*
- *Network Device drivers*
  - *Ethernet device driver*
  - *IEEE 802.15.4 device driver*
- *API Reference*

Overview The L2 stack is designed to hide the whole networking link-layer part and the related device drivers from the upper network stack. This is made through a `net_if` declared in include/zephyr/net/net_if.h.

The upper layers are unaware of implementation details beyond the net_if object and the generic API provided by the L2 layer in include/zephyr/net/net_l2.h as `net_l2`.

Only the L2 layer can talk to the device driver, linked to the net_if object. The L2 layer dictates the API provided by the device driver, specific for that device, and optimized for working together.

Currently, there are L2 layers for *Ethernet*, *IEEE 802.15.4 Soft-MAC*, *CANBUS*, *OpenThread*, Wi-Fi, and a dummy layer example that can be used as a template for writing a new one.

L2 layer API In order to create an L2 layer, or a driver for a specific L2 layer, one needs to understand how the L3 layer interacts with it and how the L2 layer is supposed to behave. See also *network stack architecture* for more details. The generic L2 API has these functions:

- `recv()`: All device drivers, once they receive a packet which they put into a `net_pkt`, will push this buffer to the network stack via `net_recv_data()`. At this point, the network stack does not know what to do with it. Instead, it passes the buffer along to the L2 stack's `recv()` function for handling. The L2 stack does what it needs to do with the packet, for example, parsing the link layer header, or handling link-layer only packets. The `recv()` function will return `NET_DROP` in case of an erroneous packet, `NET_OK` if the packet was fully consumed by the L2, or `NET_CONTINUE` if the network stack should then handle it.
- `send()`: Similar to receive function, the network stack will call this function to actually send a network packet. All relevant link-layer content will be generated and added by this function. The `send()` function returns the number of bytes sent, or a negative error code if there was a failure sending the network packet.
- `enable()`: This function is used to enable/disable traffic over a network interface. The function returns `<0` if error and `>=0` if no error.
- `get_flags()`: This function will return the capabilities of an L2 driver, for example whether the L2 supports multicast or promiscuous mode.

Network Device drivers Network device drivers fully follows Zephyr device driver model as a basis. Please refer to *Device Driver Model*.

There are, however, two differences:

- The driver_api pointer must point to a valid `net_if_api` pointer.
- The network device driver must use `NET_DEVICE_INIT_INSTANCE()` or `ETH_NET_DEVICE_INIT()` for Ethernet devices. These macros will call the `DEVICE_DEFINE()` macro, and also instantiate a unique `net_if` related to the created device driver instance.

Implementing a network device driver depends on the L2 stack it belongs to: *Ethernet*, *IEEE 802.15.4*, etc. In the next section, we will describe how a device driver should behave when receiving or sending a network packet. The rest is hardware dependent and is not detailed here.

Ethernet device driver On reception, it is up to the device driver to fill-in the network packet with as many data buffers as required. The network packet itself is a `net_pkt` and should be allocated through `net_pkt_rx_alloc_with_buffer()`. Then all data buffers will be automatically allocated and filled by `net_pkt_write()`.

After all the network data has been received, the device driver needs to call `net_recv_data()`. If that call fails, it will be up to the device driver to unreference the buffer via `net_pkt_unref()`.

On sending, the device driver send function will be called, and it is up to the device driver to send the network packet all at once, with all the buffers.

Each Ethernet device driver will need, in the end, to call `ETH_NET_DEVICE_INIT()` like this:

```
ETH_NET_DEVICE_INIT(..., CONFIG_ETH_INIT_PRIORITY,
                    &the_valid_net_if_api_instance, 1500);
```

IEEE 802.15.4 device driver Device drivers for IEEE 802.15.4 L2 work basically the same as for Ethernet. What has been described above, especially for `recv()`, applies here as well. There are two specific differences however:

- It requires a dedicated device driver API: `ieee802154_radio_api`, which overloads `net_if_api`. This is because 802.15.4 L2 needs more from the device driver than just `send()` and `recv()` functions. This dedicated API is declared in include/zephyr/net/ieee802154_radio.h. Each and every IEEE 802.15.4 device driver must provide a valid pointer on such relevantly filled-in API structure.
- Sending a packet is slightly different than in Ethernet. Most IEEE 802.15.4 PHYs support relatively small frames only, 127 bytes all inclusive: frame header, payload and frame checksum. Buffers to be sent over the radio will often not fit this frame size limitation, e.g. a buffer containing an IPv6 packet will often have to be split into several fragments and IP6 packet headers and fragments need to be compressed using a protocol like 6LoWPAN before being passed on to the radio driver. Additionally the IEEE 802.15.4 standard defines medium access (e.g. CSMA/CA), frame retransmission, encryption and other preprocessing procedures (e.g. addition of information elements) that individual radio drivers should not have to care about. This is why the `ieee802154_radio_api` requires a tx function pointer which differs from the `net_if_api` send function pointer. Zephyr's native IEEE 802.15.4 L2 implementation provides a generic `ieee802154_send()` instead, meant to be given as `net_if` send function. The implementation of `ieee802154_send()` takes care of IEEE 802.15.4 standard packet preparation procedures, splitting the packet into possibly compressed, encrypted and otherwise pre-processed fragment buffers, sending one buffer at a time through `ieee802154_radio_api` tx function and unreferencing the network packet only when the transmission as a whole was either successful or failed.

Interaction between IEEE 802.15.4 radio device drivers and L2 is bidirectional:

- L2 -> L1: Methods as `ieee802154_send()` and several IEEE 802.15.4 net management calls will call into the driver, e.g. to send a packet over the radio link or re-configure

the driver at runtime. These incoming calls will all be handled by the methods in the `ieee802154_radio_api`.

- L1 -> L2: There are several situations in which the driver needs to initiate calls into the L2/MAC layer. Zephyr's IEEE 802.15.4 L1 -> L2 adaptation API employs an "inversion-of-control" pattern in such cases avoids duplication of complex logic across independent driver implementations and ensures implementation agnostic loose coupling and clean separation of concerns between MAC (L2) and PHY (L1) whenever reverse information transfer or close co-operation between hardware and L2 is required. During driver initialization, for example, the driver calls `ieee802154_init()` to pass the interface's MAC address as well as other hardware-related configuration to L2. Similarly, drivers may indicate performance or timing critical radio events to L2 that require close integration with the hardware (e.g. `ieee802154_handle_ack()`). Calls from L1 into L2 are not implemented as methods in `ieee802154_radio_api` but are standalone functions declared and documented as such in include/zephyr/net/ieee802154_radio.h. The API documentation will clearly state which functions must be implemented by all L2 stacks as part of the L1 -> L2 "inversion-of-control" adaptation API.

Note: Standalone functions in include/zephyr/net/ieee802154_radio.h that are not explicitly documented as callbacks are considered to be helper functions within the PHY (L1) layer implemented independently of any specific L2 stack, see for example `ieee802154_is_ar_flag_set()`.

As all net interfaces, IEEE 802.15.4 device driver implementations will have to call `NET_DEVICE_INIT_INSTANCE()` in the end:

```
NET_DEVICE_INIT_INSTANCE(...,
                         the_device_init_prio,
                         &the_valid_ieee802154_radio_api_instance,
                         IEEE802154_L2,
                         NET_L2_GET_CTX_TYPE(IEEE802154_L2), 125);
```

Network Traffic Offloading

- *Network Offloading*
  - *Overview*
  - *API Reference*
- *Socket Offloading*
  - *Overview*

Network Offloading

Overview The network offloading API provides hooks that a device vendor can use to provide an alternate implementation for an IP stack. This means that the actual network connection

creation, data transfer, etc., is done in the vendor HAL instead of the Zephyr network stack.

API Reference
Network Offloading Interface

Socket Offloading

Overview In addition to the network offloading API, Zephyr allows offloading of networking functionality at the socket API level. With this approach, vendors who provide an alternate implementation of the networking stack, exposing socket API for their networking devices, can easily integrate it with Zephyr.

See drivers/wifi/simplelink/simplelink_sockets.c for a sample implementation on how to integrate network offloading at socket level.

Link Layer Address Handling

- *Overview*
- *API Reference*

Overview The link layer addresses are set for network interfaces so that L2 connectivity works correctly in the network stack. Typically the link layer addresses are 6 bytes long like in Ethernet but for IEEE 802.15.4 the link layer address length is 8 bytes.

API Reference
Network Link Address Library

Ethernet Management

- *Overview*
- *API Reference*

Overview Ethernet management API provides functions to manage the Ethernet network interface low level status. The caller of these functions can:

- raise `carrier ON` or `carrier OFF` management events
- raise `VLAN enabled` or `VLAN disabled` management events

Typically the `carrier OFF` event would be generated by the Ethernet device driver when it notices that the Ethernet cable is disconnected. The `carrier ON` event would be generated if the Ethernet device driver notices that the Ethernet cable is re-connected.

Currently the VLAN events are generated by the Ethernet L2 layer when a specific VLAN tag is either enabled or disabled.

The user application can monitor these events if it needs to act when the corresponding status changes.

Traffic Classification

Overview Traffic classification is an automated process that categorizes computer network traffic according to various parameters. For Zephyr, the VLAN priority code point (PCP) is used to classify both received and sent network packets. See more information about VLAN priority at IEEE 802.1Q.

By default, all network traffic is treated equal in Zephyr. If desired, the option `CONFIG_NET_TC_TX_COUNT` can be used to set the number of transmit queues. The option `CONFIG_NET_TC_RX_COUNT` can be used to set the number of receive queues. Each traffic class queue corresponds to a specific kernel work queue. Each kernel work queue has a priority. The VLAN priority is mapped to a certain traffic class according to rules specified in IEEE 802.1Q spec chapter I.3, chapter 8.6.6 table 8-4, and chapter 34.5 table 34-1. Each traffic class is in turn mapped to a certain kernel work queue. The maximum number of traffic classes for both Rx and Tx is 8.

See subsys/net/ip/net_tc.c for details of how various mappings are done.

Network Packet Filtering

- *Overview*
- *Examples*
- *API Reference*

Overview The Network Packet Filtering facility provides the infrastructure to construct custom rules for accepting and/or denying packet transmission and reception. It also allows to modify the priority of incoming network packets. This can be used to create a basic firewall, control network traffic, etc.

The `CONFIG_NET_PKT_FILTER` must be set in order to enable the relevant APIs.

Both the transmission and reception paths may have a list of filter rules. Each rule is made of a set of conditions and a packet outcome. Every packet is subjected to the conditions attached to a rule. When all the conditions for a given rule are true then the packet outcome is immediately determined as specified by the current rule and no more rules are considered. If one condition is false then the next rule in the list is considered.

Packet outcome is either `NET_OK` to accept the packet, `NET_DROP` to drop it or `NET_CONTINUE` to modify its priority on the fly.

When the outcome is `NET_CONTINUE` the priority is updated but the final outcome is not yet determined and processing continues. If all conditions of multiple rules are true, then the packet gets the priority of the rule last considered.

A rule is represented by a `npf_rule` object. It can be inserted to, appended to or removed from a rule list contained in a `npf_rule_list` object using `npf_insert_rule()`, `npf_append_rule()`, and `npf_remove_rule()`.

There are different sets of rules for different layers in the network stack. Some of the rules are applied for L2 layer like Ethernet, and some for L3 layer where IPv4 or IPv6 protocol is handled.

The local_in rules are for matching incoming protocol types like UDP or TCP packets that are run on top of IPv4 or IPv6. The rule support for different layers can be controlled by relevant Kconfig options mentioned below.

- npf_send_rules is a rule list applied to outgoing packets in L2 layer
- npf_recv_rules is a rule list applied to incoming packets in L2 layer
- npf_ipv4_recv_rules is a rule list applied for incoming IPv4 packets. Can be enabled or disabled by CONFIG_NET_PKT_FILTER_IPV4_HOOK option.
- npf_ipv6_recv_rules is a rule list applied for incoming IPv6 packets. Can be enabled or disabled by CONFIG_NET_PKT_FILTER_IPV6_HOOK option.
- npf_local_in_recv_rules is a rule list applied for incoming UDP or TCP packets. Can be enabled or disabled by CONFIG_NET_PKT_FILTER_LOCAL_IN_HOOK option.

If a filter rule list is empty then NET_OK is assumed. If a non-empty rule list runs to the end then NET_DROP is assumed. However it is recommended to always terminate a non-empty rule list with an explicit default termination rule, either npf_default_ok or npf_default_drop.

Rule conditions are represented by a npf_test. This structure can be embedded into a larger structure when a specific condition requires extra test data. It is up to the test function for such conditions to retrieve the outer structure from the provided npf_test structure pointer.

Convenience macros are provided in include/zephyr/net/net_pkt_filter.h to statically define condition instances for various conditions, and NPF_RULE() and NPF_PRIORITY() to create a rule instance with an immediate outcome or a priority change.

See also net-pkt-filter sample for an example of how to create and manage packet filters. The network shell has a net filter command that can be used to see the installed rules at runtime.

Examples Here's an example usage:

```
static NPF_SIZE_MAX(maxsize_200, 200);
static NPF_ETH_TYPE_MATCH(ip_packet, NET_ETH_PTYPE_IP);

static NPF_RULE(small_ip_pkt, NET_OK, ip_packet, maxsize_200);

void install_my_filter(void)
{
    npf_insert_recv_rule(&npf_default_drop);
    npf_insert_recv_rule(&small_ip_pkt);
}
```

The above would accept IP packets that are 200 bytes or smaller, and drop all other packets.

Another (less efficient) way to achieve the same result could be:

```
static NPF_SIZE_MIN(minsize_201, 201);
static NPF_ETH_TYPE_UNMATCH(not_ip_packet, NET_ETH_PTYPE_IP);

static NPF_RULE(reject_big_pkts, NET_DROP, minsize_201);
static NPF_RULE(reject_non_ip, NET_DROP, not_ip_packet);

void install_my_filter(void) {
    npf_append_recv_rule(&reject_big_pkts);
    npf_append_recv_rule(&reject_non_ip);
    npf_append_recv_rule(&npf_default_ok);
}
```

This example assigns priorities to different network traffic. It gives network control priority (NET_PRIORITY_NC) to the ptp packets, critical applications priority (NET_PRIORITY_CA) to the in-

ternet traffic of version 6, excellent effort (NET_PRIORITY_EE) for internet protocol version 4 traffic, and the lowest background priority (NET_PRIORITY_BK) to lldp and arp.

Priority rules are only really useful if multiple traffic class queues are enabled in the project configuration CONFIG_NET_TC_RX_COUNT. The mapping from the priority of the packet to the traffic class queue is in accordance with the standard 802.1Q and depends on the CONFIG_NET_TC_RX_COUNT.

```
static NPF_ETH_TYPE_MATCH(is_arp, NET_ETH_PTYPE_ARP);
static NPF_ETH_TYPE_MATCH(is_lldp, NET_ETH_PTYPE_LLDP);
static NPF_ETH_TYPE_MATCH(is_ptp, NET_ETH_PTYPE_PTP);
static NPF_ETH_TYPE_MATCH(is_ipv4, NET_ETH_PTYPE_IP);
static NPF_ETH_TYPE_MATCH(is_ipv6, NET_ETH_PTYPE_IPV6);

static NPF_PRIORITY(priority_bk, NET_PRIORITY_BK, is_arp, is_lldp);
static NPF_PRIORITY(priority_ee, NET_PRIORITY_EE, is_ipv4);
static NPF_PRIORITY(priority_ca, NET_PRIORITY_CA, is_ipv6);
static NPF_PRIORITY(priority_nc, NET_PRIORITY_NC, is_ptp);

void install_my_filter(void) {
    npf_append_recv_rule(&priority_bk);
    npf_append_recv_rule(&priority_ee);
    npf_append_recv_rule(&priority_ca);
    npf_append_recv_rule(&priority_nc);
    npf_append_recv_rule(&npf_default_ok);
}
```

Basic Filter Conditions

Ethernet Filter Conditions

Network Shell Network shell, and its companion shells provide helpers for figuring out network status, enabling/disabling features, and issuing commands like ping or DNS resolving. Note that net-shell should probably not be used in production code as it will require extra memory. See also *generic shell* for detailed shell information.

Note that by default both the enabled or disabled net-shell commands are available to the user. This helps user to discover what commands are available and how to enable them. This extra help can be turned off by disabling CONFIG_NET_SHELL_SHOW_DISABLED_COMMANDS option.

The following net-shell commands are implemented:

Table 10: net-shell commands

Command	Description
net allocs	Print network memory allocations. Only available if CONFIG_NET_DEBUG_NET_PKT_ALLOC is set.
net arp	Print information about IPv4 ARP cache. Only available if CONFIG_NET_ARP is set in IPv4 enabled networks.

continues on next page

Table 10 – continued from previous page

Command	Description
net bridge	Print information and manipulate Ethernet bridges. Only available if CONFIG_NET_ETHERNET_BRIDGE_SHELL is set.
net capture	Monitor network traffic See *Monitor Network Traffic* for details.
net cm	Connection manager shell. Only available if CONFIG_NET_CONNECTION_MANAGER is set.
net conn	Print information about network connections.
net dhcpv4	Enable / disable DHCPv4 client or server support. Only available if CONFIG_NET_DHCPV4_SERVER or CONFIG_NET_DHCPV4 is set.
net dhcpv6	Enable / disable DHCPv6 client support. Only available if CONFIG_NET_DHCPV6 is set.
net dns	Show how DNS is configured. The command can also be used to resolve a DNS name. Only available if CONFIG_DNS_RESOLVER is set.
net events	Enable network event monitoring. Only available if CONFIG_NET_MGMT_EVENT_MONITOR is set.
net filter	View network packet filter rules. Only available if CONFIG_NET_PKT_FILTER is set.
net ftp	Connect to FTP server to transfer files. Only available if CONFIG_FTP_CLIENT is set.
net gptp	Print information about gPTP support. Only available if CONFIG_NET_GPTP is set.
net http	Show HTTP server information, or send HTTP GET/POST/PUT/DELETE requests. Only available if CONFIG_HTTP_SERVER or CONFIG_HTTP_CLIENT is set.
net iface	Print information about network interfaces.
net ipv4	Print IPv4 specific information and configuration. Only available if CONFIG_NET_IPV4 is set.
net ipv6	Print IPv6 specific information and configuration. Only available if CONFIG_NET_IPV6 is set.
net mem	Print information about network memory usage. The command will print more information if CONFIG_NET_BUF_POOL_USAGE is set.
net nbr	Print neighbor information. Only available if CONFIG_NET_IPV6 is set.
net ping	Ping a network host.
net pkt	Print low level network packet information for debugging purposes.
net pmtu	Print MTU path discovery information. Only available if CONFIG_NET_IPV6_PMTU or CONFIG_NET_IPV4_PMTU is set.
net ppp	Print Point-to-Point protocol information. Only available if CONFIG_NET_L2_PPP and CONFIG_NET_PPP are set.
net ptp	Print information about PTP support. Use net ptp <port> for detailed per-port view. Only available if CONFIG_PTP is set.
net qbv	Show and configure IEEE 802.1Qbv Time-Aware Shaper (TAS) information. Only available if CONFIG_NET_QBV is set.
net quic	Show and configure QUIC transport. Only available if CONFIG_QUIC is set.
net resume	Resume a network interface if network power management is enabled.
net route	Show IPv6 or IPv4 network routes. Only available if CONFIG_NET_IPV6_ROUTING or CONFIG_NET_IPV4_ROUTING is set.
net sockets	Show network socket information and statistics. Only available if CONFIG_NET_SOCKETS_OBJ_CORE and CONFIG_OBJ_CORE are set.
net ssh	SSH client support. Only available if CONFIG_SSH_CLIENT is set.
net sshd	SSH server support. Only available if CONFIG_SSH_SERVER is set.
net ssh_key	SSH key generation/removing/saving/loading support. Only available if CONFIG_SSH_CLIENT or CONFIG_SSH_SERVER is set.
net stats	Show network statistics.
net suspend	Suspend a network interface if network power management is enabled.
net tcp	Connect/send data/close TCP connection. Only available if CONFIG_NET_TCP is set.
net udp	Send UDP data directly from shell. Only available if CONFIG_NET_UDP is set.

continues on next page

Table 10 – continued from previous page

Command	Description
net virtual	Show and manipulate network virtual interfaces. Only available if CONFIG_NET_L2_VIRTUAL is set.
net vlan	Show Ethernet virtual LAN information. Only available if CONFIG_NET_VLAN is set.
net websocket	Print websocket information. Only available if CONFIG_WEBSOCKET_CLIENT is set.
net wg	Show WireGuard VPN information and setup VPNs. Only available if CONFIG_WIREGUARD is set.

The Wi-Fi shell provides commands to scan, connect, disconnect and configure Wi-Fi networks. Following Wi-Fi shell commands are implemented:

Table 11: wifi-shell commands

Command	Description
wifi <cmd>	Multiple commands for Wi-Fi network connection, disconnection, scanning and configuration. Only available if CONFIG_NET_L2_WIFI_SHELL is set.
wifi cred	Show/add/delete Wi-Fi network credentials. Only available if CONFIG_WIFI_CREDENTIALS_SHELL is set. See *Wi-Fi credentials Library* for details.

The TLS credentials shell provides commands to list, add, delete and retrieve TLS credential information either from a volatile or protected backend storage. Following TLS credentials shell commands are implemented. These commands are only available if CONFIG_TLS_CREDENTIALS_SHELL is set. See *TLS Credentials Shell* for details.

Table 12: tls-credentials-shell commands

Command	Description
cred buf	Buffer in credential data so it can be added.
cred add	Add a TLS credential.
cred del	Delete a TLS credential.
cred get	Retrieve the contents of a TLS credential.
cred list	List stored TLS credentials.

TLS Credentials Shell The TLS Credentials shell provides a command-line interface for managing installed TLS credentials.

Commands

Buffer Credential (buf) Buffer data incrementally into the credential buffer so that it can be added using the *Add Credential (add)* command.

Alternatively:

- Clear the credential buffer.
- Load credential directly to the credential buffer, ending with Ctrl + c.

Usage To append <DATA> to the credential buffer, use:

```
cred buf <DATA>
```

Use this as many times as needed to load the full credential into the credential buffer, then use the *Add Credential (add)* command to store it.

To load <DATA> directly to the credential buffer, use:

```
cred buf load
<DATA>
Ctrl + c
```

To clear the credential buffer, use:

```
cred buf clear
```

Arguments

Argument	Description
<DATA>	Text data to be appended to credential buffer. It can be either text, or base64-encoded binary. See *Add Credential (add)* and *Storage/Retrieval Formats* for details.

Add Credential (add) Add a TLS credential to the TLS Credential store.

Credential contents can be provided in-line with the call to `cred add`, or will otherwise be sourced from the credential buffer.

Usage To add a TLS credential using the data from the credential buffer, use:

```
cred add <SECTAG> <TYPE> <BACKEND> <FORMAT>
```

To add a TLS credential using data provided with the same command, use:

```
cred add <SECTAG> <TYPE> <BACKEND> <FORMAT> <DATA>
```

Arguments

Argument	Description
<SECTAG>	The sectag to use for the new credential. Can be any non-negative integer.
<TYPE>	The type of credential to add. See *Credential Types* for valid values.
<BACKEND>	Reserved. Must always be DEFAULT (case-insensitive).
<FORMAT>	Specifies the storage format of the provided credential. See *Storage/Retrieval Formats* for valid values.
<DATA>	If provided, this argument will be used as the credential data, instead of any data in the credential buffer. Can be either text, or base64-encoded binary.

Delete Credential (del) Delete a specified credential from the credential store.

Usage To delete a credential matching a specified sectag and credential type (if it exists), use:

```
cred del <SECTAG> <TYPE>
```

Arguments

Argument	Description
<SECTAG>	The sectag of the credential to delete. Can be any non-negative integer.
<TYPE>	The type of credential to delete. See *Credential Types* for valid values.

Get Credential Contents (`get`) Retrieve and print the contents of a specified credential.

Usage To retrieve and print a credential matching a specified sectag and credential type (if it exists), use:

```
cred get <SECTAG> <TYPE> <FORMAT>
```

Arguments

Argument	Description
<SECTAG>	The sectag of the credential to get. Can be any non-negative integer.
<TYPE>	The type of credential to get. See *Credential Types* for valid values.
<FORMAT>	Specifies the retrieval format for the provided credential. See *Storage/Retrieval Formats* for valid values.

List Credentials (`list`) List TLS credentials in the credential store.

Usage To list all available credentials, use:

```
cred list
```

To list all credentials with a specified sectag, use:

```
cred list <SECTAG>
```

To list all credentials with a specified credential type, use:

```
cred list any <TYPE>
```

To list all credentials with a specified credential type and sectag, use:

```
cred list <SECTAG> <TYPE>
```

Arguments

Argument	Description
<SECTAG>	Optional. If provided, only list credentials with this sectag. Pass any or omit to allow any sectag. Otherwise, can be any non-negative integer.
<TYPE>	Optional. If provided, only list credentials with this credential type. Pass any or omit to allow any credential type. Otherwise, see *Credential Types* for valid values.

Output The command outputs all matching credentials in the following (CSV-compliant) format:

```
<SECTAG>,<TYPE>,<DIGEST>,<STATUS>
```

Where:

Symbol	Value
<SECTAG>	The sectag of the listed credential. A non-negative integer.
<TYPE>	Credential type short-code (see *Credential Types* for details) of the listed credential.
<DIGEST>	A string digest representing the credential contents. The exact nature of this digest may vary depending on credentials storage backend, but currently for all backends this is a base64 encoded SHA256 hash of the raw credential contents (so different storage formats for essentially identical credentials will have different digests).
<STATUS>	Status code indicating success or failure with generating a digest of the listed credential. 0 if successful, negative error code specific to the storage backend otherwise. Lines for which status is not zero will be printed with error formatting.

After the list is printed, a final summary of the found credentials will be printed in the form:

```
<N> credentials found.
```

Where <N> is the number of credentials found, and is zero if none are found.

Credential Types The following keywords (case-insensitive) may be used to specify a credential type:

Keyword(s)	Meaning
CA_CERT, CA	A trusted CA certificate.
SERVER_CERT, SELF_CERT, CLIENT_CERT, CLIENT, SELF, SERV	Self or server certificate.
PRIVATE_KEY, PK	A private key.
PRE_SHARED_KEY, PSK	A pre-shared key.
PRE_SHARED_KEY_ID, PSK_ID	ID for pre-shared key.

Storage/Retrieval Formats The *tls_credentials* module treats stored credentials as arbitrary binary buffers.

For convenience, the TLS credentials shell offers four formats for providing and later retrieving these buffers using the shell.

These formats and their (case-insensitive) keywords are as follows:

K w	Meaning	Behavior during storage (`cred add`)	Behavior during retrieval (`cred get`)
B	Credential is handled by shell as base64 and stored without NULL termination.	Data entered into shell will be decoded from base64 into raw binary before storage. No terminator will be appended.	Stored data will be encoded into base64 before being printed.
B	Credential is handled by shell as base64 and stored with NULL termination.	Data entered into shell will be decoded from base64 into raw binary and a NULL terminator will be appended before storage.	NULL terminator will be truncated from stored data before said data is encoded into base64 and then printed.
S	Credential is handled by shell as literal string and stored without NULL termination.	Text data entered into shell will be passed into storage as-written, without a NULL terminator.	Stored data will be printed as text. Non-printable characters will be printed as ?
S	Credential is handled by shell as literal string and stored with NULL-termination.	Text data entered into shell will be passed into storage as-written, with a NULL terminator.	NULL terminator will be truncated from stored data before said data is printed as text. Non-printable characters will be printed as ?

The `BIN` format can be used to install credentials of any type, since base64 can be used to encode any concievable binary buffer. The remaining three formats are provided for convenience in special use-cases.

For example:

- To install printable pre-shared-keys, use `STR` to enter the PSK without first encoding it. This ensures it is stored without a NULL terminator.
- To install DER-formatted X.509 certificates (or other raw-binary credentials, such as non-printable PSKs) base64-encode the binary and use the `BIN` format.
- To install PEM-formatted X.509 certificates or certificate chains, base64 encode the full PEM string (including new-lines and `----BEGIN X ----` / `----END X----` markers), and then use the `BINT` format to make sure the stored string is NULL-terminated. This is required because Zephyr does not support multi-line strings in the shell. Otherwise, the `STRT` format could be used for this purpose without base64 encoding. It is possible to use `BIN` instead if you manually encode a NULL terminator into the base64.

Time Sensitive Networking

generic Precision Time Protocol (gPTP)

- *Overview*
- *Supported features*
- *Supported hardware*
- *Enabling the stack*
- *Static timeReceiver operation*
- *Application interfaces*
- *Testing*

- *API Reference*

Overview This gPTP stack supports the protocol and procedures as defined in the IEEE 802.1AS-2011 standard (Timing and Synchronization for Time-Sensitive Applications in Bridged Local Area Networks).

Supported features The stack handles communications and state machines defined in the IEEE 802.1AS-2011 standard. Mandatory requirements for a full-duplex point-to-point link end-point, as defined in Annex A of the standard, are supported.

The stack is in principle capable of handling communications on multiple network interfaces (also defined as "ports" in the standard) and thus act as a 802.1AS bridge. However, this mode of operation has not been validated on the Zephyr OS.

The stack can also operate as a statically configured time receiver on networks that follow the IEEE 802.1AS automotive profile, where no Announce messages are exchanged. See *Static timeReceiver operation* below.

Supported hardware Although the stack itself is hardware independent, Ethernet frame timestamping support must be enabled in ethernet drivers.

Boards supported:

- frdm_k64f
- nucleo_h743zi
- nucleo_h745zi_q
- nucleo_f767zi
- sam_e70_xplained
- native_sim (only usable for simple testing, limited capabilities due to lack of hardware clock)
- qemu_x86 (emulated, limited capabilities due to lack of hardware clock)

Enabling the stack The following configuration option must me enabled in `prj.conf` file.

- `CONFIG_NET_GPTP`

Static timeReceiver operation Networks built after the IEEE 802.1AS automotive profile (AVnu "Automotive Ethernet AVB Functional and Interoperability Specification") use static port roles instead of the Best Master Clock Algorithm. A bridge on such a network transmits Sync and Follow_Up messages but no Announce messages, and is not required to answer Pdelay requests on its timeTransmitter ports. The default stack cannot synchronize to such a bridge: without a received Announce a port never reaches the time receiver ("slave") role.

Enabling `CONFIG_NET_GPTP_STATIC_TIME_RECEIVER` configures the node as a statically configured time receiver: BMCA and all Announce handling are bypassed, every port is pinned to the time receiver role, asCapable is forced so synchronization does not depend on the Pdelay measurement, and the local clock is disciplined from the received Sync and Follow_Up messages alone. The node never becomes grandmaster and never transmits Sync or Announce messages, even if `CONFIG_NET_GPTP_GM_CAPABLE` is set. This mirrors the linuxptp ptp4l automotive time receiver configuration (BMCA "noop", clientOnly, inhibit_announce, asCapable "true", ignore_source_id). The standards analog of disabling the BMCA this way is the external port configuration of IEEE 802.1AS-2020 (clause 10.3.14, derived from IEEE 1588-2019 clause 17.6.2).

Application interfaces The following Application Interfaces as defined in section 9 of the standard are available:

- `ClockSourceTime` interface (`gptp_clk_src_time_invoke()`)
- `ClockTargetPhaseDiscontinuity` interface (`gptp_register_phase_dis_cb()`)
- `ClockTargetEventCapture` interface (`gptp_event_capture()`)

Testing The stack has been informally tested using the OpenAVnu gPTP and Linux ptp4l daemons. The gPTP sample application from the Zephyr source distribution can be used for testing.

Precision Time Protocol (PTP)

- *Overview*
- *Supported features*
- *Network transmission modes*
- *Supported Management messages*
- *Timestamping notes*

- *Supported hardware*
- *Enabling the stack*
- *Testing*
- *API Reference*

Overview PTP is a network protocol implemented in the application layer, used to synchronize clocks in a computer network. It's accurate up to less than a microsecond. The stack supports the protocol and procedures as defined in the IEEE 1588-2019 standard (IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems). It has multiple profiles, and can be implemented on top of L2 (Ethernet) or L3 (UDP/IPv4 or UDP/IPv6). Its accuracy is achieved by using hardware timestamping of the protocol packets.

Zephyr's implementation of PTP stack consist following items:

- PTP stack thread that handles incoming messages and events
- Integration with ptp_clock driver
- PTP stack initialization executed during system init

The implementation automatically creates PTP Ports (each PTP Port corresponds to unique interface).

Supported features Implementation of the stack doesn't support all features specified in the standard. In the table below all supported features are listed.

Table 13: Supported features

Feature	Supported
Ordinary Clock	yes
Boundary Clock	yes
Transparent Clock	
Management Node	
End to end delay mechanism	yes
Peer to peer delay mechanism	yes (two-step)
Multicast operation mode	yes
Hybrid operation mode	yes
Unicast operation mode	
Non-volatile storage	
UDP IPv4 transport protocol	yes
UDP IPv6 transport protocol	yes
IEEE 802.3 (Ethernet) transport protocol	yes
Hardware timestamping	yes
Software timestamping	
TIME_RECEIVER_ONLY PTP Instance	yes
TIME_TRANSMITTER_ONLY PTP Instance	

Network transmission modes The network transmission mode is selected with the `PTP_NETWORK_MODE` Kconfig choice:

- Multicast mode (`CONFIG_PTP_NETWORK_MODE_MULTICAST`, the default) is the standard PTP mode whereby all PTP messages are sent to the default multicast addresses. The implication is that every node receives the `Delay_Req` and `Delay_Resp` message pairs of all other nodes, thereby increasing the amount of traffic on the network. This is usually not a problem on smaller networks employing only a few timeReceivers.

- Hybrid mode (CONFIG_PTP_NETWORK_MODE_HYBRID) still sends Announce, Sync and Follow_Up messages to the default multicast addresses, but a timeReceiver sends its Delay_Req messages as unicast directly to the protocol address (IP address, or MAC address for the IEEE 802.3 transport) of the current timeTransmitter, which in turn responds with a unicast Delay_Resp to the requesting timeReceiver. This reduces the level of PTP traffic on the network, which can be a factor when scaling to larger networks employing many timeReceivers. Hybrid mode only requires the network to support multicast transmission from the timeTransmitter to the timeReceivers. The mode is compatible with the hybrid_e2e option of linuxptp and the hybrid network mode of sfptpd; unicast negotiation is not supported.

  If the timeTransmitter fails to answer CONFIG_PTP_HYBRID_FALLBACK_ATTEMPTS consecutive unicast Delay_Req messages, the PTP Port logs an error, reverts to multicast delay measurement and stays in multicast until a new timeTransmitter is selected. The fallback can be disabled with CONFIG_PTP_NETWORK_MODE_HYBRID_NO_FALLBACK, in which case the port always keeps sending unicast Delay_Req messages.

  Hybrid mode requires the End-to-End delay mechanism (CONFIG_PTP_DELAY_MECHANISM_E2E) and is supported on all transport protocols (UDP IPv4, UDP IPv6 and IEEE 802.3).

Supported Management messages Based on Table 59 from section 15.5.2.3 of the IEEE 1588-2019 following management TLVs are supported:

Table 14: Supported management message's IDs

Management_ID	Management_ID name	Allowed actions
0x0000	NULL_PTP_MANAGEMENT	GET SET COMMAND

Timestamping notes When RX hardware timestamps are unavailable or invalid, synchronization falls back to reading PHC time during receive processing. This can introduce additional jitter from software handling latency (packet path and scheduling) between frame arrival and PHC read.

This behavior is expected for L2 AF_PACKET paths without true driver-provided RX hardware timestamps.

For IEEE 802.3 transport, Sync is sent in two-step mode and Follow_Up is generated from TX timestamp callbacks. If a TX timestamp is missing or late, the stack logs a warning and skips Follow_Up for that Sync sequence, then continues normal Sync transmission on subsequent intervals (best-effort behavior).

Peer-to-peer delay measurement can be selected with `CONFIG_PTP_DELAY_MECHANISM_P2P`. The first supported P2P mode is two-step `Pdelay_Req` / `Pdelay_Resp` / `Pdelay_Resp_Follow_Up`. One-step `Pdelay_Resp` samples are rejected and logged for a later implementation.

Supported hardware Although the stack itself is hardware independent, Ethernet frame timestamping support must be enabled in ethernet drivers.

Boards supported:

- nucleo_h563zi
- nucleo_h743zi
- nucleo_h745zi_q
- nucleo_f767zi
- frdm_mcxn947
- native_sim (only usable for simple testing, limited capabilities due to lack of hardware clock)

Enabling the stack The following configuration option must me enabled in `prj.conf` file.

- `CONFIG_PTP`

Testing The stack has been informally tested using the Linux ptp4l daemons. It has also been tested with the nucleo_h563zi and frdm_mcxn947 board against a GPS clock, both with a direct Ethernet connection and with a PTP-capable switch in between. All tests were performed using the PTP sample application, with UDP IPv4, UDP IPv6, and IEEE 802.3 transport.

The following table summarizes the informal test matrix:

	IEEE 802.3	UDP IPv4	UDP IPv6
ptp4l daemons	yes	yes	yes
GPS Clock (direct link)	yes	yes	yes
PTP-capable switch	yes	yes	yes
GPS Clock + PTP-capable switch	yes	yes	yes

Peer-to-peer delay measurement is implemented and validated for ordinary-clock use. Boundary-clock operation is expected to share the same port-level Pdelay machinery but has not yet been validated on multi-port hardware.

The PTP sample application from the Zephyr source distribution can be used for testing.

zperf: Network Traffic Generator

- *Overview*
- *Sample Usage*
- *iperf3*
- *Session Management*
- *Custom Data Upload*
- *Raw TX Mode*

Overview zperf is a shell utility which allows to generate network traffic in Zephyr. The tool may be used to evaluate network bandwidth.

zperf is compatible with iPerf 2.0.10 and newer. For compatibility with older versions, enable `CONFIG_NET_ZPERF_LEGACY_HEADER_COMPAT`. Alternatively, zperf can speak iperf3, see *iperf3*. A build speaks one of the two.

zperf can be enabled in any application, a dedicated sample is also present in Zephyr. See zperf sample application for details.

Sample Usage If Zephyr acts as a client, iPerf must be executed in server mode. For example, the following command line must be used for UDP testing:

```
$ iperf -s -l 1K -u -V -B 2001:db8::2
```

For TCP testing, the command line would look like this:

```
$ iperf -s -l 1K -V -B 2001:db8::2
```

In the Zephyr console, zperf can be executed as follows:

```
zperf udp upload 2001:db8::2 5001 10 1K 1M
```

A UDP baud rate of `0` sends as fast as possible, the same as `iperf -b 0`.

For TCP the zperf command would look like this:

```
zperf tcp upload 2001:db8::2 5001 10 1K 1M
```

If the IP addresses of Zephyr and the host machine are specified in the config file, zperf can be started as follows:

```
zperf udp upload2 v6 10 1K 1M
```

or like this if you want to test TCP:

```
zperf tcp upload2 v6 10 1K 1M
```

If Zephyr is acting as a server, set the download mode as follows for UDP:

```
zperf udp download 5001
```

or like this for TCP:

```
zperf tcp download 5001
```

and in the host side, iPerf must be executed with the following command line if you are testing UDP:

```
$ iperf -l 1K -u -V -c 2001:db8::1 -p 5001
```

and this if you are testing TCP:

```
$ iperf -l 1K -V -c 2001:db8::1 -p 5001
```

iPerf output can be limited by using the -b option if Zephyr is not able to receive all the packets in orderly manner.

iperf3 With `CONFIG_NET_ZPERF_IPERF3`, zperf interoperates with iperf3 instead of iPerf 2. The support is experimental. The zperf API and shell commands stay the same, and the default port becomes 5201, the iperf3 default.

When Zephyr acts as a server, enable the protocols to accept:

```
zperf tcp download
zperf udp download
```

An iperf3 client chooses TCP or UDP for each test and uses one port for both, with a TCP control connection either way. The two commands therefore share the listening port: each enables its own protocol, and a test asking for one that is not enabled is refused. On the host:

```
$ iperf3 -c 2001:db8::1
$ iperf3 -c 2001:db8::1 -u -b 10M
```

When Zephyr acts as a client, run `iperf3 -s` on the host, and in the Zephyr console:

```
zperf tcp upload 2001:db8::2 5201 10 1K
zperf udp upload 2001:db8::2 5201 10 1K 10M
```

A test runs over a single stream. Reverse (`-R`), bidirectional (`--bidir`) and parallel (`-P`) tests, and omitting the start of a test (`-O`), are refused with the message iperf3 prints for an option the server does not implement. One test runs at a time, and a second client is told that the server is busy. Multicast and `CONFIG_ZPERF_SESSION_PER_THREAD` are iPerf 2 features.

Points to keep in mind when comparing with iPerf 2:

- An iperf3 server counts TCP data until the client ends the test on the control connection, which can overtake the last of the data, so it may report slightly less than the client sent. An iPerf 2 server counts until the connection closes.
- For UDP, datagrams lost after the last one the server received are counted as lost in the zperf upload report, as with iPerf 2. iperf3 itself leaves them out.
- iperf3 does not report reordering, so an upload reports no out-of-order packets.
- The server reads only the header of each UDP datagram, relying on `ZSOCK_MSG_TRUNC` to learn its full length. A socket offload driver that ignores the flag makes it count too few bytes.
- A test takes a control connection and a data stream on each end, and closed connections linger in TIME_WAIT for a while after each test. Allow for them in `CONFIG_NET_MAX_CONTEXTS` and `CONFIG_NET_MAX_CONN`, as the sample's `overlay-iperf3.conf` does.

Session Management If `CONFIG_ZPERF_SESSION_PER_THREAD` option is set, then multiple upload sessions can be done at the same time if user supplies `-a` option when starting the upload. Each session will have their own work queue to run the test. The session test results can be viewed also after the tests have finished. The sessions can be started with `-w` option which then lets the worker threads to wait a start signal so that all the threads can be started at the same time. This will prevent the case where the zperf shell cannot run because it is running in lower priority than the already started session thread. If you have only one upload session, then the `-w` is not really needed.

Following zperf shell commands are available for session management:

zperf shell command	Description
`jobs`	Show currently active or finished sessions
`jobs all`	Show statistics of finished sessions
`jobs clear`	Clear finished session statistics
`jobs start`	Start all the waiting sessions

Example:

```
uart:~$ zperf udp upload -a -t 5 192.0.2.2 5001 10 1K 1M
Remote port is 5001
Connecting to 192.0.2.2
Duration:       10.00 s
Packet size:    1000 bytes
Rate:           1000 kbps
Starting...
```

(continues on next page)

(continued from previous page)

```
Rate:           1.00 Mbps
Packet duration 7 ms

uart:~$ zperf jobs all

```

Custom Data Upload zperf supports more advanced data upload profiling by setting a custom data source through `zperf_upload_params.data_loader`. This enables the generation of custom packet contents instead of sending a constant packet consisting solely of the `z` character. An example use case would be determining the maximum throughput of uploading data from an external flash memory chip.

Raw TX Mode zperf supports raw packet transmission mode for testing custom L2 frames or vendor-specific protocols. This mode bypasses UDP/TCP and sends raw packets directly using packet sockets.

To enable raw TX mode, set the following Kconfig options:

```
CONFIG_NET_SOCKETS_PACKET=y
CONFIG_NET_ZPERF_RAW_TX=y
```

The maximum header size can be configured with `CONFIG_NET_ZPERF_RAW_TX_MAX_HDR_SIZE` (default: 64 bytes).

Before using raw TX mode, TX injection mode must be enabled on the network interface:

```
uart:~$ net iface txinjection 1 on
```

The raw TX upload command syntax is:

```
zperf raw upload [-a] <if_index> <header_hex> [<duration_sec>] [<packet_size>]␣
↪[<rate_kbps>]
```

Where:

- `-a`: Optional async mode flag
- `if_index`: Network interface index (e.g., 1)
- `header_hex`: User-provided header as hex string (vendor metadata + frame header)
- `duration_sec`: Test duration in seconds (default: 1)
- `packet_size`: Total packet size including header (default: 256)
- `rate_kbps`: Target rate in Kbps, supports K/M suffixes (default: 10). `0` sends as fast as possible.

Example for sending raw 802.11 frames with vendor metadata:

```
uart:~$ zperf raw upload 1␣
↪12345678000400030000000088000000ffffffffffa06960e35215a06960e3521500000000aaaa030000000800␣
↪10 1024 50M
```

The header hex string contains:

- Vendor metadata (first 12 bytes in this example)
- 802.11 QoS Data header with LLC/SNAP

The payload (filled with `z` characters) is automatically appended to reach the specified packet size.

Connection Manager

Overview Connection Manager is a collection of optional Zephyr features that aim to allow applications to monitor and control connectivity (access to IP-capable networks) with minimal concern for the specifics of underlying network technologies.

Using Connection Manager, applications can use a single abstract API to control network association and monitor Internet access, and avoid excessive use of technology-specific boilerplate.

This allows an application to potentially support several very different connectivity technologies (for example, Wi-Fi and LTE) with a single codebase.

Applications can also use Connection Manager to generically manage and use multiple connectivity technologies simultaneously.

Structure Connection Manager is split into the following two subsystems:

- *Connectivity monitoring* (header file `include/zephyr/net/conn_mgr_monitoring.h`) monitors all available *Zephyr network interfaces (ifaces)* and triggers *network management* events indicating when IP connectivity is gained or lost.
- *Connectivity control* (header file `include/zephyr/net/conn_mgr_connectivity.h`) provides an abstract API for controlling iface network association.

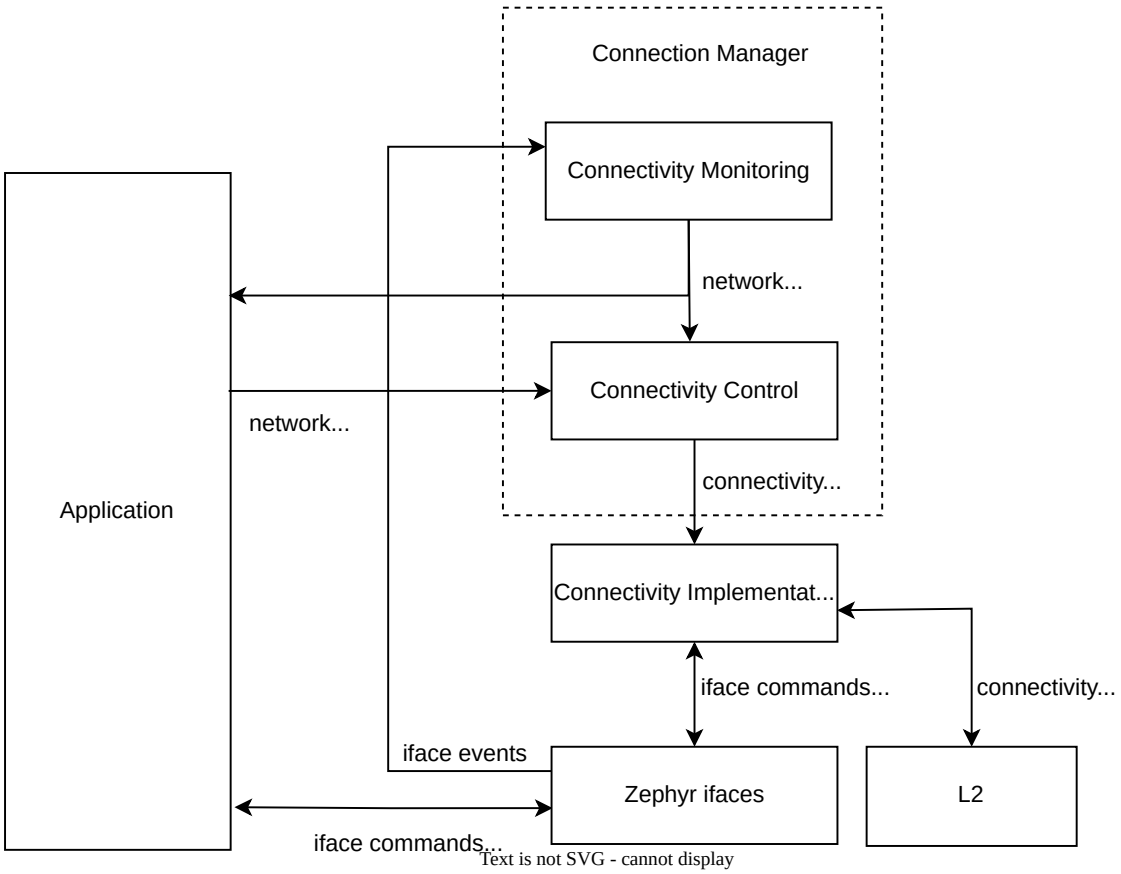

Fig. 10: A simplified view of how Connection Manager integrates with Zephyr and the application.

See *here* for a more detailed version.

Connectivity monitoring Connectivity monitoring tracks all available ifaces (whether or not they support *Connectivity control*) as they transition through various *operational states* and acquire or lose assigned IP addresses.

Each available iface is considered ready if it meets the following criteria:

- The iface is admin-up
  - This means the iface has been instructed to become operational-up (ready for use). This is done by a call to `net_if_up()`.
- The iface is oper-up
  - This means the interface is completely ready for use; It is online, and if applicable, has associated with a network.
  - See *Network interface state management* for details.
- The iface has at least one assigned IP address
  - Both IPv4 and IPv6 addresses are acceptable. This condition is met as soon as one or both of these is assigned.

  - See *Network Interface* for details on iface IP assignment.
- The iface has not been ignored
  - Ignored ifaces are always treated as unready.
  - See *Ignoring ifaces* for more details.

> **Note**
>
> Typically, iface state and IP assignment are updated either by the iface's *L2 implementation* or bound *connectivity implementation*.
>
> See *Implement iface state reporting* for details.

A ready iface ceases to be ready the moment any of the above conditions is lost.

When at least one iface is ready, the `NET_EVENT_L4_CONNECTED` *network management* event is triggered, and IP connectivity is said to be ready.

Afterwards, ifaces can become ready or unready without firing additional events, so long as there always remains at least one ready iface.

When there are no longer any ready ifaces left, the `NET_EVENT_L4_DISCONNECTED` *network management* event is triggered, and IP connectivity is said to be unready.

> **Note**
>
> Connection Manager also fires the following more specific `CONNECTED` / `DISCONNECTED` events:
>
> - `NET_EVENT_L4_IPV4_CONNECTED`
> - `NET_EVENT_L4_IPV4_DISCONNECTED`
> - `NET_EVENT_L4_IPV6_CONNECTED`
> - `NET_EVENT_L4_IPV6_DISCONNECTED`
>
> These are similar to `NET_EVENT_L4_CONNECTED` and `NET_EVENT_L4_DISCONNECTED`, but specifically track whether IPv4- and IPv6-capable ifaces are ready.

Usage Connectivity monitoring is enabled if the `CONFIG_NET_CONNECTION_MANAGER` Kconfig option is enabled.

To receive connectivity updates, create and register a listener for the `NET_EVENT_L4_CONNECTED` and `NET_EVENT_L4_DISCONNECTED` *network management* events:

```
/* Callback struct where the callback will be stored */
struct net_mgmt_event_callback l4_callback;

/* Callback handler */
static void l4_event_handler(struct net_mgmt_event_callback *cb,
                             uint32_t event, struct net_if *iface)
{
        if (event == NET_EVENT_L4_CONNECTED) {
                LOG_INF("Network connectivity gained!");
        } else if (event == NET_EVENT_L4_DISCONNECTED) {
                LOG_INF("Network connectivity lost!");
        }

        /* Otherwise, it's some other event type we didn't register for. */
```

(continues on next page)

(continued from previous page)

```
}

/* Call this before Connection Manager monitoring initializes */
static void my_application_setup(void)
{
        /* Configure the callback struct to respond to (at least) the L4_CONNECTED
         * and L4_DISCONNECTED events.
         *
         *
         * Note that the callback may also be triggered for events other than␣
↪those specified here!
         * (See the net_mgmt documentation)
         */
        net_mgmt_init_event_callback(
                &l4_callback, l4_event_handler,
                NET_EVENT_L4_CONNECTED | NET_EVENT_L4_DISCONNECTED
        );

        /* Register the callback */
        net_mgmt_add_event_callback(&l4_callback);
}
```

You can also use NET_MGMT_REGISTER_EVENT_HANDLER to register your callback handler at compile time, instead of at runtime. That way, you can ensure your callback is registered before Connection Manager monitoring initializes.

```
static void l4_event_handler(uint64_t event, struct net_if *iface, void *info,
                             size_t info_length, void *user_data)
{
        if (event == NET_EVENT_L4_CONNECTED) {
                LOG_INF("Network connectivity gained!");
        } else if (event == NET_EVENT_L4_DISCONNECTED) {
                LOG_INF("Network connectivity lost!");
        }

        /* Otherwise, it's some other event type we didn't register for. */
}

NET_MGMT_REGISTER_EVENT_HANDLER(l4_callback, l4_event_handler,
                                NET_EVENT_L4_CONNECTED |␣
↪NET_EVENT_L4_DISCONNECTED, NULL);
```

See *Listening to network events* for more details on listening for net_mgmt events.

Note

To avoid missing initial connectivity events, you should register your listener(s) before Connection Manager monitoring initializes. See *Avoiding missed notifications* for strategies to ensure this.

Avoiding missed notifications Connectivity monitoring may trigger events immediately upon initialization.

If your application registers its event listeners after connectivity monitoring initializes, it is possible to miss this first wave of events, and not be informed the first time network connectivity is gained.

If this is a concern, your application should *register its event listeners* before connectivity monitoring initializes.

Connectivity monitoring initializes using the SYS_INIT APPLICATION initialization priority specified by the CONFIG_NET_CONNECTION_MANAGER_MONITOR_PRIORITY Kconfig option.

You can register your callbacks before this initialization by using SYS_INIT with an earlier initialization priority than this value, for instance priority 0:

```
static int my_application_setup(void)
{
        /* Register callbacks here */
        return 0;
}

SYS_INIT(my_application_setup, APPLICATION, 0);
```

If this is not feasible, you can instead request that connectivity monitoring resend the latest connectivity events at any time by calling conn_mgr_mon_resend_status():

```
static void my_late_application_setup(void)
{
  /* Register callbacks here */

  /* Once done, request that events be re-triggered */
  conn_mgr_mon_resend_status();
}
```

Ignoring ifaces Applications can request that ifaces be ignored by Connection Manager by calling conn_mgr_ignore_iface() with the iface to be ignored.

Alternatively, an entire *L2 implementation* can be ignored by calling conn_mgr_ignore_l2().

This has the effect of individually ignoring all the ifaces using that *L2 implementation*.

While ignored, the iface is treated by Connection Manager as though it were unready for network traffic, no matter its actual state.

This may be useful, for instance, if your application has configured one or more ifaces that cannot (or for whatever reason should not) be used to contact the wider Internet.

Bulk convenience functions optionally skip ignored ifaces.

See conn_mgr_ignore_iface() and conn_mgr_watch_iface() for more details.

Connectivity monitoring API Include header file include/zephyr/net/conn_mgr_monitoring.h to access these.

Connection Manager API

Connectivity control Many network interfaces require a network association procedure to be completed before being usable.

For such ifaces, connectivity control can provide a generic API to request network association (conn_mgr_if_connect()) and disassociation (conn_mgr_if_disconnect()). Network interfaces implement support for this API by *binding themselves to a connectivity implementation*.

Using this API, applications can associate with networks with minimal technology-specific boilerplate.

Connectivity control also provides the following additional features:

- Standardized *persistence and timeout* behaviors during association.

- *Bulk functions* for controlling the admin state and network association of all available ifaces simultaneously.
- Optional *convenience automations* for common connectivity actions.

Basic operation The following sections outline the basic operation of Connection Manager's connectivity control.

Binding Before an iface can be commanded to associate or disassociate using Connection Manager, it must first be bound to a *connectivity implementation*. Binding is performed by the provider of the iface, not by the application (see *Binding an iface to an implementation*), and can be thought of as an extension of the iface declaration.

Once an iface is bound, all connectivity commands passed to it (such as `conn_mgr_if_connect()` or `conn_mgr_if_disconnect()`) will be routed to the corresponding implementation function in the connectivity implementation.

> **Note**
>
> To avoid inconsistent behavior, all connectivity implementations must adhere to the *implementation guidelines*.

Connecting Once a bound iface is admin-up (see *Network interface state management*), `conn_mgr_if_connect()` can be called to cause it to associate with a network.

If association succeeds, the connectivity implementation will mark the iface as operational-up (see *Network interface state management*).

If association fails unrecoverably, the *fatal error event* will be triggered.

You can configure an optional *timeout* for this process.

> **Note**
>
> The `conn_mgr_if_connect()` function is intentionally minimalistic, and does not take any kind of configuration. Each connectivity implementation should provide a way to pre-configure or automatically configure any required association settings or credentials. See *Allow connectivity pre-configuration* for details.

Connection loss If connectivity is lost due to external factors, the connectivity implementation will mark the iface as operational-down.

Depending on whether *persistence* is set, the iface may then attempt to reconnect.

Manual disconnection The application can also request that connectivity be intentionally abandoned by calling `conn_mgr_if_disconnect()`.

In this case, the connectivity implementation will disassociate the iface from its network and mark the iface as operational-down (see *Network interface state management*). A new connection attempt will not be initiated, regardless of whether persistence is enabled.

Timeouts and Persistence Connection Manager requires that all connectivity implementations support the following standard key features:

- *Connection timeouts*
- *Connection persistence*

These features describe how ifaces should behave during connect and disconnect events. You can individually set them for each iface.

Note

It is left to connectivity implementations to successfully and accurately implement these two features as described below. See *Implementing timeouts and persistence* for more details from the connectivity implementation perspective.

The Connection Manager also implements the following optional feature:

- *Interface idle timeouts*

Note

The only requirement on the connectivity implementation to implement idle timeouts is to call `conn_mgr_if_used()` each time the interface is used.

Connection Timeouts When `conn_mgr_if_connect()` is called on an iface, a connection attempt begins.

The connection attempt continues indefinitely until it succeeds, unless a timeout has been specified for the iface (using `conn_mgr_if_set_timeout()`).

In that case, the connection attempt will be abandoned if the timeout elapses before it succeeds. If this happens, the *timeout event* is raised.

Interface Idle Timeout The connection manager enables users to apply an inactivity timeout on an interface (`conn_mgr_if_set_idle_timeout()`). Once connected, if the interface goes for the configured number of seconds without any activity, the interface is automatically disconnected. If this happens, the *idle timeout event* is raised. An idle timeout is considered an unintentional connection loss for the purposes of *Connection persistence*.

Connection Persistence Each iface also has a connection persistence setting that you can enable or disable by setting the `CONN_MGR_IF_PERSISTENT` flag with `conn_mgr_binding_set_flag()`.

This setting specifies how the iface should handle unintentional connection loss.

If persistence is enabled, any unintentional connection loss will initiate a new connection attempt, with a new timeout if applicable.

Otherwise, the iface will not attempt to reconnect.

Note

Persistence not does affect connection attempt behavior. Only the timeout setting affects this.

For instance, if a connection attempt on an iface times out, the iface will not attempt to reconnect, even if it is persistent.

Conversely, if there is not a specified timeout, the iface will try to connect forever until it succeeds, even if it is not persistent.

See *Persistence during connection attempts* for the equivalent implementation guideline.

Control events Connectivity control triggers *network management* events to inform the application of important state changes.

See *Trigger connectivity control events* for the corresponding connectivity implementation guideline.

Fatal Error The NET_EVENT_CONN_IF_FATAL_ERROR event is raised when an iface encounters an error from which it cannot recover (meaning any subsequent attempts to associate are guaranteed to fail, and all such attempts should be abandoned).

Handlers of this event will be passed a pointer to the iface for which the fatal error occurred. Individual connectivity implementations may also pass an application-specific data pointer.

Timeout The NET_EVENT_CONN_IF_TIMEOUT event is raised when an *iface association* attempt *times out*.

Handlers of this event will be passed a pointer to the iface that timed out attempting to associate.

Idle Timeout The NET_EVENT_CONN_IF_IDLE_TIMEOUT event is raised when an interface is considered *inactive*.

Handlers of this event will be passed a pointer to the iface that timed out attempting to associate.

Listening for control events You can listen for control events as follows:

```
/* Declare a net_mgmt callback struct to store the callback */
struct net_mgmt_event_callback my_conn_evt_callback;

/* Declare a handler to receive control events */
static void my_conn_evt_handler(struct net_mgmt_event_callback *cb,
                                uint32_t event, struct net_if *iface)
{
        if (event == NET_EVENT_CONN_IF_TIMEOUT) {
                /* Timeout occurred, handle it */
        } else if (event == NET_EVENT_CONN_IF_FATAL_ERROR) {
                /* Fatal error occurred, handle it */
        }

        /* Otherwise, it's some other event type we didn't register for. */
}

int main()
{
        /* Configure the callback struct to respond to (at least) the␣
↪CONN_IF_TIMEOUT
         * and CONN_IF_FATAL_ERROR events.
         *
         * Note that the callback may also be triggered for events other than␣
↪those specified here!
         * (See the net_mgmt documentation)
         */

        net_mgmt_init_event_callback(
                &conn_mgr_conn_callback, conn_mgr_conn_handler,
                    NET_EVENT_CONN_IF_TIMEOUT | NET_EVENT_CONN_IF_FATAL_ERROR
        );

        /* Register the callback */
```

(continues on next page)

(continued from previous page)

```
        net_mgmt_add_event_callback(&conn_mgr_conn_callback);
        return 0;
}
```

See *Listening to network events* for more details on listening for net_mgmt events.

Automated behaviors There are a few actions related to connectivity that are (by default at least) performed automatically for the user.

Automatic admin-up

In Zephyr, ifaces are automatically taken admin-up (see *Network interface state management* for details on iface states) during initialization.

Applications can disable this behavior by setting the `NET_IF_NO_AUTO_START` interface flag with `net_if_flag_set()`.

Automatic connect

By default, Connection Manager will automatically connect any *bound* iface that becomes admin-up.

Applications can disable this by setting the `CONN_MGR_IF_NO_AUTO_CONNECT` connectivity flag with `conn_mgr_if_set_flag()`.

Automatic admin-down

By default, Connection Manager will automatically take any bound iface admin-down if it has given up on associating.

Applications can disable this for all ifaces by disabling the `CONFIG_NET_CONNECTION_MANAGER_AUTO_IF_DOWN` Kconfig option, or for individual ifaces by setting the `CONN_MGR_IF_NO_AUTO_DOWN` connectivity flag with `conn_mgr_if_set_flag()`.

Connectivity control API Include header file `include/zephyr/net/conn_mgr_connectivity.h` to access these.

Connection Manager Connectivity API

Bulk API Connectivity control provides several bulk functions allowing all ifaces to be controlled at once.

You can restrict these functions to operate only on non-*ignored* ifaces if desired.

Include header file `include/zephyr/net/conn_mgr_connectivity.h` to access these.

Connection Manager Connectivity Bulk API

Connectivity Implementations

Overview Connectivity implementations are technology-specific modules that allow specific Zephyr ifaces to support *Connectivity Control*. They are responsible for translating generic *connectivity control API* calls into hardware-specific operations. They are also responsible for implementing standardized *persistence and timeout* behaviors.

See the *implementation guidelines* for details on writing conformant connectivity implementations.

Architecture The *implementation API* allows connectivity implementations to be *defined* at build time using `CONN_MGR_CONN_DEFINE`.

This creates a static instance of the `conn_mgr_conn_impl` struct, which then stores a reference to the passed in `conn_mgr_conn_api` struct (which should be populated with implementation callbacks).

Once defined, you can reference implementations by name and bind them to any unbound iface using `CONN_MGR_BIND_CONN`. Make sure not to accidentally bind two connectivity implementations to a single iface.

Once the iface is bound, *connectivity control API* functions can be called on the iface, and they will be translated to the corresponding implementation functions in `conn_mgr_conn_api`.

Binding an iface does not directly modify its `iface struct`.

Instead, an instance of `conn_mgr_conn_binding` is created and appended an internal *iterable section*.

This binding structure will contain a reference to the bound iface, the connectivity implementation it is bound to, as well as a pointer to a per-iface *context pointer*.

This iterable section can then be iterated over to find out what (if any) connectivity implementation has been bound to a given iface. This search process is used by most of the functions in the *connectivity control API*. As such, these functions should be called sparingly, due to their relatively high search cost.

A single connectivity implementation may be bound to multiple ifaces. See *Do not instance implementations* for more details.

Context Pointer Since a single connectivity implementation may be shared by several Zephyr ifaces, each binding instantiates a context container (of *configurable type*) unique to that binding. Each binding is then instantiated with a reference to that container, which implementations can then use to access per-iface state information.

See also *Do not access bindings without locking them* and *Do not instance implementations*.

Defining an implementation A connectivity implementation may be defined as follows:

```
/* Create the API implementation functions */
int my_connect_impl(struct conn_mgr_conn_binding *const binding) {
        /* Cause your underlying technology to associate */
}
int my_disconnect_impl(struct conn_mgr_conn_binding *const binding) {
        /* Cause your underlying technology to disassociate */
}
void my_init_impl(struct conn_mgr_conn_binding *const binding) {
        /* Perform any required initialization for your underlying technology */
}

/* Declare the API struct */
static struct conn_mgr_conn_api my_impl_api = {
        .connect = my_connect_impl,
        .disconnect = my_disconnect_impl,
        .init = my_init_impl,
        /* ... so on */
};
```

(continues on next page)

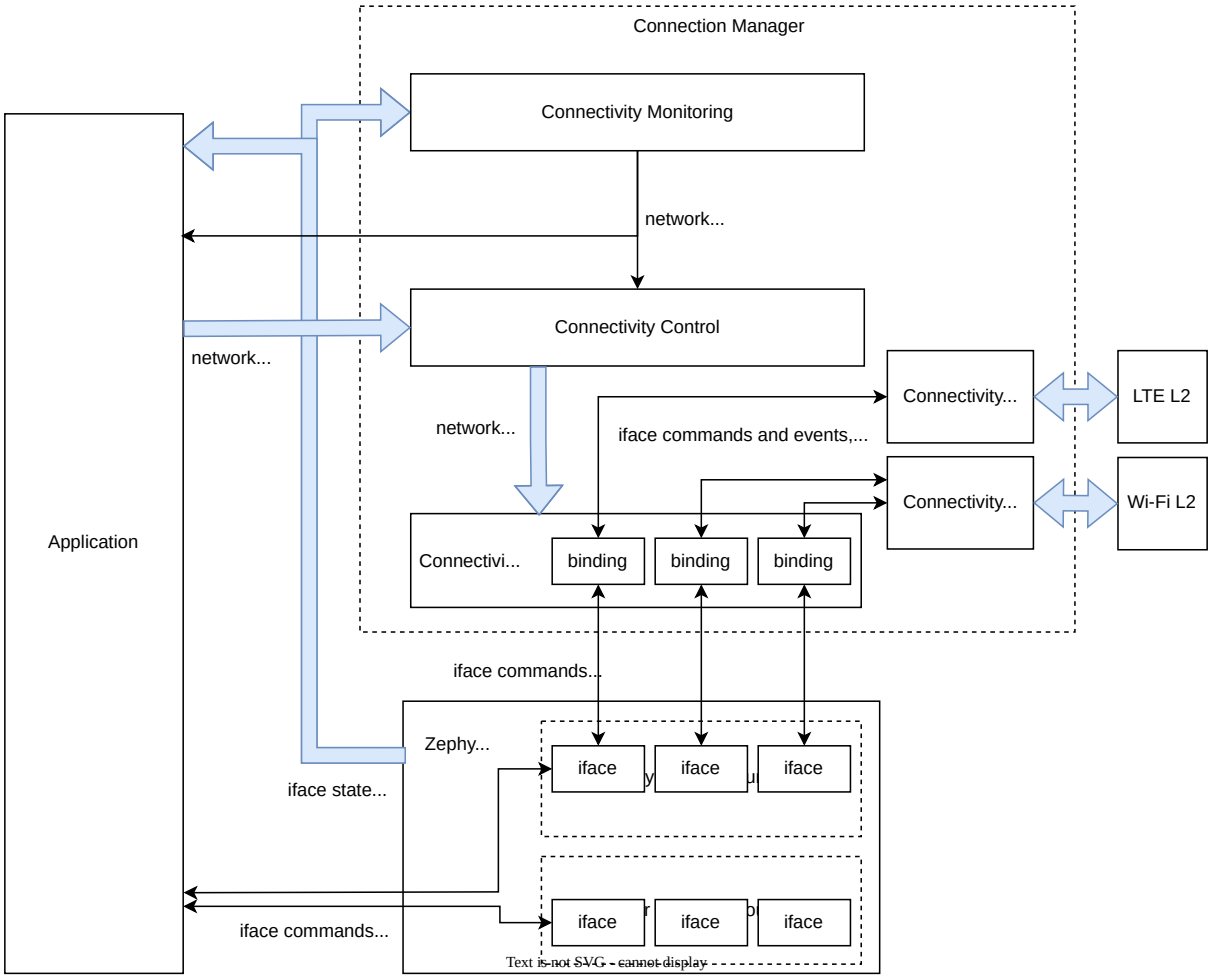

Fig. 11: A detailed view of how Connection Manager integrates with Zephyr and the application.
See *here* for a simplified version.

(continued from previous page)

```
/* Define the implementation (named MY_CONNECTIVITY_IMPL) */
CONN_MGR_CONN_DEFINE(MY_CONNECTIVITY_IMPL, &my_impl_api);
```

Note

This does not work unless you also *declare the context pointer type*.

Declaring an implementation publicly Once defined, you can make a connectivity implementation available to other compilation units by declaring it (in a header file) as follows:

Listing 8: `my_connectivity_header.h`

```
CONN_MGR_CONN_DECLARE_PUBLIC(MY_CONNECTIVITY_IMPL);
```

The header file that contains this declaration must be included in any compilation units that need to reference the implementation.

Declaring a context type For `CONN_MGR_CONN_DEFINE` to work, you must declare a corresponding context pointer type. This is because all connectivity bindings contain a *Context Pointer* of their associated context pointer type.

If you are using `CONN_MGR_CONN_DECLARE_PUBLIC`, declare this type alongside the declaration:

Listing 9: `my_connectivity_impl.h`

```
#define MY_CONNECTIVITY_IMPL_CTX_TYPE struct my_context_type *
CONN_MGR_CONN_DECLARE_PUBLIC(MY_CONNECTIVITY_IMPL);
```

Then, make sure to include the header file before calling `CONN_MGR_CONN_DEFINE`:

Listing 10: `my_connectivity_impl.c`

```
#include "my_connectivity_impl.h"

CONN_MGR_CONN_DEFINE(MY_CONNECTIVITY_IMPL, &my_impl_api);
```

Otherwise, it is sufficient to simply declare the context pointer type immediately before the call to `CONN_MGR_CONN_DEFINE`:

```
#define MY_CONNECTIVITY_IMPL_CTX_TYPE struct my_context_type *
CONN_MGR_CONN_DEFINE(MY_CONNECTIVITY_IMPL, &my_impl_api);
```

Note

Naming is important. Your context pointer type declaration must use the same name as your implementation declaration, but with `_CTX_TYPE` appended.

In the previous example, the context type is named `MY_CONNECTIVITY_IMPL_CTX_TYPE`, because `MY_CONNECTIVITY_IMPL` was used as the connectivity implementation name.

If your connectivity implementation does not need a context pointer, simply declare the type as void:

```
#define MY_CONNECTIVITY_IMPL_CTX_TYPE void *
```

Binding an iface to an implementation A defined connectivity implementation may be bound to an iface by calling `CONN_MGR_BIND_CONN` anywhere after the iface's device definition:

```
/* Define an iface */
NET_DEVICE_INIT(my_iface,
        /* ... the specifics here don't matter ... */
);

/* Now bind MY_CONNECTIVITY_IMPL to that iface --
 * the name used should match with the above
 */
CONN_MGR_BIND_CONN(my_iface, MY_CONNECTIVITY_IMPL);
```

Connectivity implementation guidelines Rather than implement all features centrally, Connection Manager relies on each connectivity implementation to implement many behaviors and features individually.

This approach allows Connection Manager to remain lean, and allows each connectivity implementation to choose the most appropriate approach to these behaviors for itself. However, it relies on trust that all connectivity implementations will faithfully implement the features that have been delegated to them.

To maintain consistency between all connectivity implementations, observe the following guidelines when writing your own implementation:

Completely implement timeout and persistence All connectivity implementations must offer complete support for *timeout and persistence*, such that a user can disable or enable these features, regardless of the inherent behavior of the underlying technology. In other words, no matter how the underlying technology behaves, your implementation must make it appear to the end user to behave exactly as specified in the *Timeouts and Persistence* section.

See *Implementing timeouts and persistence* for a detailed technical discussion on implementing timeouts and persistence.

Conform to API specifications Each `implementation API function` you implement should behave as-described in the corresponding connectivity control API function.

For example, your implementation of `conn_mgr_conn_api.connect` should conform to the behavior described for `conn_mgr_if_connect()`.

Allow connectivity pre-configuration Connectivity implementations should provide means for applications to pre-configure all necessary connection parameters (for example, network SSID, or PSK, if applicable), before the call to `conn_mgr_if_connect()`. It should not be necessary to provide this information as part of, or following the `conn_mgr_if_connect()` call, although implementations *should await this information if it is not provided*.

Await valid connectivity configuration If network association fails because the application pre-configured invalid connection parameters, or did not configure connection parameters at all, this should be treated as a network failure.

In other words, the connectivity implementation should not give up on the connection attempt, even if valid connection parameters have not been configured.

Instead, the connectivity implementation should asynchronously wait for valid connection parameters to be configured, either indefinitely, or until the configured *connectivity timeout* elapses.

An exception to this is if the network interface has been configured as non-persistent and the connectivity implementation defines an implementation for `conn_mgr_conn_api.has_connection_config`.

In this case, to reduce power consumption and prevent unnecessary state transitions, `conn_mgr_if_connect()` will exit early without bringing the interface up if `conn_mgr_conn_api.has_connection_config` returns `false`. The `NET_EVENT_CONN_IF_NO_CONFIGURATION` event will be emitted to notify subscribers of the misconfiguration.

Implement iface state reporting All connectivity implementations must keep bound iface state up to date.

To be specific:

- Set the iface to dormant, carrier-down, or both during `binding init`.
  - See *Network interface state management* for details regarding iface carrier and dormant states.
- Update dormancy and carrier state so that the iface is non-dormant and carrier-up whenever (and only when) association is complete and connectivity is ready.
- Set the iface either to dormant or to carrier-down as soon as interruption of service is detected.
  - It is acceptable to gate this behind a small timeout (separate from the connection timeout) for network technologies where service is commonly intermittent.
- If the technology also handles IP assignment, ensure those IP addresses are *assigned to the iface*.

Note

iface state updates do not necessarily need to be performed directly by connectivity implementations.

For instance:

- IP assignment is not necessary if *DHCP* is used for the iface.
- The connectivity implementation does not need to update iface dormancy if the underlying *L2 implementation* already does so.

Do not use iface state as implementation state Zephyr ifaces may be accessed from other threads without respecting the binding mutex. As such, Zephyr iface state may change unpredictably during connectivity implementation callbacks.

Therefore, do not base implementation behaviors on iface state.

Keep iface state updated to reflect network availability, but do not read iface state for any purpose.

If you need to keep track of dormancy or IP assignment, use a separate state variable stored in the *context pointer*.

Remain non-interferent Connectivity implementations should not prevent applications from interacting directly with associated technology-specific APIs.

In other words, it should be possible for an application to directly use your underlying technology without breaking your connectivity implementation.

If exceptions to this are absolutely necessary, they should be constrained to specific API calls and should be documented.

Note

While connectivity implementations must not break, it is acceptable for implementations to have potentially unexpected behavior if applications attempt to directly control the association state.

For instance, if an application directly instructs an underlying technology to disassociate, it would be acceptable for the connectivity implementation to interpret this as an unexpected connection loss and immediately attempt to re-associate.

Remain non-blocking All connectivity implementation callbacks should be non-blocking.

For instance, calls to `conn_mgr_conn_api.connect` should initiate a connection process and return immediately.

One exception is `conn_mgr_conn_api.init`, whose implementations are permitted to block.

However, bear in mind that blocking during this callback will delay system init, so still consider offloading time-consuming tasks to a background thread.

Make API immediately ready Connectivity implementations must be ready to receive API calls immediately after `conn_mgr_conn_api.init`.

For instance, a call to `conn_mgr_conn_api.connect` must eventually lead to an association attempt, even if called immediately after `conn_mgr_conn_api.init`.

If the underlying technology cannot be made ready for connect commands immediately when `conn_mgr_conn_api.init` is called, calls to `conn_mgr_conn_api.connect` must be queued in a non-blocking fashion, and then executed later when ready.

Do not store state information outside the context pointer Connection Manager provides a context pointer to each binding.

Connectivity implementations should store all state information in this context pointer.

The only exception is connectivity implementations that are meant to be bound to only a single iface. Such implementations may use statically declared state instead.

See also *Do not instance implementations*.

Access ifaces only through binding structs Do not use statically declared ifaces or externally acquire references to ifaces.

For example, do not use `net_if_get_default()` under the assumption that the bound iface will be the default iface.

Instead, always use the `iface pointer` provided by the relevant `binding struct`. See also *Do not access bindings without locking them*.

Make implementations optional at compile-time Connectivity implementations should provide a Kconfig option to enable or disable the implementation without affecting bound iface availability.

In other words, it should be possible to configure builds that include Connectivity Manager, as well as the iface that would have been bound to the implementation, but not the implementation itself, nor its binding.

Do not instance implementations Do not declare a separate connectivity implementation for every iface you are going to bind to.

Instead, bind one global connectivity implementation to all of your ifaces, and use the context pointer to store state relevant to individual ifaces.

See also *Do not access bindings without locking them* and *Access ifaces only through binding structs*.

Do not access bindings without locking them Bindings may be accessed and modified at random by multiple threads, so modifying or reading from a binding without first `locking it` may lead to unpredictable behavior.

This applies to all descendents of the binding, including anything in the *context container*.

Make sure to `unlock` the binding when you are done accessing it.

Note

A possible exception to this rule is if the resource in question is inherently thread-safe.

However, be careful taking advantage of this exception. It may still be possible to create a race condition, for instance when accessing multiple thread-safe resources simultaneously.

Therefore, it is recommended to simply always lock the binding, whether or not the resource being accessed is inherently thread-safe.

Do not disable built-in features Do not attempt to prevent the use of built-in features (such as *Timeouts and Persistence* or *Automated behaviors*).

All connectivity implementations must fully support these features. Implementations must not attempt to force certain features to be always enabled or always disabled.

Trigger connectivity control events Connectivity control *network management* events are not triggered automatically by Connection Manager.

Connectivity implementations must trigger these events themselves.

Trigger `NET_EVENT_CONN_CMD_IF_TIMEOUT` when a connection *timeout* occurs. See *Timeout* for details.

Trigger `NET_EVENT_CONN_IF_FATAL_ERROR` when a fatal (non-recoverable) connection error occurs. See *Fatal Error* for details.

See *Network Management* for details on firing network management events.

Implementing timeouts and persistence First, see *Timeouts and Persistence* for a high-level description of the expected behavior of timeouts and persistence.

Connectivity implementations must fully conform to that description, regardless of the behavior of the underlying connectivity technology.

Sometimes this means writing extra logic in the connectivity implementation to fake certain behaviors. The following sections discuss various common edge-cases and nuances and how to handle them.

Inherently persistent technologies If the underlying technology automatically attempts to reconnect or retry connection after connection loss or failure, the connectivity implementation must manually cancel such attempts when they are in conflict with timeout or persistence settings.

For example:

- If the underlying technology automatically attempts to reconnect after losing connection, and persistence is disabled for the iface, the connectivity implementation should immediately cancel this reconnection attempt.
- If a connection attempt times out on an iface whose underlying technology does not have a built-in timeout, the connectivity implementation must simulate a timeout by cancelling the connection attempt manually.

Technologiess that give up on connection attempts If the underlying technology has no mechanism to retry connection attempts, or would give up on them before the user-configured timeout, or would not reconnect after connection loss, the connectivity implementation must manually re-request connection to counteract these deviances.

- If your underlying technology is not persistent, you must manually trigger reconnect attempts when persistence is enabled.
- If your underlying technology does not support a timeout, you must manually cancel connection attempts if the timeout is enabled.
- If your underlying technology forces a timeout, you must manually trigger a new connection attempts if that timeout is shorter than the Connection Manager timeout.

Technologies with association retry Many underlying technologies do not usually associate in a single attempt.

Instead, these underlying technologies may need to make multiple back-to-back association attempts in a row, usually with a small delay.

In these situations, the connectivity implementation should treat this series of back-to-back association sub-attempts as a single unified connection attempt.

For instance, after a sub-attempt failure, persistence being disabled should not prevent further sub-attempts, since they all count as one single overall connection attempt. See also *Persistence during connection attempts*.

At which point a series of failed sub-attempts should be considered a failure of the connection attempt as a whole is up to each implementation to decide.

If the connection attempt crosses this threshold, but the configured timeout has not yet elapsed, or there is no timeout, sub-attempts should continue.

Persistence during connection attempts Persistence should not affect any aspect of implementation behavior during a connection attempt. Persistence should only affect whether or not connection attempts are automatically triggered after a connection loss.

The configured timeout should fully determine whether connection retry should be performed.

Implementation API Include header file `include/zephyr/net/conn_mgr_connectivity_impl.h` to access these.

Only for use by connectivity implementations.

Connection Manager Connectivity Implementation API

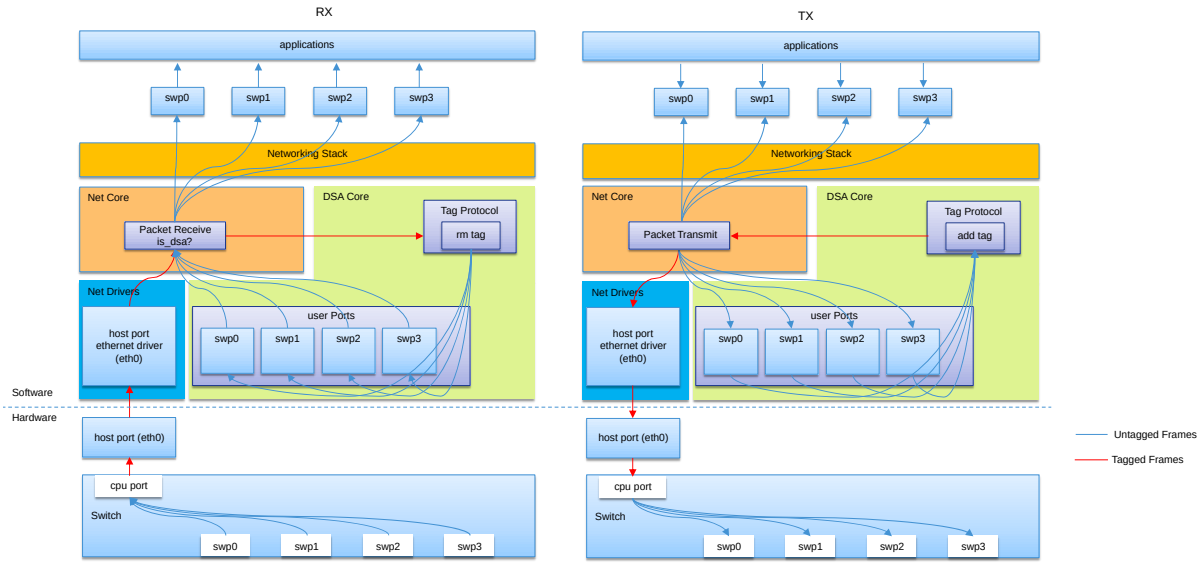
Distributed Switch Architecture (DSA)

- *DSA switch TX/RX process*
- *Host interface*

- *Switch interface*
- *Switch tagging protocols*
- *Networking stack process*
- *DSA device driver support*
- *Common pitfalls using DSA setups*
- *TODO work*

Distributed Switch Architecture (DSA) is not something new. It has been a mature subsystem in Linux for many years. This document just skips the background, terms and any knowledge related description, as user may find all of these in Linux DSA documentation.

DSA switch TX/RX process The DSA switch TX/RX process is as below.



Host interface Host interface network devices use regular and unmodified ethernet driver working as DSA conduit port, which manages the switch through processor.

Switch interface The switch interfaces are also exposed as standard ethernet interfaces in zephyr. The one connected to conduit port work as CPU port, and the others for user purpose work as user ports.

Switch tagging protocols Generally, switch tagging protocols are vendor specific. They all contain something which:

- identifies which port the Ethernet frame came from/should be sent to
- provides a reason why this frame was forwarded to the management interface

And tag on the packets to give them a switch frame header. But there are also tag-less case. It depends on the vendor.

Networking stack process In order to have the DSA subsystem process the Ethernet switch specific tagging protocol via conduit port.

For RX path, put `dsa_recv()` at beginning of `net_recv_data()` in `subsys/net/ip/net_core.c` to handle first for untagging and re-directing interface.

For TX path, the switch interfaces register as standard ethernet devices with `dsa_xmit()` as `ethernet_api->send`. The `dsa_xmit()` processes the tagging and re-directing to conduit port work.

DSA device driver support As the DSA core driver interacts with subsystems/drivers including MDIO, PHY and device tree to to support the common DSA setup and working process. The device driver support is much easy.

For device tree, the switch description should be following the `dts/bindings/dsa/dsa.yaml`.

For device driver, all needed to prepare are `dsa_api`, private data if has, and `dsa_port_config`. The macro functions could be utilized. And below is an example of i.MX NETC.

- `DSA_SWITCH_INST_INIT`
- `DSA_PORT_INST_INIT`

```
#define DSA_NETC_PORT_INST_INIT(port, n)                                        \
        COND_CODE_1(DT_NUM_PINCTRL_STATES(port),                                \
                    (PINCTRL_DT_DEFINE(port);), (EMPTY))                        \
        struct dsa_netc_port_config dsa_netc_##n##_##port##_config = {          \
             .pincfg = COND_CODE_1(DT_NUM_PINCTRL_STATES(port),                 \
                                   (PINCTRL_DT_DEV_CONFIG_GET(port)), NULL),    \
             .phy_mode = NETC_PHY_MODE(port),                                   \
        };                                                                      \
        struct dsa_port_config dsa_##n##_##port##_config = {                    \
             .mcfg = NET_ETH_MAC_DT_CONFIG_INIT(port),                          \
             .port_idx = DT_REG_ADDR(port),                                     \
             .phy_dev = DEVICE_DT_GET_OR_NULL(DT_PHANDLE(port, phy_handle)),    \
             .phy_mode = DT_PROP_OR(port, phy_connection_type, ""),             \
             .ethernet_connection = DEVICE_DT_GET_OR_NULL(DT_PHANDLE(port,
↪ethernet)),   \
             .prv_config = &dsa_netc_##n##_##port##_config,                     \
        };                                                                      \
        DSA_PORT_INST_INIT(port, n, &dsa_##n##_##port##_config)

#define DSA_NETC_DEVICE(n)                                                      \
        AT_NONCACHEABLE_SECTION_ALIGN(static netc_cmd_bd_t
```

(continues on next page)

(continued from previous page)

```
↪dsa_netc_##n##_cmd_bd[8],        \
                                    NETC_BD_ALIGN);                                ␣
↪         \
        static struct dsa_netc_data dsa_netc_data_##n = {                          ␣
↪         \
                .cmd_bd = dsa_netc_##n##_cmd_bd,                                   ␣
↪         \
        };                                                                         ␣
↪         \
        DSA_SWITCH_INST_INIT(n, &dsa_netc_api, &dsa_netc_data_##n,␣
↪DSA_NETC_PORT_INST_INIT);
```

Common pitfalls using DSA setups This is copied from Linux DSA documentation. It applies to zephyr too. Although conduit port and cpu port exposed as ethernet device in zephyr, they are not able to be used.

> **Note**
>
> Once a conduit network device is configured to use DSA (dev->dsa_ptr becomes non-NULL), and the switch behind it expects a tagging protocol, this network interface can only exclusively be used as a conduit interface. Sending packets directly through this interface (e.g.: opening a socket using this interface) will not make us go through the switch tagging protocol transmit function, so the Ethernet switch on the other end, expecting a tag will typically drop this frame.

TODO work Comparing to Linux, there are too much features to support in/based on zephyr DSA. But basically bridge layer should be supported. Then DSA could provide two options for users to use switch ports.

- Standalone mode: all user ports work as regular ethernet devices. No switching.
- Bridge mode: switch mode enabled with adding user ports into virtual bridge device. IP address could be assigned to the bridge.

4.1.2 Bluetooth

This section contains information regarding the Bluetooth stack of the Zephyr OS. You can use this information to understand the principles behind the operation of the layers and how they were implemented.

Zephyr includes a complete Bluetooth Low Energy stack from application to radio hardware, as well as portions of a Classical Bluetooth (BR/EDR) Host layer.

Supported features

Since its inception, Zephyr has had a strong focus on Bluetooth and, in particular, on Bluetooth Low Energy (LE). Through the contributions of several companies and individuals involved in existing open source implementations of the Bluetooth specification (Linux's BlueZ) as well as the design and development of Bluetooth LE radio hardware, the protocol stack in Zephyr has grown to be mature and feature-rich, as can be seen in the section below.

- Bluetooth v5.3 compliant
  - Highly configurable
    - Features, buffer sizes/counts, stack sizes, etc.

  - Portable to all architectures supported by Zephyr (including big and little endian, alignment flavors and more)
  - Support for *all combinations* of Host and Controller builds:
    * Controller-only (HCI) over UART, SPI, USB and IPC physical transports
    * Host-only over UART, SPI, and IPC (shared memory)
    * Combined (Host + Controller)
- *Bluetooth-SIG qualifiable*
  - Conformance tests run regularly on all layers (Controller and Host, except BT Classic) on Nordic Semiconductor hardware.
- *Bluetooth Low Energy Controller* (LE Link Layer)
  - Unlimited role and connection count, all roles supported
  - All v5.3 specification features supported (except a few minor items)
  - Concurrent multi-protocol support ready
  - Intelligent scheduling of roles to minimize overlap
  - Portable design to any open Bluetooth LE radio, currently supports Nordic Semiconductor nRF52x and nRF53x SoC Series, as well as proprietary radios
  - Supports little and big endian architectures, and abstracts the hard real-time specifics so that they can be encapsulated in a hardware-specific module
  - Support for Controller (HCI) builds over different physical transports
  - Isochronous channels
- *Bluetooth Host*
  - Generic Access Profile (GAP) with all possible LE roles
    * Peripheral & Central
    * Observer & Broadcaster
    * Multiple PHY support (2Mbit/s, Coded)
    * Extended Advertising
    * Periodic Advertising (including Sync Transfer)
  - GATT (Generic Attribute Profile)
    * Server (to be a sensor)
    * Client (to connect to sensors)
    * Enhanced ATT (EATT)
    * GATT Database Hash
    * GATT Multiple Notifications
  - Pairing support, including the Secure Connections feature from Bluetooth 4.2
  - Non-volatile storage support for permanent storage of Bluetooth-specific settings and data
  - Bluetooth Mesh support
    * Relay, Friend Node, Low-Power Node (LPN) and GATT Proxy features
    * Both Provisioning roles and bearers supported (PB-ADV & PB-GATT)
    * Foundation Models included
    * Highly configurable, fits as small as 16k RAM devices

  - Basic Bluetooth BR/EDR (Classic) support
    * Generic Access Profile (GAP)
    * Logical Link Control and Adaptation Protocol (L2CAP)
    * Serial Port emulation (RFCOMM protocol)
    * Service Discovery Protocol (SDP)
  - Clean HCI driver abstraction
    * 3-Wire (H:5) & 5-Wire (H:4) UART
    * SPI
    * Local controller support as a virtual HCI driver
  - Verified with multiple popular controllers
  - Isochronous channels
  - *LE Audio*

Qualification

Details on the Bluetooth SIG qualification process can be found at: https://www.bluetooth.com/develop-with-bluetooth/qualify

Qualification setup The Zephyr Bluetooth host can be qualified using Bluetooth's PTS (Profile Tuning Suite) software. It is originally a manual process, but is automated by using the AutoPTS automation software.

The setup is described in more details in the pages linked below.

AutoPTS on Windows 10 with nRF52 board This tutorial shows how to setup AutoPTS client and server to run both on Windows 10. We use WSL1 with Ubuntu only to build a Zephyr project to an elf file, because Zephyr SDK is not available on Windows yet. Tutorial covers only nrf52840dk.

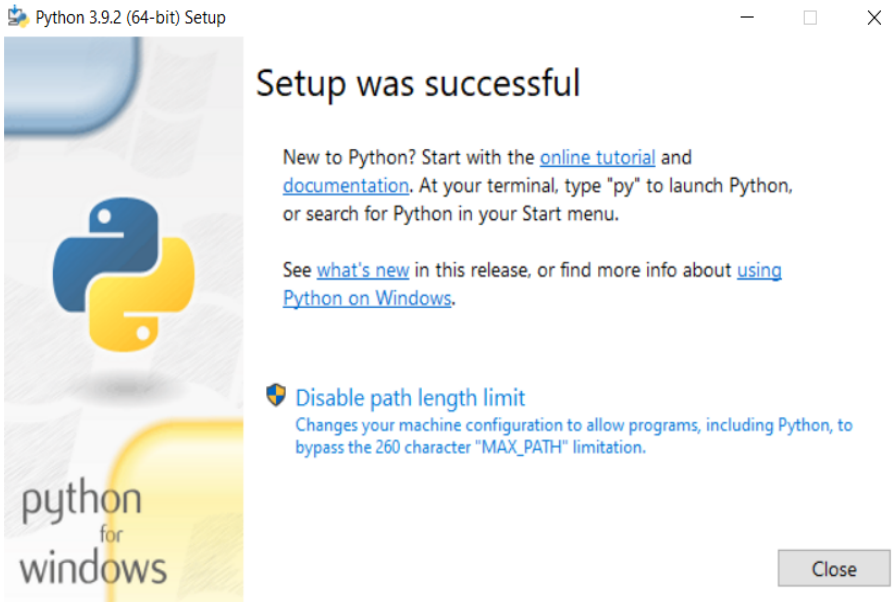
- *Update Windows and drivers*
- *Install Python 3*
- *Install Git*
- *Install PTS 8*
- *Setup Zephyr project for Windows*
- *Install nrftools*
- *Connect devices*
- *Flash board*
- *Setup auto-pts project*
- *Install socat.exe*
- *Running AutoPTS*
- *Troubleshooting*

Update Windows and drivers Update Windows in:

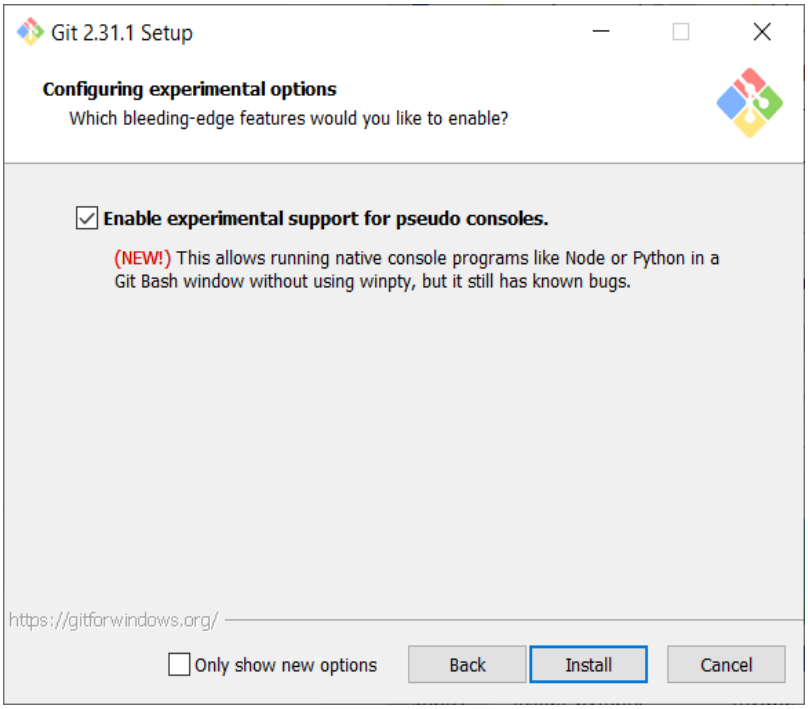
Start -> Settings -> Update & Security -> Windows Update

Update drivers, following the instructions from your hardware vendor.

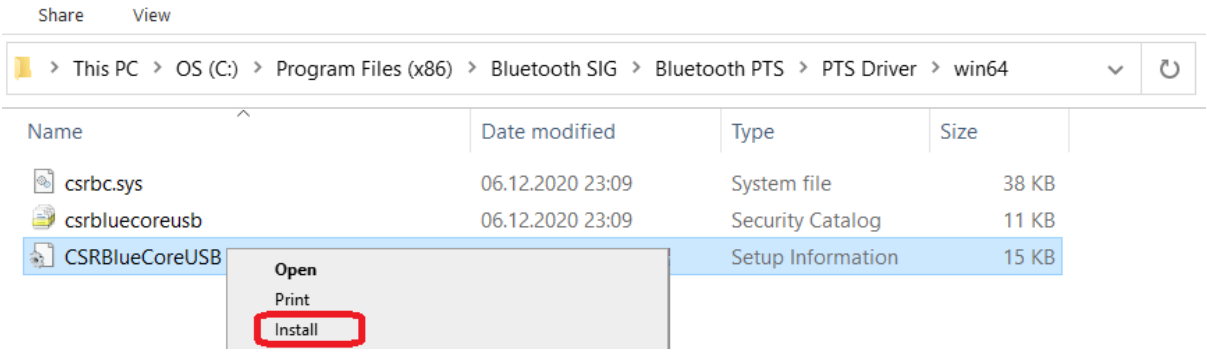
Install Python 3 Download and install Python 3. Setup was tested with versions >=3.8. Let the installer add the Python installation directory to the PATH and disable the path length limitation.



Install Git Download and install Git. During installation enable option: Enable experimental support for pseudo consoles. We will use Git Bash as Windows terminal.



Install PTS 8 Install latest PTS from https://www.bluetooth.org. Remember to install drivers from installation directory "C:/Program Files (x86)/Bluetooth SIG/Bluetooth PTS/PTS Driver/win64/CSRBlueCoreUSB.inf"

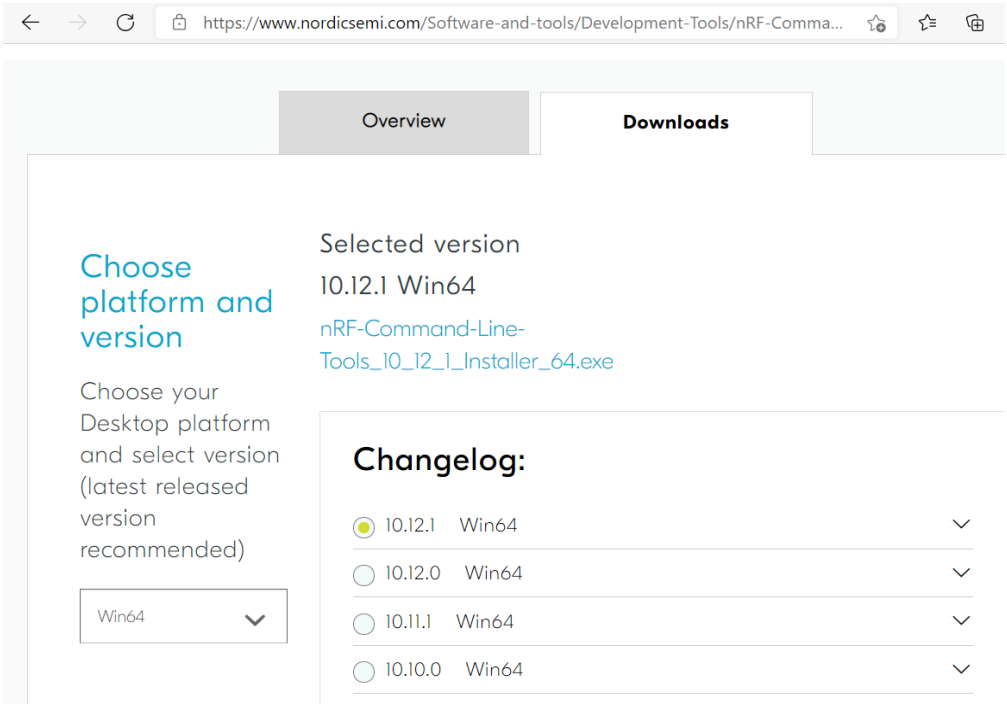


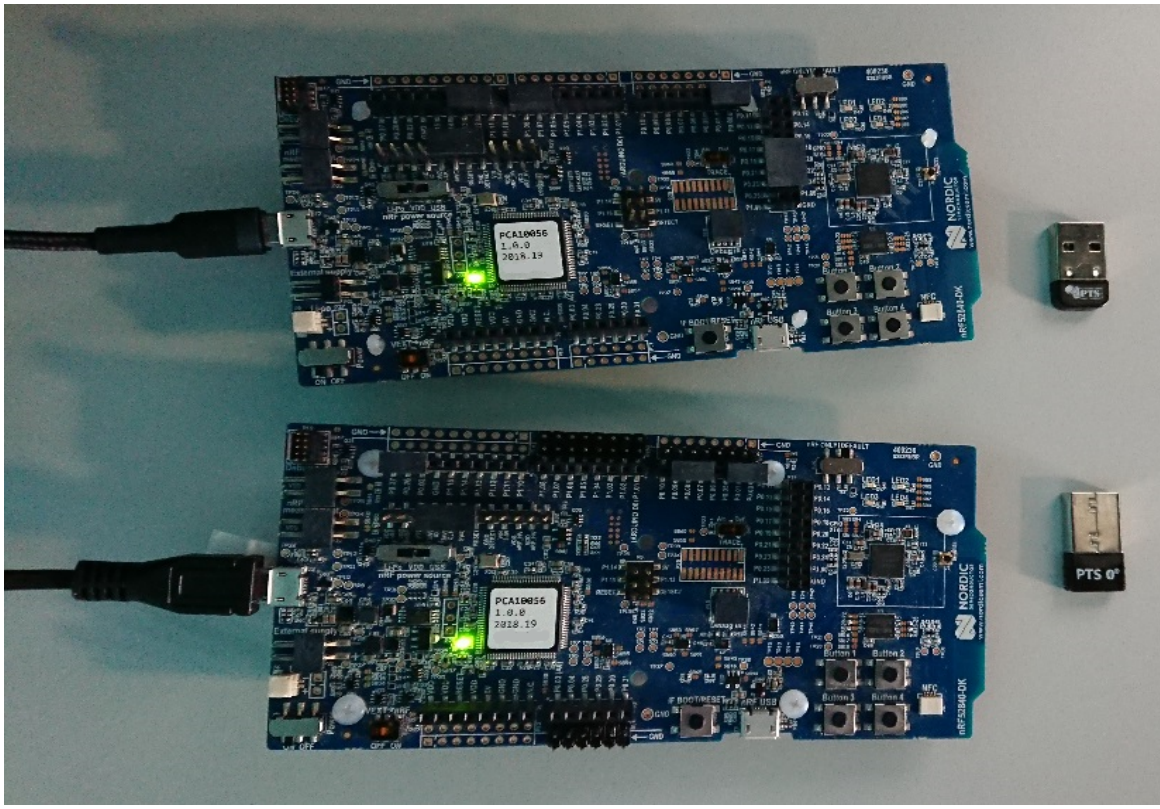
Note

Starting with PTS 8.0.1 the Bluetooth Protocol Viewer is no longer included. So to capture Bluetooth events, you have to download it separately.

Setup Zephyr project for Windows Perform Windows setup from *Getting Started Guide*.

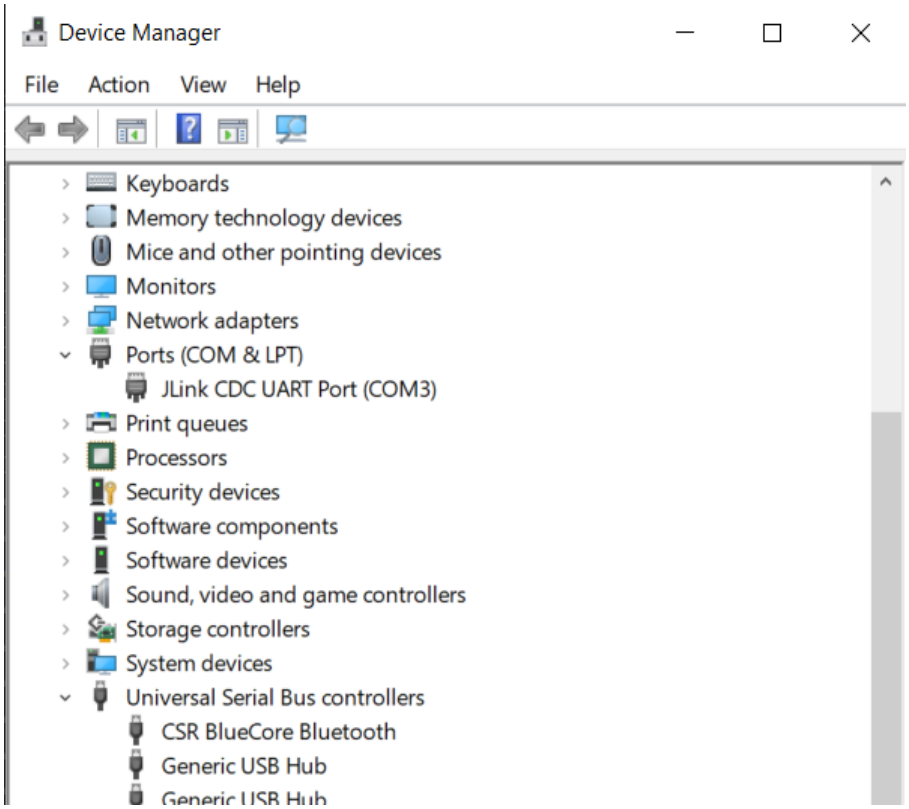
Install nrftools On Windows download latest nrftools (version >= 10.12.1) from site https://www.nordicsemi.com/Software-and-tools/Development-Tools/nRF-Command-Line-Tools/Download and run default install.





Connect devices

Flash board In Device Manager find COM port of your nrf board. In my case it is COM3.



In Git Bash, go to zephyrproject

```
cd ~/zephyrproject
```

Build the auto-pts tester app

```
west build -p auto -b nrf52840dk/nrf52840 zephyr/tests/bluetooth/tester/
```

You can display flashing options with:

```
west flash --help
```

and flash board with built earlier elf file:

```
west flash --no-rebuild --board-dir /dev/ttyS2 --elf-file ~/
↪zephyrproject/build/zephyr/zephyr.elf
```

Note that west does not accept COMs, so use /dev/ttyS2 as the COM3 equivalent, /dev/ttyS2 as the COM3 equivalent, etc.(/dev/ttyS + decremented COM number).

Setup auto-pts project In Git Bash, clone project repo:

```
git clone https://github.com/auto-pts/auto-pts.git
```

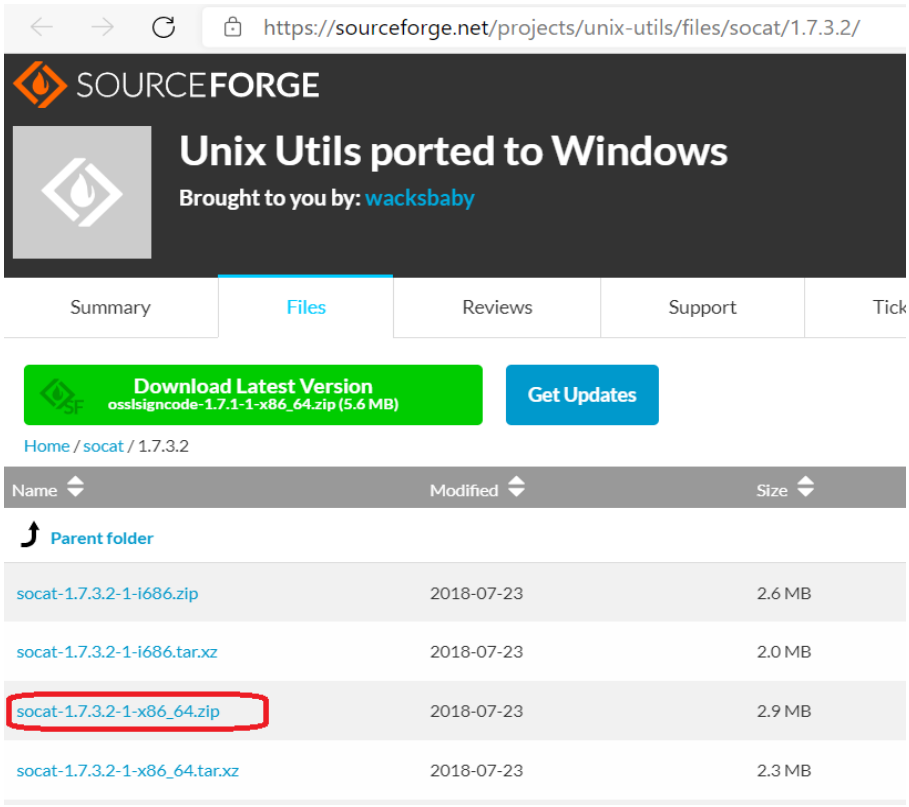
Go into the project folder:

```
cd auto-pts
```

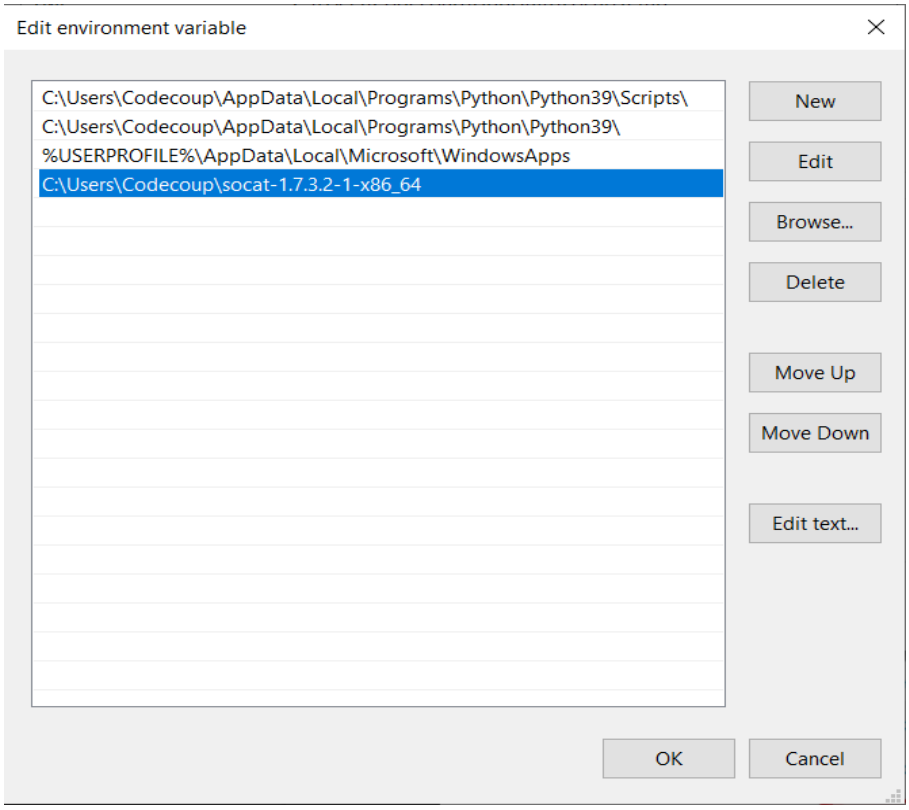
Install required python modules:

```
pip3 install --user wheel
pip3 install --user -r autoptsserver_requirements.txt
pip3 install --user -r autoptsclient_requirements.txt
```

Install socat.exe Download and extract socat.exe from https://sourceforge.net/projects/unix-utils/files/socat/1.7.3.2/ into folder ~/socat-1.7.3.2-1-x86_64/.

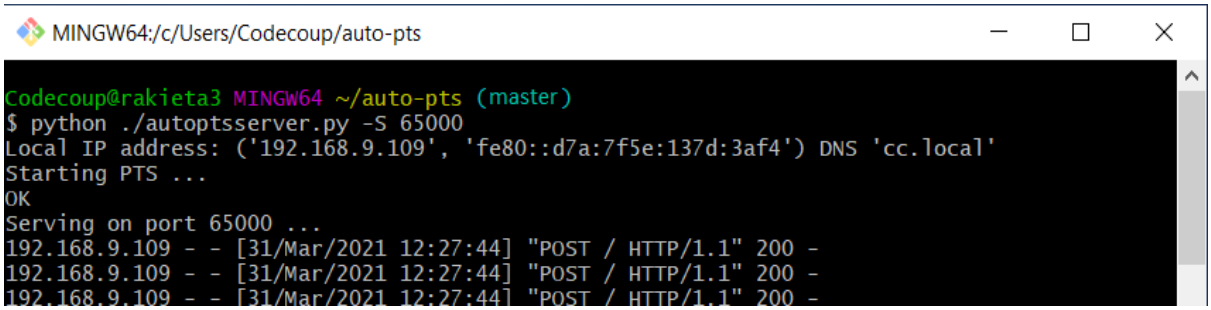


Add path to directory of socat.exe to PATH:



Running AutoPTS Server and client by default will run on localhost address. Run server:

```
python ./autoptsserver.py -S 65000
```



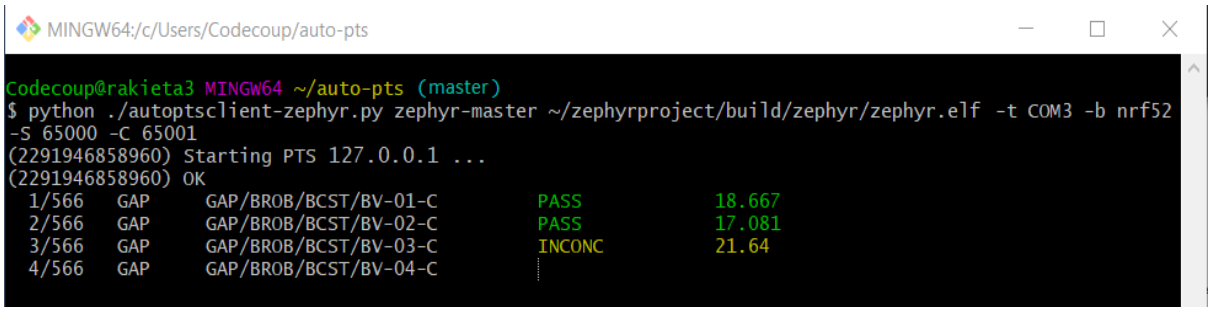
Note

If the error "ImportError: No module named pywintypes" appeared after the fresh setup, uninstall and install the pywin32 module:

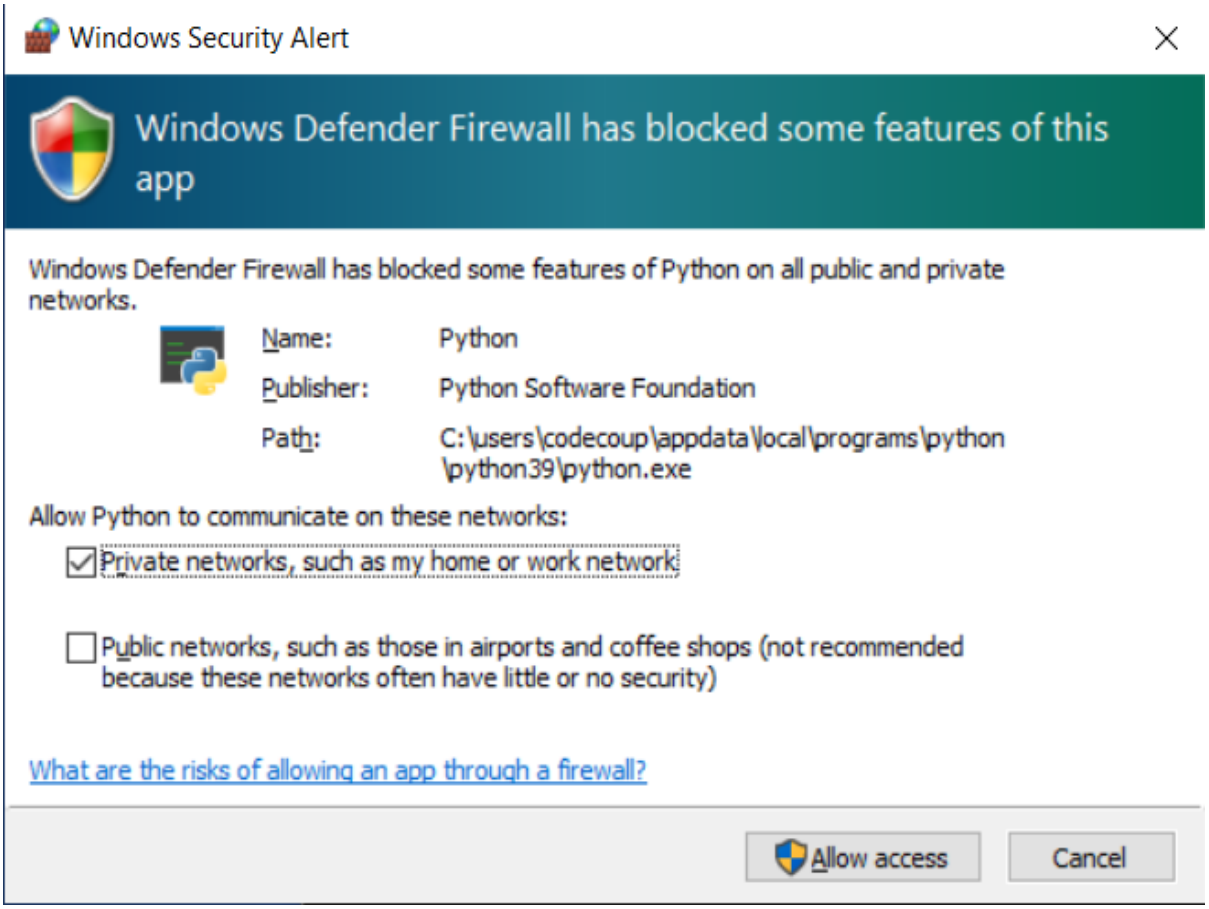
```
pip install --upgrade --force-reinstall pywin32
```

Run client:

```
python ./autoptsclient-zephyr.py zephyr-master ~/
↪zephyrproject/build/zephyr/zephyr.elf -t COM3 -b nrf52 -S 65000 -C 65001
```



At the first run, when Windows asks, enable connection through firewall:



Troubleshooting

- "When running actual hardware test mode, I have only BTP TIMEOUTs."

This is a problem with connection between auto-pts client and board. There are many possible causes. Try:

- Clean your auto-pts and zephyr repos with

Warning

This command will force the irreversible removal of all uncommitted files in the repo.

```
git clean -fdx
```

then build and flash tester elf again.

- If you have set up Windows on virtual machine, check if guest extensions are installed properly or change USB compatibility mode in VM settings to USB 2.0.
- Check, if firewall in not blocking python.exe or socat.exe.
- Check if board sends ready event after restart (hex 00 00 80 ff 00 00). Open serial connection to board with e.g. PuTTy with proper COM and baud rate. After board reset you should see some strings in console.
- Check if socat.exe creates tunnel to board. Run in console

```
socat.exe -x -v tcp-listen:65123 /dev/ttyS2,raw,b115200
```

where /dev/ttyS2 is the COM3 equivalent. Open PuTTY, set connection type to Raw, IP to 127.0.0.1, port to 65123. After board reset you should see some strings in console.

AutoPTS on Linux This tutorial shows how to setup AutoPTS client on Linux with AutoPTS server running on Windows 10 virtual machine. Tested with Ubuntu 20.4 and Linux Mint 20.4.

You must have a Zephyr development environment set up. See *Getting Started Guide* for details.

Supported methods to test zephyr bluetooth host:

- Testing Zephyr Host Stack on QEMU
- Testing Zephyr Host Stack on native_sim
- Testing Zephyr combined (controller + host) build on Real hardware (such as nRF52)

For running with QEMU or native_sim, see *Running on QEMU or native_sim*.

- *Setup Linux*
- *Setup Windows 10/11 virtual machine*
  - *Update Windows*
  - *Setup NAT*
  - *Setup static IP*
  - *Install Python 3*
  - *Install Git*
  - *Install PTS*
  - *Connect PTS dongle*
- *Connect devices (only required in the actual hardware test mode)*
- *Setup auto-pts project*
  - *AutoPTS client on Linux*
  - *Autopts server on Windows virtual machine*
- *Running AutoPTS*
  - *Testing Zephyr Host Stack on hardware*
  - *Testing Zephyr Host Stack on QEMU*
  - *Testing Zephyr Host Stack on native_sim*
- *Troubleshooting*
  - *After running one test, I need to restart my Windows virtual machine to run another, because of fail verdict from APICOM in PTS logs*
  - *I cannot start autoptsserver-zephyr.py. I always get a Python error*
  - *The PTS automation window keeps opening and closing*

Setup Linux Please follow *Getting Started Guide* on how to setup Linux for building and flashing applications.

Setup Windows 10/11 virtual machine Choose and install your hypervisor like VMWare Workstation(preferred) or VirtualBox. On VirtualBox could be some issues, if your host has fewer than 6 CPU.

Create Windows virtual machine instance. Make sure it has at least 2 cores and installed guest extensions.

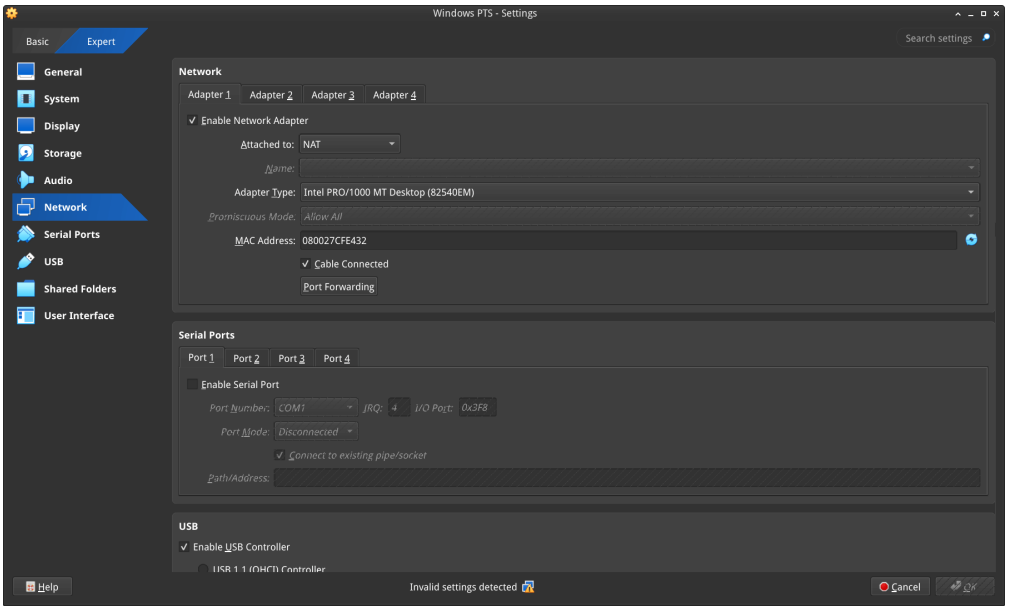
Setup tested with VirtualBox 7.2.4 and VMWare Workstation 16.1.1 Pro.

Update Windows Update Windows in:

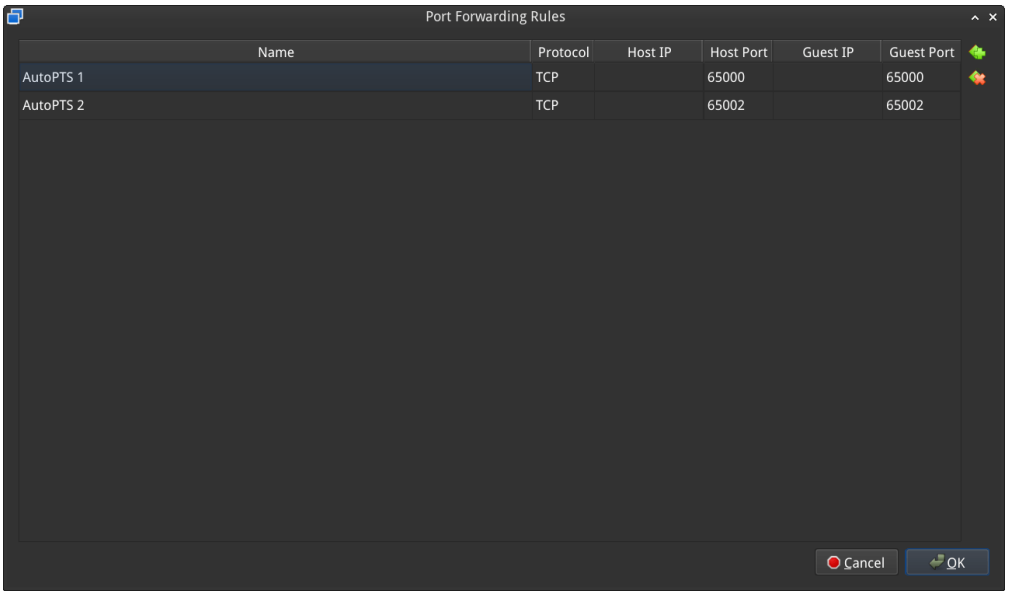
Start -> Settings -> Update & Security -> Windows Update

Setup NAT It is possible to use NAT and portforwarding to setup communication between a Linux host and a Windows guest. This is easiest setup for VirtualBox, and does not require any static IPs to be configured, and will not get blocked by the Windows Firewall.

VirtualBox Open virtual machine network settings. On adapter 1 you will have created by default NAT. Open the Port Forwarding menu an add the ports you want.

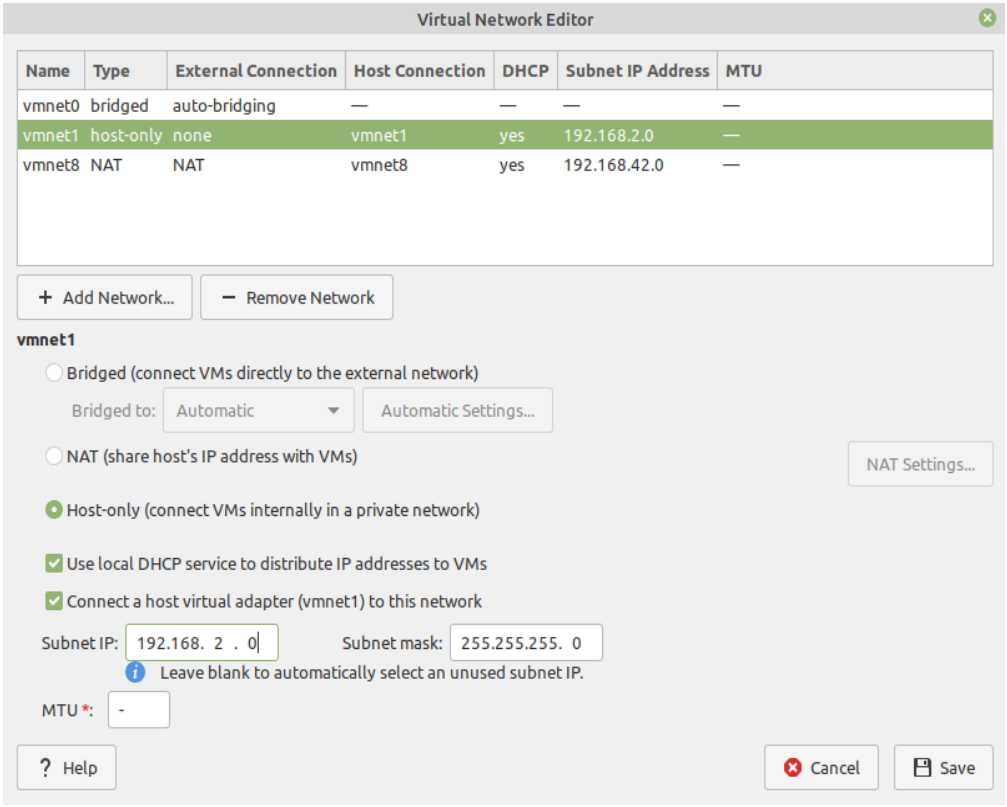


For example setting up the following will allow you to use `localhost:65000` and `localhost:65002` (or `127.0.0.0:65000` and `127.0.0.0:65002`) to connect to an AutoPTS Server in Windows running on ports 65000 and 65002.

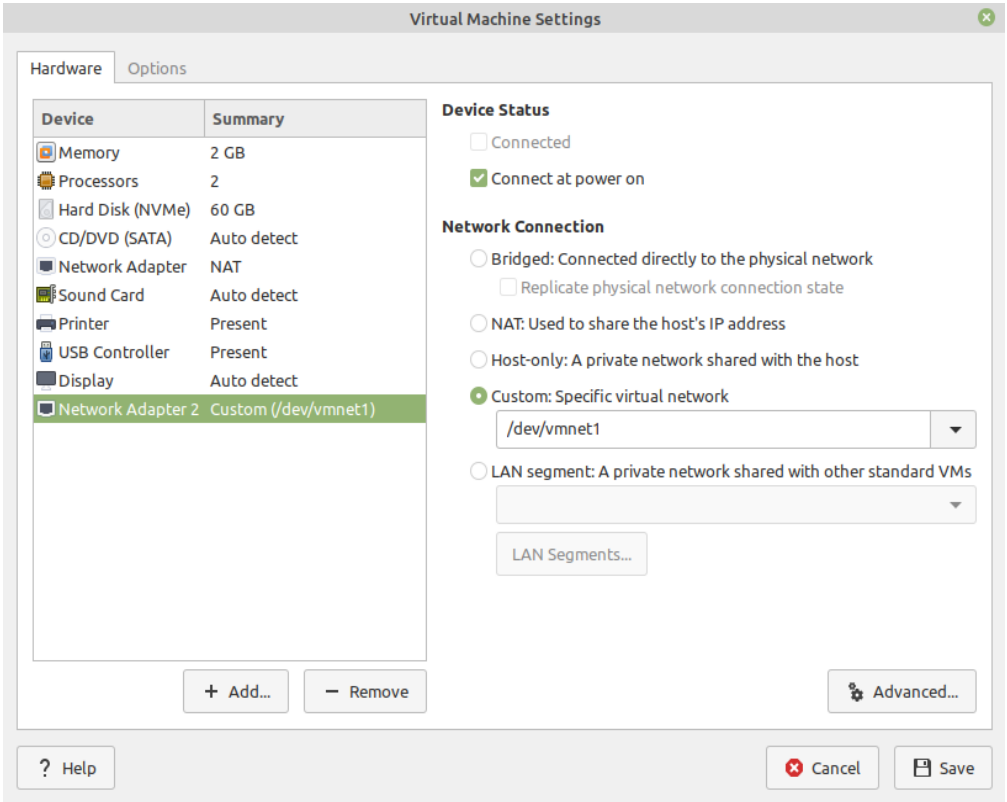


Setup static IP If you cannot or do not want to use NAT it is possible to configure a static IP.

VMWare Works On Linux, open Virtual Network Editor app and create network:



Open virtual machine network settings. Add custom adapter:



If you type 'ifconfig' in terminal, you should be able to find your host IP:

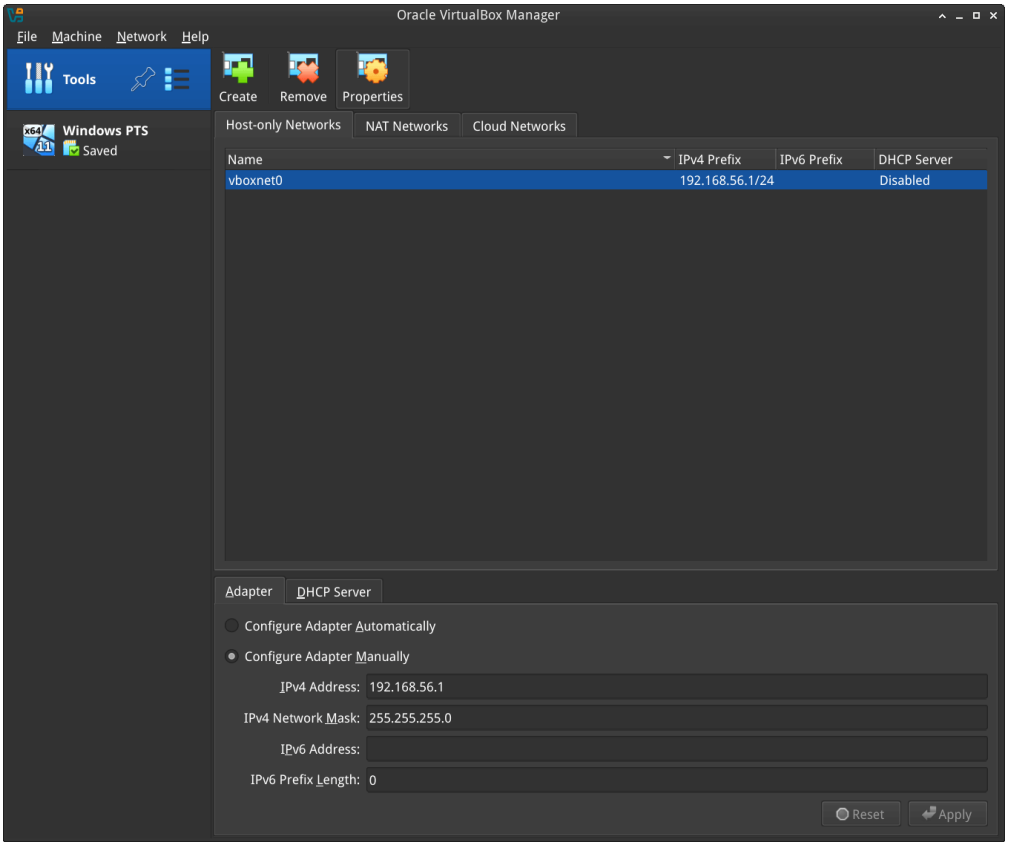
```
vmnet1: flags=4163<UP,BROADCAST,RUNNING,MULTICAST>  mtu 1500
        inet 192.168.2.1  netmask 255.255.255.0  broadcast 192.168.2.255
        inet6 fe80::250:56ff:fec0:1  prefixlen 64  scopeid 0x20<link>
        ether 00:50:56:c0:00:01  txqueuelen 1000  (Ethernet)
        RX packets 0  bytes 0 (0.0 B)
        RX errors 0  dropped 0  overruns 0  frame 0
        TX packets 42  bytes 0 (0.0 B)
        TX errors 0  dropped 0 overruns 0  carrier 0  collisions 0
```

VirtualBox VirtualBox on Linux, macOS and Solaris Oracle VM VirtualBox will only allow IP addresses in `192.168.56.0/21` range to be assigned to host-only adapters, so if using a static address with VirtualBox this is the only address range you can use.

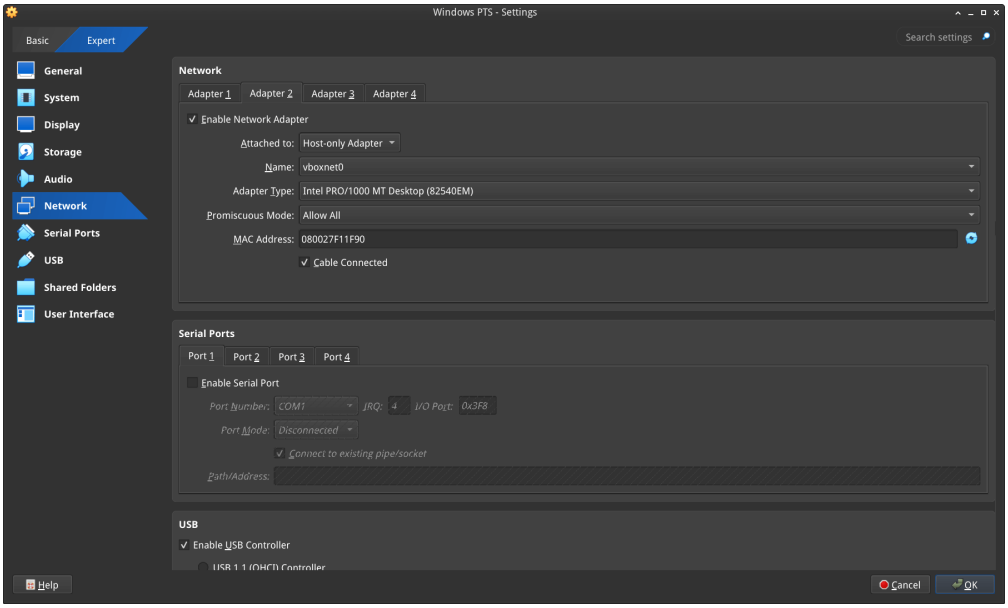
Go to:

File -> Tools -> Network Manager

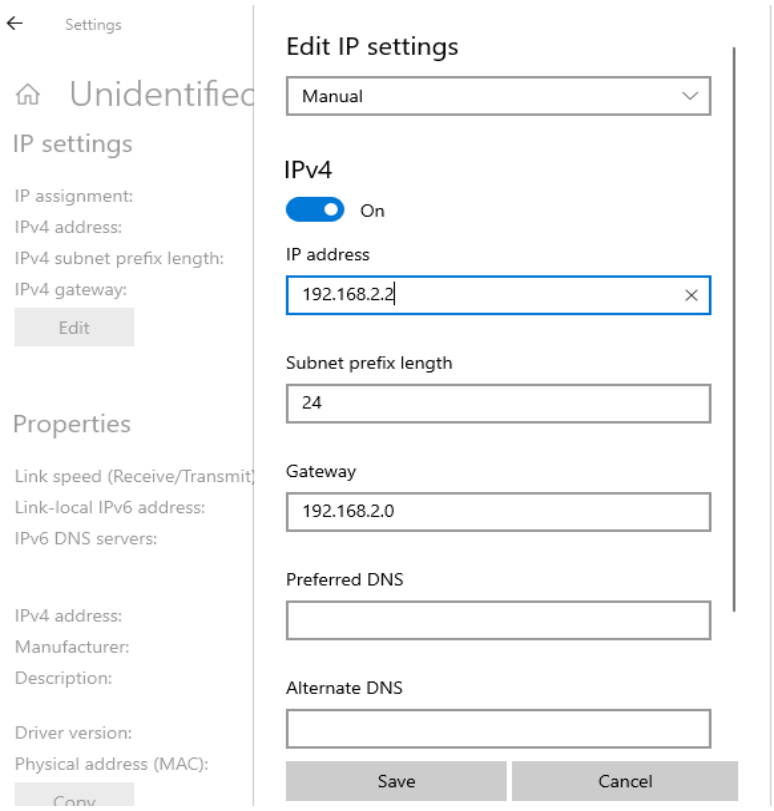
and create network:



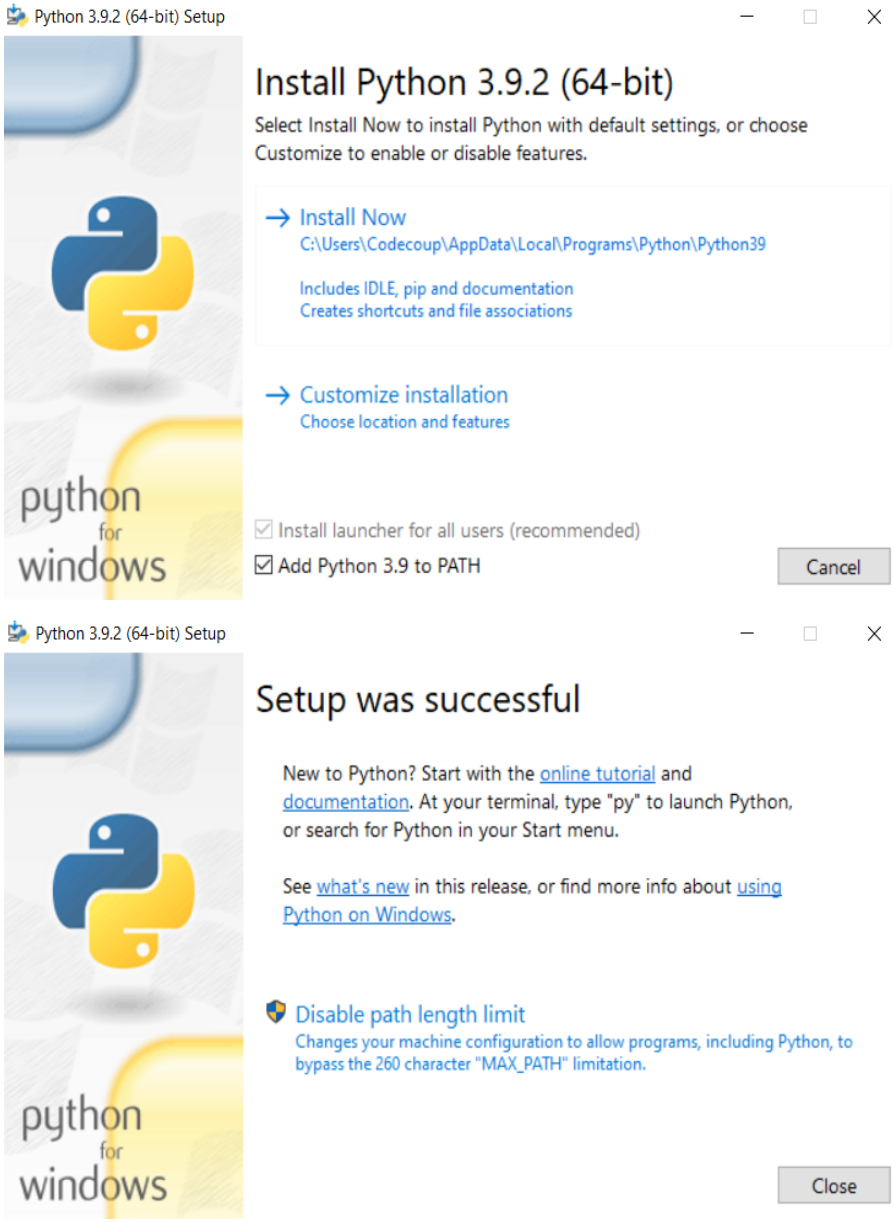
Open virtual machine network settings. On adapter 1 you will have created by default NAT. Add adapter 2:



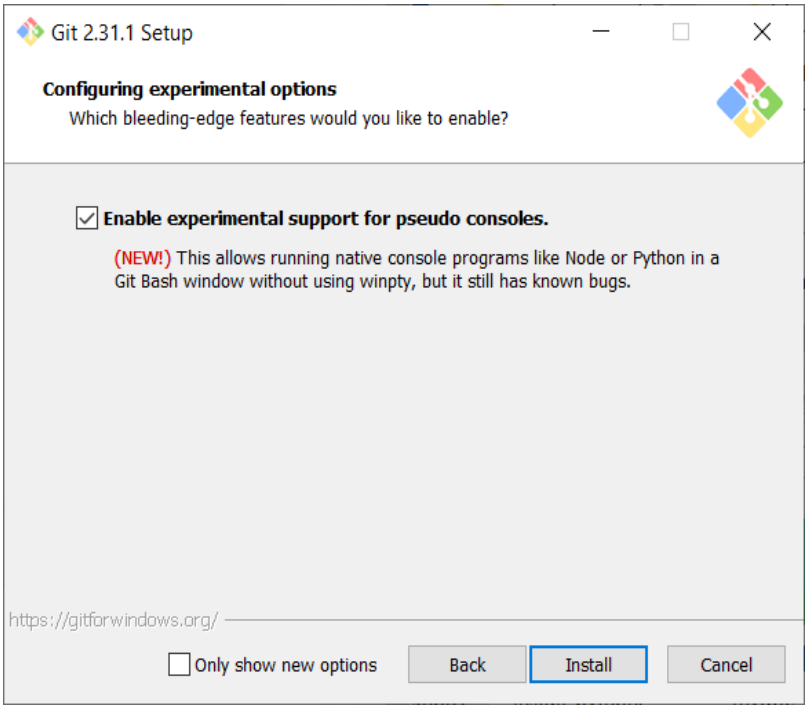
Windows Setup static IP on Windows virtual machine. Go to Settings -> Network & Internet -> Ethernet -> Unidentified network -> Edit and set:



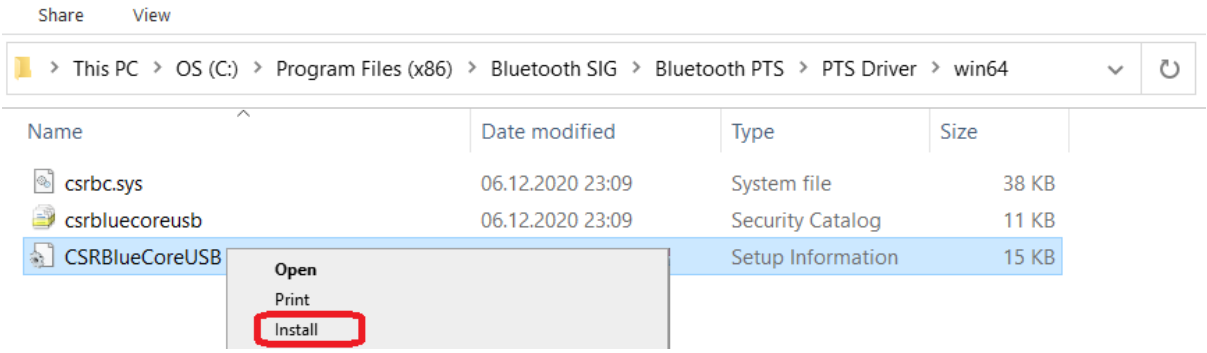
Install Python 3 Download and install latest Python 3 on Windows. Let the installer add the Python installation directory to the PATH and disable the path length limitation.



Install Git Download and install Git. During installation enable option: Enable experimental support for pseudo consoles. We will use Git Bash as Windows terminal.



Install PTS On Windows virtual machine, install the latest PTS from https://pts.bluetooth.com/download. Remember to install drivers from installation directory "C:/Program Files (x86)/Bluetooth SIG/Bluetooth PTS/PTS Driver/win64/CSRBlueCoreUSB.inf"



Note

Starting with PTS 8.0.1 the Bluetooth Protocol Viewer is no longer included. So to capture Bluetooth events, you have to download it separately.

Connect PTS dongle With VirtualBox there should be no problem. Just find dongle in Devices -> USB and connect.

With VMWare you might need to use some trick, if you cannot find dongle in VM -> Removable Devices. Type in Linux terminal:

```
usb-devices
```

and find in output your PTS Bluetooth USB dongle

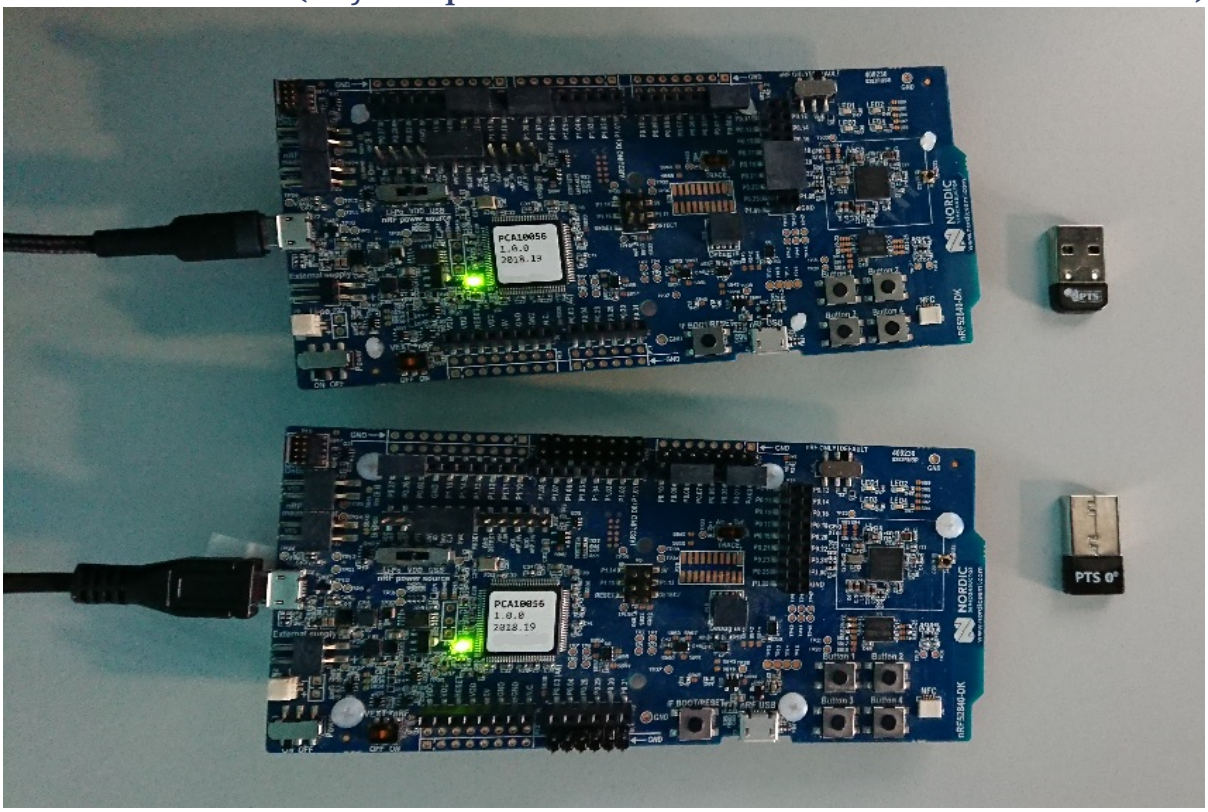
```
T:  Bus=01 Lev=01 Prnt=01 Port=01 Cnt=01 Dev#=  6 Spd=12  MxCh= 0
D:  Ver= 2.00 Cls=e0(wlcon) Sub=01 Prot=01 MxPS=64 #Cfgs=  1
P:  Vendor=0a12 ProdID=0001 Rev=25.20
S:  Product=CSR rck PTS Dongle
C:  #Ifs= 3 Cfg#= 1 Atr=c0 MxPwr=0mA
```

Note Vendor and ProdID number. Close VMWare Workstation and open .vmx of your virtual machine (path similar to /home/codecoup/vmware/Windows 10/Windows 10.vmx) in text editor. Write anywhere in the file following line:

```
usb.autoConnect.device0 = "0x0a12:0x0001"
```

just replace 0x0a12 with Vendor number and 0x0001 with ProdID number you found earlier.

Connect devices (only required in the actual hardware test mode)



Setup auto-pts project

AutoPTS client on Linux Clone auto-pts project:

```
git clone https://github.com/auto-pts/auto-pts.git
```

Install socat, that is used to transfer BTP data stream from UART's tty file:

```
sudo apt-get install python-setuptools socat
```

Install required python modules:

```
cd auto-pts
pip3 install --user -r autoptsclient_requirements.txt
```

Autopts server on Windows virtual machine In Git Bash, clone auto-pts project repo:

```
git clone https://github.com/auto-pts/auto-pts.git
```

Install required python modules:

```
cd auto-pts
pip3 install --user wheel
pip3 install --user -r autoptsserver_requirements.txt
```

Restart virtual machine.

Running AutoPTS Please follow the information from https://github.com/zephyrproject-rtos/zephyr/tree/main/tests/bluetooth/tester on how to build, flash and run the Bluetooth Tester application.

Server and client by default will run on localhost address. Run the server in the Windows virtual machine:

```
python ./autoptsserver.py
```

```
codecoup@DESKTOP-5SFTBGB MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py
Local IP address: ('10.0.2.15', 'fe80::ccb2:6ca1:6368:342a') DNS 'home'
Local IP address: ('192.168.2.2', 'fe80::fd12:15d5:2ddb:9147') DNS None
Starting PTS ...
OK
Serving on port 65000 ...
```

See also https://github.com/auto-pts/auto-pts for additional information on how to run auto-pts.

Testing Zephyr Host Stack on hardware

```
python ./autoptsclient-zephyr.py zephyr-master -t /dev/ttyACM0 -b BOARD -i␣
↪SERVER_IP -l LOCAL_IP
```

Where `/dev/ttyACM0` is the tty for the board, `BOARD` is the board to use (e.g. `nrf53_audio`), `SERVER_IP` is the IP of the AutoPTS server, `LOCAL_IP` is the local IP of the Linux machine.

Testing Zephyr Host Stack on QEMU A Bluetooth controller needs to be mounted. For running with HCI UART, please visit bluetooth_hci_uart.

```
python ./autoptsclient-zephyr.py zephyr-master BUILD_DIR/zephyr/zephyr.elf -i␣
↪SERVER_IP -l LOCAL_IP
```

Where `BUILD_DIR` is the build directory, `SERVER_IP` is the IP of the AutoPTS server, `LOCAL_IP` is the local IP of the Linux machine.

Testing Zephyr Host Stack on native_sim When tester application has been built for native_sim it produces a `zephyr.exe` file, that can be run as a native Linux application. Depending on your system, you may need to perform the following steps to successfully run `zephyr.exe`.

Setting capabilities Since the application will need access to connect to a socket for HCI, you may need to perform the following

```
setcap cap_net_raw,cap_net_admin,cap_sys_admin+ep zephyr.exe
```

This is not required if you run `zephyr.exe` or `./autoptsclient-zephyr.py` with e.g. `sudo`.

Downing the HCI controller You may also need to "down" or "power off" the HCI controller before running `zephyr.exe`. This can be done either with `hciconfig` as

```
hciconfig hciX down
```

Where `hciX` is a value like `hci0`. You may run `hciconfig` to get a list of your HCI devices.

Since `hciconfig` is deprecated on some systems, you may need to use

```
btmgmt -i hciX power off
```

Similar to `hciconfig`, `btmgmt info` may be used to list current controllers and their states.

Both `hciconfig` and `btmgmt` may require `sudo` when powering down a controller.

Running the client The application can be run as

```
python ./autoptsclient-zephyr.py zephyr-master --hci HCI␣
↪BUILD_DIR/zephyr/zephyr.exe -i SERVER_IP -l LOCAL_IP
```

Where `HCI` is the HCI index, e.g. `0` or `1`, `BUILD_DIR` is the build directory, `SERVER_IP` is the IP of the AutoPTS server, `LOCAL_IP` is the local IP of the Linux machine.

Troubleshooting

After running one test, I need to restart my Windows virtual machine to run another, because of fail verdict from APICOM in PTS logs It means your virtual machine has not enough processor cores or memory. Try to add more in settings. Note that a host with 4 CPUs could be not enough with VirtualBox as hypervisor. In this case, choose rather VMWare Workstation.

I cannot start autoptsserver-zephyr.py. I always get a Python error

```
codecoup@DESKTOP-5SFTBGB MINGW64 ~/auto-pts (master)
$ python ./autoptsserver.py
Local IP address: ('10.0.2.15', 'fe80::ccb2:6ca1:6368:342a') DNS 'home'
Local IP address: ('192.168.2.2', 'fe80::fd12:15d5:2ddb:9147') DNS None
Starting PTS ...

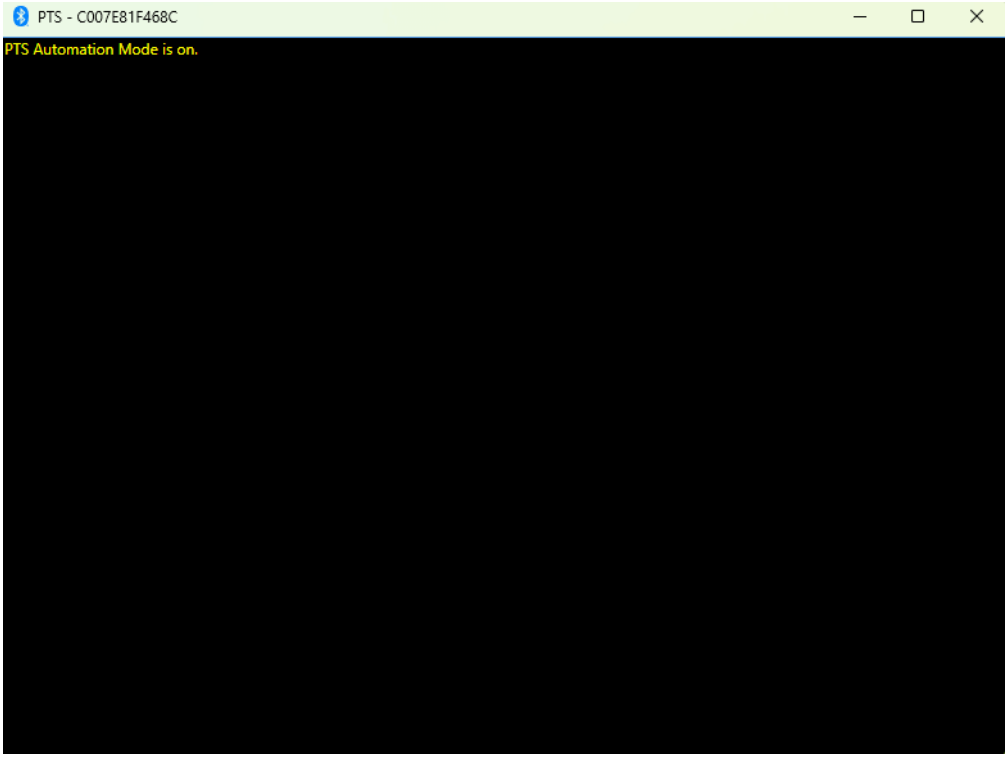
```

One or more of the following steps should help:

- Close all PTS Windows.
- Replug PTS bluetooth dongle.
- Delete temporary workspace. You will find it in auto-pts-code/workspaces/zephyr/zephyr-master/ as temp_zephyr-master. Be careful, do not remove the original one zephyr-master.pqw6.
- Restart Windows virtual machine.

The PTS automation window keeps opening and closing This indicates that it fails to capture a PTS dongle. If the AutoPTS server is able to find and use a PTS dongle, then the title of the window will show the Bluetooth address of the dongle. If this does not happen then ensure that the dongle is plugged in, updated and recognized by PTS.



If it still fails to run tests after this, please ensure that the Bluetooth Protocol Viewer is installed.

ICS Features The Zephyr ICS file for the Host features can be downloaded here: `ICS_Zephyr_Bluetooth_Host.pts`.

Use the Bluetooth Qualification website to view and edit the ICS.

Qualified releases The Zephyr Project provides a pre-qualified Bluetooth host stack to make it easy for users to build qualified Bluetooth products. It can be included in a product qualification design, providing feature coverage and reducing qualification effort. The scope of qualification may vary by release, and the details can be checked below.

Release	Design Number	Details
v4.4	Q385945	Bluetooth qualification listing 332380

Stack Architecture

Overview This page describes the software architecture of Zephyr's Bluetooth protocol stack.

Note

Zephyr supports mainly Bluetooth Low Energy (LE), the low-power version of the Bluetooth specification. Zephyr also has limited support for portions of the BR/EDR Host.

Bluetooth LE Layers There are 3 main layers that together constitute a full Bluetooth Low Energy protocol stack:

- **Host**: This layer sits right below the application, and is comprised of multiple (non real-time) network and transport protocols enabling applications to communicate with peer devices in a standard and interoperable way.
- **Controller**: The Controller implements the Link Layer (LE LL), the low-level, real-time protocol which provides, in conjunction with the Radio Hardware, standard-interoperable over-the-air communication. The LL schedules packet reception and transmission, guarantees the delivery of data, and handles all the LL control procedures.
- **Radio Hardware**: Hardware implements the required analog and digital baseband functional blocks that permit the Link Layer firmware to send and receive in the 2.4GHz band of the spectrum.

Host Controller Interface The Bluetooth Specification describes the format in which a Host must communicate with a Controller. This is called the Host Controller Interface (HCI) protocol. HCI can be implemented over a range of different physical transports like UART, SPI, or USB. This protocol defines the commands that a Host can send to a Controller and the events that it can expect in return, and also the format for user and protocol data that needs to go over the air. The HCI ensures that different Host and Controller implementations can communicate in a standard way making it possible to combine Hosts and Controllers from different vendors.

Configurations The three separate layers of the protocol and the standardized interface make it possible to implement the Host and Controller on different platforms. The two following configurations are commonly used:

- **Single-chip configuration**: In this configuration, a single microcontroller implements all three layers and the application itself. This can also be called a system-on-chip (SoC) implementation. In this case the Bluetooth Host and the Bluetooth Controller communicate directly through function calls and queues in RAM. The Bluetooth specification does not specify how HCI is implemented in this single-chip configuration and so how HCI commands, events, and data flows between the two can be implementation-specific. This configuration is well suited for those applications and designs that require a small footprint and the lowest possible power consumption, since everything runs on a single IC.
- **Dual-chip configuration**: This configuration uses two separate ICs, one running the Application and the Host, and a second one with the Controller and the Radio Hardware. This is sometimes also called a connectivity-chip configuration. This configuration allows for a wider variety of combinations of Hosts when using the Zephyr OS as a Controller. Since HCI ensures interoperability among Host and Controller implementations, including of course Zephyr's very own Bluetooth Host and Controller, users of the Zephyr Controller can choose to use whatever Host running on any platform they prefer. For example, the host can be the Linux Bluetooth Host stack (BlueZ) running on any processor capable of supporting Linux. The Host processor may of course also run Zephyr and the Zephyr OS Bluetooth Host. Conversely, combining an IC running the Zephyr Host with an external Controller that does not run Zephyr is also supported.

Build Types The Zephyr software stack as an RTOS is highly configurable, and in particular, the Bluetooth subsystem can be configured in multiple ways during the build process to include only the features and layers that are required to reduce RAM and ROM footprint as well as power

consumption. Here's a short list of the different Bluetooth-enabled builds that can be produced from the Zephyr project codebase:

- **Controller-only build**: When built as a Bluetooth Controller, Zephyr includes the Link Layer and a special application. This application is different depending on the physical transport chosen for HCI:
  - bluetooth_hci_uart
  - bluetooth_hci_usb
  - bluetooth_hci_spi

  This application acts as a bridge between the UART, SPI or USB peripherals and the Controller subsystem, listening for HCI commands, sending application data and responding with events and received data. A build of this type sets the following Kconfig option values:
  - `CONFIG_BT=y`
  - `CONFIG_BT_HCI=y`
  - `CONFIG_BT_HCI_RAW=y`

  The controller itself needs to be enabled as well, typically by making sure the corresponding device tree node is enabled.
- **Host-only build**: A Zephyr OS Host build will contain the Application and the Bluetooth Host, along with an HCI driver (UART or SPI) to interface with an external Controller chip. A build of this type sets the following Kconfig option values:
  - `CONFIG_BT=y`
  - `CONFIG_BT_HCI=y`

  Additionally, if the platform supports also a local controller, it needs to be disabled, typically by disabling the corresponding device tree node. This is done together with enabling the device tree node for some other HCI driver and making sure that the `zephyr,bt-hci` device tree chosen property points at it.

  All of the samples located in `samples/bluetooth` except for the ones used for Controller-only builds can be built as Host-only
- **Combined build**: This includes the Application, the Host and the Controller, and it is used exclusively for single-chip (SoC) configurations. A build of this type sets the following Kconfig option values:
  - `CONFIG_BT=y`
  - `CONFIG_BT_HCI=y`

  The controller itself needs to be enabled as well, typically by making sure the corresponding device tree node is enabled.

  All of the samples located in `samples/bluetooth` except for the ones used for Controller-only builds can be built as Combined

The picture below shows the SoC or single-chip configuration when using a Zephyr combined build (a build that includes both a Bluetooth Host and a Controller in the same firmware image that is programmed onto the chip):

When using connectivity or dual-chip configurations, several Host and Controller combinations are possible, some of which are depicted below:

When using a Zephyr Host (left side of image), two instances of Zephyr OS must be built with different configurations, yielding two separate images that must be programmed into each of the chips respectively. The Host build image contains the application, the Bluetooth Host and the selected HCI driver (UART or SPI), while the Controller build runs either the bluetooth_hci_uart, or the bluetooth_hci_spi app to provide an interface to the Bluetooth Controller.

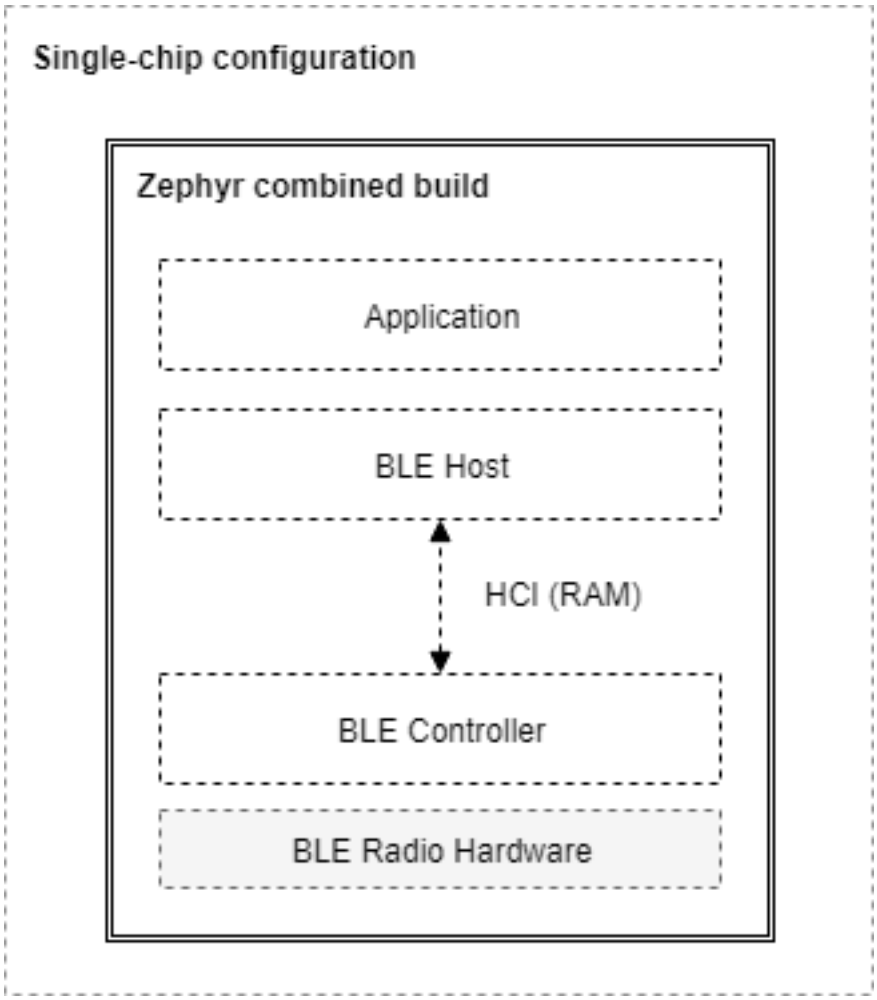


Fig. 12: A Combined build on a Single-Chip configuration

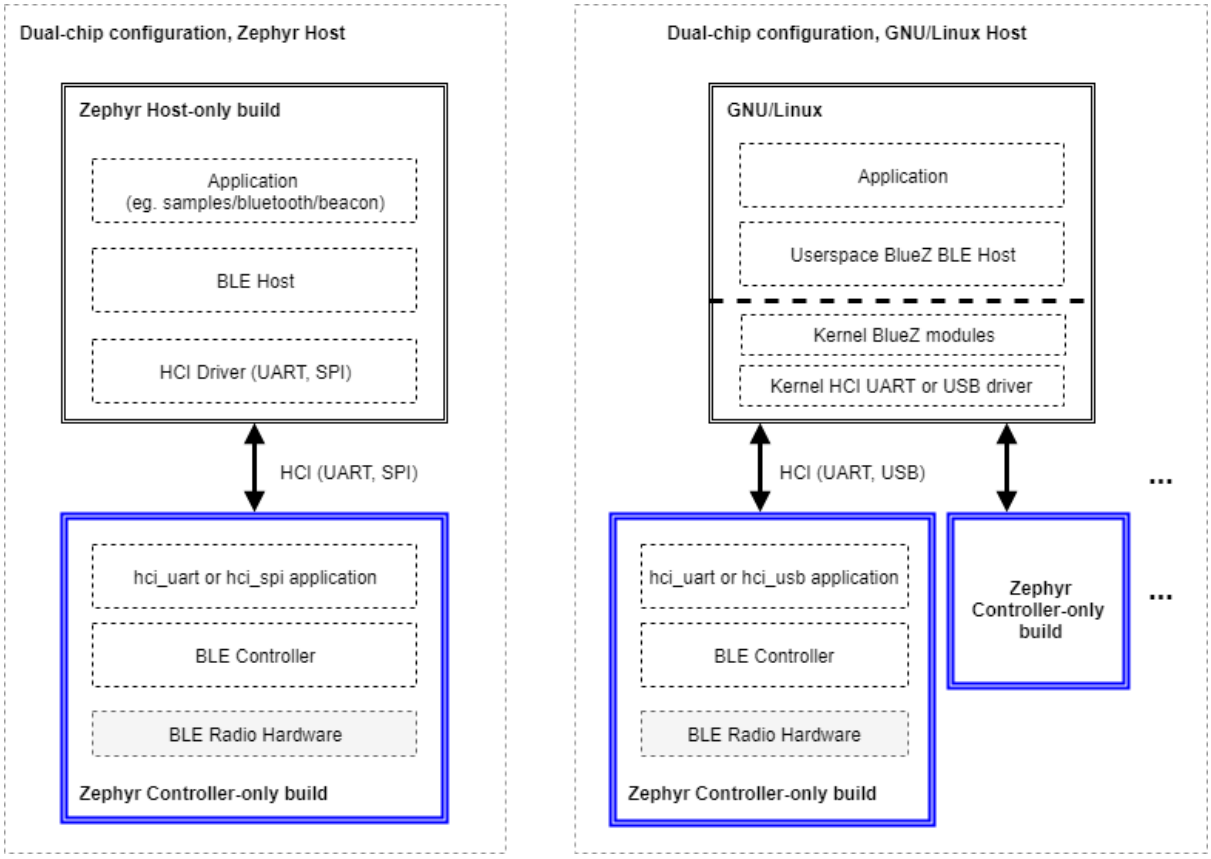

Fig. 13: Host-only and Controller-only builds on dual-chip configurations

This configuration is not limited to using a Zephyr OS Host, as the right side of the image shows. One can indeed take one of the many existing GNU/Linux distributions, most of which include Linux's own Bluetooth Host (BlueZ), to connect it via UART or USB to one or more instances of the Zephyr OS Controller build. BlueZ as a Host supports multiple Controllers simultaneously for applications that require more than one Bluetooth radio operating at the same time but sharing the same Host stack.

Source tree layout The stack is split up as follows in the source tree:

subsys/bluetooth/host
: *The host stack*. This is where the HCI command and event handling as well as connection tracking happens. The implementation of the core protocols such as L2CAP, ATT, and SMP is also here.

subsys/bluetooth/controller
: *Bluetooth LE Controller* implementation. Implements the controller-side of HCI, the Link Layer as well as access to the radio transceiver.

include/zephyr/bluetooth/
: *Public API* header files. These are the header files applications need to include in order to use Bluetooth functionality.

drivers/bluetooth/
: HCI transport drivers. Every HCI transport needs its own driver. For example, the two common types of UART transport protocols (3-Wire and 5-Wire) have their own drivers.

samples/bluetooth/
: Sample Bluetooth code. This is a good reference to get started with Bluetooth application development.

tests/bluetooth/
: Test applications. These applications are used to verify the functionality of the Bluetooth stack, but are not necessary the best source for sample code (see samples/bluetooth instead).

doc/services/connectivity/bluetooth/
: Extra documentation, such as PICS documents.

LE Host

The Bluetooth Host implements all the higher-level protocols and profiles, and most importantly, provides a high-level API for applications. The following diagram depicts the main protocol & profile layers of the host.

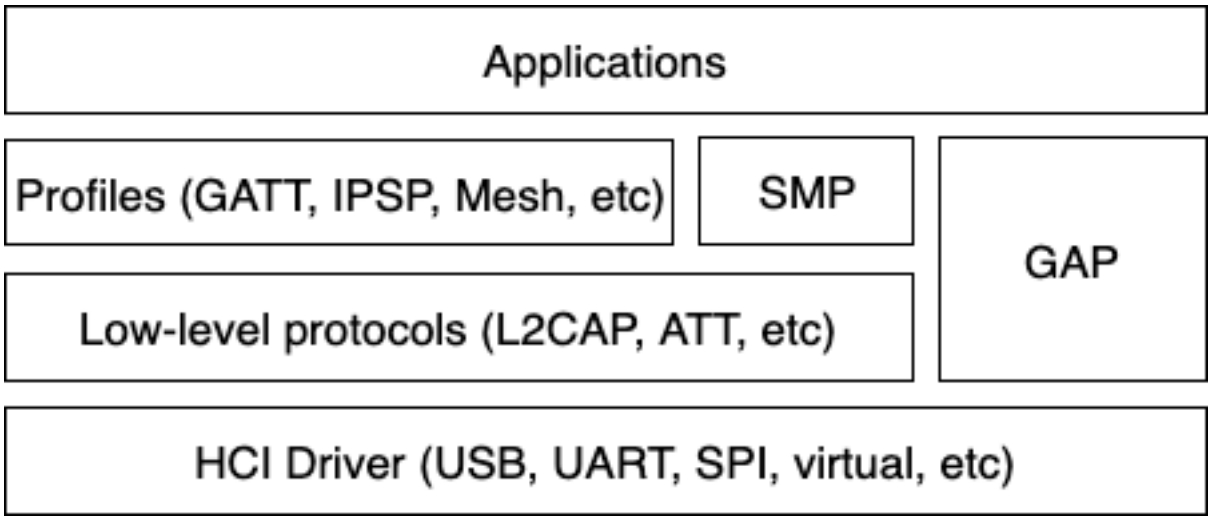

Fig. 14: Bluetooth Host protocol & profile layers.

Lowest down in the host stack sits a so-called HCI driver, which is responsible for abstracting away the details of the HCI transport. It provides a basic API for delivering data from the controller to the host, and vice-versa.

Perhaps the most important block above the HCI handling is the Generic Access Profile (GAP). GAP simplifies Bluetooth LE access by defining four distinct roles of Bluetooth usage:

- Connection-oriented roles
  - Peripheral (e.g. a smart sensor, often with a limited user interface)
  - Central (typically a mobile phone or a PC)
- Connection-less roles
  - Broadcaster (sending out Bluetooth LE advertisements, e.g. a smart beacon)
  - Observer (scanning for Bluetooth LE advertisements)

Each role comes with its own build-time configuration option: `CONFIG_BT_PERIPHERAL`, `CONFIG_BT_CENTRAL`, `CONFIG_BT_BROADCASTER` & `CONFIG_BT_OBSERVER`. Of the connection-oriented roles central implicitly enables observer role, and peripheral implicitly enables broadcaster role. Usually the first step when creating an application is to decide which roles are needed and go from there. Bluetooth Mesh is a slightly special case, requiring at least the observer and broadcaster roles, and possibly also the Peripheral role. This will be described in more detail in a later section.

Peripheral role Most Zephyr-based Bluetooth LE devices will most likely be peripheral-role devices. This means that they perform connectable advertising and expose one or more GATT

services. After registering services using the `bt_gatt_service_register()` API the application will typically start connectable advertising using the `bt_le_adv_start()` API.

There are several peripheral sample applications available in the tree, such as samples/bluetooth/peripheral_hr.

Central role Central role may not be as common for Zephyr-based devices as peripheral role, but it is still a plausible one and equally well supported in Zephyr. Rather than accepting connections from other devices a central role device will scan for available peripheral device and choose one to connect to. Once connected, a central will typically act as a GATT client, first performing discovery of available services and then accessing one or more supported services.

To initially discover a device to connect to the application will likely use the `bt_le_scan_start()` API, wait for an appropriate device to be found (using the scan callback), stop scanning using `bt_le_scan_stop()` and then connect to the device using `bt_conn_le_create()`.

There are some sample applications for the central role available in the tree, such as samples/bluetooth/central_hr.

Observer role An observer role device will use the `bt_le_scan_start()` API to scan for device, but it will not connect to any of them. Instead it will simply utilize the advertising data of found devices, combining it optionally with the received signal strength (RSSI).

Broadcaster role A broadcaster role device will use the `bt_le_adv_start()` API to advertise specific advertising data, but the type of advertising will be non-connectable, i.e. other device will not be able to connect to it.

Connections Connection handling and the related APIs can be found in the *Connection Management* section.

Callback execution contexts The Host delivers events to the application through registered callbacks, for example those in `bt_conn_cb`, `bt_le_scan_cb` or `bt_l2cap_chan_ops`. Unless documented otherwise, these callbacks are invoked from a thread context, never from an ISR. Most run in a context internal to the stack, but some are today invoked synchronously from within the API call that triggers them, and so run in the calling thread: for example `bt_unpair()` invokes `bond_deleted`, and `bt_gatt_unsubscribe()` can invoke `notify` with `NULL` data, before returning. Neither behavior is part of the API: a callback delivered synchronously today may be deferred to a stack-internal context in a future release, or vice versa, and the specific thread has changed between releases before and may change again. Applications should rely only on the guarantees above, not on being called from, or before the return of, anything in particular.

When a callback runs in a context internal to the stack, that context is shared with the stack's own processing: time spent in the callback delays other Bluetooth activity, and blocking carries an additional risk, since a wait that only Bluetooth processing itself can satisfy becomes a deadlock, because that processing cannot proceed until the callback returns. The classic example is allocating a buffer with `K_FOREVER` from a pool that is replenished by the same context that runs the callback. As applications cannot rely on which context a given callback uses, the practices below apply to every callback.

Calling Bluetooth APIs from callbacks is common and supported, even though most of them may block; the blocking risk is then managed rather than avoided:

- Keep callbacks short, and defer work that is long-running or blocks indefinitely to an application-owned thread or work queue.
- Prefer allocations with `K_NO_WAIT` or a bounded timeout over `K_FOREVER`, and handle the failure.
- Size buffer pools (for example `CONFIG_BT_L2CAP_TX_BUF_COUNT` or `CONFIG_BT_ATT_TX_COUNT`) so that allocations made from callbacks do not have to wait.

Security To achieve a secure relationship between two Bluetooth devices a process called pairing is used. This process can either be triggered implicitly through the security properties of GATT services, or explicitly using the `bt_conn_set_security()` API on a connection object.

To achieve a higher security level, and protect against Man-In-The-Middle (MITM) attacks, it is recommended to use some out-of-band channel during the pairing. If the devices have a sufficient user interface this "channel" is the user itself. The capabilities of the device are registered using the `bt_conn_auth_cb_register()` API. The `bt_conn_auth_cb` struct that's passed to this API has a set of optional callbacks that can be used during the pairing - if the device lacks some feature the corresponding callback may be set to NULL. For example, if the device does not have an input method but does have a display, the `passkey_entry` and `passkey_confirm` callbacks would be set to NULL, but the `passkey_display` would be set to a callback capable of displaying a passkey to the user.

Depending on the local and remote security requirements & capabilities, there are four possible security levels that can be reached:

`BT_SECURITY_L1`
: No encryption and no authentication.

`BT_SECURITY_L2`
: Encryption but no authentication (no MITM protection).

`BT_SECURITY_L3`
: Encryption and authentication using the legacy pairing method from Bluetooth 4.0 and 4.1.

`BT_SECURITY_L4`
: Encryption and authentication using the LE Secure Connections feature available since Bluetooth 4.2.

Note

Mesh has its own security solution through a process called provisioning. It follows a similar procedure as pairing, but is done using separate mesh-specific APIs.

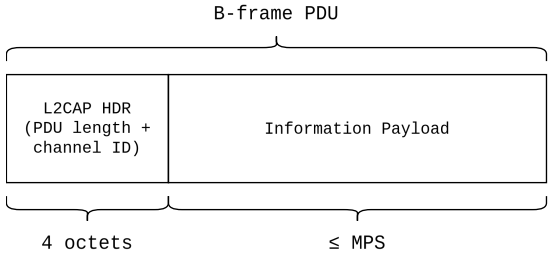
L2CAP L2CAP stands for the Logical Link Control and Adaptation Protocol. It is a common layer for all communication over Bluetooth connections, however an application comes in direct contact with it only when using it in the so-called Connection-oriented Channels (CoC) mode. More information on this can be found in the *L2CAP API section*.

Terminology The definitions are from the Core Specification version 5.4, volume 3, part A 1.4.

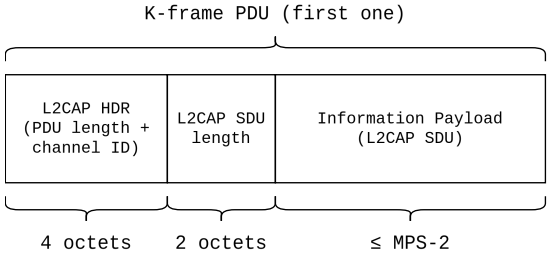
Term	Description
Upper layer	Layer above L2CAP, it exchanges data in form of SDUs. It may be an application or a higher level protocol.
Lower layer	Layer below L2CAP, it exchanges data in form of PDUs (or fragments). It is usually the HCI.
Service Data Unit (SDU)	Packet of data that L2CAP exchanges with the upper layer. This term is relevant only in Enhanced Retransmission mode, Streaming mode, Retransmission mode and Flow Control Mode, not in Basic L2CAP mode.
Protocol Data Unit (PDU)	Packet of data containing L2CAP data. PDUs always start with Basic L2CAP header. Types of PDUs for LE: *B-frames* and *K-frames*. Types of PDUs for BR/EDR: I-frames, S-frames, C-frames and G-frames.
Maximum Transmission Unit (MTU)	Maximum size of an SDU that the upper layer is capable of accepting.
Maximum Payload Size (MPS)	Maximum payload size that the L2CAP layer is capable of accepting. In Basic L2CAP mode, the MTU size is equal to MPS. In credit-based channels without segmentation, the MTU is MPS minus 2.
Basic L2CAP header	Present at the beginning of each PDU. It contains two fields, the PDU length and the Channel Identifier (CID).

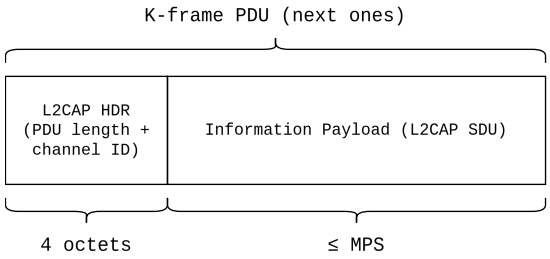
PDU Types

B-frame: Basic information frame PDU used in Basic L2CAP mode. It contains the payload received from the upper layer or delivered to the upper layer as its payload.



K-frame: Credit-based frame PDU used in LE Credit Based Flow Control mode and Enhanced Credit Based Flow Control mode. It contains a SDU segment and additional protocol information.



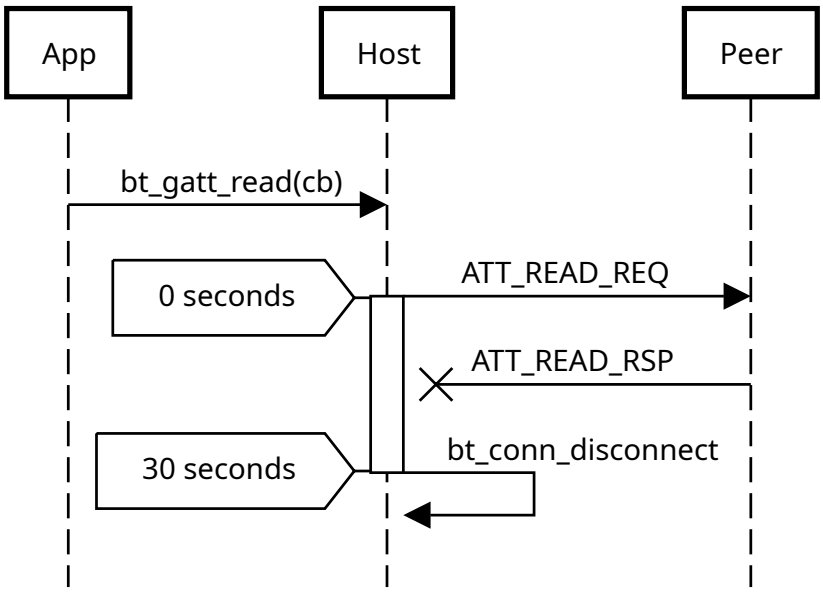


Relevant Kconfig

Kconfig symbol	Description
CONFIG_BT_BUF_ACL_RX_SIZE	Represents the MPS
CONFIG_BT_L2CAP_TX_MTU	Represents the L2CAP MTU
CONFIG_BT_L2CAP_DYNAMIC_CHAN	Enables LE Credit Based Flow Control and thus the stack may use *K-frame* PDUs

GATT The Generic Attribute Profile is the most common means of communication over LE connections. A more detailed description of this layer and the API reference can be found in the *GATT API reference section*.

ATT timeout If the peer device does not respond to an ATT request (such as read or write) within the ATT timeout, the host will automatically initiate a disconnect. This simplifies error handling by reducing rare failure conditions to a common disconnection, allowing developers to manage unexpected disconnects without special cases for ATT timeouts.



Mesh Mesh is a little bit special when it comes to the needed GAP roles. By default, mesh requires both observer and broadcaster role to be enabled. If the optional GATT Proxy feature is desired, then peripheral role should also be enabled.

The API reference for mesh can be found in the *Mesh API reference section*.

LE Audio The LE audio is a set of profiles and services that utilizes GATT and Isochronous Channel to provide audio over Bluetooth Low Energy. The architecture and API references can be found in *Bluetooth Audio Architecture*.

Persistent storage The Bluetooth host stack uses the settings subsystem to implement persistent storage to flash. This requires the presence of a flash driver and a designated "storage" partition on flash. A typical set of configuration options needed will look something like the following:

```
CONFIG_BT_SETTINGS=y
CONFIG_FLASH=y
CONFIG_FLASH_PAGE_LAYOUT=y
CONFIG_FLASH_MAP=y
CONFIG_NVS=y
CONFIG_SETTINGS=y
```

Once enabled, it is the responsibility of the application to call settings_load() after having initialized Bluetooth (using the `bt_enable()` API).

LE Audio Stack

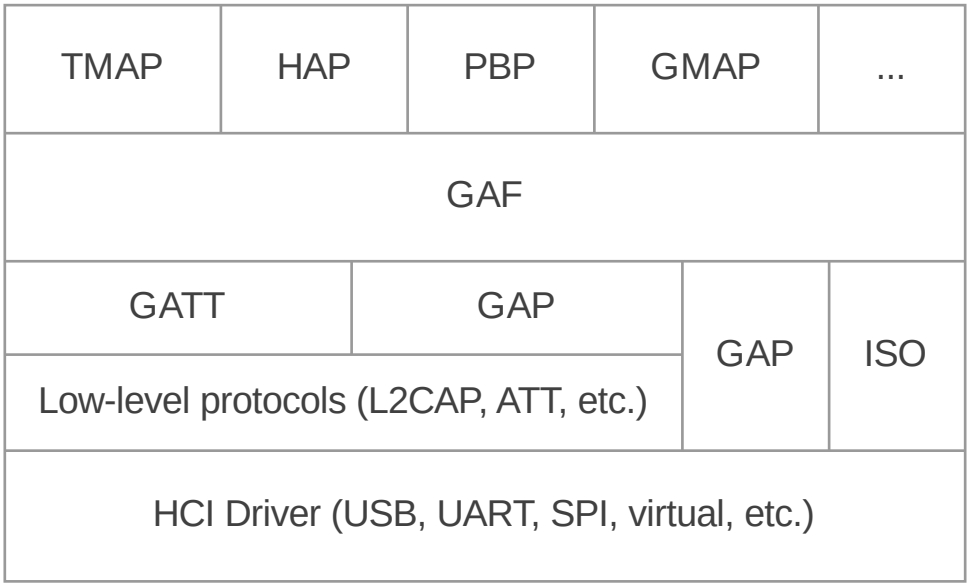


Fig. 15: Bluetooth Audio Architecture

Overall design The overall design of the LE Audio stack is that the implementation follows the specifications as closely as possible, both in terms of structure but also naming. Most API functions are prefixed by the specification acronym (e.g. `bt_bap` for the Basic Audio Profile (BAP) and `bt_vcp` for the Volume Control Profile (VCP)). The functions are then further prefixed with the specific role from each profile where applicable (e.g. `bt_bap_unicast_client_discover()` and `bt_vcp_vol_rend_set_vol()`). There are usually a function per procedure defined by the profile or service specifications, and additional helper or meta functions that do not correspond to procedures.

The structure of the files generally also follow this, where BAP related files are prefixed with `bap` and VCP related files are prefixed with `vcp`. If the file is specific for a profile role, the role is also embedded in the file name.

Generic Audio Framework (GAF) The Generic Audio Framework (GAF) is considered the middleware of the Bluetooth LE Audio architecture. The GAF contains the profiles and services that allows higher layer applications and profiles to set up streams, change volume, control media and telephony and more. The GAF builds on GATT, GAP and isochronous channels (ISO).

GAF uses GAP to connect, advertise and synchronize to other devices. GAF uses GATT to configure streams, associate streams with content (e.g. media or telephony), control volume and more. GAF uses ISO for the audio streams themselves, both as unicast (connected) audio streams or broadcast (unconnected) audio streams.

GAF mandates the use of the LC3 codec, but also supports other codecs.

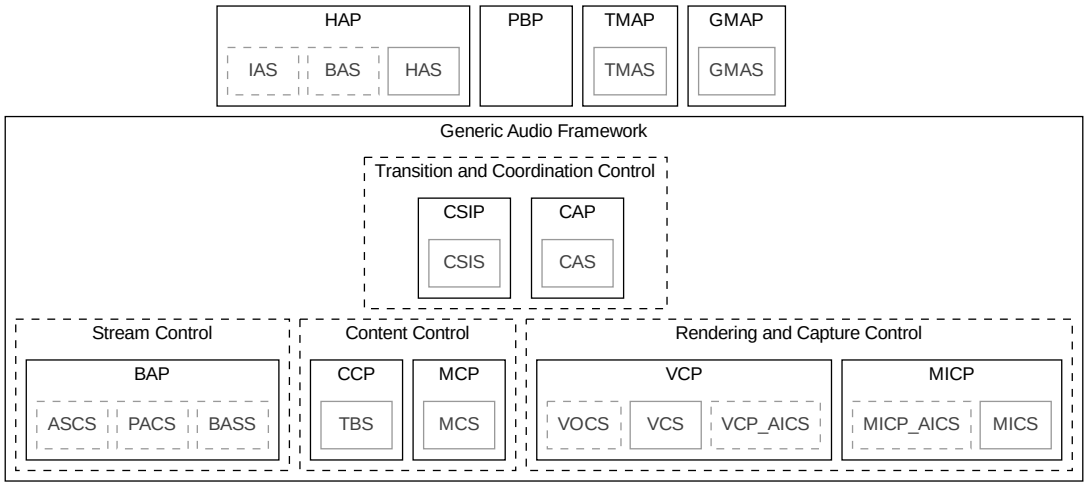

Fig. 16: Generic Audio Framework (GAF)

The top-level profiles TMAP and HAP are not part of the GAF, but rather provide top-level requirements for how to use the GAF.

GAF and the top layer profiles have been implemented in Zephyr with the following structure.

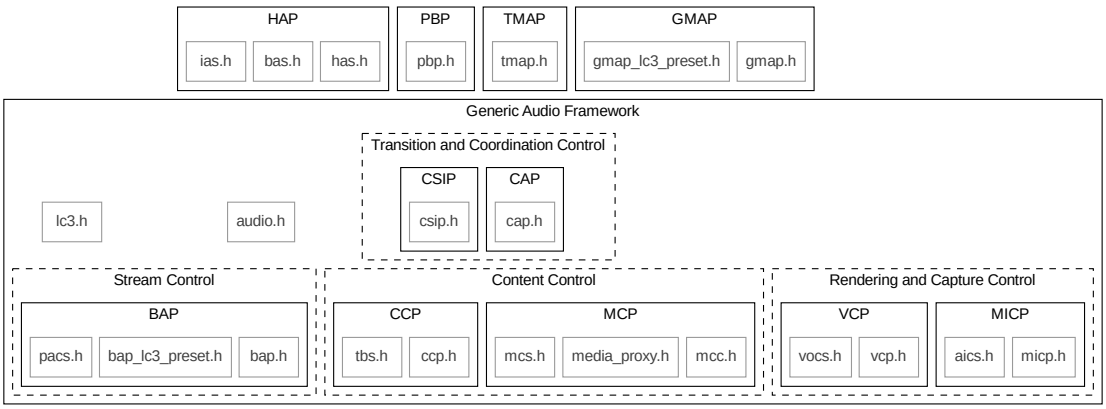

Fig. 17: Zephyr Generic Audio Framework

Profile Dependencies The LE Audio profiles depend on other profiles and services, as outlined in the following tables. In these tables 'Server' refers to acting in the GATT server role, and 'Client'

refers to acting in the GATT client role for the specific service. If a profile role depends on another profile that depends on a service, then that dependency is implicitly also applied to that profile. For example, if the CAP Acceptor uses the BAP Unicast Server role, then the requirements on the ASCS Server and PACS Server also apply to the CAP Acceptor.

The dependencies for Stream Control (BAP) are in the following table.

Table 15: BAP dependencies

	Unicast Server	Unicast Client	Broadcast Source	Broadcast Sink	Scan Delegator	Broadcast Assistant
BAP Scan Delegator				M		
ASCS Client		M				
ASCS Server	M					
PACS Client		M				O
PACS Server	M			M		
BASS Client						M
BASS Server					M	

Note:

- As the table shows, the Broadcast Source role has no dependencies on other LE Audio profiles or services

The dependencies for Content Control (MCP and CCP) are in the following tables.

Table 16: MCP dependencies

	Media Control Server	Media Control Client
GMCS Server	M	
GMCS Client		M
MCS Server	O	
MCS Client		O
OTS Server	O	
OTS Client		O

Table 17: CCP dependencies

	Call Control Server	Call Control Client
GTBS Server	M	
GTBS Client		M
TBS Server	M	
TBS Client		M

The dependencies for Rendering Control (MICP and VCP) are in the following tables.

Table 18: MICP dependencies

	Microphone Controller	Microphone Device
MICS Server	M	
MICS Client		M
AICS Server	O	
AICS Client		O

Table 19: VCP dependencies

	Volume Renderer	Volume Controller
VCS Server	M	
VCS Client		M
VOCS Server	O	
VOCS Client		O
AICS Server	O	
AICS Client		O

The last element in GAF is Transition and Coordination Control (CAP and CSIP) with the dependencies from the following tables.

Table 20: CAP dependencies

	Acceptor	Initiator	Commander
CAS Server	M		C.8
CAS Client		M	M
BAP Unicast Client		C.1	
BAP Unicast Server	C.2		
BAP Broadcast Source		C.1	
BAP Broadcast Sink	C.2		
BAP Broadcast Assistant			C.4, C.6
BAP Scan Delegator	C.3		C.6
VCP Volume Controller			C.6
VCP Volume Renderer	O		
MICP Microphone Controller			C.6
MICP Microphone Device	O		
CCP Call Control Server		O	
CCP Call Control Client	O		C.6
MCP Media Control Server		O	
MCP Media Control Client	O		C.6
CSIP Set Coordinator		C.5	M
CSIP Set Member	C.7		

Notes:

- C.1: Support at least one of BAP Unicast Client or BAP Broadcast Source
- C.2: Support at least one of BAP Unicast Server or BAP Broadcast Sink
- C.3: Mandatory if BAP Broadcast Sink
- C.4: Mandatory if BAP Scan Delegator
- C.5: Mandatory if BAP Unicast Client
- C.6: Support at least one
- C.7: Mandatory if part of a coordinated set
- C.8: Mandatory if the Commander transmits CAP announcements

Table 21: CSIP dependencies

	Set Member	Set Coordinator
CSIS Server	M	
CSIS Client		M

The dependencies of the higher level profiles (GMAP, HAP, PBP and TMAP) are listed in the following tables.

Table 22: GMAP dependencies

	Unicast Game Gateway	Unicast Game Terminal	Broadcast Game Sender	Broadcast Game Receiver
GMAS Server	M	M	O	M
GMAS Client	M	O	O	O
CAP Initiator	M		M	
CAP Acceptor		M		M
CAP Commander	M		M	
BAP Broadcast Source			M	
BAP Broadcast Sink				M
BAP Unicast Client	M			
BAP Unicast Server		M		
VCP Volume Controller	M			
VCP Volume Renderer		C.1		M
MICP Microphone Controller	O			
MICP Microphone Device		C.2		

Notes:

- C.1 Mandatory if the UGT supports the UGT Sink feature
- C.2 Optional if the UGT supports the UGT Source feature

Table 23: HAP dependencies

	Hearing Aid	Hearing Aid Unicast Client	Hearing Aid Remote Controller
HAS Client			M
HAS Server	M		
CAP Initiator		M	
CAP Acceptor	M		
CAP Commander			M
BAP Unicast Client		M	
BAP Unicast Server	M		
VCP Volume Controller			M
VCP Volume Renderer	M		
VOCS Server	C.1		
AICS Server	O		
MICP Microphone Controller			O
MICP Microphone Device	C.2		
CCP Call Control Client	O		
CCP Call Control Server		O	
CSIP Set Coordinator		M	M
CSIP Set Member	C.3		
BAS Server	C.4		
IAS Server	O		

Notes:

- C.1 Mandatory if the HA supports the Volume Baslance feature and is part of a Binaural Hearing Aid Set
- C.2 Mandatory if the HA supports the BAP Audio Source Role
- C.3 Mandatory if the HA is capable of being part of a Binaural Hearing Aid set
- C.4 If equipped with batteries
- C.5 If CCP Call Control Server is supported

Table 24: PBP dependencies

	Public Broadcast Source	Public Broadcast sink	Public Broadcast Assistant
CAP Initiator	M		
CAP Acceptor		M	
CAP Commander			M
BAP Broadcast Assistant			M

Table 25: TMAP dependencies

	Call Gateway	Call Terminal	Unicast Media Sender	Unicast Media Receiver	Broadcast Media Sender	Broadcast Media Receiver
TMAS Server	M	M	M	M	O	M
TMAS Client	O	O	O	O	O	O
CAP Initiator	M		M		M	
CAP Acceptor		M		M		M
CAP Commander	M	O	M	O	O	O
BAP Broadcast Source					M	
BAP Broadcast Sink						M
BAP Unicast Client	M		M			
BAP Unicast Server		M		M		
VCP Volume Controller	M		M			
VCP Volume Renderer		C.1		M		M
MCP Media Control Server			M			
CCP Call Control Server	M					

Notes:

- C.1 Mandatory to support if the BAP Unicast Server is acting as an Audio Sink

Bluetooth Audio Stack Status The following table shows the current status and support of the profiles in the Bluetooth Audio Stack.

Table 26: Bluetooth Audio Profile status

Module	Role	Version	Added in Release	Status	Remaining
VCP	Volume Renderer	1.0.0	2.6	• Feature complete • Shell Module • BSIM test	• Sample Application
	Volume Controller	1.0.0	2.6	• Feature complete • Shell Module • BSIM test	• Sample Application
MICP	Microphone Device	1.0.0	2.7	• Feature complete • Shell Module • BSIM test	• Sample Application
	Microphone Controller	1.0.0	2.7	• Feature complete • Shell Module • BSIM test	• Sample Application

Using the Bluetooth Audio Stack To use any of the profiles in the Bluetooth Audio Stack, including the top-level profiles outside of GAF, `CONFIG_BT_AUDIO` shall be enabled. This Kconfig option allows the enabling of the individual profiles inside of the Bluetooth Audio Stack. Each profile can generally be enabled on its own, but enabling higher-layer profiles (such as CAP, TMAP and HAP) will typically require enabling some of the lower layer profiles.

It is, however, possible to create a device that uses e.g. only Stream Control (with just the BAP), without using any of the content control or rendering/capture control profiles, or vice versa. Using the higher layer profiles will however typically provide a better user experience and better interoperability with other devices.

Common Audio Profile (CAP) The Common Audio Profile introduces restrictions and requirements on the lower layer profiles. The procedures in CAP works on one or more streams for one or more devices. Is it thus possible via CAP to do a single function call to setup multiple streams across multiple devices.

The figure below shows a complete structure of the procedures in CAP and how they correspond to procedures from the other profiles. The circles with I, A and C show whether the procedure has active involvement or requirements from the CAP Initiator, CAP Accept and CAP Commander roles respectively.

The API reference for CAP can be found in *Common Audio Profile*.

Stream Control (BAP) Stream control is implemented by the Basic Audio Profile. This profile defines multiple roles:

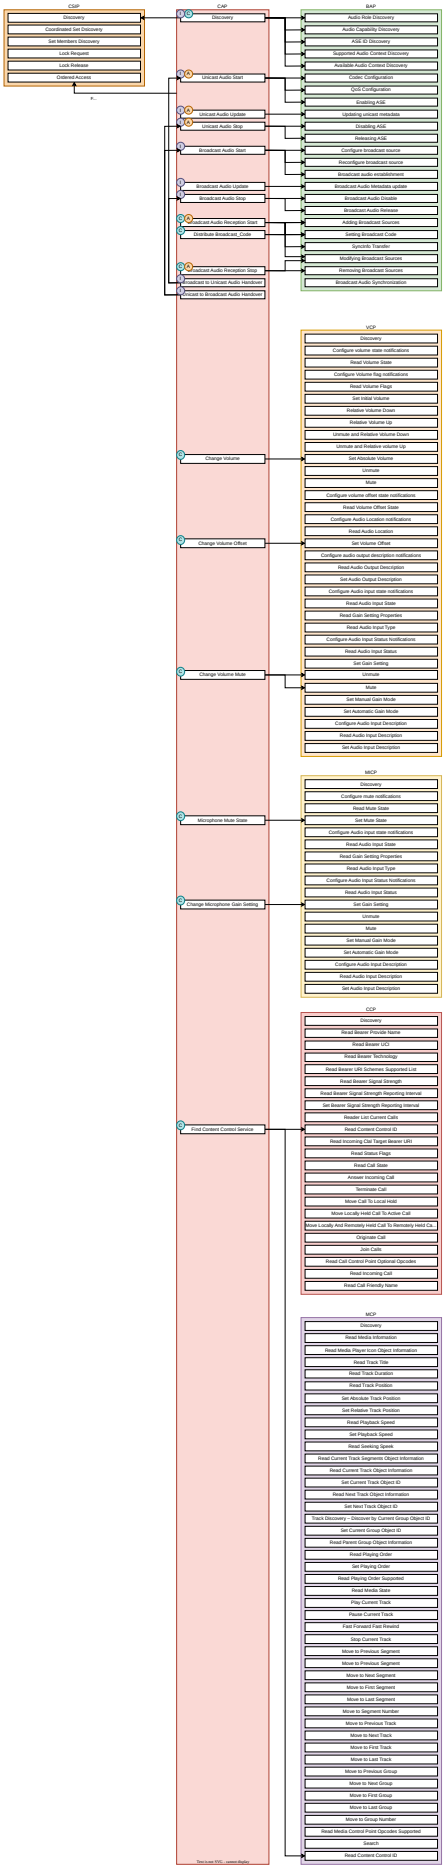

Fig. 18: Common Audio Profile Procedures

- Unicast Client
- Unicast Server
- Broadcast Source
- Broadcast Sink
- Scan Delegator
- Broadcast Assistant

Each role can be enabled individually, and it is possible to support more than one role.

Notes about the stream control services There are 3 services primarily used by stream control using the Basic Audio Profile.

Audio Stream Control Service (ASCS) ASCS is a service used exclusively for setting up unicast streams, and is located on the BAP Unicast Server device. The service exposes one or more endpoints that can either be a sink or source endpoint, from the perspective of the Unicast Server. That means a sink endpoint is always audio from the Unicast Client to the Unicast Server, and a source endpoint is always from the Unicast Server to the Unicast Client.

Unlike most other GATT services, ASCS requires that each characteristic in the service has unique data per client. This means that if a Unicast Server is connected to multiple Unicast Clients, the Unicast Clients are not able to see or control the endpoints configured by the other clients. For example if a person's smartphone is streaming audio to a headset, then the same person will not be able to see or control that stream from their smartwatch.

Broadcast Audio Scan Service (BASS) BASS is a service that is exclusively used by the Scan Delegator and Broadcast Assistant. The main purpose of the service is to offload scanning from low power peripherals to e.g. phones and PCs. Unlike ASCS where the data is required to be unique per client, the data in BASS (called receive states) are (usually) shared among all connected clients. That means it is possible for a person to tell their headphones to synchronize to a Broadcast Source using their phone, and then later tell their headphones to stop synchronizing using their smartwatch.

A Broadcast Assistant can be any device, and may only support this one role without any audio capabilities. This allows legacy devices that do not support periodic advertisements or isochronous channels to still provide an interface and scan offloading for peripherals. The Bluetooth SIG has provided a guide on how to develop such legacy Broadcast Assistants that can be found at https://www.bluetooth.com/bluetooth-resources/developing-auracast-receivers-with-an-assistant-application-for-legacy-smartphones/. An important note about this guide is that many operating systems (especially on phones), do not allow generic usage of the BASS UUID, effectively making it impossible to implement your own Broadcast Assistant, because you cannot access the BASS.

Published Audio Capabilities Service (PACS) PACS is used to expose a device's audio capabilities in Published Audio Capabilities (PAC) records. PACS is used by nearly all roles, where the Unicast Client and Broadcast Assistant will act as PACS clients, and Unicast Server and Broadcast Sink will act as PACS servers. These records contain information about the codec, and which values are supported by each codec. The values for the LC3 codec are defined by the Bluetooth Assigned numbers (https://www.bluetooth.com/specifications/assigned-numbers/), and the values for other codecs such as SBC are left undefined/implementation specific for BAP.

PACS also usually shares the same data between each connected client, but by using functions such as `bt_pacs_conn_set_available_contexts_for_conn()`, it is possible to set specific values for specific clients.

The API reference for stream control can be found in *Bluetooth Audio*.

Rendering and Capture Control Rendering and capture control is implemented by the Volume Control Profile (VCP) and Microphone Control Profile (MICP).

The VCP implementation supports the following roles

- Volume Control Service (VCS) Server
- Volume Control Service (VCS) Client

The MICP implementation supports the following roles

- Microphone Control Profile (MICP) Microphone Device (server)
- Microphone Control Profile (MICP) Microphone Controller (client)

The API reference for volume control can be found in *Bluetooth Volume Control*.

The API reference for Microphone Control can be found in *Bluetooth Microphone Control*.

Content Control Content control is implemented by the Call Control Profile (CCP) and Media Control Profile (MCP).

The CCP implementation is not yet implemented in Zephyr.

The MCP implementation supports the following roles

- Media Control Service (MCS) Server via the Media Proxy module
- Media Control Client (MCC)

The API reference for media control can be found in *Bluetooth Media Control*.

Generic TBS and Generic MCS Both the Telephone Bearer Service (TBS) used by CCP and the Media Control Service (MCS) used by MCP have the concept of generic instances of the services called Generic TBS (GTBS) and Generic MCS (GMCS).

While these share a common name prefix, the behavior of these two may be significantly different.

Generic TBS The TBS spec defines GTBS as

> GTBS provides a single point of access and exposes a representation of its internal telephone bearers into a single telephone bearer. This service provides telephone status and control of the device as a single unit with a single set of characteristics. It is left up to the implementation to determine what telephone bearer a characteristic of GTBS represents at any time. There is no specified manner of representing a characteristic from each individual TBS that resides on the device to the same characteristic of the GTBS.
>
> For example, if there is more than one TBS on a device and each has a unique telephone bearer name (e.g., Name1 and Name2), the way the GTBS represents the telephone bearer name is left up to the implementation. GTBS is suited for clients that do not need to access or control all the information available on specific telephone bearers.

This means that a GTBS instance represents one or more telephone bearers. A telephone bearer could be any application on a device that can handle (telephone) calls, such as the default Call application on a smartphone, but also other applications such as Signal, Discord, Teams, Slack, etc.

GTBS may be standalone (i.e. the device only has a GTBS instance without any TBS instances), and the behavior of the GTBS is mostly left up to the implementation. In Zephyr the implementation of GTBS is that it contains some generic information, such as the provider name which is defined to simply be “Generic TBS”, but the majority of the information in the GTBS instance in Zephyr has been implemented to be a union of the data of the other bearers. For example if you have a bearer for regular phone calls and Teams and have an active call in both bearers, then each of

those bearers will report a single call, but the GTBS instance will report 2 calls, making it possible for a simple Call Control Client to control all calls from a single bearer. Similarly the supported URIs for each bearer are also made into a union in GTBS, and when placing a call using the GTBS the server will pick the most suited bearer depending on the URI. For example calls with URI `tel` would go to the regular phone application, and calls with the URI `skype` would go to the Teams application.

In conclusion the GTBS implementation in Zephyr is a union of the non-generic telephone bearers.

Generic MCS The MCS spec defines GMCS as

> The GMCS provides status and control of media playback for the device as a single unit. An MCS instance describes and controls the media playback for a specific media player within the device. A device implements MCS instances to allow clients to access the separate internal media player entities.

and where the behavior of GMCS is defined as

> ... the behavior of MCS and GMCS is identical, and all the characteristics and the characteristics' behaviors are the same. The term "MCS" is used throughout the document. Unless otherwise specifically stated in this specification, the same meaning applies to GMCS as well.

This means that a GMCS instance works the same way as an MCS instance, and it follows that GMCS

> controls the media playback for a specific media player within the device

A media player on a device could be anything that plays media, such as a Spotify or Youtube application on a smartphone. Thus if a device has multiple MCS instances, then each of these control media for that specific application, but the GMCS also controls media playback for a specific media player. GMCS can thus be considered a pointer to a specific MCS instance, and control either e.g. Spotify or Youtube, but not both.

The MCS spec does however provide an example of GMCS where a device can

> Implement a GMCS that provides status and control of media playback for the device as a whole.

Which may indicate that an implementation may use GMCS to represent all media players with GMCS and not a specific media player as stated above. In the case where a device does not have any MCS instances and only GMCS, then GMCS will point to a generic instance.

The Zephyr implementation of MCS and GMCS is incomplete, and currently only supports instantiating a single instance that can either be an MCS or GMCS. This means that the implementation is neither complete nor spec-compliant.

Difference between GTBS and GMCS The definitions and implementations of GTBS and GMCS as stated above are notably different. GTBS works as a union between the other TBS instances (if any), and GMCS works as a pointer to a specific MCS instance (if any). This effectively means that a simple Call Control Client can control all calls just using GTBS, but a Media Control Client may only be able to control a single player using GMCS.

Coordinated Sets Coordinated Sets is implemented by the Coordinated Sets Identification Profile (CSIP).

The CSIP implementation supports the following roles

- Coordinated Set Identification Service (CSIP) Set Member
- Coordinated Set Identification Service (CSIP) Set Coordinator

The API reference for media control can be found in *Bluetooth Coordinated Sets*.

Specification correctness and data location The implementations are designed to ensure specification compliance as much as possible. When a specification introduces a requirement with e.g. a **shall** then the implementation should attempt to ensure that this requirement is always followed. Depending on the context of this, the implementation ensures this by rejecting invalid parameters from the application, or from the remote devices.

Some requirements from the specifications are not or can not be handled by the stack itself for various reasons. One reason when the stack cannot handle a requirement is if the data related to the requirement is exclusively controlled by the application. An example of this is the advertising data, where multiple services have requirements for what to advertise and when, but where both the advertising state and data is exclusively controlled by the application.

Oppositely there are also requirements from the specification, where the data related to the requirement is exclusively controlled by the stack. An example of this is the Volume Control Service (VCS) state, where the specifications mandate that the VCP Volume Renderer (VCS server) modify the values without a choice, e.g. when setting the absolutely volume. In cases like this the application is only notified about the change with a callback, but cannot reject the request (the stack will reject any invalid requests).

Generally when the data is simple (like the VCS state which only takes up a few bytes), the data is kept in and controlled by the stack, as this can ensure that the requirements can be handled by the stack, making it easier to use a profile role correctly. When the data is more complex (e.g. the PAC records), the data may be kept by the application and the stack only contains a reference to it. When the data is very application specific (e.g. advertising data), the data is kept in and controlled by the application.

As a rule of thumb, the return types of the callbacks for each profile implementation indicate whether the data is controlled by the stack or the application. For example all the callbacks for the VCP Volume Renderer have the return type of `void`, but the return type of the BAP Unicast Server callbacks are `int`, indicating that the application not only controls a lot of the Unicast Server data, but can also reject the requests. The choice of what the return type of the callbacks often depend on the specifications, and how much control the role has in a given context.

Things worth knowing or considering when using LE Audio This section describes a few things to consider when contributing to or using LE Audio in Zephyr. The things described by this section are not unique to Zephyr as they are defined by the specifications.

Security requirements All LE Audio services require Security Level 2 but where the key must be 128-bit and derived via an OOB method or via LE Secure connections. There is no Core-spec defined way of reporting this in GATT, as ATT does not have a specific error code for missing OOB method or LE Secure Connections (although there is a way to report wrong key size).

In Zephyr we do not force the device to always use these, as a device that uses LE Audio may also use other profiles and services that do not require such security. We guard all access to services using a custom security check implemented in subsys/bluetooth/audio/audio.c, where all LE Audio services must use the internal `BT_AUDIO_CHRC` macro for proper security verification.

Access to the LTK for encrypted SIRKs in CSIS The Coordinated Set Identification Service (CSIS) may encrypt the SIRK (set identity resolving key). The process of encrypting the SIRK requires the LTK as the encryption key, which is typically not exposed to higher layer implementations such as CSIS. This does not have any effect on the security though.

MTU requirements The Basic Audio Profile (BAP) has a requirement that both sides shall support a minimum ATT_MTU of at least 64 on the unenhanced ATT bearer or at least one enhanced ATT bearer. The requirement comes from the preferred (or sometimes mandatory) use of GATT Write Without Response, and where support for Write Long Characteristic Value is optional in most cases.

If a ASCS device supports values larger than the minimum ATT_MTU of 64 octets, then it shall support Read long Characteristic Value by setting `CONFIG_BT_ATT_PREPARE_COUNT` to a non-zero value.

LE Audio resources

This section contains some links and reference to resources that are useful for either contributors to the LE Audio Stack in Zephyr, LE Audio application developers or both.

The LE audio channel on Discord Zephyr has a specific Discord channel for LE Audio development, which is open to all. Find it here at https://discordapp.com/channels/720317445772017664/1207326649591271434 or simply search for "bt-audio" from within Discord. Since the `#bt-audio` channel is open for all, we cannot discuss any specifications that are in development in that channel. For discussions that require a Bluetooth SIG membership we refer to the `#bt-sig` Discord channel found at https://discordapp.com/channels/720317445772017664/869172014018097162.

Zephyr weekly meetings Anyone who is a Bluetooth SIG member and a Zephyr member can join the weekly meetings where we discuss and plan the development of LE Audio in Zephyr. You can find the time of the meetings by joining the Bluetooth-sig group at https://lists.zephyrproject.org/g/Bluetooth-sig.

Github project LE Audio in Zephyr has its own Github project available at https://github.com/orgs/zephyrproject-rtos/projects/26. The project is mostly automated, and the LE Audio contributors almost only rely on the automated workflows to present the state of development. Anyone is able to pick any of the open issues and work on it. If you cannot assign the issue to yourself, please leave a comment in the issue itself or ping the Discord channel for help.

Bluetooth SIG errata for LE Audio There are many specifications for LE Audio, and several of them are still being updated and developed. To get an overview of the errata for the LE Audio specifications you can visit

- Generic Audio (GA) errata https://bluetooth.atlassian.net/wiki/spaces/GA/pages/1634402349/GAWG+Errata+Lists
- Hearing Aid (HA) errata https://bluetooth.atlassian.net/wiki/spaces/HA/pages/1634140216/HA+WG+Errata+List
- Audio, Telephony and Automotive (ATA) errata https://bluetooth.atlassian.net/wiki/spaces/ATA/pages/1668481034/ATA+Errata+Lists

Access to errata requires a Bluetooth SIG membership.

Bluetooth SIG working groups for LE Audio There are 3 working groups in the Bluetooth SIG related to LE Audio:

- Generic Audio (GA) https://www.bluetooth.org/groups/group.aspx?gId=665
- Hearing Aid (HA) https://www.bluetooth.org/groups/group.aspx?gId=605
- Audio, Telephony, and Automotive (ATA) https://www.bluetooth.org/groups/group.aspx?gId=659

By joining these groups you will also get emails from their respective mailing lists, where multiple questions and discussions are handled. The working groups also have scheduled weekly meetings, where issues and the development of the specifications are handled.

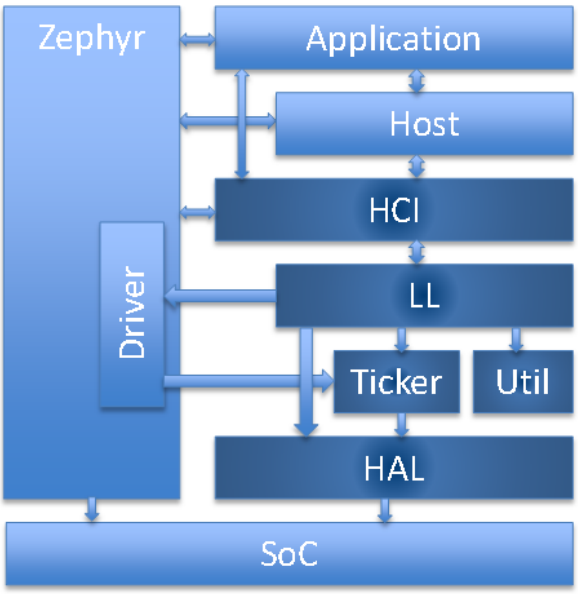
Access to the Bluetooth SIG working groups requires a Bluetooth SIG membership.

The LE Audio Book There is a free ebook on LE Audio at https://www.bluetooth.com/bluetooth-resources/le-audio-book/. The book was released in January 2022, and thus before some of the specifications were finalized, but also before some of the released updates to the specifications. Nevertheless the book still provides a good explanation for many of the concepts and ideas, but please refer to the individual specifications for technical information.

Bluetooth SIG informational papers, reports and guides The Bluetooth SIG occasionally release new informational papers, report and guides. These can be found at https://www.bluetooth.com/bluetooth-resources/?tags=le-audio&keyword. Here you will also find the aforementioned LE Audio book, among many other good resources.

Samples All of the LE Audio samples are located in `samples/bluetooth/audio`.

LE Controller



Overview

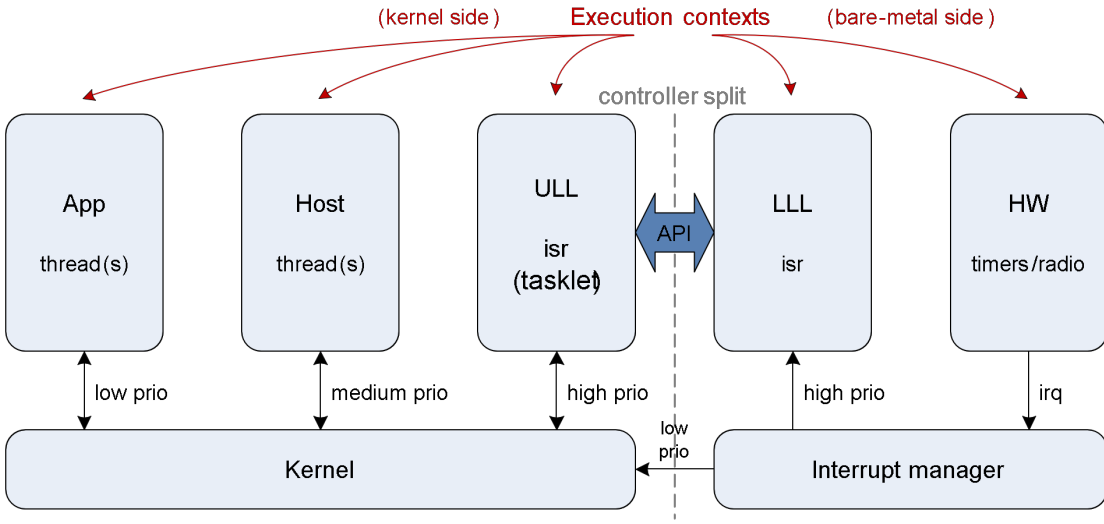
1. HCI
   - Host Controller Interface, Bluetooth standard
   - Provides Zephyr Bluetooth HCI Driver
2. HAL
   - Hardware Abstraction Layer
   - Vendor Specific, and Zephyr Driver usage
3. Ticker
   - Soft real time radio/resource scheduling
4. LL_SW

- Software-based Link Layer implementation
- States and roles, control procedures, packet controller

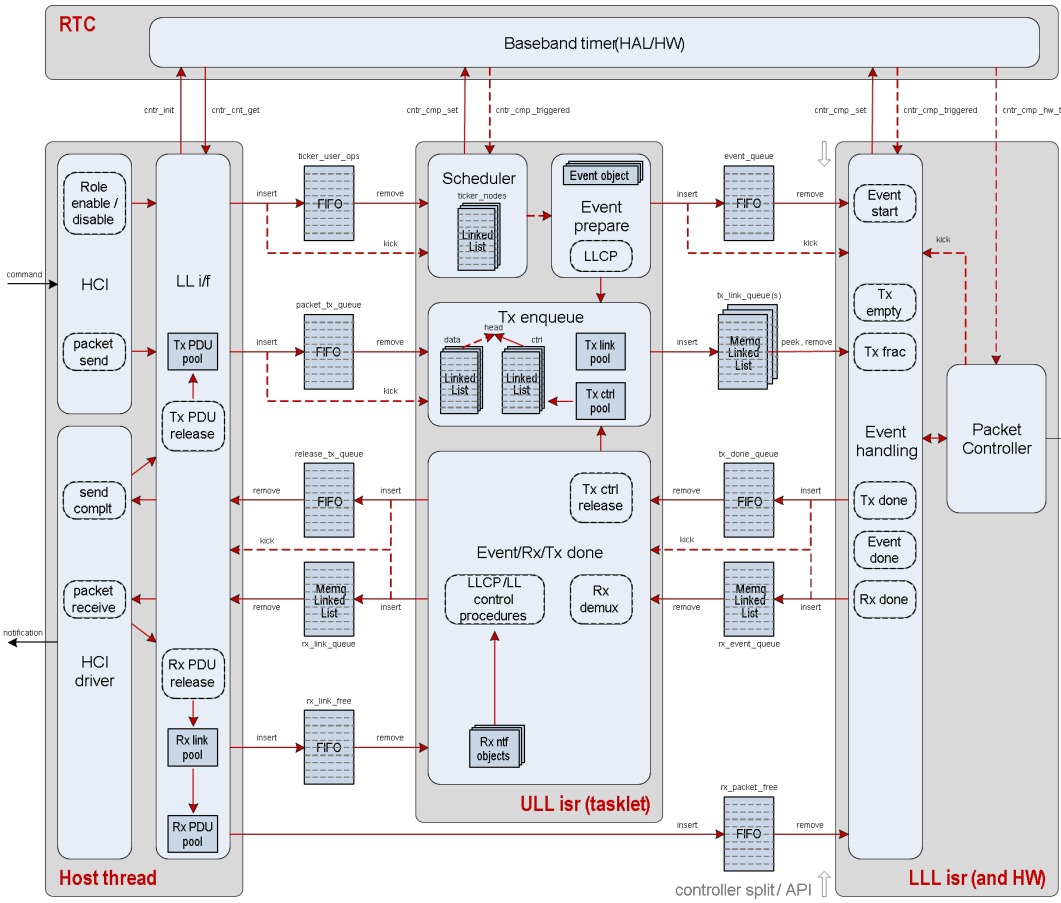
5. Util
   - Bare metal memory pool management
   - Queues of variable count, lockless usage
   - FIFO of fixed count, lockless usage
   - Mayfly concept based deferred ISR executions

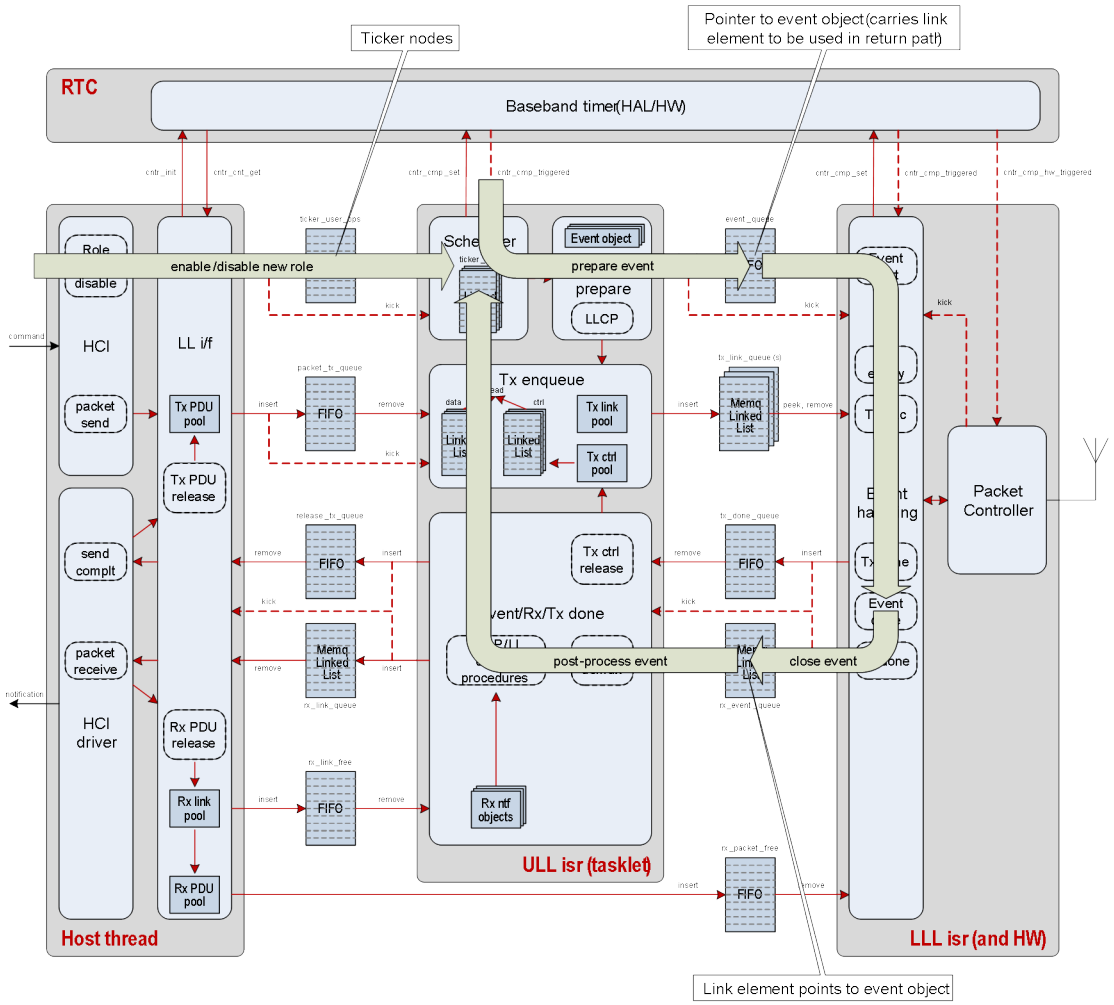
Architecture

Execution Overview

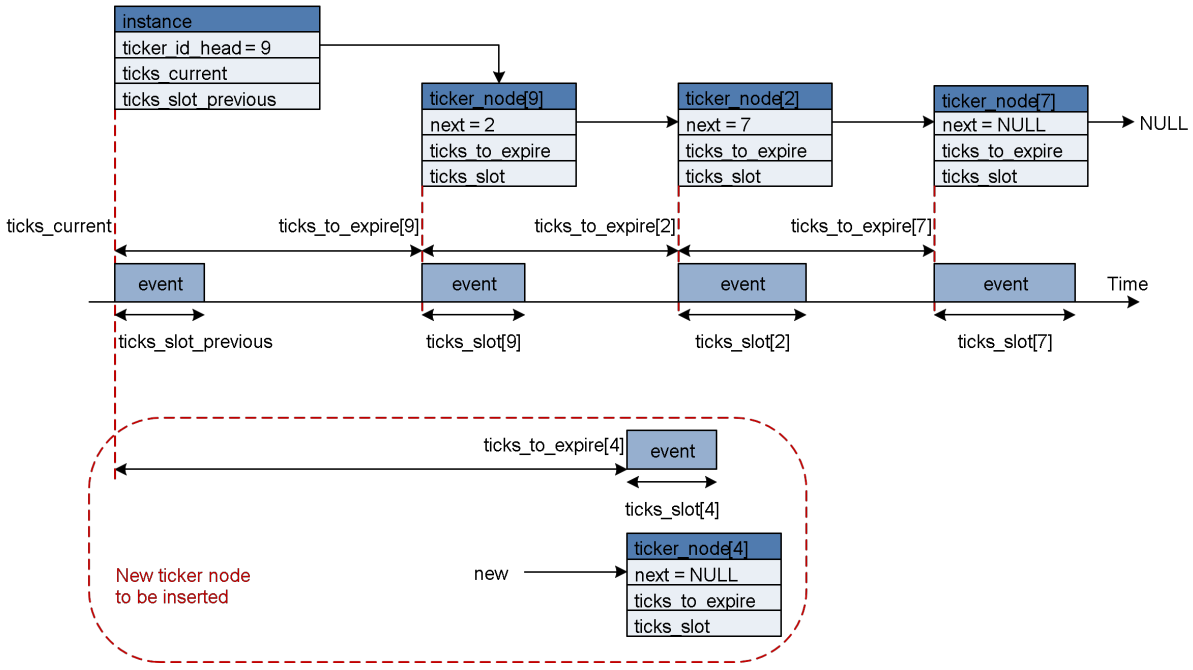


Architecture Overview



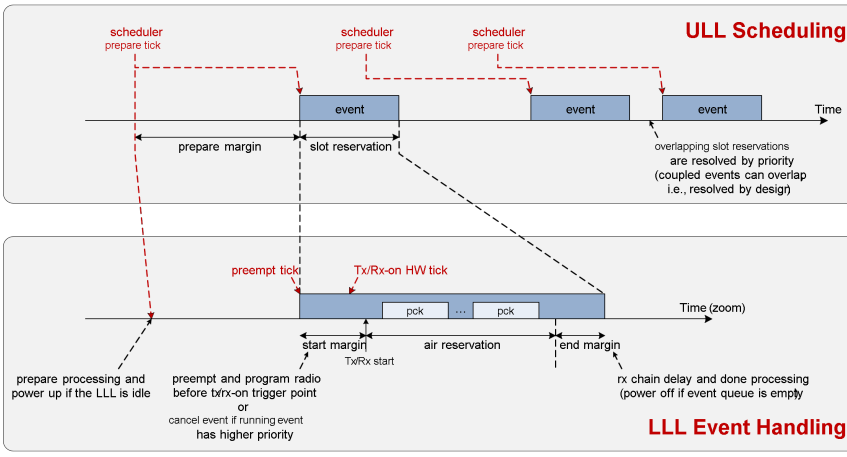


Scheduling

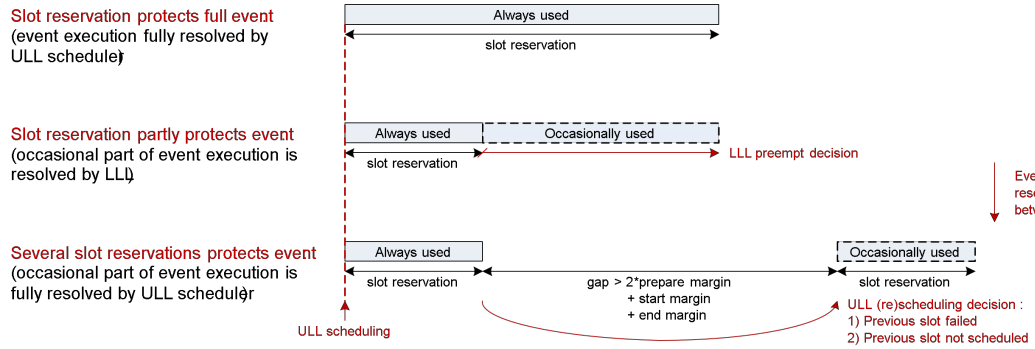


Ticker

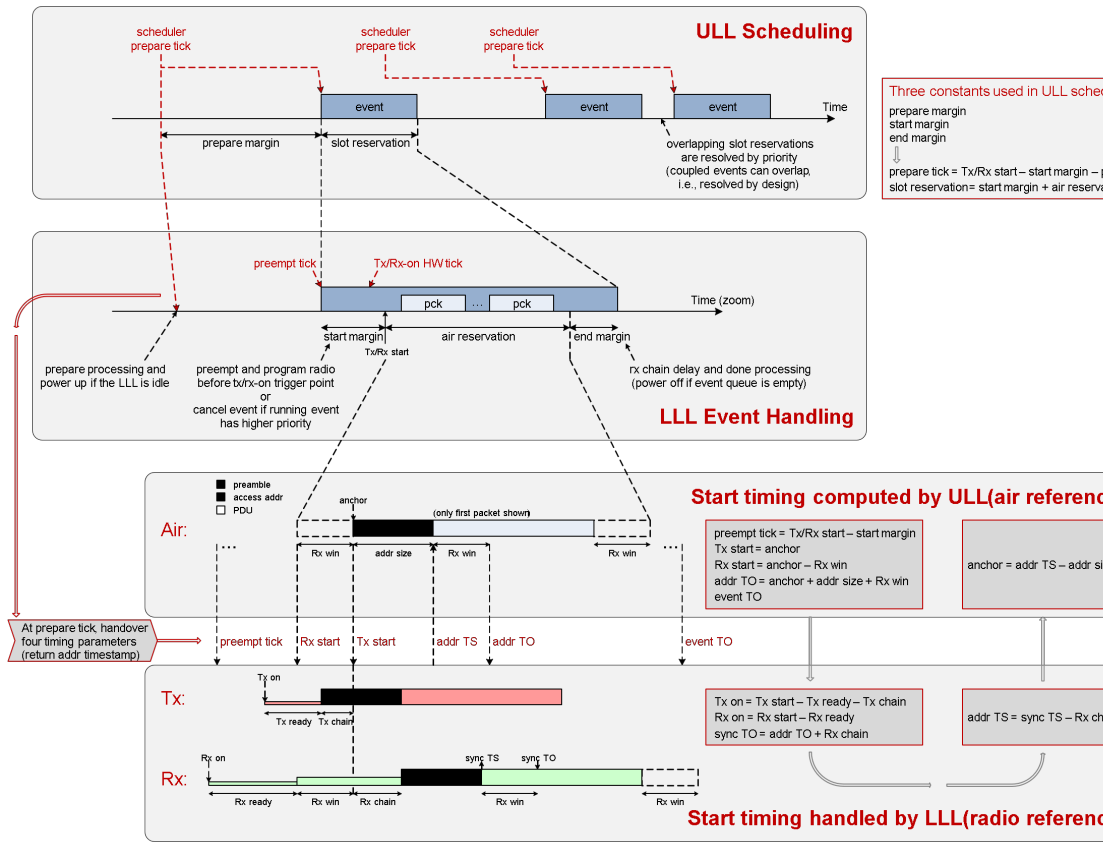
Upper Link Layer and Lower Link Layer

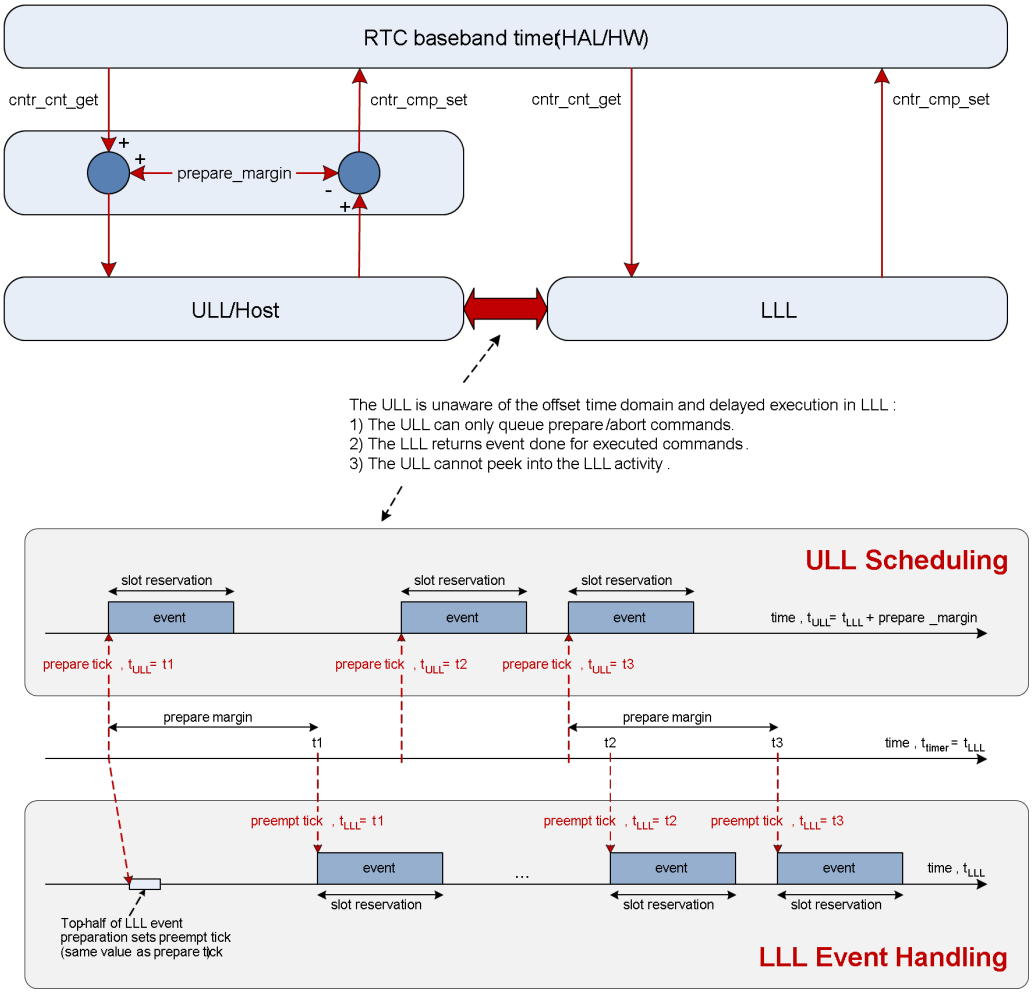


Scheduling Variants

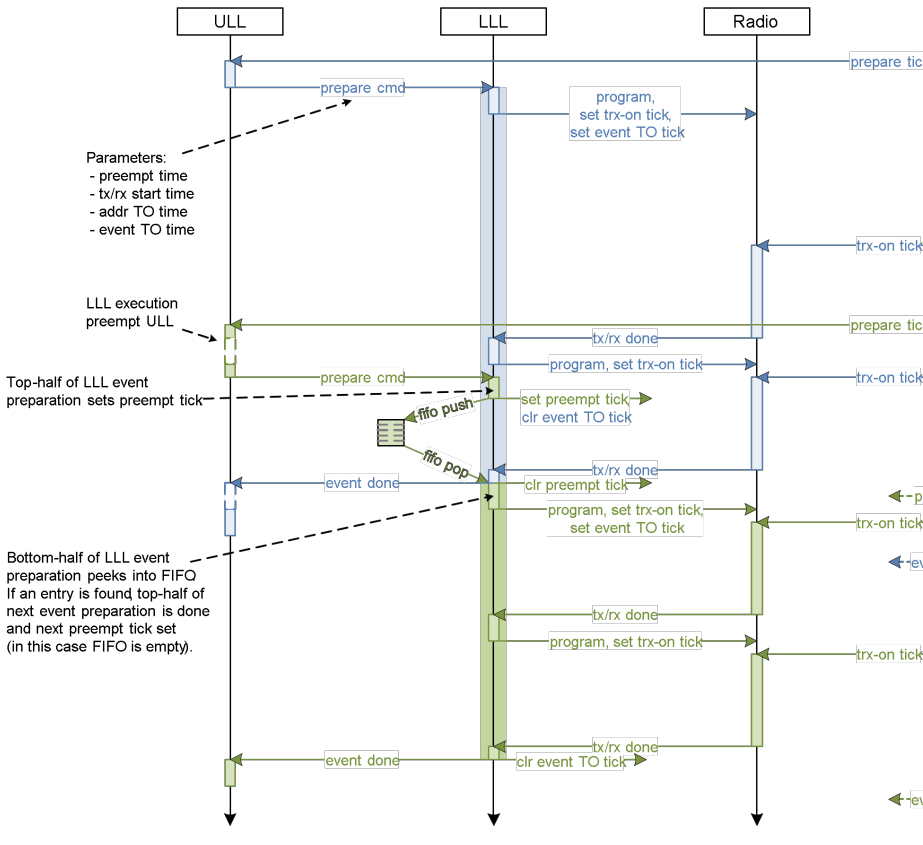


ULL and LLL Timing



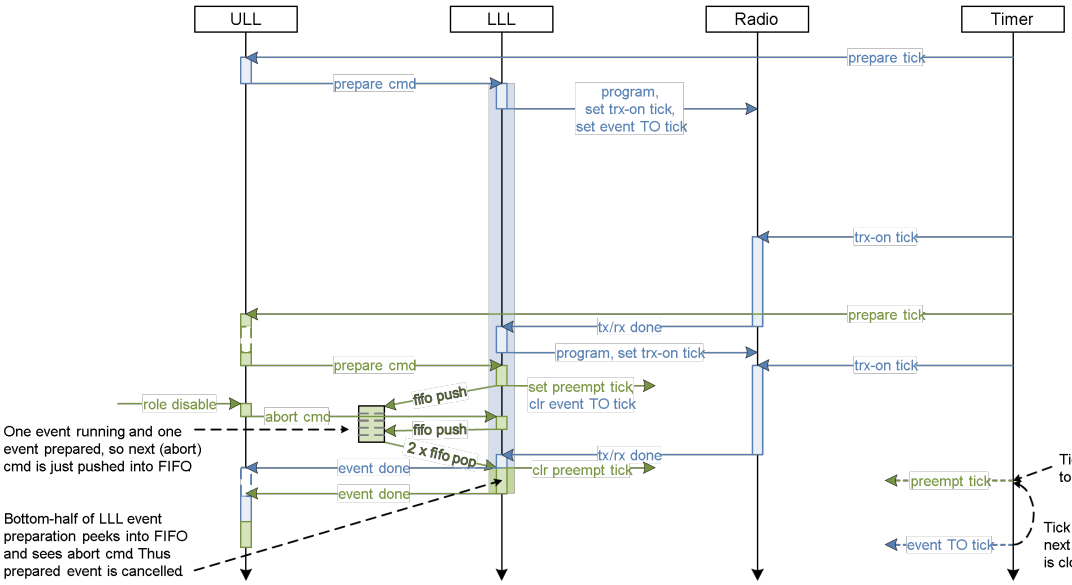


Event Handling

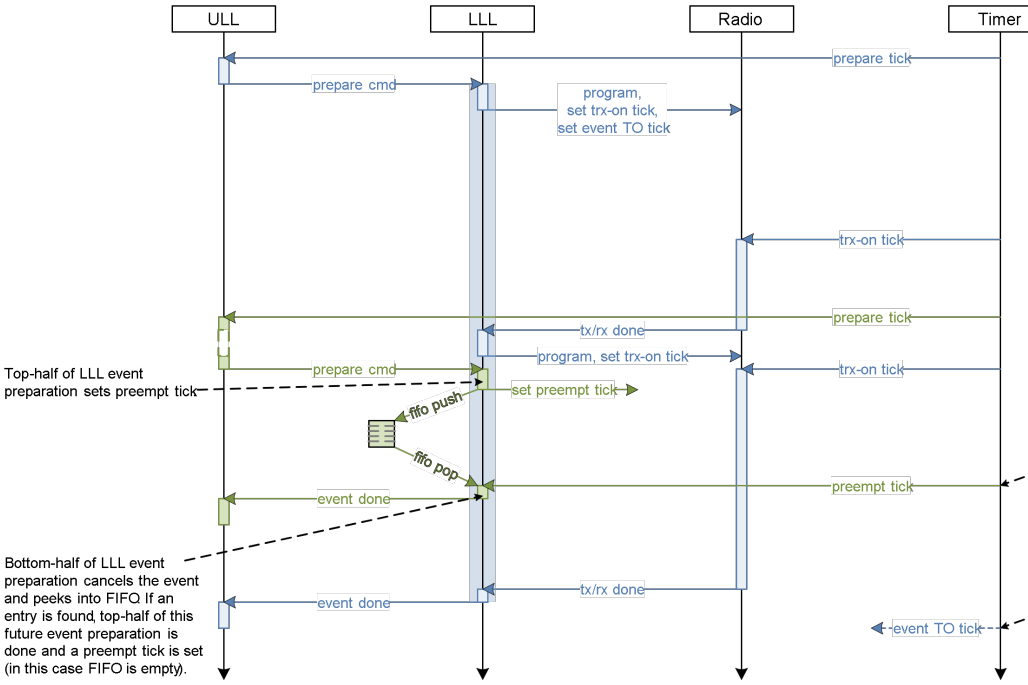


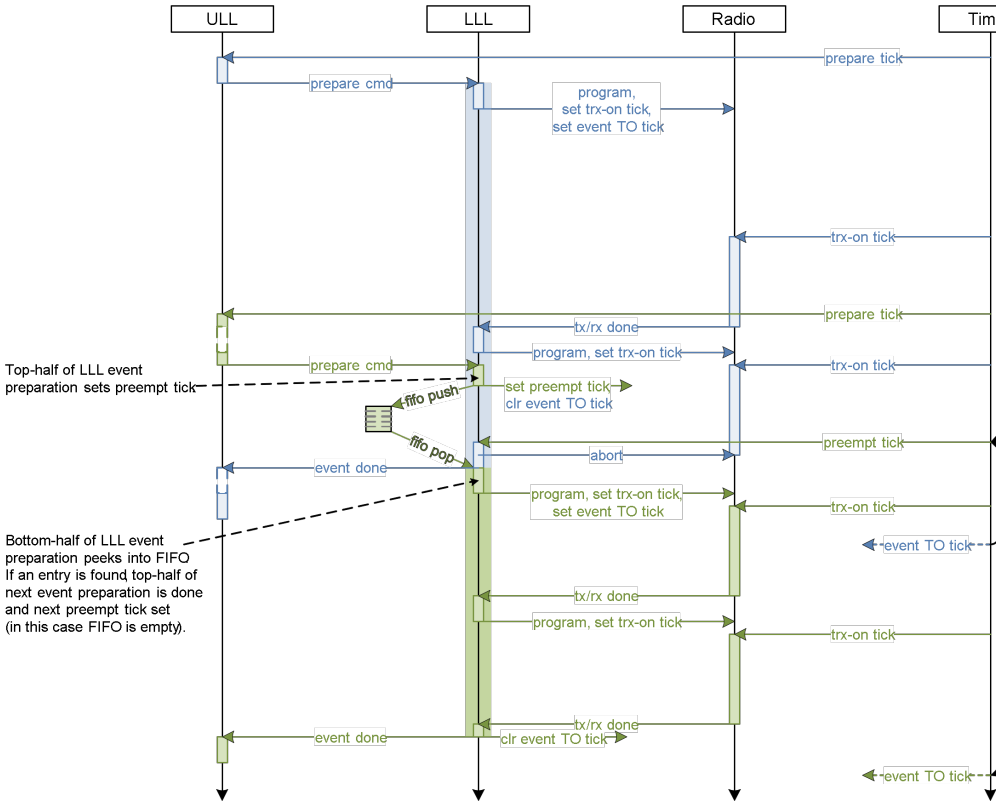
Scheduling Closely Spaced Events

Aborting Active Event



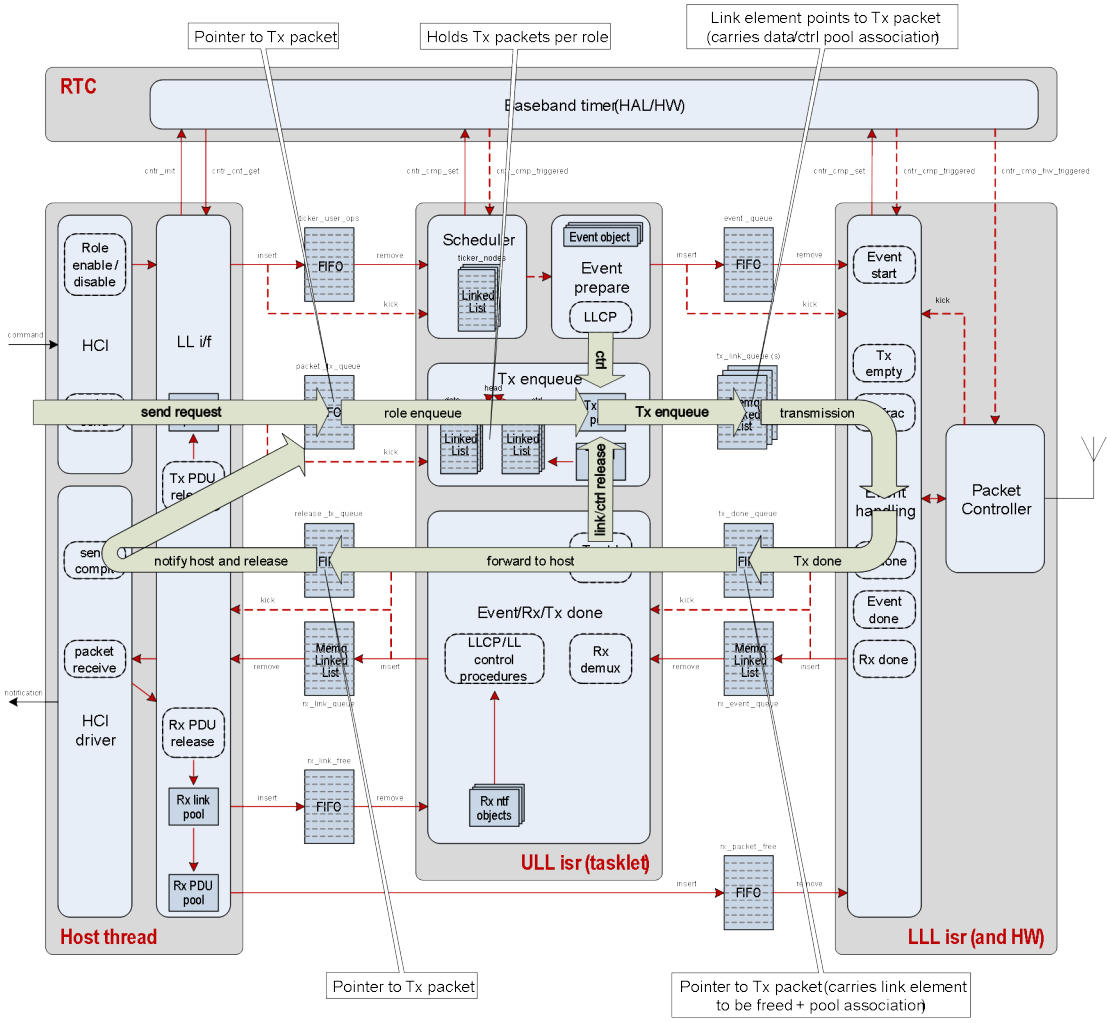
Cancelling Pending Event



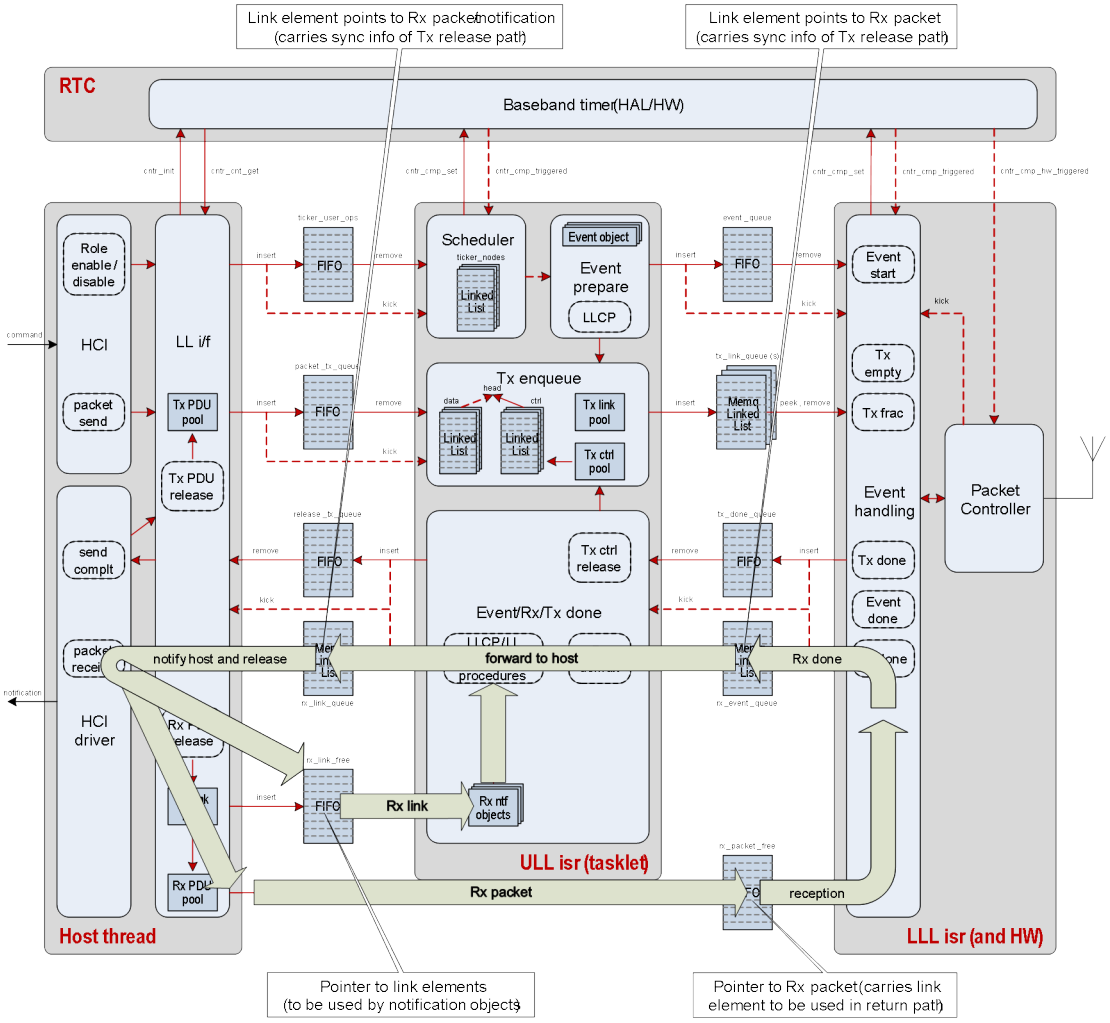


Pre-emption of Active Event

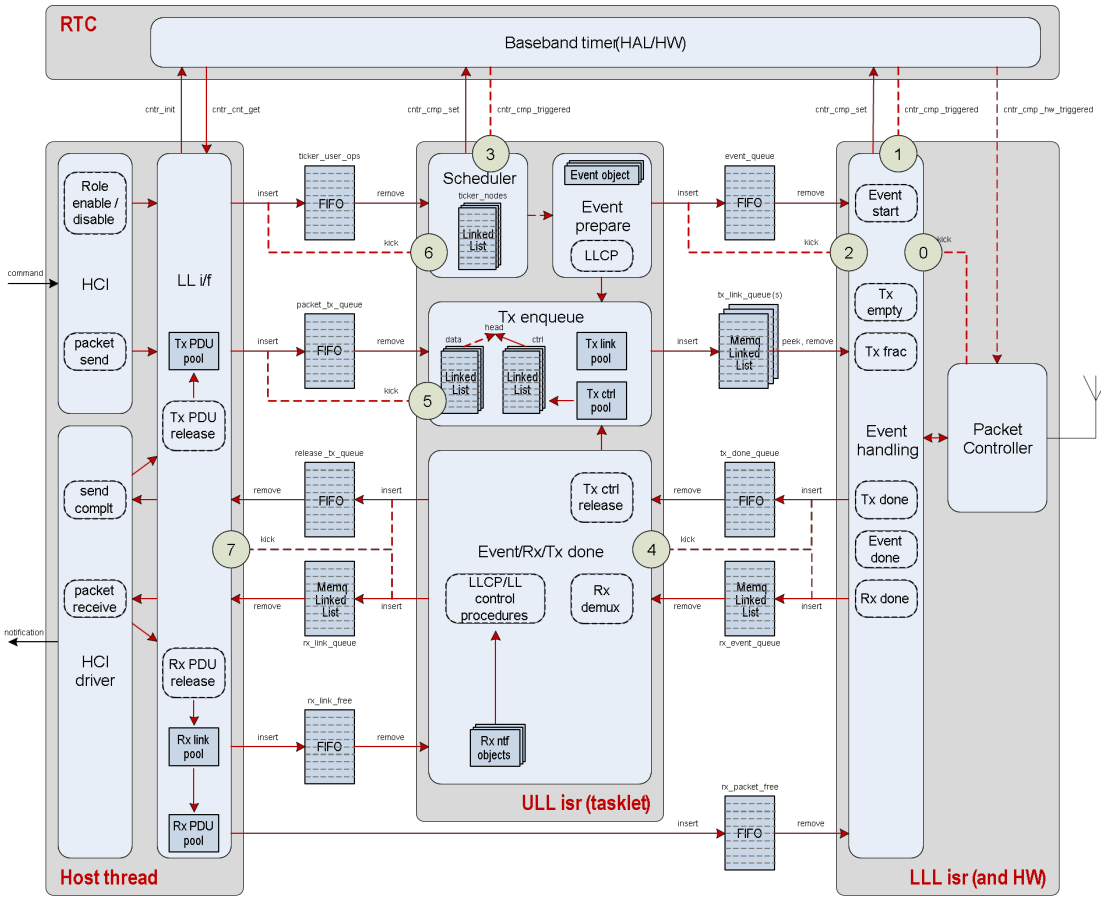
Data Flow



Transmit Data Flow



Receive Data Flow



Execution Priorities

- Event handle (0, 1) < Event preparation (2, 3) < Event/Rx done (4) < Tx request (5) < Role management (6) < Host (7).
- LLL is vendor ISR, ULL is Mayfly ISR concept, Host is kernel thread.

Link Layer Control Procedures Following is a brief fly in on the main concepts in the implementation of control procedures handling in ULL.

Three main execution contexts

- **HCI/LLCP API**
  - Miscellaneous procedure initiation API
  - From ull_llcp.c::ull_cp_<proc>() for initiating local procedures
  - Interface with running procedures, local and remote
- **lll_prepare context to drive ull_cp_run()**
  - LLCP main state machine entry/tick'er
  - From ull_peripheral.c/ull_central.c::ticker_cb via ull_conn_llcp()
- **rx_demux context to drive ull_cp_tx_ack() and ull_cp_rx()**
  - LLCP tx ack handling and PDU reception
  - From ull_conn.c::ull_conn_rx()
  - Handles passing PDUs into running procedures as well as possibly initiating remote procedures

Data structures and PDU helpers

- **struct llcp_struct**
  - Main LLCP data store
  - Defined in ull_conn_types.h and declared as part of struct ll_conn
  - Holds local and remote procedure request queues as well as conn specific LLCP data
  - Basic conn-level abstraction
- **struct proc_ctx**
  - General procedure context data, contains miscellaneous procedure data and state as well as sys_snode_t for queueing
  - Defined in ull_llcp_internal.h, declared/instantiated through ull_llcp.c::create_procedure()
  - Also holds node references used in tx_ack as well as rx_node retention mechanisms
- **struct llcp_mem_pool**
  - Mem pool used to implement procedure contexts resource - instantiated in both a local and a remote version
  - Used through ull_llcp.c::create_procedure()
- **Miscellaneous pdu gymnastics**
  - Encoding and decoding of control pdus done by ull_llcp_pdu.c::llcp_pdu_encode/decode_<PDU>()
  - Miscellaneous pdu validation handled by ull_llcp.c::pdu_validate_<PDU>() via ull_llcp.c::pdu_is_valid()

LLCP local and remote request/procedure state machines

- **ull_llcp_local.c**
  - State machine handling local initiated procedures
  - Naming concept: lr _<...> => local request machine
  - Local procedure queue handling
  - Local run/rx/tx_ack switch
- **ull_llcp_remote.c**
  - Remote versions of the above
  - Naming concept: rr_<...> => remote request machine
  - Also handling of remote procedure initiation by llcp_rx_new()
  - Miscellaneous procedure collision handling (in rr_st_idle())
- **ull_llcp_common/conn_upd/phy/enc/cc/chmu.c**
  - Individual procedure implementations (ull_llcp_common.c collects the simpler ones)
  - Naming concept: lp_<...> => local initiated procedure, rp_<...> => remote initiated procedure
  - Handling of procedure flow from init (possibly through instant) to completion and host notification if applicable

Miscellaneous concepts

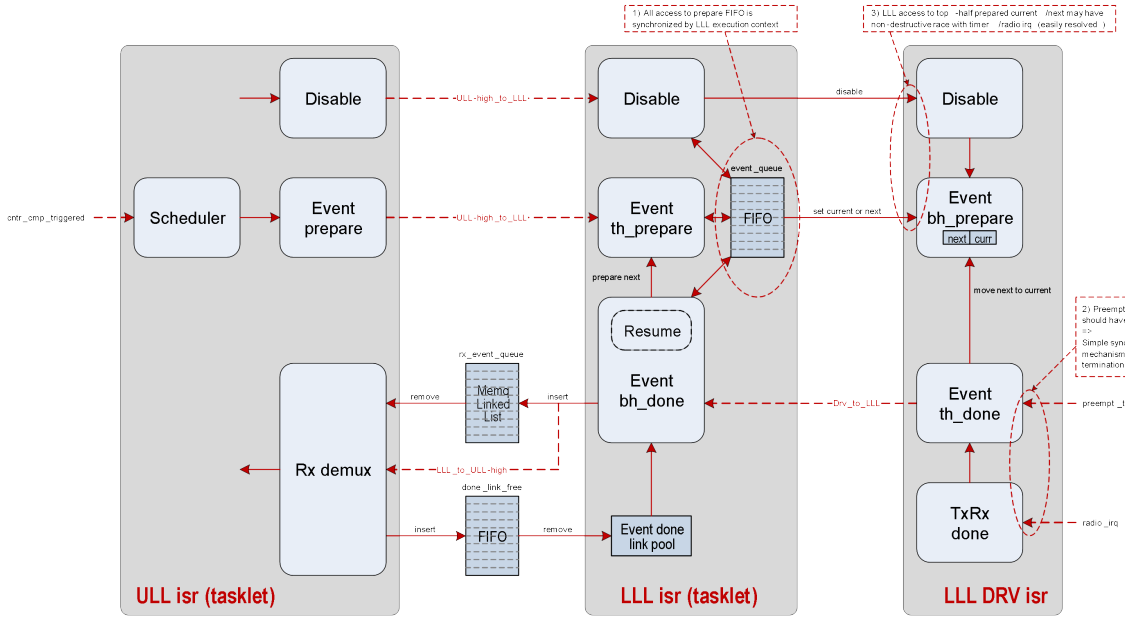
- **Procedure collision handling**
  - See BT spec for explanation
  - Basically some procedures can exist in parallel but some can't - for instance only one instant based at a time
  - Spec states rules for how to handle/resolve collisions when they happen
- **Termination handling**
  - Specific rules apply re. how termination is handled.
  - Since we have resource handling re. procedure contexts and terminate must always be available this is handled as a special case
  - Note also - there are miscellaneous cases where connection termination is triggered on invalid peer behavior
- **New remote procedure handling**
  - Table new_proc_lut[] maps LLCP PDUs to procedures/roles used in llcp_rr_new()
  - Note - for any given connection, there can only ever be ONE remote procedure in the remote procedure queue
- **Miscellaneous minors**
  - pause/resume concepts - there are two (see spec for details)
  - procedure execution can be paused by the encryption procedure
  - data TX can be paused by PHY, DLE and ENC procedure
  - RX node retention - ensures no waiting for allocation of RX node when needed for notification

Miscellaneous unit test concepts

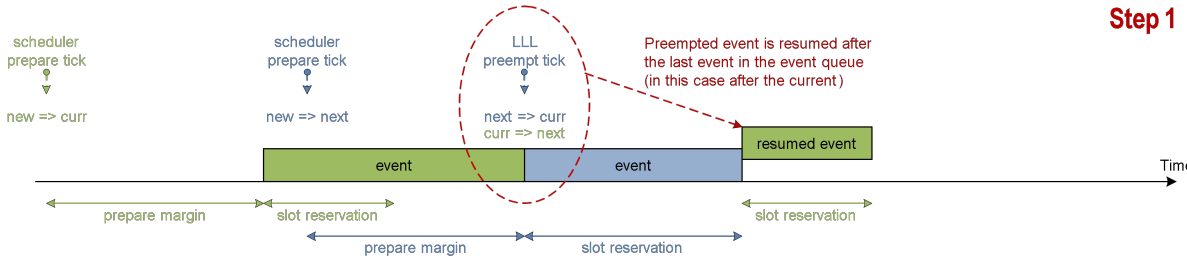
- **Individual ZTEST unit test for each procedure**
  - zephyr/tests/bluetooth/controller/ctrl_<proc>
- **Rx node handling is mocked**
  - Different configs are handled by separate conf files (see ctrl_conn_update for example)
  - ZTEST(periph_rem_no_param_req, test_conn_update_periph_rem_accept_no_param_req)
- **Emulated versions of rx_demux/prepare context used in unit tests - testing ONLY procedure PDU flow**
  - event_prepare()/event_done() helpers emulating LLL prepare/done flow
  - lt_rx()/lt_tx() 'lower tester' emulation of rx/tx
  - ut_rx_node() 'upper tester' emulation of notification flow handling
  - Bunch of helpers to generate and parse PDUs, as well as miscellaneous mocked ull_stuff()

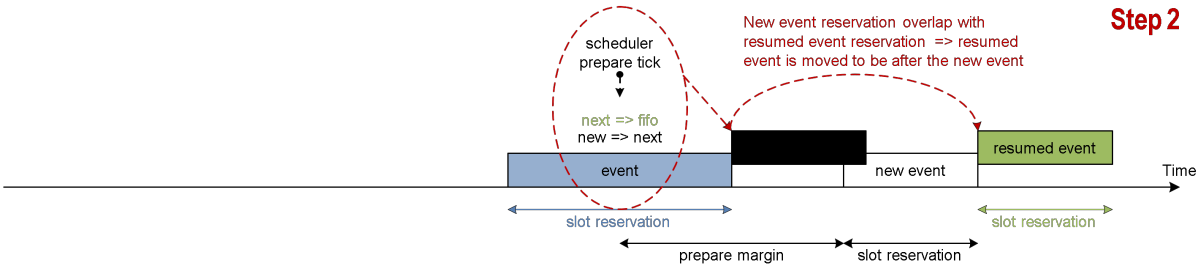
Lower Link Layer

LLL Execution

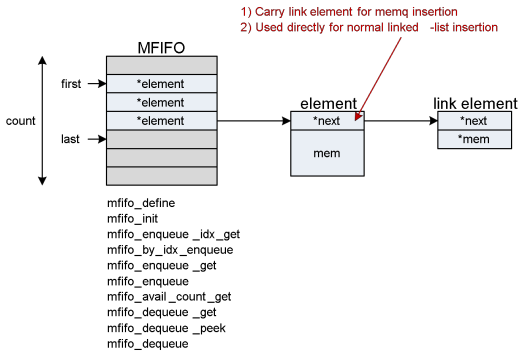


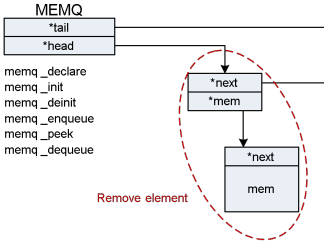
LLL Resume



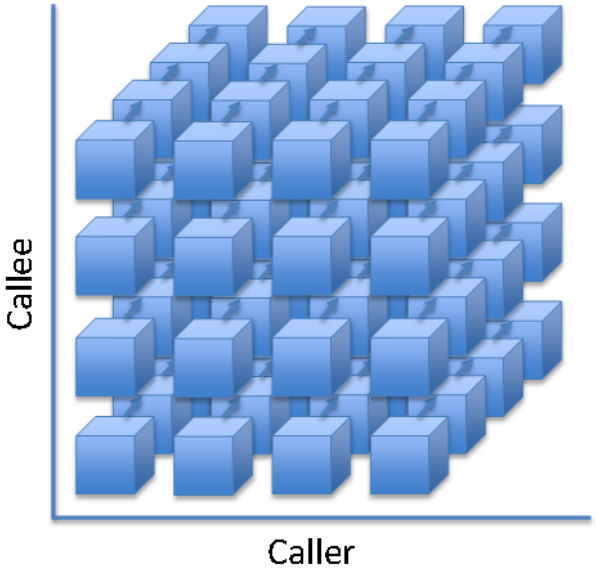


Bare metal utilities



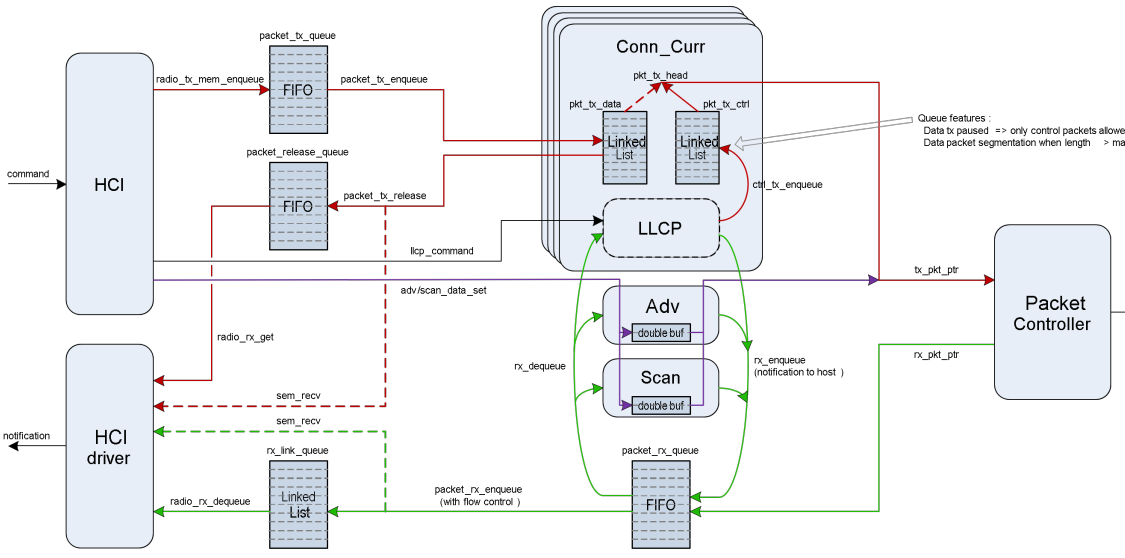


Memory FIFO and Memory Queue



Mayfly

- Mayfly are multi-instance scalable ISR execution contexts
- What a Work is to a Thread, Mayfly is to an ISR
- List of functions executing in ISRs
- Execution priorities map to IRQ priorities
- Facilitate cross execution context scheduling
- Race-to-idle execution
- Lock-less, bare metal



Legacy Controller

Bluetooth Low Energy Controller - Vendor Specific Details

Hardware Requirements

Nordic Semiconductor The Nordic Semiconductor Bluetooth Low Energy Controller implementation requires the following hardware peripherals.

Table 27: SoC Peripheral Use

Resource	nRF Peripheral	# instances	Zephyr Driver Accessible	Description
Clock	NRF_CLOCK	1	Yes	• A Low Frequency Clock (LFCLOCK) or sleep clock, for low power consumption between Bluetooth radio events • A High Frequency Clock (HFCLOCK) or active clock, for high precision packet timing and software based transceiver state switching with inter-frame space (tIFS) timing inside Bluetooth radio events
RTC [a]	NRF_RTC0	1	**No**	• Uses 2 capture/compare registers
Timer	NRF_TIMER0 or NRF_TIMER4 and NRF_TIMER1	2 or 1 Page 891, 1	**No**	• 2 instances, one each for packet timing and tIFS software switching, respectively • 7 capture/compare registers (3 mandatory, 1 optional for ISR profiling, 4 for single timer tIFS switching) on first instance • 4 capture/compare registers for second instance, if single tIFS timer is not used.
PPI [b]	NRF_PPI	21 channels (20[2]), and 2 channel groups[3]	Yes[4]	• Used for radio mode switching to achieve tIFS timings, for PA/LNA control
DPPI [c]	NRF_DPPI	20 channels, and 2 channel groups Page 89	Yes Page 8	• Used for radio mode switching to achieve tIFS timings, for PA/LNA control
SWI [d]	NRF_SWI4 and NRF_SWI5, or NRF_SWI2 and NRF_SWI3[5]	2	**No**	• 2 instances, for Lower Link Layer and Upper Link Layer Low priority execution context
Radio	NRF_RADIO	1	**No**	• 2.4 GHz radio transceiver with multiple radio standards such as 1 Mbps, 2 Mbps and Coded PHY S2/S8 Long Range Bluetooth Low Energy technology
RNG [e]	NRF_RNG	1	Yes	
ECB [f]	NRF_ECB	1	**No**	
CBC-CCM [g]	NRF_CCM	1	**No**	
AAR [h]	NRF_AAR	1	**No**	
GPIO [i]	NRF_GPIO	2 GPIO pins for PA and LNA, 1 each	Yes	• Additionally, 10 Debug GPIO pins (optional)
GPIOTE [j]	NRF_GPIOTE	1	Yes	• Used for PA/LNA
TEMP [k]	NRF_TEMP	1	Yes	• For RC sourced LFCLOCK calibration
UART [l]	NRF_UART0	1	Yes	• For HCI interface in Controller only builds
IPC [m]	NRF_IPC Page	1	Yes	• For HCI interface in Controller only builds

Application Development

Bluetooth applications are developed using the common infrastructure and approach that is described in the *Application Development* section of the documentation.

Additional information that is only relevant to Bluetooth applications can be found on this page.

- *Thread safety*
- *Hardware setup*
  - *Embedded*
  - *Host on Linux with an external Controller*
  - *Simulated nRF5x with BabbleSim*
- *Initialization*
- *Bluetooth Application Example*
- *More Examples*

Thread safety Calling into the Bluetooth API is intended to be thread safe, unless otherwise noted in the documentation of the API function. The effort to ensure that this is the case for all API calls is an ongoing one, but the overall goal is formally stated in this paragraph. Bug reports and Pull Requests that move the subsystem in the direction of such goal are welcome.

Hardware setup This section describes the options you have when building and debugging Bluetooth applications with Zephyr. Depending on the hardware that is available to you, the requirements you have and the type of development you prefer you may pick one or another setup to match your needs.

There are 3 possible setups:

1. *Embedded*
2. *External controller*
   - *QEMU host*
   - *native_sim host*
3. *Simulated nRF5x with BabbleSim*

Embedded This setup relies on all software running directly on the embedded platform(s) that the application is targeting. All the *Configurations* and *Build Types* are supported but you might need to build Zephyr more than once if you are using a dual-chip configuration or if you have multiple cores in your SoC each running a different build type (e.g., one running the Host, the other the Controller).

To start developing using this setup follow the *Getting Started Guide*, choose one (or more if you are using a dual-chip solution) boards that support Bluetooth and then *run the application*).

There is a way to access the *HCI* traffic between the Host and Controller, even if there is no physical transport. See *Embedded HCI tracing* for instructions.

[1] `CONFIG_BT_CTLR_SW_SWITCH_SINGLE_TIMER=y`
[0] `CONFIG_BT_CTLR_TIFS_HW=n`
[2] When not using pre-defined PPI channels
[3] For software-based tIFS switching
[4] Drivers that use nRFx interfaces
[5] For nRF53x Series

Note

This is currently only available on GNU/Linux

Host on Linux with an external Controller This setup relies on a "dual-chip" *configuration* which is comprised of the following devices:

1. A *Host-only* application running in the *QEMU* emulator or the native_sim native port of Zephyr
2. A Controller, which can be one of the following types:
   - A commercially available Controller
   - A *Controller-only* build of Zephyr
   - A *Virtual controller*

Warning

Certain external Controllers are either unable to accept the Host to Controller flow control parameters that Zephyr sets by default (Qualcomm), or do not transmit any data from the Controller to the Host (Realtek). If you see a message similar to:

```
<wrn> bt_hci_core: opcode 0x0c33 status 0x12
```

when booting your sample of choice (make sure you have enabled `CONFIG_LOG` in your `prj.conf` before running the sample), or if there is no data flowing from the Controller to the Host, then you need to disable Host to Controller flow control. To do so, set `CONFIG_BT_HCI_ACL_FLOW_CONTROL=n` in your `prj.conf`.

QEMU You can run the Zephyr Host on the *QEMU emulator* and have it interact with a physical external Bluetooth Controller.

Refer to *Running on QEMU or native_sim* for full instructions on how to build and run an application in this setup.

Note

This is currently only available on GNU/Linux

native_sim The native_sim target builds your Zephyr application with the Zephyr kernel, and some minimal HW emulation as a native Linux executable.

This executable is a normal Linux program, which can be debugged and instrumented like any other, and it communicates with a physical or virtual external Controller. Refer to:

- *Running on QEMU or native_sim* for the physical controller
- *Running on a Virtual Controller and native_sim* for the virtual controller

Note

This is currently only available on GNU/Linux

Simulated nRF5x with BabbleSim The nrf52_bsim and nrf5340bsim boards, are simulated target boards which emulate the necessary peripherals of a nRF52/53 SOC to be able to develop and test Bluetooth LE applications. These boards, use:

- BabbleSim to simulate the nRF5x modem and the radio environment.
- The POSIX arch and native simulator to emulate the processor, and run natively on your host.
- Models of the nrf5x HW

Just like with the native_sim target, the build result is a normal Linux executable. You can find more information on how to run simulations with one or several devices in either of these boards's documentation.

With the nrf52_bsim, typically you do *Combined builds*, but it is also possible to build the controller with one of the bluetooth_hci_uart samples in one simulated device, and the host with the H4 driver instead of the integrated controller in another simulated device.

With the nrf5340bsim, you can build with either, both controller and host on its network core, or, with the network core running only the controller, the application core running the host and your application, and the HCI transport over IPC.

Initialization The Bluetooth subsystem is initialized using the `bt_enable()` function. The caller should ensure that function succeeds by checking the return code for errors. If a function pointer is passed to `bt_enable()`, the initialization happens asynchronously, and the completion is notified through the given function.

Bluetooth Application Example A simple Bluetooth beacon application is shown below. The application initializes the Bluetooth Subsystem and enables non-connectable advertising, effectively acting as a Bluetooth Low Energy broadcaster.

```

/*
 * Set Advertisement data. Based on the Eddystone specification:
 * https://github.com/google/eddystone/blob/master/protocol-specification.md
 * https://github.com/google/eddystone/tree/master/eddystone-url
 */
static const struct bt_data ad[] = {
        BT_DATA_BYTES(BT_DATA_FLAGS, BT_LE_AD_NO_BREDR),
        BT_DATA_BYTES(BT_DATA_UUID16_ALL, 0xaa, 0xfe),
        BT_DATA_BYTES(BT_DATA_SVC_DATA16,
                      0xaa, 0xfe, /* Eddystone UUID */
                      0x10, /* Eddystone-URL frame type */
                      0x00, /* Calibrated Tx power at 0m */
                      0x00, /* URL Scheme Prefix http://www. */
                      'z', 'e', 'p', 'h', 'y', 'r',
                      'p', 'r', 'o', 'j', 'e', 'c', 't',
                      0x08) /* .org */
};

/* Set Scan Response data */
static const struct bt_data sd[] = {
        BT_DATA(BT_DATA_NAME_COMPLETE, DEVICE_NAME, DEVICE_NAME_LEN),
};
```

(continues on next page)

(continued from previous page)

```

static void bt_ready(int err)
{
        bt_addr_le_t addr = {0};
        size_t count = 1;

        if (err) {
                printk("Bluetooth init failed (err %d)\n", err);
                return;
        }

        printk("Bluetooth initialized\n");

        /* Start advertising */
        err = bt_le_adv_start(BT_LE_ADV_NCONN_IDENTITY, ad, ARRAY_SIZE(ad),
                              sd, ARRAY_SIZE(sd));
        if (err) {
                printk("Advertising failed to start (err %d)\n", err);
                return;
        }

        /* For connectable advertising you would use
         * bt_le_oob_get_local().  For non-connectable non-identity
         * advertising an non-resolvable private address is used;
         * there is no API to retrieve that.
         */

        bt_id_get(&addr, &count);

        printk("Beacon started, advertising as %s\n", bt_addr_le_str(&addr));
}

int main(void)
{
        int err;

        printk("Starting Beacon Demo\n");

        /* Initialize the Bluetooth Subsystem */
        err = bt_enable(bt_ready);
        if (err) {
                printk("Bluetooth init failed (err %d)\n", err);
        }
        return 0;
}
```

The key APIs employed by the beacon sample are `bt_enable()` that's used to initialize Bluetooth and then `bt_le_adv_start()` that's used to start advertising a specific combination of advertising and scan response data.

More Examples More sample Bluetooth applications are available in `samples/bluetooth/`.

API

Bluetooth Classic Host and profiles

Service Discovery Protocol (SDP)

API Reference

Service Discovery Protocol (SDP)

Bluetooth Logical Link Control and Adaptation Protocol (L2CAP) for BR/EDR L2CAP BR/EDR provides support for Bluetooth Classic L2CAP (Logical Link Control and Adaptation Protocol) features including ECHO request/response and connectionless data channels.

ECHO Request/Response The L2CAP ECHO feature allows testing the connection by sending ECHO requests and receiving ECHO responses. Applications can register callbacks to monitor ECHO packets and send ECHO data. The feature is enabled through the configuration option: `CONFIG_BT_CLASSIC`.

Registering ECHO Callbacks To monitor ECHO request/response packets, register a `bt_l2cap_br_echo_cb` callback structure:

```
static void echo_req_cb(struct bt_conn *conn, uint8_t identifier, struct net_buf␣
↪*buf)
{
    /* Handle ECHO request */
}

static void echo_rsp_cb(struct bt_conn *conn, struct net_buf *buf)
{
    /* Handle ECHO response */
}

static struct bt_l2cap_br_echo_cb echo_cb = {
    .req = echo_req_cb,
    .rsp = echo_rsp_cb,
};

bt_l2cap_br_echo_cb_register(&echo_cb);
```

Sending ECHO Request To send an ECHO request, allocate a buffer with `BT_L2CAP_BR_ECHO_REQ_RESERVE` bytes reserved for the L2CAP header:

```
struct net_buf *buf;

buf = net_buf_alloc(&pool, K_FOREVER);
net_buf_reserve(buf, BT_L2CAP_BR_ECHO_REQ_RESERVE);
net_buf_add_mem(buf, data, data_len);

bt_l2cap_br_echo_req(conn, buf);
```

Sending ECHO Response To send an ECHO response (typically in response to a received ECHO request), allocate a buffer with `BT_L2CAP_BR_ECHO_RSP_RESERVE` bytes reserved for the L2CAP header:

```
struct net_buf *buf;

buf = net_buf_alloc(&pool, K_FOREVER);
net_buf_reserve(buf, BT_L2CAP_BR_ECHO_RSP_RESERVE);
```

(continues on next page)

(continued from previous page)

```
net_buf_add_mem(buf, data, data_len);

bt_l2cap_br_echo_rsp(conn, buf);
```

The identifier parameter must match the identifier from the received ECHO request to properly correlate the response with the request.

Connectionless Data Channel The connectionless data channel allows sending and receiving data to/from a specific PSM (Protocol/Service Multiplexer) without establishing a connection-oriented L2CAP channel. The feature is enabled through the configuration option: `CONFIG_BT_L2CAP_CONNLESS`.

Registering Connectionless Callbacks To receive connectionless data, register a `bt_l2cap_br_connless_cb` callback structure:

```
static void connless_recv_cb(struct bt_conn *conn, uint16_t psm, struct net_buf␣
↪*buf)
{
    /* Handle received connectionless data */
}

static struct bt_l2cap_br_connless_cb connless_cb = {
    .psm = MY_PSM,  /* Or 0 to receive all */
    .sec_level = BT_SECURITY_L1,
    .recv = connless_recv_cb,
};

bt_l2cap_br_connless_register(&connless_cb);
```

Sending Connectionless Data To send connectionless data, allocate a buffer with `BT_L2CAP_CONNLESS_RESERVE` bytes reserved:

```
struct net_buf *buf;

buf = net_buf_alloc(&pool, K_FOREVER);
net_buf_reserve(buf, BT_L2CAP_CONNLESS_RESERVE);
net_buf_add_mem(buf, data, data_len);

bt_l2cap_br_connless_send(conn, psm, buf);
```

Related code samples

- Basic Audio Profile (BAP) Broadcast Audio AssistantUse BAP Broadcast Assistant functionality.
- Basic Audio Profile (BAP) Broadcast Audio SinkUse BAP Broadcast Sink functionality.
- Basic Audio Profile (BAP) Broadcast Audio SourceUse BAP Broadcast Source functionality.
- Basic Audio Profile (BAP) Unicast Audio ClientUse BAP Unicast Client functionality.
- Basic Audio Profile (BAP) Unicast Audio ServerUse BAP Unicast Server functionality.
- Common Audio Profile (CAP) AcceptorAdvertise audio availability to CAP Initiators using the CAP Acceptor role.
- Public Broadcast Profile (PBP) Public Broadcast SinkUse PBP Public Broadcast Sink functionality.
- Public Broadcast Profile (PBP) Public Broadcast SourceUse PBP Public Broadcast Source functionality.
- Telephone and Media Audio Profile (TMAP) Broadcast Media Receiver (BMR)Implement the TMAP Broadcast Media Receiver (BMR) role.
- Telephone and Media Audio Profile (TMAP) Broadcast Media Sender (BMS)Implement the LE Audio TMAP Broadcast Media Sender (BMS) role.
- Telephone and Media Audio Profile (TMAP) CentralImplement the TMAP Call Gateway (CG) and Unicast Media Sender (UMS) roles.
- Telephone and Media Audio Profile (TMAP) PeripheralImplement the TMAP Call Terminal (CT) and Unicast Media Receiver (UMR) roles.
